CHAPTER ONE

WHAT IS HPX?

HPX is a C++ Standard Library for Concurrency and Parallelism. It implements all of the corresponding facilities as defined by the C++ Standard. Additionally, in HPX we implement functionalities proposed as part of the ongoing C++ standardization process. We also extend the C++ Standard APIs to the distributed case. HPX is developed by the STE||AR group (see People).

The goal of HPX is to create a high quality, freely available, open source implementation of a new programming model for conventional systems, such as classic Linux based Beowulf clusters or multi-socket highly parallel SMP nodes. At the same time, we want to have a very modular and well designed runtime system architecture which would allow us to port our implementation onto new computer system architectures. We want to use real-world applications to drive the development of the runtime system, coining out required functionalities and converging onto a stable API which will provide a smooth migration path for developers.

The API exposed by HPX is not only modeled after the interfaces defined by the C++11/14/17/20 ISO standard. It also adheres to the programming guidelines used by the Boost collection of C++ libraries. We aim to improve the scalability of today’s applications and to expose new levels of parallelism which are necessary to take advantage of the exascale systems of the future.
WHAT’S SO SPECIAL ABOUT HPX?

- HPX exposes a uniform, standards-oriented API for ease of programming parallel and distributed applications.
- It enables programmers to write fully asynchronous code using hundreds of millions of threads.
- HPX provides unified syntax and semantics for local and remote operations.
- HPX makes concurrency manageable with dataflow and future based synchronization.
- It implements a rich set of runtime services supporting a broad range of use cases.
- HPX exposes a uniform, flexible, and extendable performance counter framework which can enable runtime adaptivity.
- It is designed to solve problems conventionally considered to be scaling-impaired.
- HPX has been designed and developed for systems of any scale, from hand-held devices to very large scale systems.
- It is the first fully functional implementation of the ParalleX execution model.
- HPX is published under a liberal open-source license and has an open, active, and thriving developer community.

2.1 Why HPX?

Current advances in high performance computing (HPC) continue to suffer from the issues plaguing parallel computation. These issues include, but are not limited to, ease of programming, inability to handle dynamically changing workloads, scalability, and efficient utilization of system resources. Emerging technological trends such as multi-core processors further highlight limitations of existing parallel computation models. To mitigate the aforementioned problems, it is necessary to rethink the approach to parallelization models. ParalleX contains mechanisms such as multi-threading, parcels, global name space support, percolation and local control objects (LCO). By design, ParalleX overcomes limitations of current models of parallelism by alleviating contention, latency, overhead and starvation. With ParalleX, it is further possible to increase performance by at least an order of magnitude on challenging parallel algorithms, e.g., dynamic directed graph algorithms and adaptive mesh refinement methods for astrophysics. An additional benefit of ParalleX is fine-grained control of power usage, enabling reductions in power consumption.
2.1.1 ParalleX—a new execution model for future architectures

ParalleX is a new parallel execution model that offers an alternative to the conventional computation models, such as message passing. ParalleX distinguishes itself by:

- Split-phase transaction model
- Message-driven
- Distributed shared memory (not cache coherent)
- Multi-threaded
- Futures synchronization
- Local Control Objects (LCOs)
- Synchronization for anonymous producer-consumer scenarios
- Percolation (pre-staging of task data)

The ParalleX model is intrinsically latency hiding, delivering an abundance of variable-grained parallelism within a hierarchical namespace environment. The goal of this innovative strategy is to enable future systems delivering very high efficiency, increased scalability and ease of programming. ParalleX can contribute to significant improvements in the design of all levels of computing systems and their usage from application algorithms and their programming languages to system architecture and hardware design together with their supporting compilers and operating system software.

2.1.2 What is HPX?

High Performance ParalleX (HPX) is the first runtime system implementation of the ParalleX execution model. The HPX runtime software package is a modular, feature-complete, and performance-oriented representation of the ParalleX execution model targeted at conventional parallel computing architectures, such as SMP nodes and commodity clusters. It is academically developed and freely available under an open source license. We provide HPX to the community for experimentation and application to achieve high efficiency and scalability for dynamic adaptive and irregular computational problems. HPX is a C++ library that supports a set of critical mechanisms for dynamic adaptive resource management and lightweight task scheduling within the context of a global address space. It is solidly based on many years of experience in writing highly parallel applications for HPC systems.

The two-decade success of the communicating sequential processes (CSP) execution model and its message passing interface (MPI) programming model have been seriously eroded by challenges of power, processor core complexity, multi-core sockets, and heterogeneous structures of GPUs. Both efficiency and scalability for some current (strong scaled) applications and future Exascale applications demand new techniques to expose new sources of algorithm parallelism and exploit unused resources through adaptive use of runtime information.

The ParalleX execution model replaces CSP to provide a new computing paradigm embodying the governing principles for organizing and conducting highly efficient scalable computations greatly exceeding the capabilities of today’s problems. HPX is the first practical, reliable, and performance-oriented runtime system incorporating the principal concepts of the ParalleX model publicly provided in open source release form.

HPX is designed by the STE||AR\(^5\) Group (Systems Technology, Emergent Parallelism, and Algorithm Research) at Louisiana State University (LSU)\(^6\)’s Center for Computation and Technology (CCT)\(^7\) to enable developers to exploit the full processing power of many-core systems with an unprecedented degree of parallelism. STE||AR\(^8\) is a research group focusing on system software solutions and scientific application development for hybrid and many-core hardware architectures.

7 https://www.cct.lsu.edu
8 https://stellar-group.org
2.1.3 What makes our systems slow?

Estimates say that we currently run our computers at well below 100% efficiency. The theoretical peak performance (usually measured in FLOPS\(^\text{10}\) — floating point operations per second) is much higher than any practical peak performance reached by any application. This is particularly true for highly parallel hardware. The more hardware parallelism we provide to an application, the better the application must scale in order to efficiently use all the resources of the machine. Roughly speaking, we distinguish two forms of scalability: strong scaling (see Amdahl’s Law\(^\text{11}\)) and weak scaling (see Gustafson’s Law\(^\text{12}\)). Strong scaling is defined as how the solution time varies with the number of processors for a fixed total problem size. It gives an estimate of how much faster we can solve a particular problem by throwing more resources at it. Weak scaling is defined as how the solution time varies with the number of processors for a fixed problem size per processor. In other words, it defines how much more data can we process by using more hardware resources.

In order to utilize as much hardware parallelism as possible an application must exhibit excellent strong and weak scaling characteristics, which requires a high percentage of work executed in parallel, i.e., using multiple threads of execution. Optimally, if you execute an application on a hardware resource with N processors it either runs N times faster or it can handle N times more data. Both cases imply 100% of the work is executed on all available processors in parallel. However, this is just a theoretical limit. Unfortunately, there are more things that limit scalability, mostly inherent to the hardware architectures and the programming models we use. We break these limitations into four fundamental factors that make our systems SLOW:

- Starvation occurs when there is insufficient concurrent work available to maintain high utilization of all resources.
- Latencies are imposed by the time-distance delay intrinsic to accessing remote resources and services.
- Overhead is work required for the management of parallel actions and resources on the critical execution path, which is not necessary in a sequential variant.
- Waiting for contention resolution is the delay due to the lack of availability of oversubscribed shared resources.

Each of those four factors manifests itself in multiple and different ways; each of the hardware architectures and programming models expose specific forms. However, the interesting part is that all of them are limiting the scalability of applications no matter what part of the hardware jungle we look at. Hand-helds, PCs, supercomputers, or the cloud, all suffer from the reign of the 4 horsemen: Starvation, Latency, Overhead, and Contention. This realization is very important as it allows us to derive the criteria for solutions to the scalability problem from first principles, and it allows us to focus our analysis on very concrete patterns and measurable metrics. Moreover, any derived results will be applicable to a wide variety of targets.

2.1.4 Technology demands new response

Today’s computer systems are designed based on the initial ideas of John von Neumann\(^\text{13}\), as published back in 1945, and later extended by the Harvard architecture\(^\text{14}\). These ideas form the foundation, the execution model, of computer systems we use currently. However, a new response is required in the light of the demands created by today’s technology.

So, what are the overarching objectives for designing systems allowing for applications to scale as they should? In our opinion, the main objectives are:

---

9 https://stellar-group.org
10 http://en.wikipedia.org/wiki/FLOPS
11 http://en.wikipedia.org/wiki/Amdahl%27s_law
12 http://en.wikipedia.org/wiki/Gustafson%27s_law
• Performance: as previously mentioned, scalability and efficiency are the main criteria people are interested in.
• Fault tolerance: the low expected mean time between failures (MTBF\textsuperscript{15}) of future systems requires embracing faults, not trying to avoid them.
• Power: minimizing energy consumption is a must as it is one of the major cost factors today, and will continue to rise in the future.
• Generality: any system should be usable for a broad set of use cases.
• Programmability: for programmer this is a very important objective, ensuring long term platform stability and portability.

What needs to be done to meet those objectives, to make applications scale better on tomorrow’s architectures? Well, the answer is almost obvious: we need to devise a new execution model—a set of governing principles for the holistic design of future systems—targeted at minimizing the effect of the outlined SLOW factors. Everything we create for future systems, every design decision we make, have to be validated against this single, uniform metric. This includes changes in the hardware architecture we prevalently use today, and it certainly involves new ways of writing software, starting from the operating system, runtime system, compilers, and at the application level. However, the key point is that all those layers have to be co-designed; they are interdependent and cannot be seen as separate facets. The systems we have today have been evolving for over 50 years now. All layers function in a certain way, relying on the other layers to do so. But we do not have the time to wait another 50 years for a new coherent system to evolve. The new paradigms are needed now—therefore, co-design is the key.

2.1.5 Governing principles applied while developing HPX

As it turn out, we do not have to start from scratch. Not everything has to be invented and designed anew. Many of the ideas needed to combat the 4 horsemen already exist, many for more than 30 years. All it takes is to gather them into a coherent approach. We’ll highlight some of the derived principles we think to be crucial for defeating SLOW. Some of those are focused on high-performance computing, others are more general.

2.1.6 Focus on latency hiding instead of latency avoidance

It is impossible to design a system exposing zero latencies. In an effort to come as close as possible to this goal many optimizations are mainly targeted towards minimizing latencies. Examples for this can be seen everywhere, such as low latency network technologies like InfiniBand\textsuperscript{16}, caching memory hierarchies in all modern processors, the constant optimization of existing MPI\textsuperscript{17} implementations to reduce related latencies, or the data transfer latencies intrinsic to the way we use GPGPUs\textsuperscript{18} today. It is important to note that existing latencies are often tightly related to some resource having to wait for the operation to be completed. At the same time it would be perfectly fine to do some other, unrelated work in the meantime, allowing the system to hide the latencies by filling the idle-time with useful work. Modern systems already employ similar techniques (pipelined instruction execution in the processor cores, asynchronous input/output operations, and many more). What we propose is to go beyond anything we know today and to make latency hiding an intrinsic concept of the operation of the whole system stack.

\textsuperscript{15} http://en.wikipedia.org/wiki/Mean_time_between_failures
\textsuperscript{16} http://en.wikipedia.org/wiki/InfiniBand
\textsuperscript{17} https://en.wikipedia.org/wiki/Message_Passing_Interface
\textsuperscript{18} http://en.wikipedia.org/wiki/GPGPU
2.1.7 Embrace fine-grained parallelism instead of heavyweight threads

If we plan to hide latencies even for very short operations, such as fetching the contents of a memory cell from main memory (if it is not already cached), we need to have very lightweight threads with extremely short context switching times, optimally executable within one cycle. Granted, for mainstream architectures, this is not possible today (even if we already have special machines supporting this mode of operation, such as the Cray XMT\(^{19}\)). For conventional systems, however, the smaller the overhead of a context switch and the finer the granularity of the threading system, the better will be the overall system utilization and its efficiency. For today’s architectures we already see a flurry of libraries providing exactly this type of functionality: non-pre-emptive, task-queue based parallelization solutions, such as Intel Threading Building Blocks (TBB)\(^{20}\), Microsoft Parallel Patterns Library (PPL)\(^{21}\), Cilk++\(^{22}\), and many others. The possibility to suspend a current task if some preconditions for its execution are not met (such as waiting for I/O or the result of a different task), seamlessly switching to any other task which can continue, and to reschedule the initial task after the required result has been calculated, which makes the implementation of latency hiding almost trivial.

2.1.8 Rediscover constraint-based synchronization to replace global barriers

The code we write today is riddled with implicit (and explicit) global barriers. By “global barriers,” we mean the synchronization of the control flow between several (very often all) threads (when using OpenMP\(^{23}\)) or processes (MPI\(^{24}\)). For instance, an implicit global barrier is inserted after each loop parallelized using OpenMP\(^{25}\) as the system synchronizes the threads used to execute the different iterations in parallel. In MPI\(^{26}\) each of the communication steps imposes an explicit barrier onto the execution flow as (often all) nodes have to be synchronized. Each of those barriers is like the eye of a needle the overall execution is forced to be squeezed through. Even minimal fluctuations in the execution times of the parallel threads (jobs) causes them to wait. Additionally, it is often only one of the executing threads that performs the actual reduce operation, which further impedes parallelism. A closer analysis of a couple of key algorithms used in science applications reveals that these global barriers are not always necessary. In many cases it is sufficient to synchronize a small subset of the threads. Any operation should proceed whenever the preconditions for its execution are met, and only those. Usually there is no need to wait for iterations of a loop to finish before you can continue calculating other things; all you need is to complete the iterations that produce the required results for the next operation. Good bye global barriers, hello constraint based synchronization! People have been trying to build this type of computing (and even computers) since the 1970s. The theory behind what they did is based on ideas around static and dynamic dataflow. There are certain attempts today to get back to those ideas and to incorporate them with modern architectures. For instance, a lot of work is being done in the area of constructing dataflow-oriented execution trees. Our results show that employing dataflow techniques in combination with the other ideas, as outlined herein, considerably improves scalability for many problems.

2.1.9 Adaptive locality control instead of static data distribution

While this principle seems to be a given for single desktop or laptop computers (the operating system is your friend), it is everything but ubiquitous on modern supercomputers, which are usually built from a large number of separate nodes (i.e., Beowulf clusters), tightly interconnected by a high-bandwidth, low-latency network. Today’s prevalent programming model for those is MPI, which does not directly help with proper data distribution, leaving it to the programmer to decompose the data to all of the nodes the application is running on. There are a couple of specialized languages and programming environments based on PGAS\(^{27}\) (Partitioned Global Address Space) designed to over-

\(^{19}\) http://en.wikipedia.org/wiki/Cray_XMT
\(^{20}\) https://www.threadingbuildingblocks.org/
\(^{22}\) https://software.intel.com/en-us/articles/intel-cilk-plus/
\(^{23}\) https://openmp.org/wp/
\(^{24}\) https://en.wikipedia.org/wiki/Message_Passing_Interface
\(^{25}\) https://openmp.org/wp/
\(^{26}\) https://en.wikipedia.org/wiki/Message_Passing_Interface
\(^{27}\) https://www.pgas.org/
come this limitation, such as Chapel\textsuperscript{28}, X10\textsuperscript{29}, UPC\textsuperscript{30}, or Fortress\textsuperscript{31}. However, all systems based on PGAS rely on static data distribution. This works fine as long as this static data distribution does not result in heterogeneous workload distributions or other resource utilization imbalances. In a distributed system these imbalances can be mitigated by migrating part of the application data to different localities (nodes). The only framework supporting (limited) migration today is Charm++\textsuperscript{32}. The first attempts towards solving related problem go back decades as well, a good example is the Linda coordination language\textsuperscript{33}. Nevertheless, none of the other mentioned systems support data migration today, which forces the users to either rely on static data distribution and live with the related performance hits or to implement everything themselves, which is very tedious and difficult. We believe that the only viable way to flexibly support dynamic and adaptive locality control is to provide a global, uniform address space to the applications, even on distributed systems.

2.1.10 Prefer moving work to the data over moving data to the work

For the best performance it seems obvious to minimize the amount of bytes transferred from one part of the system to another. This is true on all levels. At the lowest level we try to take advantage of processor memory caches, thus, minimizing memory latencies. Similarly, we try to amortize the data transfer time to and from GPGPUs\textsuperscript{34} as much as possible. At high levels we try to minimize data transfer between different nodes of a cluster or between different virtual machines on the cloud. Our experience (well, it’s almost common wisdom) shows that the amount of bytes necessary to encode a certain operation is very often much smaller than the amount of bytes encoding the data the operation is performed upon. Nevertheless, we still often transfer the data to a particular place where we execute the operation just to bring the data back to where it came from afterwards. As an example let’s look at the way we usually write our applications for clusters using MPI. This programming model is all about data transfer between nodes. MPI is the prevalent programming model for clusters, and it is fairly straightforward to understand and to use. Therefore, we often write applications in a way that accommodates this model, centered around data transfer. These applications usually work well for smaller problem sizes and for regular data structures. The larger the amount of data we have to churn and the more irregular the problem domain becomes, the worse the overall machine utilization and the (strong) scaling characteristics become. While it is not impossible to implement more dynamic, data driven, and asynchronous applications using MPI, it is somewhat difficult to do so. At the same time, if we look at applications that prefer to execute the code close to the locality where the data was placed, i.e., utilizing active messages (for instance based on Charm++\textsuperscript{35}), we see better asynchrony, simpler application codes, and improved scaling.

2.1.11 Favor message driven computation over message passing

Today’s prevalently used programming model on parallel (multi-node) systems is MPI. It is based on message passing, as the name implies, which means that the receiver has to be aware of a message about to come in. Both codes, the sender and the receiver, have to synchronize in order to perform the communication step. Even the newer, asynchronous interfaces require explicitly coding the algorithms around the required communication scheme. As a result, everything but the most trivial MPI applications spends a considerable amount of time waiting for incoming messages, thus, causing starvation and latencies to impede full resource utilization. The more complex and more dynamic the data structures and algorithms become, the larger the adverse effects. The community discovered message-driven and data-driven methods of implementing algorithms a long time ago, and systems such as Charm++\textsuperscript{36} have already integrated active messages demonstrating the validity of the concept. Message-driven computation allows for sending messages without requiring the receiver to actively wait for them. Any incoming message is handled asynchronously and triggers

\textsuperscript{28} https://chapel.cray.com/
\textsuperscript{29} https://x10-lang.org/
\textsuperscript{30} https://upc.lbl.gov/
\textsuperscript{31} https://labs.oracle.com/projects/plrg/Publications/index.html
\textsuperscript{32} https://charm.cs.uiuc.edu/
\textsuperscript{33} http://en.wikipedia.org/wiki/Linda_(coordination_language)
\textsuperscript{34} http://en.wikipedia.org/wiki/GPGPU
\textsuperscript{35} https://charm.cs.uiuc.edu/
\textsuperscript{36} https://charm.cs.uiuc.edu/
the encoded action by passing along arguments and—possibly—continuations. HPX combines this scheme with work-
queue based scheduling as described above, which allows the system to almost completely overlap any communication
with useful work, thereby minimizing latencies.

2.2 Quick start

This section is intended to get you to the point of running a basic HPX program as quickly as possible. To that end we
skip many details but instead give you hints and links to more details along the way.

We assume that you are on a Unix system with access to reasonably recent packages. You should have cmake and
make available for the build system (pkg-config is also supported, see Using HPX with pkg-config).

2.2.1 Getting HPX

Download a tarball of the latest release from HPX Downloads and unpack it or clone the repository directly using
git:

```shell
git clone https://github.com/STEllAR-GROUP/hpx.git
```

It is also recommended that you check out the latest stable tag:

```shell
git checkout 1.6.0
```

2.2.2 HPX dependencies

The minimum dependencies needed to use HPX are Boost and Portable Hardware Locality (HWLOC). If these
are not available through your system package manager, see Installing Boost and Installing Hwloc for instructions on
how to build them yourself. In addition to Boost and Portable Hardware Locality (HWLOC), it is recommended that
you don’t use the system allocator, but instead use either tcmalloc from google-perftools (default) or jemalloc for better performance. If you would like to try HPX without a custom allocator at this point, you can configure HPX
to use the system allocator in the next step.

A full list of required and optional dependencies, including recommended versions, is available at Prerequisites.

2.2.3 Building HPX

Once you have the source code and the dependencies, set up a separate build directory and configure the project.
Assuming all your dependencies are in paths known to CMake, the following gets you started:

```bash
# In the HPX source directory
mkdir build && cd build
cmake -DCMAKE_INSTALL_PREFIX=/install/path..
made install
```

---

37 https://hpx.stellar-group.org/downloads/
38 https://www.boost.org/
39 https://www.open-mpi.org/projects/hwloc/
40 https://code.google.com/p/gperftools
41 http://jemalloc.net
This will build the core HPX libraries and examples, and install them to your chosen location. If you want to install HPX to system folders, simply leave out the CMAKE_INSTALL_PREFIX option. This may take a while. To speed up the process, launch more jobs by passing the -jN option to make.

**Tip:** Do not set only -j (i.e. -j without an explicit number of jobs) unless you have a lot of memory available on your machine.

**Tip:** If you want to change CMake variables for your build, it is usually a good idea to start with a clean build directory to avoid configuration problems. It is especially important that you use a clean build directory when changing between Release and Debug modes.

If your dependencies are in custom locations, you may need to tell CMake where to find them by passing one or more of the following options to CMake:

```
-DBOOST_ROOT=/path/to/boost
-DHWLOC_ROOT=/path/to/hwloc
-DTCMALLOC_ROOT=/path/to/tcmalloc
-DJEMALLOC_ROOT=/path/to/jemalloc
```

If you want to try HPX without using a custom allocator pass -DHPX_WITH_MALLOC=system to CMake.

**Important:** If you are building HPX for a system with more than 64 processing units, you must change the CMake variables HPX_WITH_MORE_THAN_64_THREADS (to On) and HPX_WITH_MAX_CPU_COUNT (to a value at least as big as the number of (virtual) cores on your system).

To build the tests, run make tests. To run the tests, run either make test or use ctest for more control over which tests to run. You can run single tests for example with ctest --output-on-failure -R tests. unit.parallel.algorithms.for_loop or a whole group of tests with ctest --output-on-failure -R tests.unit.

If you did not run make install earlier, do so now or build the hello_world_1 example by running:

```
make hello_world_1
```

HPX executables end up in the bin directory in your build directory. You can now run hello_world_1 and should see the following output:

```
./bin/hello_world_1
Hello World!
```

You’ve just run an example which prints Hello World! from the HPX runtime. The source for the example is in examples/quickstart/hello_world_1.cpp. The hello_world_distributed example (also available in the examples/quickstart directory) is a distributed hello world program, which is described in Remote execution with actions: Hello world. It provides a gentle introduction to the distributed aspects of HPX.

**Tip:** Most build targets in HPX have two names: a simple name and a hierarchical name corresponding to what type of example or test the target is. If you are developing HPX it is often helpful to run make help to get a list of available targets. For example, make help | grep hello_world outputs the following:

```
... examples.quickstart.hello_world_2
... hello_world_2
```
It is also possible to build, for instance, all quickstart examples using `make examples.quickstart`.

### 2.2.4 Installing and building HPX via vcpkg

You can download and install HPX using the vcpkg `<https://github.com/Microsoft/vcpkg>` dependency manager:

```bash
git clone https://github.com/Microsoft/vcpkg.git
cd vcpkg
./bootstrap-vcpkg.sh
./vcpkg integrate install
vcpkg install hpx
```

The HPX port in vcpkg is kept up to date by Microsoft team members and community contributors. If the version is out of date, please create an issue or pull request `<https://github.com/Microsoft/vcpkg>` on the vcpkg repository.

### 2.2.5 Hello, World!

The following `CMakeLists.txt` is a minimal example of what you need in order to build an executable using CMake and HPX:

```cmake
cmake_minimum_required(VERSION 3.17)
project(my_hpx_project CXX)
find_package(HPX REQUIRED)
add_executable(my_hpx_program main.cpp)
target_link_libraries(my_hpx_program HPX::hpx HPX::wrap_main HPX::iostreams_component)
```

**Note:** You will most likely have more than one `main.cpp` file in your project. See the section on *Using HPX with CMake-based projects* for more details on how to use `add_hpx_executable`.

**Note:** `HPX::wrap_main` is required if you are implicitly using `main()` as the runtime entry point. See *Re-use the main() function as the main HPX entry point* for more information.

**Note:** `HPX::iostreams_component` is optional for a minimal project but lets us use the HPX equivalent of std::cout, i.e., the **HPX The HPX I/O-streams component** functionality in our application.

Create a new project directory and a `CMakeLists.txt` with the contents above. Also create a `main.cpp` with the contents below.

```cpp
#include <hpx/hpx_main.hpp>
#include <hpx/iostream.hpp>
```

(continues on next page)
int main()
{
    // Say hello to the world!
    hpx::cout << "Hello World!\n" << hpx::flush;
    return 0;
}

Then, in your project directory run the following:

mkdir build && cd build
cmake -DCMAKE_PREFIX_PATH=/path/to/hpx/installation ..
make all
./my_hpx_program

The program looks almost like a regular C++ hello world with the exception of the two includes and hpx::cout. When you include hpx_main.hpp some things will be done behind the scenes to make sure that main actually gets launched on the HPX runtime. So while it looks almost the same you can now use futures, async, parallel algorithms and more which make use of the HPX runtime with lightweight threads. hpx::cout is a replacement for std::cout to make sure printing never blocks a lightweight thread. You can read more about hpx::cout in The HPX I/O-streams component. If you rebuild and run your program now, you should see the familiar Hello World!:

./my_hpx_program
Hello World!

Note: You do not have to let HPX take over your main function like in the example. You can instead keep your normal main function, and define a separate hpx_main function which acts as the entry point to the HPX runtime. In that case you start the HPX runtime explicitly by calling hpx::init:

```
#include <hpx/hpx_init.hpp>
#include <hpx/iostream.hpp>

int hpx_main(int, char**)
{
    // Say hello to the world!
    hpx::cout << "Hello World!\n" << hpx::flush;
    return hpx::finalize();
}

int main(int argc, char* argv[])
{
    return hpx::init(argc, argv);
}
```
You can also use `hpx::start` and `hpx::stop` for a non-blocking alternative, or use `hpx::resume` and `hpx::suspend` if you need to combine HPX with other runtimes.

See *Starting the HPX runtime* for more details on how to initialize and run the HPX runtime.

---

**Caution:** When including `hpx_main.hpp` the user-defined `main` gets renamed and the real `main` function is defined by HPX. This means that the user-defined `main` must include a return statement, unlike the real `main`. If you do not include the return statement, you may end up with confusing compile time errors mentioning `user_main` or even runtime errors.

### 2.2.6 Writing task-based applications

So far we haven’t done anything that can’t be done using the C++ standard library. In this section we will give a short overview of what you can do with HPX on a single node. The essence is to avoid global synchronization and break up your application into small, composable tasks whose dependencies control the flow of your application. Remember, however, that HPX allows you to write distributed applications similarly to how you would write applications for a single node (see *Why HPX?* and *Writing distributed HPX applications*).

If you are already familiar with `async` and `futures` from the C++ standard library, the same functionality is available in HPX.

The following terminology is essential when talking about task-based C++ programs:

- **lightweight thread**: Essential for good performance with task-based programs. Lightweight refers to smaller stacks and faster context switching compared to OS threads. Smaller overheads allow the program to be broken up into smaller tasks, which in turns helps the runtime fully utilize all processing units.
- **async**: The most basic way of launching tasks asynchronously. Returns a `future<T>`.
- **future<T>**: Represents a value of type T that will be ready in the future. The value can be retrieved with `get` (blocking) and one can check if the value is ready with `is_ready` (non-blocking).
- **shared_future<T>**: Same as `future<T>` but can be copied (similar to `std::unique_ptr` vs `std::shared_ptr`).
- **continuation**: A function that is to be run after a previous task has run (represented by a future). `then` is a method of `future<T>` that takes a function to run next. Used to build up dataflow DAGs (directed acyclic graphs). `shared_futures` help you split up nodes in the DAG and functions like `when_all` help you join nodes in the DAG.

The following example is a collection of the most commonly used functionality in HPX:

```cpp
#include <hpx/hpx_main.hpp>
#include <hpx/include/lcos.hpp>
#include <hpx/include/parallel_generate.hpp>
#include <hpx/include/parallel_sort.hpp>
#include <hpx/iostream.hpp>
#include <random>
#include <vector>

void final_task(
    hpx::future<hpx::tuple<hpx::future<double>, hpx::future<void>>>)
{
    hpx::cout << "in final_task" << hpx::endl;
}
```

(continues on next page)
Avoid ABI incompatibilities between C++11/C++17 as std::rand has exception specification in libstdc++.

```cpp
int rand_wrapper()
{
    return std::rand();
}
```

```cpp
int main(int, char**) {
    // A function can be launched asynchronously. The program will not block here until the result is available.
    hpx::future<int> f = hpx::async([]() { return 42; });
    hpx::cout << "Just launched a task!" << hpx::endl;

    // Use get to retrieve the value from the future. This will block this task until the future is ready, but the HPX runtime will schedule other tasks if there are tasks available.
    hpx::cout << "f contains " << f.get() << hpx::endl;

    // Let's launch another task.
    hpx::future<double> g = hpx::async([]() { return 3.14; });

    // Tasks can be chained using the then method. The continuation takes the future as an argument.
    hpx::future<double> result = g.then([](hpx::future<double>&& gg) {
        // This function will be called once g is ready. gg is g moved into the continuation.
        return gg.get() * 42.0 * 42.0;
    });

    // You can check if a future is ready with the is_ready method.
    hpx::cout << "Result is ready? " << result.is_ready() << hpx::endl;

    // You can launch other work in the meantime. Let's sort a vector.
    std::vector<int> v(1000000);

    // We fill the vector synchronously and sequentially.
    hpx::generate(hpx::execution::seq, std::begin(v), std::end(v), &rand_wrapper);

    // We can launch the sort in parallel and asynchronously.
    hpx::future<void> done_sorting = hpx::parallel::sort(
        hpx::execution::par( // In parallel.
            hpx::execution::task), // Asynchronously.
        std::begin(v), std::end(v));

    // We launch the final task when the vector has been sorted and result is ready using when_all.
    auto all = hpx::when_all(result, done_sorting).then(&final_task);

    // We can wait for all to be ready.
    all.wait();

    // all must be ready at this point because we waited for it to be ready.
    hpx::cout << (all.is_ready() ? "all is ready!" : "all is not ready...") << hpx::endl;
}
```

(continues on next page)
Try copying the contents to your main.cpp file and look at the output. It can be a good idea to go through the program step by step with a debugger. You can also try changing the types or adding new arguments to functions to make sure you can get the types to match. The type of the then method can be especially tricky to get right (the continuation needs to take the future as an argument).

**Note:** HPX programs accept command line arguments. The most important one is --hpx:threads=N to set the number of OS threads used by HPX. HPX uses one thread per core by default. Play around with the example above and see what difference the number of threads makes on the sort function. See *Launching and configuring HPX applications* for more details on how and what options you can pass to HPX.

**Tip:** The example above used the construction hpx::when_all(...).then(...). For convenience and performance it is a good idea to replace uses of hpx::when_all(...).then(...) with dataflow. See *Dataflow: Interest calculator* for more details on dataflow.

**Tip:** If possible, try to use the provided parallel algorithms instead of writing your own implementation. This can save you time and the resulting program is often faster.

### 2.2.7 Next steps

If you haven’t done so already, reading the *Terminology* section will help you get familiar with the terms used in HPX.

The *Examples* section contains small, self-contained walkthroughs of example HPX programs. The *Local to remote: 1D stencil* example is a thorough, realistic example starting from a single node implementation and going stepwise to a distributed implementation.

The *Manual* contains detailed information on writing, building and running HPX applications.

### 2.3 Terminology

This section gives definitions for some of the terms used throughout the HPX documentation and source code.

**Locality** A locality in HPX describes a synchronous domain of execution, or the domain of bounded upper response time. This normally is just a single node in a cluster or a NUMA domain in a SMP machine.

**Active Global Address Space**

AGAS HPX incorporates a global address space. Any executing thread can access any object within the domain of the parallel application with the caveat that it must have appropriate access privileges. The model does not assume that global addresses are cache coherent; all loads and stores will deal directly with the site of the target object. All global addresses within a Synchronous Domain are assumed to be cache coherent for those processor cores that incorporate transparent caches. The Active Global Address Space used by HPX differs from research PGAS\(^{42}\) models. Partitioned Global Address Space is passive in their means of address

---

\(^{42}\) [https://www.pgas.org/](https://www.pgas.org/)
translation. Copy semantics, distributed compound operations, and affinity relationships are some of the global functionality supported by AGAS.

**Process** The concept of the “process” in HPX is extended beyond that of either sequential execution or communicating sequential processes. While the notion of process suggests action (as do “function” or “subroutine”) it has a further responsibility of context, that is, the logical container of program state. It is this aspect of operation that process is employed in HPX. Furthermore, referring to “parallel processes” in HPX designates the presence of parallelism within the context of a given process, as well as the coarse grained parallelism achieved through concurrency of multiple processes of an executing user job. HPX processes provide a hierarchical name space within the framework of the active global address space and support multiple means of internal state access from external sources.

**Parcel** The Parcel is a component in HPX that communicates data, invokes an action at a distance, and distributes flow-control through the migration of continuations. Parcels bridge the gap of asynchrony between synchronous domains while maintaining symmetry of semantics between local and global execution. Parcels enable message-driven computation and may be seen as a form of “active messages”. Other important forms of message-driven computation predating active messages include dataflow tokens\(^{43}\), the J-machine’s\(^{44}\) support for remote method instantiation, and at the coarse grained variations of Unix remote procedure calls, among others. This enables work to be moved to the data as well as performing the more common action of bringing data to the work. A parcel can cause actions to occur remotely and asynchronously, among which are the creation of threads at different system nodes or synchronous domains.

**Local Control Object**

**Lightweight Control Object**

**LCO** A local control object (sometimes called a lightweight control object) is a general term for the synchronization mechanisms used in HPX. Any object implementing a certain concept can be seen as an LCO. This concept encapsulates the ability to be triggered by one or more events which when taking the object into a predefined state will cause a thread to be executed. This could either create a new thread or resume an existing thread.

The LCO is a family of synchronization functions potentially representing many classes of synchronization constructs, each with many possible variations and multiple instances. The LCO is sufficiently general that it can subsume the functionality of conventional synchronization primitives such as spinlocks, mutexes, semaphores, and global barriers. However due to the rich concept an LCO can represent powerful synchronization and control functionality not widely employed, such as dataflow and futures (among others), which open up enormous opportunities for rich diversity of distributed control and operation.

See Using LCOs for more details on how to use LCOs in HPX.

**Action** An action is a function that can be invoked remotely. In HPX a plain function can be made into an action using a macro. See Applying actions for details on how to use actions in HPX.

**Component** A component is a C++ object which can be accessed remotely. A component can also contain member functions which can be invoked remotely. These are referred to as component actions. See Writing components for details on how to use components in HPX.

---

2.4 Examples

The following sections analyze some examples to help you get familiar with the HPX style of programming. We start off with simple examples that utilize basic HPX elements and then begin to expose the reader to the more complex and powerful HPX concepts.

2.4.1 Asynchronous execution with hpx::async: Fibonacci

The Fibonacci sequence is a sequence of numbers starting with 0 and 1 where every subsequent number is the sum of the previous two numbers. In this example, we will use HPX to calculate the value of the n-th element of the Fibonacci sequence. In order to compute this problem in parallel, we will use a facility known as a future.

As shown in the Fig. ?? below, a future encapsulates a delayed computation. It acts as a proxy for a result initially not known, most of the time because the computation of the result has not completed yet. The future synchronizes the access of this value by optionally suspending any HPX-threads requesting the result until the value is available. When a future is created, it spawns a new HPX-thread (either remotely with a parcel or locally by placing it into the thread queue) which, when run, will execute the function associated with the future. The arguments of the function are bound when the future is created.

Once the function has finished executing, a write operation is performed on the future. The write operation marks the future as completed, and optionally stores data returned by the function. When the result of the delayed computation is needed, a read operation is performed on the future. If the future’s function hasn’t completed when a read operation is performed on it, the reader HPX-thread is suspended until the future is ready. The future facility allows HPX to schedule work early in a program so that when the function value is needed it will already be calculated and available. We use this property in our Fibonacci example below to enable its parallel execution.
Setup

The source code for this example can be found here: fibonacci_local.cpp.

To compile this program, go to your HPX build directory (see HPX build system for information on configuring and building HPX) and enter:

```
make examples.quickstart.fibonacci_local
```

To run the program type:

```
./bin/fibonacci_local
```

This should print (time should be approximate):

```
fibonacci(10) == 55
elapsed time: 0.002430 [s]
```

This run used the default settings, which calculate the tenth element of the Fibonacci sequence. To declare which Fibonacci value you want to calculate, use the `--n-value` option. Additionally you can use the `--hpx:threads` option to declare how many OS-threads you wish to use when running the program. For instance, running:

```
./bin/fibonacci --n-value 20 --hpx:threads 4
```

Will yield:

```
fibonacci(20) == 6765
elapsed time: 0.062854 [s]
```

Walkthrough

Now that you have compiled and run the code, let’s look at how the code works. Since this code is written in C++, we will begin with the `main()` function. Here you can see that in HPX, `main()` is only used to initialize the runtime system. It is important to note that application-specific command line options are defined here. HPX uses Boost.Program Options for command line processing. You can see that our programs `--n-value` option is set by calling the `add_options()` method on an instance of `hpx::program_options::options_description`. The default value of the variable is set to 10. This is why when we ran the program for the first time without using the `--n-value` option the program returned the 10th value of the Fibonacci sequence. The constructor argument of the description is the text that appears when a user uses the `--hpx:help` option to see what command line options are available. HPX_APPLICATION_STRING is a macro that expands to a string constant containing the name of the HPX application currently being compiled.

In HPX `main()` is used to initialize the runtime system and pass the command line arguments to the program. If you wish to add command line options to your program you would add them here using the instance of the Boost class `options_description`, and invoking the public member function `.add_options()` (see Boost Documentation for more details). `hpx::init` calls `hpx_main()` after setting up HPX, which is where the logic of our program is encoded.

```c
int main(int argc, char* argv[]) {
    // Configure application-specific options
    hpx::program_options::options_description
desc_commandline("Usage: " HPX_APPLICATION_STRING " [options]");
```
desc_commandline.add_options()
    ( "n-value",
        hpx::program_options::value<std::uint64_t>()->default_value(10),
        "n value for the Fibonacci function"
    );

    // Initialize and run HPX
    hpx::init_params init_args;
    init_args.desc_cmdline = desc_commandline;

    return hpx::init(argc, argv, init_args);
}

The hpx::init function in main() starts the runtime system, and invokes hpx_main() as the first HPX-thread. Below we can see that the basic program is simple. The command line option --n-value is read in, a timer (hpx::chrono::high_resolution_timer) is set up to record the time it takes to do the computation, the fibonacci function is invoked synchronously, and the answer is printed out.

int hpx_main(hpx::program_options::variables_map& vm)
{
    // extract command line argument, i.e. fib(N)
    std::uint64_t n = vm["n-value"].as<std::uint64_t>();

    {
        // Keep track of the time required to execute.
        hpx::chrono::high_resolution_timer t;

        std::uint64_t r = fibonacci(n);

        char const* fmt = "fibonacci({1}) == {2}
                            elapsed time: {3} [s]\n";
        hpx::util::format_to(std::cout, fmt, n, r, t.elapsed());
    }

    return hpx::finalize(); // Handles HPX shutdown
}

The fibonacci function itself is synchronous as the work done inside is asynchronous. To understand what is happening we have to look inside the fibonacci function:

std::uint64_t fibonacci(std::uint64_t n)
{
    if (n < 2)
        return n;

    // Invoking the Fibonacci algorithm twice is inefficient.
    // However, we intentionally demonstrate it this way to create some
    // heavy workload.

    hpx::future<std::uint64_t> n1 = hpx::async(fibonacci, n - 1);
    hpx::future<std::uint64_t> n2 = hpx::async(fibonacci, n - 2);

    return n1.get() + n2.get(); // wait for the Futures to return their values
}

This block of code looks similar to regular C++ code. First, if (n < 2), meaning n is 0 or 1, then we return 0 or 1 (recall the first element of the Fibonacci sequence is 0 and the second is 1). If n is larger than 1

2.4. Examples
we spawn two new tasks whose results are contained in \(n1\) and \(n2\). This is done using `hpx::async` which takes as arguments a function (function pointer, object or lambda) and the arguments to the function. Instead of returning a `std::uint64_t` like `fibonacci` does, `hpx::async` returns a future of a `std::uint64_t`, i.e. `hpx::future<std::uint64_t>`. Each of these futures represents an asynchronous, recursive call to `fibonacci`. After we've created the futures, we wait for both of them to finish computing, we add them together, and return that value as our result. We get the values from the futures using the `get` method. The recursive call tree will continue until \(n\) is equal to 0 or 1, at which point the value can be returned because it is implicitly known. When this termination condition is reached, the futures can then be added up, producing the \(n\)-th value of the Fibonacci sequence.

Note that calling `get` potentially blocks the calling `HPX`-thread, and lets other `HPX`-threads run in the meantime. There are, however, more efficient ways of doing this. Examples/quickstart/fibonacci_futures.cpp contains many more variations of locally computing the Fibonacci numbers, where each method makes different tradeoffs in where asynchrony and parallelism is applied. To get started, however, the method above is sufficient and optimizations can be applied once you are more familiar with `HPX`. The example `Dataflow: Interest calculator` presents dataflow, which is a way to more efficiently chain together multiple tasks.

### 2.4.2 Asynchronous execution with `hpx::async` and actions: Fibonacci

This example extends the previous example by introducing actions: functions that can be run remotely. In this example, however, we will still only run the action locally. The mechanism to execute actions stays the same: `hpx::async`. Later examples will demonstrate running actions on remote localities (e.g. `Remote execution with actions: Hello world`).

#### Setup

The source code for this example can be found here: fibonacci.cpp.

To compile this program, go to your `HPX` build directory (see `HPX build system` for information on configuring and building `HPX`) and enter:

```sh
make examples.quickstart.fibonacci
```

To run the program type:

```sh
./bin/fibonacci
```

This should print (time should be approximate):

```
fibonacci(10) == 55
elapsed time: 0.00186288 [s]
```

This run used the default settings, which calculate the tenth element of the Fibonacci sequence. To declare which Fibonacci value you want to calculate, use the `--n-value` option. Additionally you can use the `--hpx:threads` option to declare how many OS-threads you wish to use when running the program. For instance, running:

```sh
./bin/fibonacci --n-value 20 --hpx:threads 4
```

Will yield:

```
fibonacci(20) == 6765
elapsed time: 0.233827 [s]
```
Walkthrough

The code needed to initialize the HPX runtime is the same as in the previous example:

```cpp
int main(int argc, char* argv[]) {
    // Configure application-specific options
    hpx::program_options::options_description desc_commandline("Usage: " HPX_APPLICATION_STRING " [options]");
    desc_commandline.add_options()
        ("n-value",
         hpx::program_options::value<std::uint64_t>()->default_value(10),
         "n value for the Fibonacci function");
}
```

The `hpx::init` function in `main()` starts the runtime system, and invokes `hpx_main()` as the first HPX-thread. The command line option `--n-value` is read in, a timer (`hpx::chrono::high_resolution_timer`) is set up to record the time it takes to do the computation, the `fibonacci` action is invoked synchronously, and the answer is printed out.

```cpp
int hpx_main(hpx::program_options::variables_map& vm) {
    std::uint64_t n = vm["n-value"].as<std::uint64_t>();
    hpx::chrono::high_resolution_timer t;
    fibonacci_action fib;
    std::uint64_t r = fib(hpx::find_here(), n);
    char const* fmt = "fibonacci({1}) == {2} elapsed time: {3} [s]"
    hpx::util::format_to(std::cout, fmt, n, r, t.elapsed());
}
```

Upon a closer look we see that we’ve created a `std::uint64_t` to store the result of invoking our `fibonacci_action` fib. This action will launch synchronously (as the work done inside of the action will be asynchronous itself) and return the result of the Fibonacci sequence. But wait, what is an action? And what is this `fibonacci_action`? For starters, an action is a wrapper for a function. By wrapping functions, HPX can send packets of work to different processing units. These vehicles allow users to calculate work now, later, or on certain nodes. The first argument to our action is the location where the action should be run. In this case, we just want to run the action on the machine that we are currently on, so we use `hpx::find_here`. To further understand this we turn to the code to find where `fibonacci_action` was defined:

```cpp
// forward declaration of the Fibonacci function
std::uint64_t fibonacci(std::uint64_t n);
```

A plain action is the most basic form of action. Plain actions wrap simple global functions which are not associated with any particular object (we will discuss other types of actions in Components and actions: Accumulator). In this
block of code the function `fibonacci()` is declared. After the declaration, the function is wrapped in an `action` in the declaration `HPX.PLAIN_ACTION`. This function takes two arguments: the name of the function that is to be wrapped and the name of the `action` that you are creating.

This picture should now start making sense. The function `fibonacci()` is wrapped in an `action` `fibonacci_action`, which was run synchronously but created asynchronous work, then returns a `std::uint64_t` representing the result of the function `fibonacci()`. Now, let’s look at the function `fibonacci()`:

```cpp
//fib_func
std::uint64_t fibonacci(std::uint64_t n)
{
    if (n < 2)
    {
        return n;
    }

    // We restrict ourselves to execute the Fibonacci function locally.
    hpx::naming::id_type const locality_id = hpx::find_here();

    // Invoking the Fibonacci algorithm twice is inefficient.
    // However, we intentionally demonstrate it this way to create some
    // heavy workload.

    fibonacci_action fib;
    hpx::future<std::uint64_t> n1 =
        hpx::async(fib, locality_id, n - 1);
    hpx::future<std::uint64_t> n2 =
        hpx::async(fib, locality_id, n - 2);
}
```

This block of code is much more straightforward and should look familiar from the previous example. First, if (n < 2), meaning n is 0 or 1, then we return 0 or 1 (recall the first element of the Fibonacci sequence is 0 and the second is 1). If n is larger than 1 we spawn two tasks using `hpx::async`. Each of these futures represents an asynchronous, recursive call to `fibonacci`. As previously we wait for both futures to finish computing, get the results, add them together, and return that value as our result. The recursive call tree will continue until n is equal to 0 or 1, at which point the value can be returned because it is implicitly known. When this termination condition is reached, the futures can then be added up, producing the n-th value of the Fibonacci sequence.

### 2.4.3 Remote execution with actions: Hello world

This program will print out a hello world message on every OS-thread on every `locality`. The output will look something like this:

```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 1 on locality 1
hello world from OS-thread 0 on locality 0
hello world from OS-thread 0 on locality 1
```
Setup

The source code for this example can be found here: hello_world_distributed.cpp.

To compile this program, go to your HPX build directory (see HPX build system for information on configuring and building HPX) and enter:

```make
make examples.quickstart.hello_world_distributed
```

To run the program type:

```bash
./bin/hello_world_distributed
```

This should print:

```
hello world from OS-thread 0 on locality 0
```

To use more OS-threads use the command line option `--hpx:threads` and type the number of threads that you wish to use. For example, typing:

```bash
./bin/hello_world_distributed --hpx:threads 2
```

will yield:

```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 0
```

Notice how the ordering of the two print statements will change with subsequent runs. To run this program on multiple localities please see the section How to use HPX applications with PBS.

Walkthrough

Now that you have compiled and run the code, let’s look at how the code works, beginning with `main()`:

```cpp
// Here is the main entry point. By using the include 'hpx/hpx_main.hpp' HPX // will invoke the plain old C-main() as its first HPX thread.
int main()
{
    // Get a list of all available localities.
    std::vector<hpx::naming::id_type> localities =
        hpx::find_all_localities();

    // Reserve storage space for futures, one for each locality.
    std::vector<hpx::lcos::future<void>> futures;
    futures.reserve(localities.size());

    for (hpx::naming::id_type const& node : localities)
    {
        // Asynchronously start a new task. The task is encapsulated in a
        // future, which we can query to determine if the task has
        // completed.
        typedef hello_world_foreman_action action_type;
        futures.push_back(hpx::async<action_type>(node));
    }

    // The non-callback version of hpx::lcos::wait_all takes a single parameter,
```

(continues on next page)
// a vector of futures to wait on. hpx::wait_all only returns when
// all of the futures have finished.
hpx::wait_all(futures);
return 0;
}

In this excerpt of the code we again see the use of futures. This time the futures are stored in a vector so that they

In Asynchronous execution with hpx::async and actions: Fibonacci we used hpx::find_here to specify the tar-

target of our actions. Here, we instead use hpx::find_all_localities, which returns an std::vector<> containing the identifiers of all the machines in the system, including the one that we are on.

As in Asynchronous execution with hpx::async and actions: Fibonacci our futures are set using hpx::async<>.
The hello_world_foreman_action is declared here:

// Define the boilerplate code necessary for the function 'hello_world_foreman'
// to be invoked as an HPX action.
HPXPLAIN_ACTION(hello_world_foreman, hello_world_foreman_action);

Another way of thinking about this wrapping technique is as follows: functions (the work to be done) are wrapped in

Now it is time to look at the hello_world_foreman() function which was wrapped in the action above:

```cpp
void hello_world_foreman()
{
    // Get the number of worker OS-threads in use by this locality.
    std::size_t const os_threads = hpx::get_os_thread_count();

    // Populate a set with the OS-thread numbers of all OS-threads on this
    // locality. When the hello world message has been printed on a particular
    // OS-thread, we will remove it from the set.
    std::set<std::size_t> attendance;
    for (std::size_t os_thread = 0; os_thread < os_threads; ++os_thread)
        attendance.insert(os_thread);

    // As long as there are still elements in the set, we must keep scheduling
    // HPX-threads. Because HPX features work-stealing task schedulers, we have
    // no way of enforcing which worker OS-thread will actually execute
    // each HPX-thread.
    while (!attendance.empty())
    {
        // Each iteration, we create a task for each element in the set of
        // OS-threads that have not said "Hello world". Each of these tasks
        // is encapsulated in a future.
        std::vector<hpx::lcos::future<std::size_t>> futures;
        futures.reserve(attendance.size());

        for (std::size_t worker : attendance)
        {
            // Asynchronously start a new task. The task is encapsulated in a
            // future, which we can query to determine if the task has
            // completed. We give the task a hint to run on a particular worker
```
// thread, but no guarantees are given by the scheduler that the
// task will actually run on that worker thread.
hpx::parallel::execution::default_executor exec(
  hpx::threads::thread_schedule_hint(
    static_cast<std::int16_t>(worker)));

futures.push_back(hpx::async(exec, hello_world_worker, worker));
}

// Wait for all of the futures to finish. The callback version of the
// hpx::lcos::wait_each function takes two arguments: a vector of futures,
// and a binary callback. The callback takes two arguments; the first
// is the index of the future in the vector, and the second is the
// return value of the future. hpx::lcos::wait_each doesn't return until
// all the futures in the vector have returned.
hpx::lcos::local::spinlock mtx;

hpx::lcos::wait_each(
  hpx::util::unwrapping([&](std::size_t t) {
    if (std::size_t(-1) != t)
    {
      std::lock_guard<hpx::lcos::local::spinlock> lk(mtx);
      attendance.erase(t);
    }
    futures);
  }), futures);
}

Now, before we discuss hello_world_foreman(), let’s talk about the hpx::wait_each function. The version of hpx::lcos::wait_each invokes a callback function provided by the user, supplying the callback function with the result of the future.

In hello_world_foreman(), an std::set<> called attendance keeps track of which OS-threads have printed out the hello world message. When the OS-thread prints out the statement, the future is marked as ready, and hpx::lcos::wait_each in hello_world_foreman(). If it is not executing on the correct OS-thread, it returns a value of -1, which causes hello_world_foreman() to leave the OS-thread id in attendance.

std::size_t hello_world_worker(std::size_t desired)
{
  // Returns the OS-thread number of the worker that is running this
  // HPX-thread.
  std::size_t current = hpx::get_worker_thread_num();
  if (current == desired)
  {
    // The HPX-thread has been run on the desired OS-thread.
    char const * msg = "hello world from OS-thread {1} on locality {2}\n";

    hpx::util::format_to(hpx::cout, msg, desired, hpx::get_locality_id())
      << std::flush;

    return desired;
  }

  // This HPX-thread has been run by the wrong OS-thread, make the foreman
  // try again by rescheduling it.
  return std::size_t(-1);
}
Because HPX features work stealing task schedulers, there is no way to guarantee that an action will be scheduled on a particular OS-thread. This is why we must use a guess-and-check approach.

### 2.4.4 Components and actions: Accumulator

The accumulator example demonstrates the use of components. Components are C++ classes that expose methods as a type of HPX action. These actions are called component actions.

Components are globally named, meaning that a component action can be called remotely (e.g., from another machine). There are two accumulator examples in HPX.

In the Asynchronous execution with hpx::async and actions: Fibonacci and the Remote execution with actions: Hello world, we introduced plain actions, which wrapped global functions. The target of a plain action is an identifier which refers to a particular machine involved in the computation. For plain actions, the target is the machine where the action will be executed.

Component actions, however, do not target machines. Instead, they target component instances. The instance may live on the machine that we’ve invoked the component action from, or it may live on another machine.

The component in this example exposes three different functions:

- `reset()` - Resets the accumulator value to 0.
- `add(arg)` - Adds `arg` to the accumulators value.
- `query()` - Queries the value of the accumulator.

This example creates an instance of the accumulator, and then allows the user to enter commands at a prompt, which subsequently invoke actions on the accumulator instance.

### Setup

The source code for this example can be found here: accumulator_client.cpp.

To compile this program, go to your HPX build directory (see HPX build system for information on configuring and building HPX) and enter:

```
make examples.accumulators.accumulator
```

To run the program type:

```
./bin/accumulator_client
```

Once the program starts running, it will print the following prompt and then wait for input. An example session is given below:

```
commands: reset, add [amount], query, help, quit
> add 5
> add 10
> query
15
> add 2
> query
17
> reset
> add 1
> query
```

(continues on next page)
Walkthrough

Now, let’s take a look at the source code of the accumulator example. This example consists of two parts: an 
HPX component library (a library that exposes an HPX component) and a client application which uses the library. 
This walkthrough will cover the HPX component library. The code for the client application can be found here: 
accumulator_client.cpp.

An HPX component is represented by two C++ classes:

- **A server class** - The implementation of the component’s functionality.
- **A client class** - A high-level interface that acts as a proxy for an instance of the component.

Typically, these two classes both have the same name, but the server class usually lives in different sub-namespaces 
(server). For example, the full names of the two classes in accumulator are:

- examples::server::accumulator (server class)
- examples::accumulator (client class)

The server class

The following code is from: accumulator.hpp.

All HPX component server classes must inherit publicly from the HPX component base class:

hpx::components::component_base

The accumulator component inherits from hpx::components::locking_hook. This allows the runtime sys-
tem to ensure that all action invocations are serialized. That means that the system ensures that no two actions are 
invoked at the same time on a given component instance. This makes the component thread safe and no additional 
locking has to be implemented by the user. Moreover, an accumulator component is a component because it also 
inherits from hpx::components::component_base (the template argument passed to locking_hook is used 
as its base class). The following snippet shows the corresponding code:

```cpp
/// This component exposes 3 different actions: reset, add and query.
/// [accumulator_server_inherit

class accumulator
```

Our accumulator class will need a data member to store its value in, so let’s declare a data member:

```cpp
private:
```

The constructor for this class simply initializes value_ to 0:

```cpp

Next, let’s look at the three methods of this component that we will be exposing as component actions:

```cpp
// [accumulator_methods

// Reset the components value to 0.
void reset()
```
Here are the action types. These types wrap the methods we’re exposing. The wrapping technique is very similar to the one used in the Asynchronous execution with hpx::async and actions: Fibonacci and the Remote execution with actions: Hello world:

```cpp
// serialization, etc.
//accumulator_action_types
HPX_DEFINE_COMPONENT_ACTION(accumulator, reset);
```

The last piece of code in the server class header is the declaration of the action type registration code:

```cpp
//accumulator_registration_declarations
HPX_REGISTER_ACTION_DECLARATION(
    examples::server::accumulator::reset_action,
    accumulator_reset_action);

HPX_REGISTER_ACTION_DECLARATION(
    examples::server::accumulator::add_action,
    accumulator_add_action);

HPX_REGISTER_ACTION_DECLARATION(
```

**Note:** The code above must be placed in the global namespace.

The rest of the registration code is in accumulator.cpp

```cpp
//accumulator_registration_definitions
 confessed::component<
    examples::server::accumulator
> accumulator_type;

HPX_REGISTER_COMPONENT(accumulator_type, accumulator);
```

(continues on next page)
HPX_REGISTER_ACTION(
    accumulator_type::wrapped_type::reset_action,
    accumulator_reset_action);
HPX_REGISTER_ACTION(
    accumulator_type::wrapped_type::add_action,
    accumulator_add_action);
HPX_REGISTER_ACTION(

Note: The code above must be placed in the global namespace.

The client class

The following code is from `accumulator.hpp`.

The client class is the primary interface to a component instance. Client classes are used to create components:

```cpp
// Create a component on this locality.
examples::accumulator c = hpx::new_<examples::accumulator>(hpx::find_here());
```

and to invoke component actions:

```cpp
c.add(hpx::launch::apply, 4);
```

Clients, like servers, need to inherit from a base class, this time, `hpx::components::client_base`:

```cpp
class accumulator
  : public hpx::components::client_base<
    accumulator, server::accumulator>
{
    
};
```

For readability, we typedef the base class like so:

```cpp
typedef hpx::components::client_base<
  accumulator, server::accumulator
> base_type;
```

Here are examples of how to expose actions through a client class:

There are a few different ways of invoking actions:

- **Non-blocking:** For actions that don’t have return types, or when we do not care about the result of an action, we can invoke the action using fire-and-forget semantics. This means that once we have asked HPX to compute the action, we forget about it completely and continue with our computation. We use `hpx::apply` to invoke an action in a non-blocking fashion.

```cpp
void reset(hpx::launch::apply_policy)
{
    HPX_ASSERT(this->get_id());

    typedef server::accumulator::reset_action action_type;
    hpx::apply<action_type>(this->get_id());
}
```
• **Asynchronous**: Futures, as demonstrated in *Asynchronous execution with hpx::async: Fibonacci*, *Asynchronous execution with hpx::async and actions: Fibonacci*, and the *Remote execution with actions: Hello world*, enable asynchronous action invocation. Here’s an example from the accumulator client class:

```cpp
hpx::future<argument_type> query(hpx::launch::async_policy)
{
    HPX_ASSERT(this->get_id());

typedef server::accumulator::query_action action_type;
return hpx::async<action_type>(hpx::launch::async, this->get_id());
}
```

• **Synchronous**: To invoke an action in a fully synchronous manner, we can simply call `hpx::async().get()` (i.e., create a future and immediately wait on it to be ready). Here’s an example from the accumulator client class:

```cpp
void add(argument_type arg)
{
    HPX_ASSERT(this->get_id());

    typedef server::accumulator::add_action action_type;
    action_type() (this->get_id(), arg);
}
```

Note that `this->get_id()` references a data member of the `hpx::components::client_base` base class which identifies the server accumulator instance.

`hpx::naming::id_type` is a type which represents a global identifier in *HPX*. This type specifies the target of an action. This is the type that is returned by `hpx::find_here` in which case it represents the locality the code is running on.

### 2.4.5 Dataflow: Interest calculator

*HPX* provides its users with several different tools to simply express parallel concepts. One of these tools is a *local control object* (*LCO*) called dataflow. An *LCO* is a type of component that can spawn a new thread when triggered. They are also distinguished from other components by a standard interface that allow users to understand and use them easily. A Dataflow, being an *LCO*, is triggered when the values it depends on become available. For instance, if you have a calculation X that depends on the results of three other calculations, you could set up a dataflow that would begin the calculation X as soon as the other three calculations have returned their values. Dataflows are set up to depend on other dataflows. It is this property that makes dataflow a powerful parallelization tool. If you understand the dependencies of your calculation, you can devise a simple algorithm that sets up a dependency tree to be executed. In this example, we calculate compound interest. To calculate compound interest, one must calculate the interest made in each compound period, and then add that interest back to the principal before calculating the interest made in the next period. A practical person would, of course, use the formula for compound interest:

\[
F = P(1 + i)^n
\]

where \(F\) is the future value, \(P\) is the principal value, \(i\) is the interest rate, and \(n\) is the number of compound periods. However, for the sake of this example, we have chosen to manually calculate the future value by iterating:

\[
I = Pi
\]

and

\[
P = P + I
\]
Setup

The source code for this example can be found here: interest_calculator.cpp.

To compile this program, go to your HPX build directory (see HPX build system for information on configuring and building HPX) and enter:

```
make examples.quickstart.interest_calculator
```

To run the program type:

```
./bin/interest_calculator --principal 100 --rate 5 --cp 6 --time 36
```

This should print:

```
Final amount: 134.01
Amount made: 34.0096
```

Walkthrough

Let us begin with main. Here we can see that we again are using Boost.Program Options to set our command line variables (see Asynchronous execution with hpx::async and actions: Fibonacci for more details). These options set the principal, rate, compound period, and time. It is important to note that the units of time for cp and time must be the same.

```cpp
int main(int argc, char ** argv)
{
    options_description cmdline("Usage: " HPX_APPLICATION_STRING " [options]");
    cmdline.add_options()
        ("principal", value<double>()->default_value(1000), "The principal [\$]")
        ("rate", value<double>()->default_value(7), "The interest rate [%]")
        ("cp", value<int>()->default_value(12), "The compound period [months]")
        ("time", value<int>()->default_value(12*30),
        "The time money is invested [months]")
;
```  

Next we look at hpx_main.

```cpp
int hpx_main(variables_map & vm)
{
    using hpx::shared_future;
    using hpx::make_ready_future;
    using hpx::dataflow;
    using hpx::util::unwrapping;
    hpx::naming::id_type here = hpx::find_here();

    double init_principal=vm["principal"].as<double>(); //Initial principal
    double init_rate=vm["rate"].as<double>(); //Interest rate
    int cp=vm["cp"].as<int>(); //Length of a compound period
    int t=vm["time"].as<int>(); //Length of time money is invested
```

(continues on next page)
init_rate /= 100; // Rate is a % and must be converted
t = cp; // Determine how many times to iterate interest calculation:
// How many full compound periods can fit in the time invested

// In non-dataflow terms the implemented algorithm would look like:
// int t = 5; //number of time periods to use
// double principal = init_principal;
// double rate = init_rate;
//
// for (int i = 0; i < t; ++i)
// {
// double interest = calc(principal, rate);
// principal = add(principal, interest);
// }

// Please note the similarity with the code below!

shared_future<double> principal = make_ready_future(init_principal);
shared_future<double> rate = make_ready_future(init_rate);

for (int i = 0; i < t; ++i)
{
    shared_future<double> interest = dataflow(unwrapping(calc), principal, rate);
    principal = dataflow(unwrapping(add), principal, interest);
}

// wait for the dataflow execution graph to be finished calculating our
// overall interest

double result = principal.get();

std::cout << "Final amount: " << result << std::endl;
std::cout << "Amount made: " << result-init_principal << std::endl;
}
After the shared future dependencies have been defined in `hpx_main`, we see the following statement:

```cpp
double result = principal.get();
```

This statement calls `hpx::future::get` on the shared future `principal` which had its value calculated by our for loop. The program will wait here until the entire dataflow tree has been calculated and the value assigned to `result`. The program then prints out the final value of the investment and the amount of interest made by subtracting the final value of the investment from the initial value of the investment.

### 2.4.6 Local to remote: 1D stencil

When developers write code they typically begin with a simple serial code and build upon it until all of the required functionality is present. The following set of examples were developed to demonstrate this iterative process of evolving a simple serial program to an efficient, fully-distributed HPX application. For this demonstration, we implemented a 1D heat distribution problem. This calculation simulates the diffusion of heat across a ring from an initialized state to some user-defined point in the future. It does this by breaking each portion of the ring into discrete segments and using the current segment’s temperature and the temperature of the surrounding segments to calculate the temperature of the current segment in the next timestep as shown by Fig. ?? below.

![Fig. 2.2: Heat diffusion example program flow.](image)

We parallelize this code over the following eight examples:

- Example 1
- Example 2
- Example 3
- Example 4
- Example 5
- Example 6
- Example 7
- Example 8
The first example is straight serial code. In this code we instantiate a vector \( U \) that contains two vectors of doubles as seen in the structure \texttt{stepper}.

\begin{verbatim}
// [stepper_1
struct stepper
{
    // Our partition type
    typedef double partition;

    // Our data for one time step
    typedef std::vector<partition> space;

    // Our operator
    static double heat(double left, double middle, double right)
    {
        return middle + (k*dt/(dx*dx)) * (left - 2*middle + right);
    }

    // do all the work on 'nx' data points for 'nt' time steps
    space do_work(std::size_t nx, std::size_t nt)
    {
        // \( U[t][i] \) is the state of position i at time t.
        std::vector<space> U(2);
        for (space& s : U)
            s.resize(nx);

        // Initial conditions: \( f(0, i) = i \)
        for (std::size_t i = 0; i != nx; ++i)
            U[0][i] = double(i);

        // Actual time step loop
        for (std::size_t t = 0; t != nt; ++t)
        {
            space const& current = U[t % 2];
            space& next = U[(t + 1) % 2];

            next[0] = heat(current[nx-1], current[0], current[1]);

            for (std::size_t i = 1; i != nx-1; ++i)
                next[i] = heat(current[i-1], current[i], current[i+1]);

            next[nx-1] = heat(current[nx-2], current[nx-1], current[0]);
        }

        // Return the solution at time-step 'nt'.
        return U[nt % 2];
    }
}
\end{verbatim}

Each element in the vector of doubles represents a single grid point. To calculate the change in heat distribution, the temperature of each grid point, along with its neighbors, is passed to the function \texttt{heat}. In order to improve readability, references named \texttt{current} and \texttt{next} are created which, depending on the time step, point to the first and second vector of doubles. The first vector of doubles is initialized with a simple heat ramp. After calling the heat function with the data in the \texttt{current} vector, the results are placed into the \texttt{next} vector.

In example 2 we employ a technique called futurization. Futurization is a method by which we can easily transform a code that is serially executed into a code that creates asynchronous threads. In the simplest case this involves replacing a variable with a future to a variable, a function with a future to a function, and adding a .\texttt{get()} at the point where a value is actually needed. The code below shows how this technique was applied to the \texttt{struct stepper}.
```cpp
// Our partition type
typedef hpx::shared_future<double> partition;

// Our data for one time step
typedef std::vector<partition> space;

// Our operator
static double heat(double left, double middle, double right)
{
    return middle + (k*dt/(dx*dx)) * (left - 2*middle + right);
}

// do all the work on 'nx' data points for 'nt' time steps
hpx::future<space> do_work(std::size_t nx, std::size_t nt)
{
    using hpx::dataflow;
    using hpx::util::unwrapping;

    // U[t][i] is the state of position i at time t.
    std::vector<space> U(2);
    for (space& s : U)
        s.resize(nx);

    // Initial conditions: f(0, i) = i
    for (std::size_t i = 0; i != nx; ++i)
        U[0][i] = hpx::make_ready_future(double(i));

    auto Op = unwrapping(&stepper::heat);

    // Actual time step loop
    for (std::size_t t = 0; t != nt; ++t)
    {
        space current = U[t % 2];
        space next = U[(t + 1) % 2];

        // WHEN U[t][i-1], U[t][i], and U[t][i+1] have been computed, THEN we
        // can compute U[t+1][i]
        for (std::size_t i = 0; i != nx; ++i)
        {
            next[i] = dataflow(
                hpx::launch::async, Op,
                current[idx(i, -1, nx)], current[i], current[idx(i, +1, nx)]
            );
        }
    }

    // Now the asynchronous computation is running; the above for-loop does not
    // wait on anything. There is no implicit waiting at the end of each timestep;
    // the computation of each U[t][i] will begin as soon as its dependencies
    // are ready and hardware is available.

    // Return the solution at time-step 'nt'.
    return hpx::when_all(U[nt % 2]);
}
```
In example 2, we redefine our partition type as a shared_future and, in main, create the object result, which is a future to a vector of partitions. We use result to represent the last vector in a string of vectors created for each timestep. In order to move to the next timestep, the values of a partition and its neighbors must be passed to heat once the futures that contain them are ready. In HPX, we have an LCO (Local Control Object) named Dataflow that assists the programmer in expressing this dependency. Dataflow allows us to pass the results of a set of futures to a specified function when the futures are ready. Dataflow takes three types of arguments, one which instructs the dataflow on how to perform the function call (async or sync), the function to call (in this case Op), and futures to the arguments that will be passed to the function. When called, dataflow immediately returns a future to the result of the specified function. This allows users to string dataflows together and construct an execution tree.

After the values of the futures in dataflow are ready, the values must be pulled out of the future container to be passed to the function heat. In order to do this, we use the HPX facility unwrapping, which underneath calls .get() on each of the futures so that the function heat will be passed doubles and not futures to doubles.

By setting up the algorithm this way, the program will be able to execute as quickly as the dependencies of each future are met. Unfortunately, this example runs terribly slow. This increase in execution time is caused by the overheads needed to create a future for each data point. Because the work done within each call to heat is very small, the overhead of creating and scheduling each of the three futures is greater than that of the actual useful work! In order to amortize the overheads of our synchronization techniques, we need to be able to control the amount of work that will be done with each future. We call this amount of work per overhead grain size.

In example 3, we return to our serial code to figure out how to control the grain size of our program. The strategy that we employ is to create “partitions” of data points. The user can define how many partitions are created and how many data points are contained in each partition. This is accomplished by creating the struct partition, which contains a member object data_, a vector of doubles that holds the data points assigned to a particular instance of partition.

In example 4, we take advantage of the partition setup by redefining space to be a vector of shared_futures with each future representing a partition. In this manner, each future represents several data points. Because the user can define how many data points are in each partition, and, therefore, how many data points are represented by one future, a user can control the grain size of the simulation. The rest of the code is then futurized in the same manner as example 2. It should be noted how strikingly similar example 4 is to example 2.

Example 4 finally shows good results. This code scales equivalently to the OpenMP version. While these results are promising, there are more opportunities to improve the application’s scalability. Currently, this code only runs on one locality, but to get the full benefit of HPX, we need to be able to distribute the work to other machines in a cluster. We begin to add this functionality in example 5.

In order to run on a distributed system, a large amount of boilerplate code must be added. Fortunately, HPX provides us with the concept of a component, which saves us from having to write quite as much code. A component is an object that can be remotely accessed using its global address. Components are made of two parts: a server and a client class. While the client class is not required, abstracting the server behind a client allows us to ensure type safety instead of having to pass around pointers to global objects. Example 5 renames example 4’s struct partition to partition_data and adds serialization support. Next, we add the server side representation of the data in the structure partition_server. Partition_server inherits from hpx::components::component_base, which contains a server-side component boilerplate. The boilerplate code allows a component’s public members to be accessible anywhere on the machine via its Global Identifier (GID). To encapsulate the component, we create a client side helper class. This object allows us to create new instances of our component and access its members without having to know its GID. In addition, we are using the client class to assist us with managing our asynchrony. For example, our client class partition’s member function get_data() returns a future to partition_data get_data(). This struct inherits its boilerplate code from hpx::components::client_base.

In the structure stepper, we have also had to make some changes to accommodate a distributed environment. In order to get the data from a particular neighboring partition, which could be remote, we must retrieve the data from all of the neighboring partitions. These retrievals are asynchronous and the function heat_part_data, which, amongst other things, calls heat, should not be called unless the data from the neighboring partitions have arrived. Therefore, it should come as no surprise that we synchronize this operation with another instance of
dataflow (found in heat_part). This dataflow receives futures to the data in the current and surrounding partitions by calling get_data() on each respective partition. When these futures are ready, dataflow passes them to the unwrapping function, which extracts the shared_array of doubles and passes them to the lambda. The lambda calls heat_part_data on the locality, which the middle partition is on.

Although this example could run distributed, it only runs on one locality, as it always uses hpx::find_here() as the target for the functions to run on.

In example 6, we begin to distribute the partition data on different nodes. This is accomplished in stepper::do_work() by passing the GID of the locality where we wish to create the partition to the partition constructor.

```cpp
std::vector<space> U(2);
for (space& s : U)
```

We distribute the partitions evenly based on the number of localities used, which is described in the function locidx. Because some of the data needed to update the partition in heat_part could now be on a new locality, we must devise a way of moving data to the locality of the middle partition. We accomplished this by adding a switch in the function get_data() that returns the end element of the buffer data_ if it is from the left partition or the first element of the buffer if the data is from the right partition. In this way only the necessary elements, not the whole buffer, are exchanged between nodes. The reader should be reminded that this exchange of end elements occurs in the function get_data() and, therefore, is executed asynchronously.

Now that we have the code running in distributed, it is time to make some optimizations. The function heat_part spends most of its time on two tasks: retrieving remote data and working on the data in the middle partition. Because we know that the data for the middle partition is local, we can overlap the work on the middle partition with that of the possibly remote call of get_data(). This algorithmic change, which was implemented in example 7, can be seen below:

```cpp
static double heat(double left, double middle, double right)
{
    return middle + (k*dt/(dx*dx)) * (left - 2*middle + right);
}

//stepper_7
// The partitioned operator, it invokes the heat operator above on all elements
// of a partition.
static partition heat_part(partition const& left,
    partition const& middle, partition const& right)
{
    using hpx::dataflow;
    using hpx::util::unwrapping;

    hpx::shared_future<partition_data> middle_data =
        middle.get_data(partition_server::middle_partition);

    hpx::future<partition_data> next_middle = middle_data.then(
        unwrapping{
            [middle](partition_data const& m) -> partition_data
            {
            HPX_UNUSED(middle);

            // All local operations are performed once the middle data of
            // the previous time step becomes available.
            std::size_t size = m.size();
            partition_data next(size);
            for (std::size_t i = 1; i != size-1; ++i)
                next[i] = heat(m[i-1], m[i], m[i+1]);
```
Example 8 completes the futurization process and utilizes the full potential of HPX by distributing the program flow to multiple localities, usually defined as nodes in a cluster. It accomplishes this task by running an instance of HPX main on each locality. In order to coordinate the execution of the program, the struct stepper is wrapped into a component. In this way, each locality contains an instance of stepper that executes its own instance of the function do_work(). This scheme does create an interesting synchronization problem that must be solved. When the program flow was being coordinated on the head node, the GID of each component was known. However, when we distribute the program flow, each partition has no notion of the GID of its neighbor if the next partition is on another locality. In order to make the GIDs of neighboring partitions visible to each other, we created two buffers to store the GIDs of the remote neighboring partitions on the left and right respectively. These buffers are filled by sending the GID of newly created edge partitions to the right and left buffers of the neighboring localities.

In order to finish the simulation, the solution vectors named result are then gathered together on locality 0 and added into a vector of spaces overall_result using the HPX functions gather_id and gather_here.

Example 8 completes this example series, which takes the serial code of example 1 and incrementally morphs it into a fully distributed parallel code. This evolution was guided by the simple principles of futurization, the knowledge of grainsize, and utilization of components. Applying these techniques easily facilitates the scalable parallelization of most applications.
2.5 Manual

The manual is your comprehensive guide to HPX. It contains detailed information on how to build and use HPX in different scenarios.

2.5.1 Getting HPX

There are HPX packages available for a few Linux distributions. The easiest way to get started with HPX is to use those packages. We keep an up-to-date list with instructions on the HPX Downloads page. If you use one of the available packages you can skip the next section, HPX build system, but we still recommend that you look through it as it contains useful information on how you can customize HPX at compile-time.

If there isn’t a package available for your platform you should either clone our repository:

or download a package with the source files from HPX Downloads.

2.5.2 HPX build system

The build system for HPX is based on CMake. CMake is a cross-platform build-generator tool. CMake does not build the project, it generates the files needed by your build tool (GNU make, Visual Studio, etc.) for building HPX.

This section gives an introduction on how to use our build system to build HPX and how to use HPX in your own projects.

CMake basics

CMake is a cross-platform build-generator tool. CMake does not build the project, it generates the files needed by your build tool (gnu make, visual studio, etc.) for building HPX.

In general, the HPX CMake scripts try to adhere to the general CMake policies on how to write CMake-based projects.

Basic CMake usage

This section explains basic aspects of CMake, specifically options needed for day-to-day usage.

CMake comes with extensive documentation in the form of html files and on the CMake executable itself. Execute `cmake --help` for further help options.

CMake needs to know which build tool it will generate files for (GNU make, Visual Studio, Xcode, etc.). If not specified on the command line, it will try to guess the build tool based on you environment. Once it has identified the build tool, CMake uses the corresponding generator to create files for your build tool. You can explicitly specify the generator with the command line option `-G "Name of the generator"`. To see the available generators on your platform, execute:

```
cmake --help
```

This will list the generator names at the end of the help text. Generator names are case-sensitive. Example:

```
cmake -G "Visual Studio 16 2019" path/to/hpx
```
For a given development platform there can be more than one adequate generator. If you use Visual Studio "NMake Makefiles" is a generator you can use for building with NMake. By default, CMake chooses the more specific generator supported by your development environment. If you want an alternative generator, you must tell this to CMake with the \texttt{-G} option.

**Quick start**

Here, you will use the command-line, non-interactive CMake interface.

1. Download and install CMake here: \url{CMake Downloads}\textsuperscript{50}. Version 3.17 is the minimum required version for \texttt{HPX}.

2. Open a shell. Your development tools must be reachable from this shell through the \texttt{PATH} environment variable.

3. Create a directory for containing the build. Building \texttt{HPX} on the source directory is not supported. \texttt{cd} to this directory:

   \begin{verbatim}
   mkdir mybuilddir
cd mybuilddir
   \end{verbatim}

4. Execute this command on the shell replacing \texttt{path/to/hpx} with the path to the root of your \texttt{HPX} source tree:

   \begin{verbatim}
   cmake path/to/hpx
   \end{verbatim}

CMake will detect your development environment, perform a series of tests and will generate the files required for building \texttt{HPX}. CMake will use default values for all build parameters. See the \texttt{CMake variables used to configure \texttt{HPX}} section for fine-tuning your build.

This can fail if CMake can’t detect your toolset, or if it thinks that the environment is not sane enough. In this case make sure that the toolset that you intend to use is the only one reachable from the shell and that the shell itself is the correct one for your development environment. CMake will refuse to build MinGW makefiles if you have a POSIX shell reachable through the \texttt{PATH} environment variable, for instance. You can force CMake to use various compilers and tools. Please visit \url{CMake Useful Variables}\textsuperscript{51} for a detailed overview of specific CMake variables.

**Options and variables**

Variables customize how the build will be generated. Options are boolean variables, with possible values \texttt{ON/OFF}. Options and variables are defined on the CMake command line like this:

\begin{verbatim}
cmake -DVARIABLE=value path/to/hpx
\end{verbatim}

You can set a variable after the initial CMake invocation for changing its value. You can also undefine a variable:

\begin{verbatim}
cmake -UVARIABLE path/to/hpx
\end{verbatim}

Variables are stored on the CMake cache. This is a file named \texttt{CMakeCache.txt} on the root of the build directory. Do not hand-edit it.

Variables are listed here appending its type after a colon. You should write the variable and the type on the CMake command line:

\begin{verbatim}
cmake -DVARIABLE:TYPE=value path/to/llvm/source
\end{verbatim}

\textsuperscript{50} \url{https://www.cmake.org/cmake/resources/software.html}
\textsuperscript{51} \url{https://gitlab.kitware.com/cmake/community/wikis/doc/cmake/Useful-Variables#Compilers-and-Tools}
CMake supports the following variable types: BOOL (options), STRING (arbitrary string), PATH (directory name), FILEPATH (file name).

Prerequisites

Supported platforms

At this time, HPX supports the following platforms. Other platforms may work, but we do not test HPX with other platforms, so please be warned.

<table>

<td>Any OSX system</td>
<td>x86-64</td>
</tr>
</tbody>
</table>

Software and libraries

In the simplest case, HPX depends on Boost\(^{52}\) and Portable Hardware Locality (HWLOC)\(^{53}\). So, before you read further, please make sure you have a recent version of Boost\(^{54}\) installed on your target machine. HPX currently requires at least Boost V1.66.0 to work properly. It may build and run with older versions, but we do not test HPX with those versions, so please be warned.

The installation of Boost is described in detail in Boost’s Getting Started\(^{55}\) document. However, if you’ve never used the Boost libraries (or even if you have), here’s a quick primer: Installing Boost.

It is often possible to download the Boost libraries using the package manager of your distribution. Please refer to the corresponding documentation for your system for more information.

In addition, we require a recent version of hwloc in order to support thread pinning and NUMA awareness. See Installing Hwloc for instructions on building Portable Hardware Locality (HWLOC).

HPX is written in 99.99% Standard C++ (the remaining 0.01% is platform specific assembly code). As such, HPX is compilable with almost any standards compliant C++ compiler. A compiler supporting the C++11 Standard is highly recommended. The code base takes advantage of C++11 language features when available (move semantics, rvalue references, magic statics, etc.). This may speed up the execution of your code significantly. We currently support the following C++ compilers: GCC, MSVC, ICPC and clang. For the status of your favorite compiler with HPX visit HPX Buildbot Website\(^{56}\).

<tr>
<td>Portable Hardware Locality (HWLOC)(^{65})</td>
<td>1.5</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** You need to build the following Boost libraries for HPX: Boost.Filesystem, Boost.ProgramOptions, and Boost.System. The following are not needed by default, but are required in certain configurations: Boost.Chrono, Boost.DateTime, Boost.Log, Boost.LogSetup, Boost.Regex, and Boost.Thread.

Depending on the options you chose while building and installing HPX, you will find that HPX may depend on several other libraries such as those listed below.

**Note:** In order to use a high speed parcelport, we currently recommend configuring HPX to use MPI so that MPI can be used for communication between different localities. Please set the CMake variable `MPI_CXX_COMPILER` to your MPI C++ compiler wrapper if not detected automatically.

<td>google-perftools</td>
<td>1.7.1</td>
<td>Used as a replacement for the system allocator, and for allocation diagnostics.</td>
</tr>
<tr>
<td>libunwind</td>
<td>0.97</td>
<td>Dependency of google-perftools on x86-64, used for stack unwinding.</td>
</tr>
<tr>
<td>Open MPI</td>
<td>1.8.0</td>
<td>Can be used as a highspeed communication library backend for the parcelport.</td>
</tr>
</tbody>
</table>

**Note:** When using OpenMPI please note that Ubuntu (notably 18.04 LTS) and older Debian ship an OpenMPI 2.x built with `--enable-heterogeneous` which may cause communication failures at runtime and should not be used.

### Table 2.5: Optional software prerequisites for HPX on Linux systems

<table>
<thead>
<tr>
<th>Name</th>
<th>Minimum version</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Performance Application Programming Interface (PAPI)</td>
<td></td>
<td>Used for accessing hardware performance data.</td>
</tr>
<tr>
<td>jemalloc</td>
<td>2.1.0</td>
<td>Used as a replacement for the system allocator.</td>
</tr>
<tr>
<td>mi-malloc</td>
<td>1.0.0</td>
<td>Used as a replacement for the system allocator.</td>
</tr>
<tr>
<td>Hierarchical Data Format V5 (HDF5)</td>
<td>1.6.7</td>
<td>Used for data I/O in some example applications. See important note below.</td>
</tr>
</tbody>
</table>

### Table 2.6: Optional software prerequisites for HPX on Windows systems

<table>
<thead>
<tr>
<th>Name</th>
<th>Minimum version</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hierarchical Data Format V5 (HDF5)</td>
<td>1.6.7</td>
<td>Used for data I/O in some example applications. See important note below.</td>
</tr>
</tbody>
</table>

**Important:** The C++ HDF5 libraries must be compiled with enabled thread safety support. This has to be explicitly specified while configuring the HDF5 libraries as it is not the default. Additionally, you must set the following environment variables before configuring the HDF5 libraries (this part only needs to be done on Linux):

```
export CFLAGS='-D_HDFatexit=""'
export CPPFLAGS='-D_HDFatexit=""'
```

71 [https://www.hdfgroup.org/HDF5](https://www.hdfgroup.org/HDF5)
72 [https://www.hdfgroup.org/HDF5](https://www.hdfgroup.org/HDF5)
Documentation

To build the HPX documentation, you need recent versions of the following packages:

- python3
- sphinx (Python package)
- sphinx_rtd_theme (Python package)
- breathe 4.16.0 (Python package)
- doxygen

If the Python dependencies are not available through your system package manager, you can install them using the Python package manager pip:

```
pip install --user sphinx sphinx_rtd_theme breathe
```

You may need to set the following CMake variables to make sure CMake can find the required dependencies.

**DOXYGEN_ROOT**:PATH
Specifies where to look for the installation of the Doxygen tool.

**SPHINX_ROOT**:PATH
Specifies where to look for the installation of the Sphinx tool.

**BREATHE_API_DOC_ROOT**:PATH
Specifies where to look for the installation of the Breathe tool.

Installing Boost

**Important:** When building Boost using gcc, please note that it is required to specify a `cxxflags=-std=c++14` command line argument to `b2` (bjam).

**Important:** On Windows, depending on the installed versions of Visual Studio, you might also want to pass the correct toolset to the `b2` command depending on which version of the IDE you want to use. In addition, passing `address-model=64` is highly recommended. It might also be necessary to add command line argument `--build-type=complete` to the `b2` command on the Windows platform.

The easiest way to create a working Boost installation is to compile Boost from sources yourself. This is particularly important as many high performance resources, even if they have Boost installed, usually only provide you with an older version of Boost. We suggest you download the most recent release of the Boost libraries from here: Boost Downloads. Unpack the downloaded archive into a directory of your choosing. We will refer to this directory a `$BOOST`.

Building and installing the Boost binaries is simple. Regardless of what platform you are on, the basic instructions are as follows (with possible additional platform-dependent command line arguments):

---

73 https://www.python.org
74 https://www.doxygen.org
75 http://www.sphinx-doc.org
76 https://breathe.readthedocs.io/en/latest
77 https://www.boost.org/users/download/
cd $BOOST
bootstrap --prefix=<where to install boost>
./b2 -j<N>
./b2 install

where: `<where to install boost>` is the directory the built binaries will be installed to, and `<N>` is the number of cores to use to build the Boost binaries.

After the above sequence of commands has been executed (this may take a while!), you will need to specify the directory where Boost was installed as `BOOST_ROOT('<where to install boost>')` while executing CMake for HPX as explained in detail in the sections *How to install HPX on Unix variants* and *How to install HPX on Windows*.

### Installing Hwloc

**Note:** These instructions are for everything except Windows. On Windows there is no need to build hwloc. Instead, download the latest release, extract the files, and set `HWLOC_ROOT` during CMake configuration to the directory in which you extracted the files.

We suggest you download the most recent release of hwloc from here: Hwloc Downloads[^78]. Unpack the downloaded archive into a directory of your choosing. We will refer to this directory as `$HWLOC`.

To build hwloc run:

```bash
cd $HWLOC
./configure --prefix=<where to install hwloc>
make -j<N> install
```

where: `<where to install hwloc>` is the directory the built binaries will be installed to, and `<N>` is the number of cores to use to build hwloc.

After the above sequence of commands has been executed, you will need to specify the directory where hwloc was installed as `HWLOC_ROOT('<where to install hwloc>')` while executing CMake for HPX as explained in detail in the sections *How to install HPX on Unix variants* and *How to install HPX on Windows*.

Please see Hwloc Documentation[^79] for more information about hwloc.

### Building HPX

#### Basic information

Once CMake has been run, the build process can be started. The HPX build process is highly configurable through CMake, and various CMake variables influence the build process. The build process consists of the following parts:

- The HPX core libraries (target core): This forms the basic set of HPX libraries. The generated targets are:
  - `hpx`: The core HPX library (always enabled).
  - `hpx_init`: The HPX initialization library that applications need to link against to define the HPX entry points (disabled for static builds).

[^78]: https://www.open-mpi.org/software/hwloc/v1.11
[^79]: https://www.open-mpi.org/projects/hwloc/doc/
- **hpx_wrap**: The HPX static library used to determine the runtime behavior of HPX code and respective entry points for hpx_main.h
- **iostreams_component**: The component used for (distributed) IO (always enabled).
- **component_storage_component**: The component needed for migration to persistent storage.
- **unordered_component**: The component needed for a distributed (partitioned) hash table.
- **partitioned_vector_component**: The component needed for a distributed (partitioned) vector.
- **memory_component**: A dynamically loaded plugin that exposes memory based performance counters (only available on Linux).
- **io_counter_component**: A dynamically loaded plugin that exposes I/O performance counters (only available on Linux).
- **papi_component**: A dynamically loaded plugin that exposes PAPI performance counters (enabled with HPX_WITH_PAPI:BOOL, default is Off).

- **HPX Examples** (target examples): This target is enabled by default and builds all HPX examples (disable by setting HPX_WITH_EXAMPLES:BOOL=Off). HPX examples are part of the all target and are included in the installation if enabled.

- **HPX Tests** (target tests): This target builds the HPX test suite and is enabled by default (disable by setting HPX_WITH_TESTS:BOOL=Off). They are not built by the all target and have to be built separately.

- **HPX Documentation** (target docs): This target builds the documentation, and is not enabled by default (enable by setting HPX_WITH_DOCUMENTATION:BOOL=On. For more information see Documentation.

For a complete list of available CMake variables that influence the build of HPX, see CMake variables used to configure HPX.

The variables can be used to refine the recipes that can be found at Platform specific build recipes which show some basic steps on how to build HPX for a specific platform.

In order to use HPX, only the core libraries are required (the ones marked as optional above are truly optional). When building against HPX, the CMake variable HPX_LIBRARIES will contain hpx and hpx_init (for pkgconfig, those are added to the Libs sections). In order to use the optional libraries, you need to specify them as link dependencies in your build (See Creating HPX projects).

As HPX is a modern C++ library, we require a certain minimum set of features from the C++11 standard. In addition, we make use of certain C++14 features if the used compiler supports them. This means that the HPX build system will try to determine the highest support C++ standard flavor and check for availability of those features. That is, the default will be the highest C++ standard version available. If you want to force HPX to use a specific C++ standard version, you can use the following CMake variables:

- **HPX_WITH_CXX14**: Enables C++14 support (this is the minimum requirement)
- **HPX_WITH_CXX17**: Enables C++17 support
- **HPX_WITH_CXX2A**: Enables (experimental) C++20 support
Build types

CMake can be configured to generate project files suitable for builds that have enabled debugging support or for an optimized build (without debugging support). The CMake variable used to set the build type is `CMAKE_BUILD_TYPE` (for more information see the CMake Documentation\(^{80}\)). Available build types are:

- **Debug**: Full debug symbols are available as well as additional assertions to help debugging. To enable the debug build type for the HPX API, the C++ Macro `HPX_DEBUG` is defined.
- **RelWithDebInfo**: Release build with debugging symbols. This is most useful for profiling applications
- **Release**: Release build. This disables assertions and enables default compiler optimizations.
- **RelMinSize**: Release build with optimizations for small binary sizes.

**Important**: We currently don’t guarantee ABI compatibility between Debug and Release builds. Please make sure that applications built against HPX use the same build type as you used to build HPX. For CMake builds, this means that the `CMAKE_BUILD_TYPE` variables have to match and for projects not using CMake\(^{81}\), the `HPX_DEBUG` macro has to be set in debug mode.

Platform specific notes

Some platforms require users to have special link and/or compiler flags specified to build HPX. This is handled via CMake’s support for different toolchains (see `cmake-toolchains(7)`\(^{82}\) for more information). This is also used for cross compilation.

HPX ships with a set of toolchains that can be used for compilation of HPX itself and applications depending on HPX. Please see `CMake toolchains shipped with HPX` for more information.

In order to enable full static linking with the libraries, the CMake variable `HPX_WITH_STATIC_LINKING:BOOL` has to be set to `On`.

Debugging applications using core files

For HPX to generate useful core files, HPX has to be compiled without signal and exception handlers `HPX_WITH_DISABLED_SIGNAL_EXCEPTION_HANDLERS:BOOL`. If this option is not specified, the signal handlers change the application state. For example, after a segmentation fault the stack trace will show the signal handler. Similarly, unhandled exceptions are also caught by these handlers and the stack trace will not point to the location where the unhandled exception was thrown.

In general, core files are a helpful tool to inspect the state of the application at the moment of the crash (post-mortem debugging), without the need of attaching a debugger beforehand. This approach to debugging is especially useful if the error cannot be reliably reproduced, as only a single crashed application run is required to gain potentially helpful information like a stacktrace.

To debug with core files, the operating system first has to be told to actually write them. On most Unix systems this can be done by calling:

```
ulimit -c unlimited
```

in the shell. Now the debugger can be started up with:

---

\(^{80}\) https://cmake.org/cmake/help/latest/variable/CMAKE_BUILD_TYPE.html

\(^{81}\) https://www.cmake.org

\(^{82}\) https://cmake.org/cmake/help/latest/manual/cmake-toolchains.7.html
The debugger should now display the last state of the application. The default file name for core files is `core`.

Platform specific build recipes

Note: The following build recipes are mostly user-contributed and may be outdated. We always welcome updated and new build recipes.

How to install HPX on Unix variants

- Create a build directory. HPX requires an out-of-tree build. This means you will be unable to run CMake in the HPX source tree.

```bash
cd hpx
mkdir my_hpx_build
cd my_hpx_build
```

- Invoke CMake from your build directory, pointing the CMake driver to the root of your HPX source tree.

```bash
cmake -DBOOST_ROOT=/root/of/boost/installation \
-DHWLOC_ROOT=/root/of/hwloc/installation \
[other CMake variable definitions] \ 
/path/to/source/tree
```

For instance:

```bash
cmake -DBOOST_ROOT=~/.packages/boost -DHWLOC_ROOT=~/.packages/hwloc -DCMAKE_INSTALL_ 
PREFIX=~/.packages/hpx ~/downloads/hpx_1.5.1
```

- Invoke GNU make. If you are on a machine with multiple cores, add the `-jN` flag to your make invocation, where `N` is the number of parallel processes HPX gets compiled with.

```bash
gmake -j4
```

Caution: Compiling and linking HPX needs a considerable amount of memory. It is advisable that at least 2 GB of memory per parallel process is available.

Note: Many Linux distributions use `make` as an alias for `gmake`.

- To complete the build and install HPX:

```bash
gmake install
```

Important: These commands will build and install the essential core components of HPX only. In order to build and run the tests, please invoke:

```bash
gdb <application> <core file name>
```
and in order to build (and install) all examples invoke:

```bash
cmake -DHPX_WITH_EXAMPLES=On .
gmake examples
gmake install
```

For more detailed information about using CMake, please refer to its documentation and also the section *Building HPX*. Please pay special attention to the section about `HPX_WITH_MALLOC:STRING` as this is crucial for getting decent performance.

### How to install HPX on OS X (Mac)

This section describes how to build HPX for OS X (Mac).

### Build (and install) a recent version of Boost, using Clang and libc++

To build Boost with Clang and make it link to libc++ as standard library, you’ll need to set up either of the following in your `~/user-config.jam` file:

```bash
# user-config.jam (put this file into your home directory)
#
using clang
: "<user/bin/clang++
  <cxxflags>"-std=c++11 -fcolor-diagnostics"
  <linkflags>"-stdlib=libc++ -L/path/to/libcxx/lib"
;
```

(Again, remember to replace `/path/to` with whatever you used earlier.)

Then, you can use one of the following for your build command:

```bash
b2 --build-dir=/tmp/build-boost --layout=versioned toolset=clang install -j4
```

or:

```bash
b2 --build-dir=/tmp/build-boost --layout=versioned toolset=clang install -j4
```

We verified this using Boost V1.53. If you use a different version, just remember to replace `/usr/local/include/boost-1_53` with whatever prefix you used in your installation.
Build HPX, finally

```
cd /path/to
git clone https://github.com/STEllAR-GROUP/hpx.git
mkdir build-hpx && cd build-hpx
```

To build with Clang, execute:

```
cmake .. /hpx
   -DCMAKE_CXX_COMPILER=clang++
   -DBOOST_ROOT=/path/to/boost
   -DHWLOC_ROOT=/path/to/hwloc
   -DHPX_WITH_GENERIC_CONTEXT_COROUTINES=On
make -j
```

For more detailed information about using CMake, please refer its documentation and to the section Building HPX.

Alternative installation method of HPX on OS X (Mac)

Alternatively, you can install a recent version of gcc as well as all required libraries via MacPorts:

1. Install MacPorts
2. Install CMake, gcc, hwloc:

```
sudo brew install cmake
sudo brew install boost
sudo brew install hwloc
sudo brew install make
```
3. You may also want:

```
sudo brew install gperftools
```
4. If you need to build Boost manually (the Boost package of MacPorts is built with Clang, and unfortunately doesn’t work with a GCC-build version of HPX):

```
wget https://dl.bintray.com/boostorg/release/1.69.0/source/boost_1_69_0.tar.bz2
 tar xjf boost_1_69_0.tar.bz2
pushd boost_1_69_0
export BOOST_ROOT=$HOME/boost_1_69_0
./bootstrap.sh --prefix=$BOOST_DIR
./b2 -j8
./b2 -j8 install
export DYLD_LIBRARY_PATH=$DYLD_LIBRARY_PATH:$BOOST_ROOT/lib
popd
```
5. Build HPX:

```
git clone https://github.com/STEllAR-GROUP/hpx.git
mkdir hpx-build
pushd hpx-build
export HPX_ROOT=$HOME/hpx
cmake -DCMAKE_CXX_COMPILER=g++
   -DCMAKE_CXX_FLAGS="-Wno-unused-local-typedefs"
   -DBOOST_ROOT=$BOOST_ROOT
make -j
```

(continues on next page)
6. Note that you need to set `BOOST_ROOT`, `HPX_ROOT` and `DYLD_LIBRARY_PATH` (for both `BOOST_ROOT` and `HPX_ROOT`) every time you configure, build, or run an `HPX` application.

7. Note that you need to set `HPX_WITH_GENERIC_CONTEXT_COROUTINES=On` for MacOS.

8. If you want to use `HPX` with MPI, you need to enable the MPI parcelport, and also specify the location of the MPI wrapper scripts. This can be done using the following command:

   ```bash
   cmake -DHPX_WITH_PARCELPORT_MPI=ON \n   -DCMAKE_CXX_COMPILER=g++ \n   -DMPI_CXX_COMPILER=openmpic++ \n   -DCMAKE_CXX_FLAGS="-Wno-unused-local-typedefs" \n   -DBOOST_ROOT=$BOOST_DIR \n   -DHWLOC_ROOT=/opt/local \n   -DCMAKE_INSTALL_PREFIX=$HOME/hpx \n   $(pwd)/../hpx
   ```

How to install `HPX` on Windows

Installation of required prerequisites

- Download the Boost c++ libraries from Boost Downloads\(^{83}\)
- Install the Boost library as explained in the section `Installing Boost`
- Install the hwloc library as explained in the section `Installing Hwloc`
- Download the latest version of CMake binaries, which are located under the platform section of the downloads page at CMake Downloads\(^{84}\).
- Download the latest version of `HPX` from the STEllAR website: `HPX Downloads`\(^{85}\).

Installation of the `HPX` library

- Create a build folder. `HPX` requires an out-of-tree-build. This means that you will be unable to run CMake in the `HPX` source folder.
- Open up the CMake GUI. In the input box labelled “Where is the source code:”, enter the full path to the source folder. The source directory is the one where the sources were checked out. CMakeLists.txt files in the source directory as well as the subdirectories describe the build to CMake. In addition to this, there are CMake scripts (usually ending in .cmake) stored in a special CMake directory. CMake does not alter any file in the source directory and doesn’t add new ones either. In the input box labelled “Where to build the binaries:”, enter the

\(^{83}\) https://www.boost.org/users/download/
\(^{84}\) https://www.cmake.org/cmake/resources/software.html
\(^{85}\) https://hpx.stellar-group.org/downloads/
full path to the build folder you created before. The build directory is one where all compiler outputs are stored, which includes object files and final executables.

- Add CMake variable definitions (if any) by clicking the “Add Entry” button. There are two required variables you need to define: `BOOST_ROOT` and `HWLOC_ROOT`. These variables need to be set to point to the root folder of your Boost and hwloc installations. It is recommended to set the variable `CMAKE_INSTALL_PREFIX` as well. This determines where the HPX libraries will be built and installed. If this variable is set, it has to refer to the directory where the built HPX files should be installed to.

- Press the “Configure” button. A window will pop up asking you which compilers to use. Select the Visual Studio 10 (64Bit) compiler (it usually is the default if available). The Visual Studio 2012 (64Bit) and Visual Studio 2013 (64Bit) compilers are supported as well. Note that while it is possible to build HPX for x86, we don’t recommend doing so as 32 bit runs are severely restricted by a 32 bit Windows system limitation affecting the number of HPX threads you can create.

- Press “Configure” again. Repeat this step until the “Generate” button becomes clickable (and until no variable definitions are marked in red anymore).

- Press “Generate”.

- Open up the build folder, and double-click hpx.sln.

- Build the INSTALL target.

For more detailed information about using CMake please refer its documentation and also the section *Building HPX*.

### How to build HPX under Windows 10 x64 with Visual Studio 2015

- Download the CMake V3.18.1 installer (or latest version) from [here](https://www.cmake.org)
- Download the hwloc V1.11.0 (or the latest version) from [here](http://www.open-mpi.org/software/hwloc/v1.11/downloads/hwloc-win64-build-1.11.0.zip) and unpack it.
- Download the latest Boost libraries from [here](https://www.boost.org/users/download/) and unpack them.
- Build the Boost DLLs and LIBs by using these commands from Command Line (or PowerShell). Open CMD/PowerShell inside the Boost dir and type in:

```
bootstrap.bat
```

This batch file will set up everything needed to create a successful build. Now execute:

```
b2.exe link=shared variant=release,debug architecture=x86 address-model=64 threading=multi --build-type=complete install
```

This command will start a (very long) build of all available Boost libraries. Please, be patient.

- Open CMake-GUI.exe and set up your source directory (input field ‘Where is the source code’) to the base directory of the source code you downloaded from HPX’s GitHub pages. Here’s an example of CMake path settings, which point to the Documents/GitHub/hpx folder:

Inside ‘Where is the source-code’ enter the base directory of your HPX source directory (do not enter the “src” sub-directory!). Inside ‘Where to build the binaries’ you should put in the path where all the building processes will happen. This is important because the building machinery will do an “out-of-tree” build. CMake will not touch or change the original source files in any way. Instead, it will generate Visual Studio Solution Files, which will build HPX packages out of the HPX source tree.
Fig. 2.3: Example CMake path settings.
Set three new environment variables (in CMake, not in Windows environment): `BOOST_ROOT`, `HWLOC_ROOT`, `CMAKE_INSTALL_PREFIX`. The meaning of these variables is as follows:

- `BOOST_ROOT` the _HPX_ root directory of the unpacked Boost headers/cpp files.
- `HWLOC_ROOT` the _HPX_ root directory of the unpacked Portable Hardware Locality files.
- `CMAKE_INSTALL_PREFIX` the _HPX_ root directory where the future builds of _HPX_ should be installed.

**Note:** _HPX_ is a very large software collection, so it is not recommended to use the default `C:\Program Files\hpx`. Many users may prefer to use simpler paths without whitespace, like `C:\bin\hpx` or `D:\bin\hpx` etc.

To insert new env-vars click on “Add Entry” and then insert the name inside “Name”, select `PATH` as Type and put the path-name in the “Path” text field. Repeat this for the first three variables.

This is how variable insertion will look:

![CMake adding entry](image)

Fig. 2.4: Example CMake adding entry.

Alternatively, users could provide `BOOST_LIBRARYDIR` instead of `BOOST_ROOT`; the difference is that `BOOST_LIBRARYDIR` should point to the subdirectory inside Boost root where all the compiled DLLs/LIBs are. For example, `BOOST_LIBRARYDIR` may point to the `bin.v2` subdirectory under the Boost rootdir. It is important to keep the meanings of these two variables separated from each other: `BOOST_DIR` points to the ROOT folder of the Boost library. `BOOST_LIBRARYDIR` points to the subdir inside the Boost root folder where the compiled binaries are.
• Click the ‘Configure’ button of CMake-GUI. You will be immediately presented with a small window where you can select the C++ compiler to be used within Visual Studio. This has been tested using the latest v14 (a.k.a C++ 2015) but older versions should be sufficient too. Make sure to select the 64Bit compiler.

• After the generate process has finished successfully, click the ‘Generate’ button. Now, CMake will put new VS Solution files into the BUILD folder you selected at the beginning.

• Open Visual Studio and load the HPX.sln from your build folder.

• Go to CMakePredefinedTargets and build the INSTALL project:

![Solution Explorer](image)

Fig. 2.5: Visual Studio INSTALL target.

It will take some time to compile everything, and in the end you should see an output similar to this one:

**How to install HPX on Fedora distributions**

**Important:** There are official HPX packages for Fedora. Unless you want to customize your, build you may want to start off with the official packages. Instructions can be found on the HPX Downloads page.

**Note:** This section of the manual is based off of our collaborator Patrick Diehl’s blog post [Installing hpxl on Fedora](http://diehlpk.github.io/2015/08/04/hpx-fedora.html).

• Install all packages for minimal installation:

---

90 [https://hpx.stellar-group.org/downloads/](https://hpx.stellar-group.org/downloads/)
91 [http://diehlpk.github.io/2015/08/04/hpx-fedora.html](http://diehlpk.github.io/2015/08/04/hpx-fedora.html)
Fig. 2.6: Visual Studio build output.

```
```

- Get the development branch of HPX:

```
git clone https://github.com/STEllAR-GROUP/hpx.git
```

- Configure it with CMake:

```
cd hpx
mkdir build
cd build
make -j
make install
```

**Note:** To build HPX without examples use:

```
cmake -DCMAKE_INSTALL_PREFIX=/opt/hpx -DHPX_WITH_EXAMPLES=Off ..
```

- Add the library path of HPX to ldconfig:
How to install *HPX* on Arch distributions

**Important:** There are *HPX* packages for Arch in the AUR. Unless you want to customize your build, you may want to start off with those. Instructions can be found on the *HPX* Downloads\(^2\) page.

- Install all packages for a minimal installation:

  ```bash
  sudo pacman -S gcc clang cmake boost hwloc gperftools
  ```

- For building the documentation, you will need to further install the following:

  ```bash
  sudo pacman -S doxygen python-pip
  pip install --user sphinx sphinx_rtd_theme breathe
  ```

The rest of the installation steps are the same as those for the Fedora or Unix variants.

How to install *HPX* on Debian-based distributions

- Install all packages for a minimal installation:

  ```bash
  sudo apt install cmake libboost-all-dev hwloc libgoogle-perftools-dev
  ```

- To build the documentation you will need to further install the following:

  ```bash
  sudo apt install doxygen python-pip
  pip install --user sphinx sphinx_rtd_theme breathe
  ```

  or the following if you prefer to get Python packages from the Debian repositories:

  ```bash
  sudo apt install doxygen python-sphinx python-sphinx-rtd-theme python-breathe
  ```

The rest of the installation steps are same as those for the Fedora or Unix variants.

CMake toolchains shipped with *HPX*

In order to compile *HPX* for various platforms, we provide a variety of toolchain files that take care of setting up various CMake variables like compilers, etc. They are located in the `cmake/toolchains` directory:

- *ARM-gnu*
- *BGION-gnu*
- *BGQ*
- *Cray*
- *CrayKNL*

\(^2\) https://hpx.stellar-group.org/downloads/
To use them, pass the `\texttt{-DCMAKE_TOOLCHAIN_FILE=<toolchain>}` argument to the CMake invocation.

**ARM-gcc**

CMake variables used to configure HPX

In order to configure HPX, you can set a variety of options to allow CMake to generate your specific makefiles/project files.

Variables that influence how HPX is built

The options are split into these categories:

- Generic options
- Build Targets options
- Thread Manager options
- AGAS options
- Parcelport options
- Profiling options
- Debugging options
- Modules options

Generic options

- HPX_WITH_ACTION_BASE_COMPATIBILITY:BOOL
- HPX_WITH_ASYNC_CUDA:BOOL
- HPX_WITH_AUTOMATIC_SERIALIZATION_REGISTRATION:BOOL
- HPX_WITH_BENCHMARK_SCRIPTS_PATH:PATH
- HPX_WITH_BUILD_BINARY_PACKAGE:BOOL
- HPX_WITH_CHECK_MODULE_DEPENDENCIES:BOOL
- HPX_WITH_COMPILER_WARNINGS:BOOL
- HPX_WITH_COMPILER_WARNINGS_AS_ERRORS:BOOL
- HPX_WITH_COMPRESSION_BZIP2:BOOL
- HPX_WITH_COMPRESSION_SNAPPY:BOOL
• \texttt{HPX\_WITH\_COMPRESSION\_ZLIB}:BOOL
• \texttt{HPX\_WITH\_CUDA}:BOOL
• \texttt{HPX\_WITH\_CUDA\_CLANG}:BOOL
• \texttt{HPX\_WITH\_CUDA\_COMPUTE}:BOOL
• \texttt{HPX\_WITH\_DATAPAR\_VC}:BOOL
• \texttt{HPX\_WITH\_DEPRECATED\_WARNINGS}:BOOL
• \texttt{HPX\_WITH\_DISABLED\_SIGNAL\_EXCEPTION\_HANDLERS}:BOOL
• \texttt{HPX\_WITH\_DYNAMIC\_HPX\_MAIN}:BOOL
• \texttt{HPX\_WITH\_EMBEDDED\_THREAD\_POOLS\_COMPATIBILITY}:BOOL
• \texttt{HPX\_WITH\_FAULT\_TOLERANCE}:BOOL
• \texttt{HPX\_WITH\_FULL\_RPATH}:BOOL
• \texttt{HPX\_WITH\_GCC\_VERSION\_CHECK}:BOOL
• \texttt{HPX\_WITH\_GENERIC\_CONTEXT\_COROUTINES}:BOOL
• \texttt{HPX\_WITH\_HIDDEN\_VISIBILITY}:BOOL
• \texttt{HPX\_WITH\_HIP}:BOOL
• \texttt{HPX\_WITH\_INIT\_START\_OVERLOADS\_COMPATIBILITY}:BOOL
• \texttt{HPX\_WITH\_LOGGING}:BOOL
• \texttt{HPX\_WITH\_MALLOC}:STRING
• \texttt{HPX\_WITH\_NICE\_THREADLEVEL}:BOOL
• \texttt{HPX\_WITH\_PARCEL\_COALEScing}:BOOL
• \texttt{HPX\_WITH\_POOL\_EXECUTOR\_COMPATIBILITY}:BOOL
• \texttt{HPX\_WITH\_PRECOMPILED\_HEADERS}:BOOL
• \texttt{HPX\_WITH\_PROMISE\_ALIAS\_COMPATIBILITY}:BOOL
• \texttt{HPX\_WITH\_REGISTER\_THREAD\_COMPATIBILITY}:BOOL
• \texttt{HPX\_WITH\_REGISTER\_THREAD\_OVERLOADS\_COMPATIBILITY}:BOOL
• \texttt{HPX\_WITH\_RUN\_MAIN\_EVERYWHERE}:BOOL
• \texttt{HPX\_WITH\_STACK\_OVERFLOW\_DETECTION}:BOOL
• \texttt{HPX\_WITH\_STATIC\_LINKING}:BOOL
• \texttt{HPX\_WITH\_THREA D\_AWARE\_TIMER\_COMPATIBILITY}:BOOL
• \texttt{HPX\_WITH\_THREA D\_EXECUTORS\_COMPATIBILITY}:BOOL
• \texttt{HPX\_WITH\_THREA D\_POOL\_OS\_EXECUTOR\_COMPATIBILITY}:BOOL
• \texttt{HPX\_WITH\_UNITY\_BUILD}:BOOL
• \texttt{HPX\_WITH\_UNSCOPED\_ENUM\_COMPATIBILITY}:BOOL
• \texttt{HPX\_WITH\_VIM\_YCM}:BOOL
• \texttt{HPX\_WITH\_ZERO\_COPY\_SERIALIZATION\_THRESHOLD}:STRING
HPXDocumentation, master

HPX_WITH_ACTION_BASE_COMPATIBILITY:BOOL
Enable deprecated action bases (default: OFF)

HPX_WITH_ASYNC_CUDA:BOOL
ON

HPX_WITH_AUTOMATIC.Serialization_REGISTRATION:BOOL
Use automatic serialization registration for actions and functions. This affects compatibility between HPX applications compiled with different compilers (default ON)

HPX_WITH_BENCHMARK_SCRIPTS_PATH:PATH
Directory to place batch scripts in

HPX_WITH_BUILD_BINARY_PACKAGE:BOOL
Build HPX on the build infrastructure on any LINUX distribution (default: OFF).

HPX_WITH_CHECK_MODULE_DEPENDENCIES:BOOL
Verify that no modules are cross-referenced from a different module category (default: OFF)

HPX_WITH_COMPILER_WARNINGS:BOOL
Enable compiler warnings (default: ON)

HPX_WITH_COMPILER_WARNINGS_AS_ERRORS:BOOL
Turn compiler warnings into errors (default: OFF)

HPX_WITH_COMPRESSION_BZIP2:BOOL
Enable bzip2 compression for parcel data (default: OFF).

HPX_WITH_COMPRESSION_SNAPPY:BOOL
Enable snappy compression for parcel data (default: OFF).

HPX_WITH_COMPRESSION_ZLIB:BOOL
Enable zlib compression for parcel data (default: OFF).

HPX_WITH_CUDA:BOOL
Enable HPX_WITH_ASYNC_CUDA (CUDA or HIP futures) and HPX_WITH_CUDA_COMPUTE (CUDA/HIP enabled parallel algorithms) (default: OFF)

HPX_WITH_CUDA_CLANG:BOOL
Use clang to compile CUDA code (default: OFF)

HPX_WITH_CUDA_COMPUTE:BOOL
Enable HPX CUDA/SHIP compute capability (parallel algorithms) module (default: ON, dependent on HPX_WITH_CUDA or HPX_WITH_HIP, and HPX_WITH_ASYNC_CUDA) - note: enabling this also enables CUDA/HIP futures via HPX_WITH_ASYNC_CUDA

HPX_WITH_DATAPAR_VC:BOOL
Enable data parallel algorithm support using the external Vc library (default: OFF)

HPX_WITH_DEPRECATION_WARNINGS:BOOL
Enable warnings for deprecated facilities. (default: ON)

HPX_WITH_DISABLED_SIGNAL_EXCEPTION_HANDLERS:BOOL
Disables the mechanism that produces debug output for caught signals and unhandled exceptions (default: OFF)

HPX_WITH_DYNAMIC_HPX_MAIN:BOOL
Enable dynamic overload of system main() (Linux and Apple only, default: ON)

HPX_WITH_EMBEDDED_THREAD_POOLS_COMPATIBILITY:BOOL
Enable deprecated embedded thread pools (default: OFF)

HPX_WITH_FAULT_TOLERANCE:BOOL
Build HPX to tolerate failures of nodes, i.e. ignore errors in active communication channels (default: OFF)

Chapter 2. What’s so special about HPX?
HPX_WITH_FULL_RPATH:BOOL
    Build and link HPX libraries and executables with full RPATHs (default: ON)

HPX_WITH_GCC_VERSION_CHECK:BOOL
    Don’t ignore version reported by gcc (default: ON)

HPX_WITH_GENERIC_CONTEXT_COROUTINES:BOOL
    Use Boost.Context as the underlying coroutines context switch implementation.

HPX_WITH_HIDDEN_VISIBILITY:BOOL
    Use -fvisibility=hidden for builds on platforms which support it (default OFF)

HPX_WITH_HIP:BOOL
    Enable compilation with HIPCC (default: OFF)

HPX_WITH_INIT_START_OVERLOADS_COMPATIBILITY:BOOL
    Enable deprecated init() and start() overloads functions (default: ON)

HPX_WITH_LOGGING:BOOL
    Build HPX with logging enabled (default: ON).

HPX_WITH_MALLOC:STRING
    Define which allocator should be linked in. Options are: system, tcmalloc, jemalloc, mimalloc, tbbmalloc, and custom (default is: tcmalloc)

HPX_WITH_NICE_THREADLEVEL:BOOL
    Set HPX worker threads to have high NICE level (may impact performance) (default: OFF)

HPX_WITH_PARCEL_COALEScing:BOOL
    Enable the parcel coalescing plugin (default: ON).

HPX_WITH_POOL_EXECUTOR_COMPATIBILITY:BOOL
    Enable deprecated pool executor (default: OFF)

HPX_WITH_PREFERED_HEADERS:BOOL
    Enable precompiled headers for certain build targets (experimental, requires CMake 3.16 or newer) (default OFF)

HPX_WITH_Promise_ALIAS_COMPATIBILITY:BOOL
    Enable deprecated alias of hpx::promise to hpx::lcos::promise (default: OFF)

HPX_WITH_REGISTER_THREAD_COMPATIBILITY:BOOL
    Enable deprecated register_thread/work functions in the hpx::applier namespace (default: OFF)

HPX_WITH_REGISTER_THREAD_OVERLOADS_COMPATIBILITY:BOOL
    Enable deprecated register_thread/work overloads (default: ON)

HPX_WITH_RUN_MAIN_EVERYWHERE:BOOL
    Run hpx_main by default on all localities (default: OFF).

HPX_WITH_STACKOVERFLOW_DETECTION:BOOL
    Enable stackoverflow detection for HPX threads/coroutines. (default: OFF, debug: ON)

HPX_WITH_STATIC_LINKING:BOOL
    Compile HPX statically linked libraries (Default: OFF)

HPX_WITH_THREAD_AWARE_TIMER_COMPATIBILITY:BOOL
    Enable deprecated thread_aware_timer (default: OFF)

HPX_WITH_THREAD_EXECUTORS_COMPATIBILITY:BOOL
    Enable deprecated thread executors (default: OFF)

HPX_WITH_THREAD_POOL_OS_EXECUTOR_COMPATIBILITY:BOOL
    Enable deprecated thread pool executors (default: OFF)
HPX WITH UNITY_BUILD:BOOL
Enable unity build for certain build targets (default OFF)

HPX_WITH_UNSCOPED_ENUM_COMPATIBILITY:BOOL
Enable deprecated unscoped enums (default: OFF)

HPX_WITH_VIM_YCM:BOOL
Generate HPX completion file for VIM YouCompleteMe plugin

HPX_WITH_ZERO_COPY_SERIALICATION_THRESHOLD:STRING
The threshold in bytes to when perform zero copy optimizations (default: 128)

Build Targets options

- HPX_WITH_COMPILE_ONLY_TESTS:BOOL
- HPX_WITH_DISTRIBUTED_RUNTIME:BOOL
- HPX_WITH_DOCUMENTATION:BOOL
- HPX_WITH_DOCUMENTATION_OUTPUT_FORMATS:STRING
- HPX_WITH_EXAMPLES:BOOL
- HPX_WITH_EXAMPLES_HDF5:BOOL
- HPX_WITH_EXAMPLES_OPENMP:BOOL
- HPX_WITH_EXAMPLES_QT4:BOOL
- HPX_WITH_EXAMPLES_QTHREADS:BOOL
- HPX_WITH_EXAMPLES_TBB:BOOL
- HPX_WITH_EXECUTABLE_PREFIX:STRING
- HPX_WITH_FAIL_COMPILE_TESTS:BOOL
- HPX_WITH_IO_COUNTERS:BOOL
- HPX_WITH_TESTS:BOOL
- HPX_WITH_TESTS_BENCHMARKS:BOOL
- HPX_WITH_TESTS_EXAMPLES:BOOL
- HPX_WITH_TESTS_EXTERNAL_BUILD:BOOL
- HPX_WITH_TESTS_HEADERS:BOOL
- HPX_WITH_TESTS_REGRESSIONS:BOOL
- HPX_WITH_TESTS_UNIT:BOOL
- HPX_WITH_TOOLS:BOOL

HPX_WITH_COMPILE_ONLY_TESTS:BOOL
Create build system support for compile time only HPX tests (default ON)

HPX_WITH_DISTRIBUTED_RUNTIME:BOOL
Enable the distributed runtime (default: ON). Turning off the distributed runtime completely disallows the creation and use of components and actions. Turning this option off is experimental!

HPX WITH DOCUMENTATION:BOOL
Build the HPX documentation (default OFF).
HPX\_WITH\_DOCUMENTATION\_OUTPUT\_FORMATS:STRING
List of documentation output formats to generate. Valid options are html;singlehtml;latexpdf;man. Multiple values can be separated with semicolons. (default html).

HPX\_WITH\_EXAMPLES:BOOL
Build the HPX examples (default ON)

HPX\_WITH\_EXAMPLES\_HDF5:BOOL
Enable examples requiring HDF5 support (default: OFF).

HPX\_WITH\_EXAMPLES\_OPENMP:BOOL
Enable examples requiring OpenMP support (default: OFF).

HPX\_WITH\_EXAMPLES\_QT4:BOOL
Enable examples requiring Qt4 support (default: OFF).

HPX\_WITH\_EXAMPLES\_QTHREADS:BOOL
Enable examples requiring QThreads support (default: OFF).

HPX\_WITH\_EXAMPLES\_TBB:BOOL
Enable examples requiring TBB support (default: OFF).

HPX\_WITH\_EXECUTABLE\_PREFIX:STRING
Executable prefix (default none). `hpx_` useful for system install.

HPX\_WITH\_FAIL\_COMPILE\_TESTS:BOOL
Create build system support for fail compile HPX tests (default ON)

HPX\_WITH\_IO\_COUNTERS:BOOL
Enable IO counters (default: ON)

HPX\_WITH\_TESTS:BOOL
Build the HPX tests (default ON)

HPX\_WITH\_TESTS\_BENCHMARKS:BOOL
Build HPX benchmark tests (default: ON)

HPX\_WITH\_TESTS\_EXAMPLES:BOOL
Add HPX examples as tests (default: ON)

HPX\_WITH\_TESTS\_EXTERNAL\_BUILD:BOOL
Build external cmake build tests (default: ON)

HPX\_WITH\_TESTS\_HEADERS:BOOL
Build HPX header tests (default: OFF)

HPX\_WITH\_TESTS\_REGRESSIONS:BOOL
Build HPX regression tests (default: ON)

HPX\_WITH\_TESTS\_UNIT:BOOL
Build HPX unit tests (default: ON)

HPX\_WITH\_TOOLS:BOOL
Build HPX tools (default: OFF)
Thread Manager options

- `HPX_COROUTINES_WITH_SWAP_CONTEXT_EMULATION:BOOL`
  Emulate SwapContext API for coroutines (Windows only, default: OFF)

- `HPX_SCHEDULER_MAX_TERMINATED_THREADS:STRING`
  [Deprecated] Maximum number of terminated threads collected before those are cleaned up (default: 100)

- `HPX_WITH_COROUTINE_COUNTERS:BOOL`
  Enable keeping track of coroutine creation and rebind counts (default: OFF)

- `HPX_WITH_IO_POOL:BOOL`
  Disable internal IO thread pool, do not change if not absolutely necessary (default: ON)

- `HPX_WITH_MAX_CPU_COUNT:STRING`
  HPX applications will not use more that this number of OS-Threads (empty string means dynamic) (default: 64)

- `HPX_WITH_MAX_NUMA_DOMAIN_COUNT:STRING`
  HPX applications will not run on machines with more NUMA domains (default: 8)
HPX\_WITH\_SCHEDULER\_LOCAL\_STORAGE:BOOL
Enable scheduler local storage for all HPX schedulers (default: OFF)

HPX\_WITH\_SPINLOCK\_DEADLOCK\_DETECTION:BOOL
Enable spinlock deadlock detection (default: OFF)

HPX\_WITH\_SPINLOCK\_POOL\_NUM:STRING
Number of elements a spinlock pool manages (default: 128)

HPX\_WITH\_STACKTRACES:BOOL
Attach backtraces to HPX exceptions (default: ON)

HPX\_WITH\_STACKTRACES\_DEMANGLE\_SYMBOLS:BOOL
Thread stack back trace symbols will be demangled (default: ON)

HPX\_WITH\_STACKTRACES\_STATIC\_SYMBOLS:BOOL
Thread stack back trace will resolve static symbols (default: OFF)

HPX\_WITH\_THREAD\_BACKTRACE\_DEPTH:STRING
Thread stack back trace depth being captured (default: 20)

HPX\_WITH\_THREAD\_BACKTRACE\_ON\_SUSPENSION:BOOL
Enable thread stack back trace being captured on suspension (default: OFF)

HPX\_WITH\_THREAD\_CREATION\_AND\_CLEANUP\_RATES:BOOL
Enable measuring thread creation and cleanup times (default: OFF)

HPX\_WITH\_THREAD\_CUMULATIVE\_COUNTS:BOOL
Enable keeping track of cumulative thread counts in the schedulers (default: ON)

HPX\_WITH\_THREAD\_IDLE\_RATES:BOOL
Enable measuring the percentage of overhead times spent in the scheduler (default: OFF)

HPX\_WITH\_THREAD\_LOCAL\_STORAGE:BOOL
Enable thread local storage for all HPX threads (default: OFF)

HPX\_WITH\_THREAD\_MANAGER\_IDLE\_BACKOFF:BOOL
HPX scheduler threads do exponential backoff on idle queues (default: ON)

HPX\_WITH\_THREAD\_QUEUE\_WAITTIME:BOOL
Enable collecting queue wait times for threads (default: OFF)

HPX\_WITH\_THREAD\_STACK\_MMAP:BOOL
Use mmap for stack allocation on appropriate platforms

HPX\_WITH\_THREAD\_STEALING\_COUNTS:BOOL
Enable keeping track of counts of thread stealing incidents in the schedulers (default: OFF)

HPX\_WITH\_THREAD\_TARGET\_ADDRESS:BOOL
Enable storing target address in thread for NUMA awareness (default: OFF)

HPX\_WITH\_TIMER\_POOL:BOOL
Disable internal timer thread pool, do not change if not absolutely necessary (default: ON)
AGAS options

- \( \text{HPX\_WITH\_AGAS\_DUMP\_REFCNT\_ENTRIES}: \text{BOOL} \)

**HPX\_WITH\_AGAS\_DUMP\_REFCNT\_ENTRIES**:BOOL

Enable dumps of the AGAS refcnt tables to logs (default: OFF)

Parcelport options

- \( \text{HPX\_WITH\_NETWORKING}: \text{BOOL} \)
- \( \text{HPX\_WITH\_PARCELPORT\_ACTION\_COUNTERS}: \text{BOOL} \)
- \( \text{HPX\_WITH\_PARCELPORT\_LIBFABRIC}: \text{BOOL} \)
- \( \text{HPX\_WITH\_PARCELPORT\_MPI}: \text{BOOL} \)
- \( \text{HPX\_WITH\_PARCELPORT\_TCP}: \text{BOOL} \)
- \( \text{HPX\_WITH\_PARCEL\_PROFILING}: \text{BOOL} \)

**HPX\_WITH\_NETWORKING**:BOOL

Enable support for networking and multi-node runs (default: ON)

**HPX\_WITH\_PARCELPORT\_ACTION\_COUNTERS**:BOOL

Enable performance counters reporting parcelport statistics on a per-action basis.

**HPX\_WITH\_PARCELPORT\_LIBFABRIC**:BOOL

Enable the libfabric based parcelport. This is currently an experimental feature.

**HPX\_WITH\_PARCELPORT\_MPI**:BOOL

Enable the MPI based parcelport.

**HPX\_WITH\_PARCELPORT\_TCP**:BOOL

Enable the TCP based parcelport.

**HPX\_WITH\_PARCEL\_PROFILING**:BOOL

Enable profiling data for parcels

Profiling options

- \( \text{HPX\_WITH\_APEX}: \text{BOOL} \)
- \( \text{HPX\_WITH\_GOOGLE\_PERFTOOLS}: \text{BOOL} \)
- \( \text{HPX\_WITH\_ITTNOTIFY}: \text{BOOL} \)
- \( \text{HPX\_WITH\_PAPI}: \text{BOOL} \)

**HPX\_WITH\_APEX**:BOOL

Enable APEX instrumentation support.

**HPX\_WITH\_GOOGLE\_PERFTOOLS**:BOOL

Enable Google Perftools instrumentation support.

**HPX\_WITH\_ITTNOTIFY**:BOOL

Enable Amplifier (ITT) instrumentation support.

**HPX\_WITH\_PAPI**:BOOL

Enable the PAPI based performance counter.
Debugging options

- `HPX_WITH_ATTACH_DEBUGGER_ON_TEST_FAILURE:BOOL`
  Break the debugger if a test has failed (default: OFF)

- `HPX_WITH_PARALLEL_TESTS_BIND_NONE:BOOL`
  Pass `-hpx:bind=none` to tests that may run in parallel (cmake `-j` flag) (default: OFF)

- `HPX_WITH_SANITIZERS:BOOL`
  Configure with sanitizer instrumentation support.

- `HPX_WITH_TESTS_DEBUG_LOG:BOOL`
  Turn on debug logs (`-hpx:debug-hpx-log`) for tests (default: OFF)

- `HPX_WITH_TESTS_DEBUG_LOG_DESTINATION:STRING`
  Destination for test debug logs (default: cout)

- `HPX_WITH_TESTS_MAX_THREADS_PER_LOCALITY:STRING`
  Maximum number of threads to use for tests (default: 0, use the number of threads specified by the test)

- `HPX_WITH_THREAD_DEBUG_INFO:BOOL`
  Enable thread debugging information (default: OFF, implicitly enabled in debug builds)

- `HPX_WITH_THREAD_DESCRIPTION_FULL:BOOL`
  Use function address for thread description (default: OFF)

- `HPX_WITH_THREAD_GUARD_PAGE:BOOL`
  Enable thread guard page (default: ON)

- `HPX_WITH_VALGRIND:BOOL`
  Enable Valgrind instrumentation support.

- `HPX_WITH_VERIFY_LOCKS:BOOL`
  Enable lock verification code (default: OFF, implicitly enabled in debug builds)

- `HPX_WITH_VERIFY_LOCKS_BACKTRACE:BOOL`
  Enable thread stack back trace being captured on lock registration (to be used in combination with `HPX_WITH_VERIFY_LOCKS=ON`, default: OFF)
**HPX**

**HPX_WITH_VERIFY_LOCKS_GLOBALLY**:BOOL
Enable global lock verification code (default: OFF, implicitly enabled in debug builds)

**Modules options**

- **HPX_DATASTRUCTURES_WITH_ADAPT_STD_TUPLE**:BOOL
  Enable compatibility of hpx::tuple with std::tuple. (default: ON)

- **HPX_FILESYSTEM_WITH_BOOST_FILESYSTEM_COMPATIBILITY**:BOOL
  Enable Boost.FileSystem compatibility. (default: ON)

- **HPX_PROGRAM_OPTIONS_WITH_BOOST_PROGRAM_OPTIONS_COMPATIBILITY**:BOOL
  Enable Boost.ProgramOptions compatibility. (default: OFF)

- **HPX_SERIALIZATION_WITH_BOOST_TYPES**:BOOL
  Enable serialization of certain Boost types. (default: ON)

- **HPX_TOPOLOGY_WITH_ADDITIONAL_HWLOC_TESTING**:BOOL
  Enable HWLOC filtering that makes it report no cores, this is purely an option supporting better testing - do not enable under normal circumstances. (default: OFF)

**Additional tools and libraries used by HPX**

Here is a list of additional libraries and tools that are either optionally supported by the build system or are optionally required for certain examples or tests. These libraries and tools can be detected by the **HPX** build system.

Each of the tools or libraries listed here will be automatically detected if they are installed in some standard location. If a tool or library is installed in a different location, you can specify its base directory by appending _ROOT to the variable name as listed below. For instance, to configure a custom directory for BOOST, specify BOOST_ROOT=/custom/boost/root.

**BOOST_ROOT**:PATH
Specifies where to look for the Boost installation to be used for compiling **HPX**. Set this if CMake is not able to locate a suitable version of Boost. The directory specified here can be either the root of an installed Boost distribution or the directory where you unpacked and built Boost without installing it (with staged libraries).

**HWLOC_ROOT**:PATH
Specifies where to look for the hwloc library. Set this if CMake is not able to locate a suitable version of hwloc. Hwloc provides platform-independent support for extracting information about the used hardware architecture (number of cores, number of NUMA domains, hyperthreading, etc.). **HPX** utilizes this information if available.

**PAPI_ROOT**:PATH
Specifies where to look for the PAPI library. The PAPI library is needed to compile a special component exposing PAPI hardware events and counters as **HPX** performance counters. This is not available on the Windows platform.
AMPLIFIER_ROOT:PATH
Specifies where to look for one of the tools of the Intel Parallel Studio product, either Intel Amplifier or Intel Inspector. This should be set if the CMake variable HPX_USE_ITT_NOTIFY is set to ON. Enabling ITT support in HPX will integrate any application with the mentioned Intel tools, which customizes the generated information for your application and improves the generated diagnostics.

In addition, some of the examples may need the following variables:

HDF5_ROOT:PATH
Specifies where to look for the Hierarchical Data Format V5 (HDF5) include files and libraries.

2.5.3 Creating HPX projects

Using HPX with pkg-config

How to build HPX applications with pkg-config

After you are done installing HPX, you should be able to build the following program. It prints Hello World! on the locality you run it on.

```cpp
#include <hpx/hpx_main.hpp>
#include <hpx/iostream.hpp>

int main()
{
    // Say hello to the world!
    hpx::cout << "Hello World!\n" << hpx::flush;
    return 0;
}
```

Copy the text of this program into a file called hello_world.cpp.

Now, in the directory where you put hello_world.cpp, issue the following commands (where $HPX_LOCATION is the build directory or CMAKE_INSTALL_PREFIX you used while building HPX):

```bash
export PKG_CONFIG_PATH=$PKG_CONFIG_PATH:$HPX_LOCATION/lib/pkgconfig
c++ -o hello_world hello_world.cpp
    `pkg-config --cflags --libs hpx_application`
    -lhpx_iostreamsd
```

**Important:** When using pkg-config with HPX, the pkg-config flags must go after the -o flag.

**Note:** HPX libraries have different names in debug and release mode. If you want to link against a debug HPX library, you need to use the _debug suffix for the pkg-config name. That means instead of hpx_application or hpx_component, you will have to use hpx_application_debug or hpx_component_debug. Moreover, all referenced HPX components need to have an appended d suffix. For example, instead of -lhpx_iostreams you will need to specify -lhpx_iostreamsd.

**Important:** If the HPX libraries are in a path that is not found by the dynamic linker, you will need to add the path
$HPX\_LOCATION/lib$ to your linker search path (for example LD_LIBRARY_PATH on Linux).

To test the program, type:

```
./hello_world
```

which should print Hello World! and exit.

**How to build HPX components with pkg-config**

Let’s try a more complex example involving an HPX component. An HPX component is a class that exposes HPX actions. HPX components are compiled into dynamically loaded modules called component libraries. Here’s the source code:

**hello_world_component.cpp**

```cpp
#include <hpx/config.hpp>
#if !defined(HPX_COMPUTE_DEVICE_CODE)
#include "hello_world_component.hpp"
#include <hpx/iostream.hpp>
#endif

namespace examples { namespace server {
    void hello_world::invoke()
    {
        hpx::cout << "Hello HPX World!" << std::endl;
    }
}}

HPX_REGISTER_COMPONENT_MODULE();

typedef hpx::components::component<
    examples::server::hello_world
> hello_world_type;

HPX_REGISTER_COMPONENT(hello_world_type, hello_world);

HPX_REGISTER_ACTION(
    examples::server::hello_world::invoke_action, hello_world_invoke_action);
#endif
```

**hello_world_component.hpp**

```cpp
#pragma once
#include <hpx/config.hpp>
#if !defined(HPX_COMPUTE_DEVICE_CODE)
#include <hpx/hpx.hpp>
#include <hpx/include/actions.hpp>
#include <hpx/include/lcos.hpp>
#include <hpx/include/components.hpp>
#include <hpx/serialization.hpp>
#include <utility>
#endif
```

(continues on next page)
namespace examples { namespace server {
struct HPX_COMPONENT_EXPORT hello_world :
    hpx::components::component_base<hello_world>
{
    void invoke();
    HPX_DEFINE_COMPONENT_ACTION(hello_world, invoke);
};
}
HPX_REGISTER_ACTION_DECLARATION(
    examples::server::hello_world::invoke_action, hello_world_invoke_action);

namespace examples {
struct hello_world :
    hpx::components::client_base<hello_world, server::hello_world>
{
typedef hpx::components::client_base<hello_world, server::hello_world> base_type;

    hello_world(hpx::future<hpx::naming::id_type> && f)
    : base_type(std::move(f))
    {};

    hello_world(hpx::naming::id_type && f)
    : base_type(std::move(f))
    {};

    void invoke()
    {
        hpx::async<server::hello_world::invoke_action>(this->get_id()).get();
    };
};
} // namespace examples
#endif

hello_world_client.cpp
#include <hpx/config.hpp>
#if !defined(HPX_COMPUTE_DEVICE_CODE)
#include "hello_world_component.hpp"
#include <hpx/hpx_main.hpp>

int main(int argc, char* argv[])
{
    
    // Create a single instance of the component on this locality.
    examples::hello_world client =
        hpx::new_<examples::hello_world>(hpx::find_here());

    // Invoke the component's action, which will print "Hello World!".
    client.invoke();
}
Copy the three source files above into three files (called `hello_world_component.cpp`, `hello_world_component.hpp` and `hello_world_client.cpp`, respectively).

Now, in the directory where you put the files, run the following command to build the component library. (where `$HPX_LOCATION` is the build directory or `CMAKE_INSTALL_PREFIX` you used while building `HPX`):

```
export PKG_CONFIG_PATH=$PKG_CONFIG_PATH:$HPX_LOCATION/lib/pkgconfig
c++ -o libhpx_hello_world.so hello_world_component.cpp \  
  `pkg-config --cflags --libs hpx_component` \  
  -lhpx_iostreams -DHPX_COMPONENT_NAME=hpx_hello_world
```

Now pick a directory in which to install your `HPX` component libraries. For this example, we’ll choose a directory named `my_hpx_libs`:

```
mkdir ~/my_hpx_libs
mv libhpx_hello_world.so ~/my_hpx_libs
```

**Note:** `HPX` libraries have different names in debug and release mode. If you want to link against a debug `HPX` library, you need to use the `_debug` suffix for the pkg-config name. That means instead of `hpx_application` or `hpx_component` you will have to use `hpx_application_debug` or `hpx_component_debug`. Moreover, all referenced `HPX` components need to have a appended `d` suffix, e.g. instead of `-lhpx_iostreams` you will need to specify `-lhpx_iostreamsd`.

**Important:** If the `HPX` libraries are in a path that is not found by the dynamic linker. You need to add the path `$HPX_LOCATION/lib` to your linker search path (for example `LD_LIBRARY_PATH` on Linux).

Now, to build the application that uses this component (`hello_world_client.cpp`), we do:

```
export PKG_CONFIG_PATH=$PKG_CONFIG_PATH:$HPX_LOCATION/lib/pkgconfig
c++ -o hello_world_client hello_world_client.cpp \  
  `pkg-config --cflags --libs hpx_application` \  
  -L$HOME/my_hpx_libs -lhpx_hello_world -lhpx_iostreams
```

**Important:** When using pkg-config with `HPX`, the pkg-config flags must go after the `-o` flag.

Finally, you’ll need to set your `LD_LIBRARY_PATH` before you can run the program. To run the program, type:

```
export LD_LIBRARY_PATH="$LD_LIBRARY_PATH:$HOME/my_hpx_libs"
./hello_world_client
```

which should print `Hello HPX World!` and exit.
Using *HPX* with CMake-based projects

In addition to the pkg-config support discussed on the previous pages, *HPX* comes with full CMake support. In order to integrate *HPX* into existing or new CMakeLists.txt, you can leverage the find_package command integrated into CMake. Following, is a Hello World component example using CMake.

Let’s revisit what we have. We have three files that compose our example application:

- hello_world_component.hpp
- hello_world_component.cpp
- hello_world_client.hpp

The basic structure to include *HPX* into your CMakeLists.txt is shown here:

```cpp
# Require a recent version of cmake
cmake_minimum_required(VERSION 3.17 FATAL_ERROR)

# This project is C++ based.
project(your_app CXX)

# Instruct cmake to find the HPX settings
find_package(HPX)
```

In order to have CMake find *HPX*, it needs to be told where to look for the HPXConfig.cmake file that is generated when *HPX* is built or installed. It is used by find_package(HPX) to set up all the necessary macros needed to use *HPX* in your project. The ways to achieve this are:

- Set the HPX_DIR CMake variable to point to the directory containing the HPXConfig.cmake script on the command line when you invoke CMake:

  ```
  cmake -DHPX_DIR=$HPX_LOCATION/lib/cmake/HPX ...
  ```

  where $HPX_LOCATION is the build directory or CMAKE_INSTALL_PREFIX you used when building/configuring *HPX*.

- Set the CMAKE_PREFIX_PATH variable to the root directory of your *HPX* build or install location on the command line when you invoke CMake:

  ```
  cmake -DCMAKE_PREFIX_PATH=$HPX_LOCATION ...
  ```

  The difference between CMAKE_PREFIX_PATH and HPX_DIR is that CMake will add common postfixes, such as lib/cmake/<project, to the CMAKE_PREFIX_PATH and search in these locations too. Note that if your project uses *HPX* as well as other CMake-managed projects, the paths to the locations of these multiple projects may be concatenated in the CMAKE_PREFIX_PATH.

- The variables above may be set in the CMake GUI or curses ccmake interface instead of the command line.

Additionally, if you wish to require *HPX* for your project, replace the find_package(HPX) line with find_package(HPX REQUIRED).

You can check if *HPX* was successfully found with the HPX_FOUND CMake variable.

93 https://www.cmake.org/cmake/help/latest/command/find_package.html
Using CMake targets

The recommended way of setting up your targets to use HPX is to link to the HPX: :hpx CMake target:

```
target_link_libraries(hello_world_component PUBLIC HPX::hpx)
```

This requires that you have already created the target like this:

```
add_library(hello_world_component SHARED hello_world_component.cpp)
target_include_directories(hello_world_component PUBLIC ${CMAKE_CURRENT_SOURCE_DIR})
```

When you link your library to the HPX: :hpx CMake target, you will be able use HPX functionality in your library. To use main() as the implicit entry point in your application you must additionally link your application to the CMake target HPX: :wrap_main. This target is automatically linked to executables if you are using the macros described below (Using macros to create new targets). See Re-use the main() function as the main HPX entry point for more information on implicitly using main() as the entry point.

Creating a component requires setting two additional compile definitions:

```
target_compile_options(hello_world_component
    HPX_COMPONENT_NAME=hello_world
    HPX_COMPONENT_EXPORTS)
```

Instead of setting these definitions manually you may link to the HPX: :component target, which sets HPX_COMPONENT_NAME to hpx_<target_name>, where <target_name> is the target name of your library. Note that these definitions should be PRIVATE to make sure these definitions are not propagated transitively to dependent targets.

In addition to making your library a component you can make it a plugin. To do so link to the HPX: :plugin target. Similarly to HPX: :component this will set HPX_PLUGIN_NAME to hpx_<target_name>. This definition should also be PRIVATE. Unlike regular shared libraries, plugins are loaded at runtime from certain directories and will not be found without additional configuration. Plugins should be installed into a directory containing only plugins. For example, the plugins created by HPX itself are installed into the hpx subdirectory in the library install directory (typically lib or lib64). When using the HPX: :plugin target you need to install your plugins into an appropriate directory. You may also want to set the location of your plugin in the build directory with the _OUTPUT_DIRECTORY_ CMake target properties to be able to load the plugins in the build directory. Once you’ve set the install or output directory of your plugin you need to tell your executable where to find it at runtime. You can do this either by setting the environment variable HPX_COMPONENT_PATHS or the ini setting hpx.component_paths (see --hpx:ini) to the directory containing your plugin.

Using macros to create new targets

In addition to the targets described above, HPX provides convenience macros to hide optional boilerplate code that may be useful for your project. The link to the targets described above. We recommend that you use the targets directly whenever possible as they tend to compose better with other targets.

The macro for adding an HPX component is add_hpx_component. It can be used in your CMakeLists.txt file like this:

```
# build your application using HPX
add_hpx_component(hello_world
    SOURCES hello_world_component.cpp
    HEADERS hello_world_component.hpp
    COMPONENT_DEPENDENCIES iostreams)
```
Note: add_hpx_component adds a \_component suffix to the target name. In the example above, a hello_world_component target will be created.

The available options to add_hpx_component are:

- SOURCES: The source files for that component
- HEADERS: The header files for that component
- DEPENDENCIES: Other libraries or targets this component depends on
- COMPONENT_DEPENDENCIES: The components this component depends on
- PLUGIN: Treats this component as a plugin-able library
- COMPIL_FLAGS: Additional compiler flags
- LINK_FLAGS: Additional linker flags
- FOLDER: Adds the headers and source files to this Source Group folder
- EXCLUDE_FROM_ALL: Do not build this component as part of the all target

After adding the component, the way you add the executable is as follows:

```
# build your application using HPX
add_hpx_executable(hello_world
    SOURCES hello_world_client.cpp
    COMPONENT_DEPENDENCIES hello_world)
```

Note: add_hpx_executable automatically adds a \_component suffix to dependencies specified in COMPONENT_DEPENDENCIES, meaning you can directly use the name given when adding a component using add_hpx_component.

When you configure your application, all you need to do is set the HPX_DIR variable to point to the installation of HPX.

Note: All library targets built with HPX are exported and readily available to be used as arguments to target_link_libraries\(^\text{94}\) in your targets. The HPX include directories are available with the HPX_INCLUDE_DIRS CMake variable.

Using the HPX compiler wrapper hpxcxx

The hpxcxx compiler wrapper helps to compile a HPX component, application, or object file, based on the arguments passed to it.

```
hpxcxx [-exe=<APPLICATION_NAME> | --comp=<COMPONENT_NAME> | -c] FLAGS FILES
```

The hpxcxx command requires that either an application or a component is built or -c flag is specified. If the build is against a debug build, the -g is to be specified while building.

\(^{94}\) https://www.cmake.org/cmake/help/latest/command/target_link_libraries.html
Optional FLAGS

- `-l <LIBRARY> | -l<LIBRARY>`: Links `<LIBRARY>` to the build
- `-g`: Specifies that the application or component build is against a debug build
- `-rd`: Sets `release-with-debug-info` option
- `-mr`: Sets `minsize-release` option

All other flags (like `-o OUTPUT_FILE`) are directly passed to the underlying C++ compiler.

Using macros to set up existing targets to use HPX

In addition to the `add_hpx_component` and `add_hpx_executable`, you can use the `hpx_setup_target` macro to have an already existing target to be used with the HPX libraries:

```
hpx_setup_target(target)
```

Optional parameters are:

- **EXPORT**: Adds it to the CMake export list HPXTargets
- **INSTALL**: Generates an install rule for the target
- **PLUGIN**: Treats this component as a plugin-able library
- **TYPE**: The type can be: EXECUTABLE, LIBRARY or COMPONENT
- **DEPENDENCIES**: Other libraries or targets this component depends on
- **COMPONENT_DEPENDENCIES**: The components this component depends on
- **COMPILE_FLAGS**: Additional compiler flags
- **LINK_FLAGS**: Additional linker flags

If you do not use CMake, you can still build against HPX, but you should refer to the section on *How to build HPX components with pkg-config*.

**Note:** Since HPX relies on dynamic libraries, the dynamic linker needs to know where to look for them. If HPX isn’t installed into a path that is configured as a linker search path, external projects need to either set `RPATH` or adapt `LD_LIBRARY_PATH` to point to where the HPX libraries reside. In order to set `RPATH`s, you can include `HPX_SetFullRPATH` in your project after all libraries you want to link against have been added. Please also consult the CMake documentation here\(^\text{95}\).

Using HPX with Makefile

A basic project building with HPX is through creating makefiles. The process of creating one can get complex depending upon the use of cmake parameter `HPX_WITH_HPX_MAIN` (which defaults to ON).

\(^{95}\) [https://gitlab.kitware.com/cmake/community/wikis/doc/cmake/RPATH-handling](https://gitlab.kitware.com/cmake/community/wikis/doc/cmake/RPATH-handling)
How to build HPX applications with makefile

If HPX is installed correctly, you should be able to build and run a simple Hello World program. It prints Hello World! on the locality you run it on.

```cpp
#include <hpx/hpx_main.hpp>
#include <hpx/iostream.hpp>

int main()
{
    // Say hello to the world!
    hpx::cout << "Hello World! \n" << hpx::flush;
    return 0;
}
```

Copy the content of this program into a file called hello_world.cpp.

Now, in the directory where you put hello_world.cpp, create a Makefile. Add the following code:

```bash
CXX=(CXX) # Add your favourite compiler here or let makefile choose default.
CXXFLAGS=-O3 -std=c++17
BOOST_ROOT=/path/to/boost
HWLOC_ROOT=/path/to/hwloc
TCMALLOC_ROOT=/path/to/tcmalloc
HPX_ROOT=/path/to/hpx

INCLUDE_DIRECTIVES=$((HPX_ROOT)/include $(BOOST_ROOT)/include $(HWLOC_ROOT)/include)

LIBRARY_DIRECTIVES=-L$(HPX_ROOT)/lib $(HPX_ROOT)/lib/libhpx_init.a $(HPX_ROOT)/lib/libhpx.so $(BOOST_ROOT)/lib/libboost_atomic-mt.so $(BOOST_ROOT)/lib/libboost_system-mt.so -lpthread $(TCMALLOC_ROOT)/lib/libtcmalloc_minimal.so $(HWLOC_ROOT)/lib/libhwloc.so -ldl -lrt

LINK_FLAGS=$(HPX_ROOT)/lib/libhpx_wrap.a -Wl,-wrap=main # should be left empty for HPX_WITH_HPX_MAIN=OFF

hello_world: hello_world.o
    $(CXX) $(CXXFLAGS) -o hello_world hello_world.o $(LIBRARY_DIRECTIVES) $(LINK_FLAGS)

hello_world.o:
    $(CXX) $(CXXFLAGS) -c -o hello_world.o hello_world.cpp $(INCLUDE_DIRECTIVES)
```

Important: LINK_FLAGS should be left empty if HPX_WITH_HPX_MAIN is set to OFF. Boost in the above example is build with --layout=tagged. Actual Boost flags may vary on your build of Boost.

To build the program, type:

```
make
```

A successful build should result in hello_world binary. To test, type:
How to build *HPX* components with makefile

Let’s try a more complex example involving an *HPX* component. An *HPX* component is a class that exposes *HPX* actions. *HPX* components are compiled into dynamically-loaded modules called component libraries. Here’s the source code:

**hello_world_component.cpp**

```cpp
#include <hpx/config.hpp>
#if !defined(HPX_COMPUTE_DEVICE_CODE)
#include "hello_world_component.hpp"
#include <hpx/iostream.hpp>
#endif

namespace examples { namespace server {
    void hello_world::invoke()
    {
        hpx::cout << "Hello HPX World!" << std::endl;
    }
}}
HPX_REGISTER_COMPONENT_MODULE();

typedef hpx::components::component<
    examples::server::hello_world>
    hello_world_type;
HPX_REGISTER_COMPONENT(hello_world_type, hello_world);
HPX_REGISTER_ACTION(
    examples::server::hello_world::invoke_action, hello_world_invoke_action);
#endif
```

**hello_world_component.hpp**

```cpp
#pragma once
#include <hpx/config.hpp>
#if !defined(HPX_COMPUTE_DEVICE_CODE)
#include <hpx/hpx.hpp>
#include <hpx/include/actions.hpp>
#include <hpx/include/lcos.hpp>
#include <hpx/include/components.hpp>
#include <hpx/serialization.hpp>
#include <utility>
#endif

namespace examples { namespace server {
    struct HPX_COMPONENT_EXPORT hello_world
        : hpx::components::component_base<hello_world>
    {
    }
}}
```

(continues on next page)
```cpp
void invoke();
    HPX_DEFINE_COMPONENT_ACTION(hello_world, invoke);
};
```}

```cpp
HPX_REGISTER_ACTION_DECLARATION(
    examples::server::hello_world::invoke_action, hello_world_invoke_action);

namespace examples
{
    struct hello_world :
        hpx::components::client_base<hello_world, server::hello_world>
    {
        typedef hpx::components::client_base<hello_world, server::hello_world> base_type;

        hello_world(hpx::future<hpx::naming::id_type> && f) :
            base_type(std::move(f))
        {
        }

        hello_world(hpx::naming::id_type && f) :
            base_type(std::move(f))
        {
        }

    void invoke()
    {
        hpx::async<server::hello_world::invoke_action>(this->get_id()).get();
    }
}
}
```

**hello_world_client.cpp**

```cpp
#include <hpx/config.hpp>
#if !defined(HPX_COMPUTE_DEVICE_CODE)
#include "hello_world_component.hpp"
#include <hpx/hpx_main.hpp>

int main(int argc, char* argv[])
{
    {
        // Create a single instance of the component on this locality.
        examples::hello_world client =
            hpx::new_<examples::hello_world>(hpx::find_here());

        // Invoke the component's action, which will print "Hello World!".
        client.invoke();
    }

    return 0;
}
#endif
```

Now, in the directory, create a Makefile. Add the following code:
CXX=(CXX)  # Add your favourite compiler here or let makefile choose default.
CXXFLAGS=-O3 -std=c++17
BOOST_ROOT=/path/to/boost
HWLOC_ROOT=/path/to/hwloc
TCMALLOC_ROOT=/path/to/tcmalloc
HPX_ROOT=/path/to/hpx

INCLUDE_DIRECTIVES=$(HPX_ROOT)/include $(BOOST_ROOT)/include $(HWLOC_ROOT)/include
LIBRARY_DIRECTIVES=-L$(HPX_ROOT)/lib $(BOOST_ROOT)/lib/libhpx_init.a $(HPX_ROOT)/lib/libhpx.so $(BOOST_ROOT)/lib/libboost_atomic-mt.so $(BOOST_ROOT)/lib/libboost_filesystem-mt.so $(BOOST_ROOT)/lib/libboost_program_options-mt.so $(BOOST_ROOT)/lib/libboost_regex-mt.so $(BOOST_ROOT)/lib/libboost_system-mt.so -lpthread $(TCMALLOC_ROOT)/libtcmalloc_minimal.so $(HWLOC_ROOT)/libhwloc.so -ldl -lrt
LINK_FLAGS=$(HPX_ROOT)/lib/libhpx_wrap.a -Wl,-wrap=main  # should be left empty for HPX_WITH_HPX_MAIN=OFF

hello_world_client: libhpx_hello_world hello_world_client.o
  $(CXX) $(CXXFLAGS) -o hello_world_client $(LIBRARY_DIRECTIVES) libhpx_hello_world
  $(LINK_FLAGS)

hello_world_client.o: hello_world_client.cpp
  $(CXX) $(CXXFLAGS) -o hello_world_client.o hello_world_client.cpp $(INCLUDE_DIRECTIVES)

libhpx_hello_world: hello_world_component.o
  $(CXX) $(CXXFLAGS) -o libhpx_hello_world hello_world_component.o $(LIBRARY_DIRECTIVES)

hello_world_component.o: hello_world_component.cpp
  $(CXX) $(CXXFLAGS) -c -o hello_world_component.o hello_world_component.cpp
  $(INCLUDE_DIRECTIVES)

To build the program, type:

make

A successful build should result in hello_world binary. To test, type:

./hello_world

Note: Due to high variations in CMake flags and library dependencies, it is recommended to build HPX applications and components with pkg-config or CMakeLists.txt. Writing Makefile may result in broken builds if due care is not taken. pkg-config files and CMake systems are configured with CMake build of HPX. Hence, they are stable when used together and provide better support overall.
2.5.4 Starting the HPX runtime

In order to write an application which uses services from the HPX runtime system you need to initialize the HPX library by inserting certain calls into the code of your application. Depending on your use case, this can be done in 3 different ways:

- **Minimally invasive**: Re-use the main() function as the main HPX entry point.
- **Balanced use case**: Supply your own main HPX entry point while blocking the main thread.
- **Most flexibility**: Supply your own main HPX entry point while avoiding to block the main thread.
- **Suspend and resume**: As above but suspend and resume the HPX runtime to allow for other runtimes to be used.

Re-use the main() function as the main HPX entry point

This method is the least intrusive to your code. It however provides you with the smallest flexibility in terms of initializing the HPX runtime system. The following code snippet shows what a minimal HPX application using this technique looks like:

```cpp
#include <hpx/hpx_main.hpp>

int main(int argc, char* argv[]) {
    return 0;
}
```

The only change to your code you have to make is to include the file hpx/hpx_main.hpp. In this case the function main() will be invoked as the first HPX thread of the application. The runtime system will be initialized behind the scenes before the function main() is executed and will automatically stop after main() has returned. For this method to work you must link your application to the CMake target HPX::wrap_main. This is done automatically if you are using the provided macros (Using macros to create new targets) to set up your application, but must be done explicitly if you are using targets directly (Using CMake targets). All HPX API functions can be used from within the main() function now.

**Note:** The function main() does not need to expect receiving argc and argv as shown above, but could expose the signature int main(). This is consistent with the usually allowed prototypes for the function main() in C++ applications.

All command line arguments specific to HPX will still be processed by the HPX runtime system as usual. However, those command line options will be removed from the list of values passed to argc/argv of the function main(). The list of values passed to main() will hold only the commandline options which are not recognized by the HPX runtime system (see the section HPX Command Line Options for more details on what options are recognized by HPX).

**Note:** In this mode all one-letter-shortcuts are disabled which are normally available on the HPX command line (such as -t or -l see HPX Command Line Options). This is done to minimize any possible interaction between the command line options recognized by the HPX runtime system and any command line options defined by the application.

The value returned from the function main() as shown above will be returned to the operating system as usual.

**Important:** To achieve this seamless integration, the header file hpx/hpx_main.hpp defines a macro:
```cpp
#define main hpx_startup::user_main
```

which could result in unexpected behavior.

---

**Important:** To achieve this seamless integration, we use different implementations for different operating systems. In case of Linux or macOS, the code present in `hpx_wrap.cpp` is put into action. We hook into the system function in case of Linux and provide alternate entry point in case of macOS. For other operating systems we rely on a macro:

```cpp
#define main hpx_startup::user_main
```

provided in the header file `hpx/hpx_main.hpp`. This implementation can result in unexpected behavior.

---

**Caution:** We make use of an `override` variable `include_libhpx_wrap` in the header file `hpx/hpx_main.hpp` to swiftly choose the function call stack at runtime. Therefore, the header file should only be included in the main executable. Including it in the components will result in multiple definition of the variable.

---

### Supply your own main HPX entry point while blocking the main thread

With this method you need to provide an explicit main thread function named `hpx_main` at global scope. This function will be invoked as the main entry point of your HPX application on the console `locality` only (this function will be invoked as the first HPX thread of your application). All HPX API functions can be used from within this function.

The thread executing the function `hpx::init` will block waiting for the runtime system to exit. The value returned from `hpx_main` will be returned from `hpx::init` after the runtime system has stopped.

The function `hpx::finalize` has to be called on one of the HPX localities in order to signal that all work has been scheduled and the runtime system should be stopped after the scheduled work has been executed.

This method of invoking HPX has the advantage of you being able to decide which version of `hpx::init` to call. This allows to pass additional configuration parameters while initializing the HPX runtime system.

```cpp
#include <hpx/hpx_init.hpp>

int hpx_main(int argc, char* argv[]) {
  // Any HPX application logic goes here...
  return hpx::finalize();
}

int main(int argc, char* argv[]) {
  // Initialize HPX, run hpx_main as the first HPX thread, and
  // wait for hpx::finalize being called.
  return hpx::init(argc, argv);
}
```

**Note:** The function `hpx_main` does not need to expect receiving `argc/argv` as shown above, but could expose one of the following signatures:
```
int hpx_main();
int hpx_main(int argc, char* argv[]);
int hpx_main(hpx::program_options::variables_map& vm);
```

This is consistent with (and extends) the usually allowed prototypes for the function `main()` in C++ applications.

The header file to include for this method of using HPX is `hpx/hpx_init.hpp`.

There are many additional overloads of `hpx::init` available, such as for instance to provide your own entry point function instead of `hpx_main`. Please refer to the function documentation for more details (see: `hpx/hpx_init.hpp`).

### Supply your own main HPX entry point while avoiding to block the main thread

With this method you need to provide an explicit main thread function named `hpx_main` at global scope. This function will be invoked as the main entry point of your HPX application on the console locality only (this function will be invoked as the first HPX thread of your application). All HPX API functions can be used from within this function.

The thread executing the function `hpx::start` will *not* block waiting for the runtime system to exit, but will return immediately. The function `hpx::finalize` has to be called on one of the HPX localities in order to signal that all work has been scheduled and the runtime system should be stopped after the scheduled work has been executed.

This method of invoking HPX is useful for applications where the main thread is used for special operations, such as GUIs. The function `hpx::stop` can be used to wait for the HPX runtime system to exit and should be used as the last function called in `main()`. The value returned from `hpx_main` will be returned from `hpx::stop` after the runtime system has stopped.

```
#include <hpx/hpx_start.hpp>

int hpx_main(int argc, char* argv[])
{
    // Any HPX application logic goes here...
    return hpx::finalize();
}

int main(int argc, char* argv[])
{
    // Initialize HPX, run hpx_main.
    hpx::start(argc, argv);

    // ...Execute other code here...

    // Wait for hpx::finalize being called.
    return hpx::stop();
}
```

**Note:** The function `hpx_main` does not need to expect receiving `argc/argv` as shown above, but could expose one of the following signatures:

```
int hpx_main();
int hpx_main(int argc, char* argv[]);
int hpx_main(hpx::program_options::variables_map& vm);
```
This is consistent with (and extends) the usually allowed prototypes for the function \texttt{main()} in C++ applications.

The header file to include for this method of using \texttt{HPX} is \texttt{hpx/hpx_start.hpp}.

There are many additional overloads of \texttt{hpx::start} available, such as for instance to provide your own entry point function instead of \texttt{hpx::main}. Please refer to the function documentation for more details (see: \texttt{hpx/hpx_start.hpp}).

**Suspending and resuming the HPX runtime**

In some applications it is required to combine \texttt{HPX} with other runtimes. To support this use case \texttt{HPX} provides two functions: \texttt{hpx::suspend} and \texttt{hpx::resume}. \texttt{hpx::suspend} is a blocking call which will wait for all scheduled tasks to finish executing and then put the thread pool OS threads to sleep. \texttt{hpx::resume} simply wakes up the sleeping threads so that they are ready to accept new work. \texttt{hpx::suspend} and \texttt{hpx::resume} can be found in the header \texttt{hpx/hpx_suspend.hpp}.

```cpp
#include <hpx/hpx_start.hpp>
#include <hpx/hpx_suspend.hpp>

int main(int argc, char* argv[]) {
  // Initialize HPX, don't run hpx_main
  hpx::start(nullptr, argc, argv);
  // Schedule a function on the HPX runtime
  hpx::apply(&my_function, ...);
  // Wait for all tasks to finish, and suspend the HPX runtime
  hpx::suspend();
  // Execute non-HPX code here
  // Resume the HPX runtime
  hpx::resume();
  // Schedule more work on the HPX runtime
  // hpx::finalize has to be called from the HPX runtime before hpx::stop
  hpx::apply([]() { hpx::finalize(); });
  return hpx::stop();
}
```

**Note:** \texttt{hpx::suspend} does not wait for \texttt{hpx::finalize} to be called. Only call \texttt{hpx::finalize} when you wish to fully stop the \texttt{HPX} runtime.

**Warning:**

\texttt{hpx::suspend} only waits for local tasks, i.e. tasks on the current locality, to finish executing. When using \texttt{hpx::suspend} in a multi-locality scenario the user is responsible for ensuring that any work required from other localities has also finished.
HPX also supports suspending individual thread pools and threads. For details on how to do that see the documentation for \texttt{hpx::threads::thread_pool_base}.

### Automatically suspending worker threads

The previous method guarantees that the worker threads are suspended when you ask for it and that they stay suspended. An alternative way to achieve the same effect is to tweak how quickly HPX suspends its worker threads when they run out of work. The following configuration values make sure that HPX idles very quickly:

\begin{verbatim}
hpx.max_idle_backoff_time = 1000
hpx.max_idle_loop_count = 0
\end{verbatim}

They can be set on the command line using \texttt{--hpx:ini=hpx.max_idle_backoff_time=1000} and \texttt{--hpx:ini=hpx.max_idle_loop_count=0}. See \textit{Launching and configuring HPX applications} for more details on how to set configuration parameters.

After setting idling parameters the previous example could now be written like this instead:

\begin{verbatim}
#include <hpx/hpx_start.hpp>

int main(int argc, char* argv[])
{
    // Initialize HPX, don't run hpx_main
    hpx::start(nullptr, argc, argv);

    // Schedule some functions on the HPX runtime
    // NOTE: run_as_hpx_thread blocks until completion.
    hpx::run_as_hpx_thread(&my_function, ...);
    hpx::run_as_hpx_thread(&my_other_function, ...);

    // hpx::finalize has to be called from the HPX runtime before hpx::stop
    hpx::apply([]() { hpx::finalize(); });
    return hpx::stop();
}
\end{verbatim}

In this example each call to \texttt{hpx::run_as_hpx_thread} acts as a “parallel region”.

### Working of hpx\_main\_hpp

In order to initialize HPX from \texttt{main()}, we make use of linker tricks.

It is implemented differently for different Operating Systems. Method of implementation is as follows:

- \textit{Linux}: Using linker \texttt{--wrap} option.
- \textit{Mac OSX}: Using the linker \texttt{-e} option.
- \textit{Windows}: Using \texttt{#define main hpx\_startup::user\_main}
Linux implementation

We make use of the Linux linker ld's \texttt{--wrap} option to wrap the \texttt{main()} function. This way any call to \texttt{main()} are redirected to our own implementation of main. It is here that we check for the existence of \texttt{hpx\_main.hpp} by making use of a shadow variable \texttt{include\_libhpx\_wrap}. The value of this variable determines the function stack at runtime.

The implementation can be found in \texttt{libhpx\_wrap.a}.

\textbf{Important:} It is necessary that \texttt{hpx\_main.hpp} be not included more than once. Multiple inclusions can result in multiple definition of \texttt{include\_libhpx\_wrap}.

Mac OS X implementation

Here we make use of yet another linker option \texttt{-e} to change the entry point to our custom entry function \texttt{initialize\_main}. We initialize the HPX runtime system from this function and call main from the initialized system. We determine the function stack at runtime by making use of the shadow variable \texttt{include\_libhpx\_wrap}.

The implementation can be found in \texttt{libhpx\_wrap.a}.

\textbf{Important:} It is necessary that \texttt{hpx\_main.hpp} be not included more than once. Multiple inclusions can result in multiple definition of \texttt{include\_libhpx\_wrap}.

Windows implementation

We make use of a macro \texttt{#define main hpx\_startup::user\_main} to take care of the initializations.

This implementation could result in unexpected behaviors.

2.5.5 Launching and configuring HPX applications

Configuring HPX applications

All HPX applications can be configured using special command line options and/or using special configuration files. This section describes the available options, the configuration file format, and the algorithm used to locate possible predefined configuration files. Additionally this section describes the defaults assumed if no external configuration information is supplied.

During startup any HPX application applies a predefined search pattern to locate one or more configuration files. All found files will be read and merged in the sequence they are found into one single internal database holding all configuration properties. This database is used during the execution of the application to configure different aspects of the runtime system.

In addition to the ini files, any application can supply its own configuration files, which will be merged with the configuration database as well. Moreover, the user can specify additional configuration parameters on the command line when executing an application. The HPX runtime system will merge all command line configuration options (see the description of the \texttt{--hpx\_ini,--hpx\_config, and --hpx\_app\_config} command line options).
The HPX INI File Format

All HPX applications can be configured using a special file format which is similar to the well-known Windows INI file format\(^\text{96}\). This is a structured text format allowing to group key/value pairs (properties) into sections. The basic element contained in an ini file is the property. Every property has a name and a value, delimited by an equals sign '='. The name appears to the left of the equals sign:

\[
\text{name}=\text{value}
\]

The value may contain equal signs as only the first '=' character is interpreted as the delimiter between name and value. Whitespace before the name, after the value and immediately before and after the delimiting equal sign is ignored. Whitespace inside the value is retained.

Properties may be grouped into arbitrarily named sections. The section name appears on a line by itself, in square brackets `[` and `]`. All properties after the section declaration are associated with that section. There is no explicit "end of section" delimiter; sections end at the next section declaration, or the end of the file:

```
[section]
```

In HPX sections can be nested. A nested section has a name composed of all section names it is embedded in. The section names are concatenated using a dot ".":

```
[outer_section.inner_section]
```

Here `inner_section` is logically nested within `outer_section`.

It is possible to use the full section name concatenated with the property name to refer to a particular property. For example in:

```
[a.b.c]
d = e
```

the property value of `d` can be referred to as `a.b.c.d=e`.

In HPX ini files can contain comments. Hash signs `#` at the beginning of a line indicate a comment. All characters starting with the `#` until the end of line are ignored.

If a property with the same name is reused inside a section, the second occurrence of this property name will override the first occurrence (discard the first value). Duplicate sections simply merge their properties together, as if they occurred contiguously.

In HPX ini files, a property value `${FOO:default}` will use the environmental variable `FOO` to extract the actual value if it is set and `default` otherwise. No default has to be specified. Therefore `${FOO}` refers to the environmental variable `FOO`. If `FOO` is not set or empty the overall expression will evaluate to an empty string. A property value `${section.key:default}` refers to the value held by the property `section.key` if it exists and `default` otherwise. No default has to be specified. Therefore `${section.key}` refers to the property `section.key`. If the property `section.key` is not set or empty, the overall expression will evaluate to an empty string.

**Note:** Any property `${section.key:default}` is evaluated whenever it is queried and not when the configuration data is initialized. This allows for lazy evaluation and relieves initialization order of different sections. The only exception are recursive property values, e.g. values referring to the very key they are associated with. Those property values are evaluated at initialization time to avoid infinite recursion.

\(^96\) https://en.wikipedia.org/wiki/INI_file
Built-in Default Configuration Settings

During startup any HPX application applies a predefined search pattern to locate one or more configuration files. All found files will be read and merged in the sequence they are found into one single internal data structure holding all configuration properties.

As a first step the internal configuration database is filled with a set of default configuration properties. Those settings are described on a section by section basis below.

**Note:** You can print the default configuration settings used for an executable by specifying the command line option `--hpx:dump-config`.

### The system configuration section

```
[system]
pid = <process-id>
prefix = <current prefix path of core HPX library>
executable = <current prefix path of executable>
```

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>system.pid</td>
<td>This is initialized to store the current OS-process id of the application instance.</td>
</tr>
<tr>
<td>system.prefix</td>
<td>This is initialized to the base directory HPX has been loaded from.</td>
</tr>
<tr>
<td>system.executable_prefix</td>
<td>This is initialized to the base directory the current executable has been loaded from.</td>
</tr>
</tbody>
</table>

### The hpx configuration section

```
[hpx]
location = ${HPX_LOCATION:$[system.prefix]}
component_path = ${hpx:location}/lib/hpx:${system.executable_prefix}/lib/hpx:${system.executable_prefix}/lib/hpx
master_ini_path = ${hpx:location}/share/hpx-<version>:${system.executable_prefix}/share/hpx-<version>
ini_path = ${hpx.master_ini_path}/ini
os_threads = 1
localities = 1
program_name = cmd_line =
lock_detection = ${HPX_LOCK_DETECTION:0}
throw_on_held_lock = ${HPX_THROW_ON_HELD_LOCK:1}
minimal_deadlock_detection = <debug>
spinlock_deadlock_detection = <debug>
spinlock_deadlock_detection_limit = ${HPX_SPINLOCK_DEADLOCK_DETECTION_LIMIT:1000000}
max_background_threads = ${HPX_MAX_BACKGROUND_THREADS:${hpx.os_threads}]
max_idle_loop_count = ${HPX_MAX_IDLE_LOOP_COUNT:${hpx_idle_loop_count_max}>
max_busy_loop_count = ${HPX_MAX_BUSY_LOOP_COUNT:${hpx_busy_loop_count_max}>
max_idle_backoff_time = ${HPX_MAX_IDLE_BACKOFF_TIME:${hpx_idle_backoff_time_max}>
exception_verbosity = ${HPX_EXCEPTION_VERBOSITY:2}
```

<tr>
<td><strong>hpx.</strong> component</td>
<td>Duplicates are discarded. This property can refer to a list of directories separated by ': ' (Linux, Android, and MacOS) or using '; ' (Windows).</td>
</tr>
<tr>
<td><strong>hpx.</strong> master_ini_path</td>
<td>This is initialized to the list of default paths of the main hpx.ini configuration files. This property can refer to a list of directories separated by ': ' (Linux, Android, and MacOS) or using '; ' (Windows).</td>
</tr>
<tr>
<td><strong>hpx.</strong> ini_path</td>
<td>This is initialized to the default path where <em>HPX</em> will look for more ini configuration files. This property can refer to a list of directories separated by ': ' (Linux, Android, and MacOS) or using '; ' (Windows).</td>
</tr>
<tr>
<td><strong>hpx.</strong> os_threads</td>
<td>This setting reflects the number of OS-threads used for running <em>HPX</em>-threads. Defaults to number of detected cores (not hyperthreads/PUs).</td>
</tr>
<tr>
<td><strong>hpx.</strong> locations</td>
<td>This setting reflects the number of localities the application is running on. Defaults to 1.</td>
</tr>
<tr>
<td><strong>hpx.</strong> program_name</td>
<td>This setting reflects the program name of the application instance. Initialized from the command line argv[0].</td>
</tr>
<tr>
<td><strong>hpx.</strong> cmd_line</td>
<td>This setting reflects the actual command line used to launch this application instance.</td>
</tr>
<tr>
<td><strong>hpx.</strong> lock_detection</td>
<td>This setting verifies that no locks are being held while a <em>HPX</em> thread is suspended. This setting is applicable only if <em>HPX_WITH_VERIFY_LOCKS</em> is set during configuration in CMake.</td>
</tr>
<tr>
<td><strong>hpx.</strong> throw_on_held_lock</td>
<td>This setting causes an exception if during lock detection at least one lock is being held while a <em>HPX</em> thread is suspended. This setting is applicable only if <em>HPX_WITH_VERIFY_LOCKS</em> is set during configuration in CMake. This setting has no effect if <em>hpx.lock_detection</em> = 0.</td>
</tr>
<tr>
<td><strong>hpx.</strong> minimal_deadlock_detection</td>
<td>This setting enables support for minimal deadlock detection for <em>HPX</em>-threads. By default this is set to 1 (for Debug builds) or to 0 (for Release, RelWithDebInfo, RelMinSize builds), this setting is effective only if <em>HPX_WITH_THREAD_DEADLOCK_DETECTION</em> is set during configuration in CMake.</td>
</tr>
<tr>
<td><strong>hpx.</strong> spinlock_deadlock_detection_limit</td>
<td>This setting specifies the upper limit of allowed number of spins that spinlocks don’t spin longer than specified using the <em>hpx.spinlock_deadlock_detection_limit</em>. This setting is applicable only if <em>HPX_WITH_SPINLOCK_DEADLOCK_DETECTION</em> is set during configuration in CMake. By default this is set to 1 (for Debug builds) or to 0 (for Release, RelWithDebInfo, RelMinSize builds).</td>
</tr>
<tr>
<td><strong>hpx.</strong> max_idle_loop_count_max</td>
<td>This setting defines the maximum value of the busy-loop counter in the scheduler. By default this is defined by the preprocessor constant <em>HPX_BUSY_LOOP_COUNT_MAX</em>. This is an internal setting which you should change only if you know exactly what you are doing.</td>
</tr>
<tr>
<td><strong>hpx.</strong> max_idle_backoff_time_max</td>
<td>This setting defines the maximum time (in milliseconds) for the scheduler to sleep after being idle for <em>hpx.max_idle_loop_count</em> iterations. This setting is applicable only if <em>HPX_WITH_THREAD_MANAGER_IDLE_BACKOFF</em> is set during configuration in CMake. By default this is defined by the preprocessor constant <em>HPX_IDLE_BACKOFF_TIME_MAX</em>. This is an internal setting which you should change only if you know exactly what you are doing.</td>
</tr>
<tr>
<td><strong>hpx.</strong> exceptionverbosity</td>
<td>This setting defines the verbosity of exceptions. Valid values are integers. A setting of 2 or higher prints all available information. A setting of 1 leaves out the build configuration and environment variables. A setting of 0 or lower prints only the description of the thrown exception and the file name, function, and line number where the exception was thrown. The default value is 2 or the value of the environment variable <em>HPX_EXCEPTION_VERBOSITY</em>.</td>
</tr>
<tr>
<td><strong>hpx.</strong> small_stack_size</td>
<td>This is initialized to the small stack size to be used by <em>HPX</em>-threads. Set by default to the value of the compile time preprocessor constant <em>HPX_SMALL_STACK_SIZE</em> (defaults to 0x8000). This value is used for all <em>HPX</em> threads by default, except for the thread running <em>hpx_main</em> (which runs on a large stack).</td>
</tr>
<tr>
<td><strong>hpx.</strong> stacks</td>
<td>This is initialized to the medium stack size to be used by <em>HPX</em>-threads. Set by default to the value of the compile time preprocessor constant <em>HPX_MEDIUM_STACK_SIZE</em> (defaults to 0x20000).</td>
</tr>
</tbody>
</table>

The *HPX batch* is not enabled and the *HPX_WITH_THREAD_GUARD_PAGE* option is set during configuration in CMake. This setting is used by default for the thread running *hpx_main* (which runs on a large stack). By default this is defined by the preprocessor constant *HPX_IDLE_BACKOFF_TIME_MAX*. This is an internal setting which you should change only if you know exactly what you are doing. The *HPX with_pthread_idle_backoff* option is set during configuration in CMake. By default this is set to 1000000. This setting is applicable only if *HPX_WITH_VERIFY_LOCKS* is set during configuration in CMake. By default this is set to the value of the environment variable *HPX_EXCEPTION_VERBOSITY*.
The `hpx.threadpools` configuration section

```
[hpX.threadpools]
io_pool_size = ${HPX_NUM_IO_POOL_SIZE:2}
parcel_pool_size = ${HPX_NUM_PARCEL_POOL_SIZE:2}
timer_pool_size = ${HPX_NUM_TIMER_POOL_SIZE:2}
```

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>io_pool_size</code></td>
<td>The value of this property defines the number of OS-threads created for the</td>
</tr>
<tr>

<td>internal parcel thread pool.</td>
</tr>
<tr>
<td><code>timer_pool_size</code></td>
<td>The value of this property defines the number of OS-threads created for the</td>
</tr>
<tr>
<td></td>
<td>internal timer thread pool.</td>
</tr>
</tbody>
</table>

The `hpx.thread_queue` configuration section

**Important:** These settings control internal values used by the thread scheduling queues in the HPX scheduler. You should not modify these settings except if you know exactly what you are doing.

```
[hpX.thread_queue]
min_tasks_to_steal_pending = ${HPX_THREAD_QUEUE_MIN_TASKS_TO STEAL_PENDING:0}
min_tasks_to_steal_staged = ${HPX_THREAD_QUEUE_MIN_TASKS_TO STEAL STAGED:10}
min_add_new_count = ${HPX_THREAD_QUEUE_MIN_ADD_NEW_COUNT:10}
max_add_new_count = ${HPX_THREAD_QUEUE_MAX_ADD_NEW_COUNT:10}
max_delete_count = ${HPX_THREAD_QUEUE_MAX_DELETE_COUNT:1000}
```

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>min_tasks_to_steal pending</code></td>
<td>The value of this property defines the number of pending HPX threads which</td>
</tr>
<tr>
<td></td>
<td>have to be available before neighboring cores are allowed to steal work.</td>
</tr>
<tr>
<td></td>
<td>The default is to allow stealing always.</td>
</tr>
<tr>
<td><code>min_tasks_to_steal_staged</code></td>
<td>The value of this property defines the number of staged HPX tasks have which</td>
</tr>
<tr>
<td></td>
<td>to be available before neighboring cores are allowed to steal work. The</td>
</tr>
<tr>
<td></td>
<td>default is to allow stealing only if there are more than 10 tasks available.</td>
</tr>
<tr>
<td><code>min_add_new_count</code></td>
<td>The value of this property defines the minimal number tasks to be converted</td>
</tr>
<tr>
<td></td>
<td>into HPX threads whenever the thread queues for a core have run empty.</td>
</tr>
<tr>
<td><code>max_add_new_count</code></td>
<td>The value of this property defines the maximal number tasks to be converted</td>
</tr>
<tr>
<td></td>
<td>into HPX threads whenever the thread queues for a core have run empty.</td>
</tr>
<tr>
<td><code>max_delete_count</code></td>
<td>The value of this property defines the number of terminated HPX threads to</td>
</tr>
<tr>
<td></td>
<td>discard during each invocation of the corresponding function.</td>
</tr>
</tbody>
</table>
The **hpx.components** configuration section

```
[hpX.components]
load_external = ${HPX_LOAD_EXTERNAL_COMPONENTS:1}
```

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hpx. components.load_external</td>
<td>This entry defines whether external components will be loaded on this <strong>locality</strong>. This entry normally is set to 1 and usually there is no need to directly change this value. It is automatically set to 0 for a dedicated AGAS server <strong>locality</strong>.</td>
</tr>
</tbody>
</table>

Additionally, the section `hpx.components` will be populated with the information gathered from all found components. The information loaded for each of the components will contain at least the following properties:

```
[hpX.components.<component_instance_name>]
name = <component_name>
path = <full_path_of_the_component_module>
enabled = ${hpX.components.load_external}
```

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hpx. components.&lt;component_instance_name&gt;.name</td>
<td>This is the name of a component, usually the same as the second argument to the macro used while registering the component with <code>HPX_REGISTER_COMPONENT</code>. Set by the component factory.</td>
</tr>
<tr>
<td>hpx. components.&lt;component_instance_name&gt;.path</td>
<td>This is either the full path file name of the component module or the directory the component module is located in. In this case, the component module name will be derived from the property <code>hpx.components.&lt;component_instance_name&gt;.name</code>. Set by the component factory.</td>
</tr>
<tr>
<td>hpx. components.&lt;component_instance_name&gt;.enabled</td>
<td>This setting explicitly enables or disables the component. This is an optional property. <code>HPX</code> assumed that the component is enabled if it is not defined.</td>
</tr>
</tbody>
</table>

The value for `<component_instance_name>` is usually the same as for the corresponding `name` property. However generally it can be defined to any arbitrary instance name. It is used to distinguish between different ini sections, one for each component.

The **hpx.parcel** configuration section

```
[hpX.parcel]
address = ${HPX_PARCEL_SERVER_ADDRESS:<hpx_initial_ip_address>}
port = ${HPX_PARCEL_SERVER_PORT:<hpx_initial_ip_port>}
bootstrap = ${HPX_PARCEL_BOOTSTRAP:<hpx_parcel_bootstrap>}
max_connections = ${HPX_PARCEL_MAX_CONNECTIONS:<hpx_parcel_max_connections>}
max_connections_per_locality = ${HPX_PARCEL_MAX_CONNECTIONS_PER_LOCALITY:<hpx_parcel_max_connections_per_locality>}
max_message_size = ${HPX_PARCEL_MAX_MESSAGE_SIZE:<hpx_parcel_max_message_size>}
max_outbound_message_size = ${HPX_PARCEL_MAX_OUTBOUND_MESSAGE_SIZE:<hpx_parcel_max_outbound_message_size>}
array_optimization = ${HPX_PARCEL_ARRAY_OPTIMIZATION:1}

</tbody>
</table>
Loading INI files

During startup and after the internal database has been initialized as described in the section *Built-in Default Configuration Settings*, HPX will try to locate and load additional ini files to be used as a source for configuration properties. This allows for a wide spectrum of additional customization possibilities by the user and system administrators. The sequence of locations where HPX will try loading the ini files is well defined and documented in this section. All ini files found are merged into the internal configuration database. The merge operation itself conforms to the rules as described in the section *The HPX INI File Format*.

1. Load all component shared libraries found in the directories specified by the property `hpx.component_path` and retrieve their default configuration information (see section *Loading components* for more details). This property can refer to a list of directories separated by `':'` (Linux, Android, and MacOS) or using `';'` (Windows).

2. Load all files named `hpx.ini` in the directories referenced by the property `hpx.master_ini_path`. This property can refer to a list of directories separated by `':'` (Linux, Android, and MacOS) or using `';'` (Windows).

3. Load a file named `.hpx.ini` in the current working directory, e.g. the directory the application was invoked from.

4. Load a file referenced by the environment variable `HPX_INI`. This variable is expected to provide the full path name of the ini configuration file (if any).

5. Load a file named `/etc/hpx.ini`. This lookup is done on non-Windows systems only.

6. Load a file named `.hpx.ini` in the home directory of the current user, e.g. the directory referenced by the environment variable `HOME`.

7. Load a file named `.hpx.ini` in the directory referenced by the environment variable `PWD`.

8. Load the file specified on the command line using the option `--hpx:config`.

9. Load all properties specified on the command line using the option `--hpx:ini`. The properties will be added to the database in the same sequence as they are specified on the command line. The format for those options is for instance `--hpx:ini=hpx.default_stack_size=0x4000`. In addition to the explicit command line options, this will set the following properties as implied from other settings:

   - `hpx.parcel.address` and `hpx.parcel.port` as set by `--hpx:hpx`
   - `hpx.agas.address`, `hpx.agas.port` and `hpx.agas.service_mode` as set by `--hpx:agas`
   - `hpx.program_name` and `hpx.cmd_line` will be derived from the actual command line
   - `hpx.os_threads` and `hpx.localities` as set by `--hpx:threads` and `--hpx:localities`
   - `hpx.runtime_mode` will be derived from any explicit `--hpx:console`, `--hpx:worker`, or `--hpx:connect`, or it will be derived from other settings, such as `--hpx:node=0` which implies `--hpx:console`

10. Load files based on the pattern `*.ini` in all directories listed by the property `hpx.ini_path`. All files found during this search will be merged. The property `hpx.ini_path` can hold a list of directories separated by `':'` (on Linux or Mac) or `';'` (on Windows).

11. Load the file specified on the command line using the option `--hpx:app-config`. Note that this file will be merged as the content for a top level section `[application]`.

**Note:** Any changes made to the configuration database caused by one of the steps will influence the loading process for all subsequent steps. For instance, if one of the ini files loaded changes the property `hpx.ini_path` this will
influence the directories searched in step 9 as described above.

**Important:** The HPX core library will verify that all configuration settings specified on the command line (using the `--hpx:ini` option) will be checked for validity. That means that the library will accept only known configuration settings. This is to protect the user from unintentional typos while specifying those settings. This behavior can be overwritten by appending a `!'` to the configuration key, thus forcing the setting to be entered into the configuration database, for instance: `--hpx:ini=hpx.foo! = 1`

If any of the environment variables or files listed above is not found the corresponding loading step will be silently skipped.

**Loading components**

HPX relies on loading application specific components during the runtime of an application. Moreover, HPX comes with a set of preinstalled components supporting basic functionalities useful for almost every application. Any component in HPX is loaded from a shared library, where any of the shared libraries can contain more than one component type. During startup, HPX tries to locate all available components (e.g. their corresponding shared libraries) and creates an internal component registry for later use. This section describes the algorithm used by HPX to locate all relevant shared libraries on a system. As described, this algorithm is customizable by the configuration properties loaded from the ini files (see section Loading INI files).

Loading components is a two stage process. First HPX tries to locate all component shared libraries, loads those, and generates default configuration section in the internal configuration database for each component found. For each found component the following information is generated:

```
[hpx.components.<component_instance_name>]
name = <name_of_shared_library>
path = ${component_path}
enabled = ${hpx.components.load_external}
default = 1
```

The values in this section correspond to the expected configuration information for a component as described in the section Built-in Default Configuration Settings.

In order to locate component shared libraries, HPX will try loading all shared libraries (files with the platform specific extension of a shared library, Linux: `*.so`, Windows: `*.dll`, MacOS: `*.dylib` found in the directory referenced by the ini property `hpx.component_path`).

This first step corresponds to step 1) during the process of filling the internal configuration database with default information as described in section Loading INI files.

After all of the configuration information has been loaded, HPX performs the second step in terms of loading components. During this step, HPX scans all existing configuration sections `[hpx.component.<some_component_instance_name>]` and instantiates a special factory object for each of the successfully located and loaded components. During the application’s life time, these factory objects will be responsible to create new and discard old instances of the component they are associated with. This step is performed after step 11) of the process of filling the internal configuration database with default information as described in section Loading INI files.
Application specific component example

In this section we assume to have a simple application component which exposes one member function as a component action. The header file `app_server.hpp` declares the C++ type to be exposed as a component. This type has a member function `print_greeting()` which is exposed as an action `print_greeting_action`. We assume the source files for this example are located in a directory referenced by `$APP_ROOT`:

```cpp
// file: $APP_ROOT/app_server.hpp
#include <hpx/hpx.hpp>
#include <hpx/include/iostreams.hpp>
namespace app
{
   // Define a simple component exposing one action 'print_greeting'
   class HPX_COMPONENT_EXPORT server:
      public hpx::components::component_base<server>
   {
      void print_greeting ()
      {
         hpx::cout << "Hey, how are you?\n" << hpx::flush;
      }

      // Component actions need to be declared, this also defines the
      // type 'print_greeting_action' representing the action.
      HPX_DEFINE_COMPONENT_ACTION(server, print_greeting, print_greeting_action);
   };
}

// Declare boilerplate code required for each of the component actions.
HPX_REGISTER_ACTION_DECLARATION(app::server::print_greeting_action);
```

The corresponding source file contains mainly macro invocations which define boilerplate code needed for HPX to function properly:

```cpp
// file: $APP_ROOT/app_server.cpp
#include "app_server.hpp"

// Define boilerplate required once per component module.
HPX_REGISTER_COMPONENT_MODULE();

// Define factory object associated with our component of type 'app::server'.
HPX_REGISTER_COMPONENT(app::server, app_server);

// Define boilerplate code required for each of the component actions. Use the
// same argument as used for HPX_REGISTER_ACTION_DECLARATION above.
HPX_REGISTER_ACTION(app::server::print_greeting_action);
```

The following gives an example of how the component can be used. We create one instance of the `app::server` component on the current `locality` and invoke the exposed action `print_greeting_action` using the global id of the newly created instance. Note, that no special code is required to delete the component instance after it is not needed anymore. It will be deleted automatically when its last reference goes out of scope, here at the closing brace of the block surrounding the code:

```cpp
// file: $APP_ROOT/use_app_server_example.cpp
#include <hpx/hpx_init.hpp>
#include "app_server.hpp"
```
```cpp
int hpx_main()
{
    hpx::naming::id_type app_server_instance =
        hpx::create_component<hpx::app::server>(hpx::find_here());

    app::server::print_greeting_action print_greeting;

    print_greeting(app_server_instance);
}
```

In order to make sure that the application will be able to use the component `app::server`, special configuration information must be passed to `HPX`. The simplest way to allow `HPX` to ‘find’ the component is to provide special ini configuration files, which add the necessary information to the internal configuration database. The component should have a special ini file containing the information specific to the component `app_server`.

```ini
# file: $APP_ROOT/app_server.ini
[hpx.components.app_server]
name = app_server
path = $APP_LOCATION/
```

Here `$APP_LOCATION` is the directory where the (binary) component shared library is located. `HPX` will attempt to load the shared library from there. The section name `hpx.components.app_server` reflects the instance name of the component (`app_server` is an arbitrary, but unique name). The property value for `hpx.components.app_server.name` should be the same as used for the second argument to the macro `HPX_REGISTER_COMPONENT` above.

Additionally a file `.hpx.ini` which could be located in the current working directory (see step 3 as described in the section Loading INI files) can be used to add to the ini search path for components:

```ini
# file: $PWD/.hpx.ini
[hp]
ini_path = ${hp.ini_path}:$APP_ROOT/
```

This assumes that the above ini file specific to the component is located in the directory `$APP_ROOT`.

**Note:** It is possible to reference the defined property from inside its value. `HPX` will gracefully use the previous value of `hp.ini_path` for the reference on the right hand side and assign the overall (now expanded) value to the property.

2.5. Manual 119
Logging

HPX uses a sophisticated logging framework allowing to follow in detail what operations have been performed inside the HPX library in what sequence. This information proves to be very useful for diagnosing problems or just for improving the understanding what is happening in HPX as a consequence of invoking HPX API functionality.

Default logging

Enabling default logging is a simple process. The detailed description in the remainder of this section explains different ways to customize the defaults. Default logging can be enabled by using one of the following:

- a command line switch `--hpx:debug-hpx-log`, which will enable logging to the console terminal
- the command line switch `--hpx:debug-hpx-log=<filename>`, which enables logging to a given file `<filename>`, or
- setting an environment variable `HPX_LOGLEVEL=<loglevel>` while running the HPX application. In this case `<loglevel>` should be a number between (or equal to) 1 and 5 where 1 means minimal logging and 5 causes to log all available messages. When setting the environment variable the logs will be written to a file named `hpx.<PID>.lo` in the current working directory, where `<PID>` is the process id of the console instance of the application.

Customizing logging

Generally, logging can be customized either using environment variable settings or using by an ini configuration file. Logging is generated in several categories, each of which can be customized independently. All customizable configuration parameters have reasonable defaults, allowing to use logging without any additional configuration effort. The following table lists the available categories.

<table>
<thead>
<tr>
<th>Category</th>
<th>Category shortcut</th>
<th>Information to be generated</th>
<th>Environment variable</th>
</tr>

<tbody>
<tr>
<td>General</td>
<td>None</td>
<td>Logging information generated by different subsystems of HPX, such as thread-manager, parcel layer, LCOs, etc.</td>
<td>HPX_LOGLEVEL</td>
</tr>
<tr>
<td>AGAS</td>
<td>AGAS</td>
<td>Logging output generated by the AGAS subsystem</td>
<td>HPX_AGAS_LOGLEVEL</td>
</tr>
<tr>
<td>Application</td>
<td>APP</td>
<td>Logging generated by applications.</td>
<td>HPX_APP_LOGLEVEL</td>
</tr>
</tbody>
</table>

By default, all logging output is redirected to the console instance of an application, where it is collected and written to a file, one file for each logging category.

Each logging category can be customized at two levels, the parameters for each are stored in the ini configuration sections `hpx.logging.CATEGORY` and `hpx.logging.console.CATEGORY` (where CATEGORY is the category shortcut as listed in the table above). The former influences logging at the source locality and the latter modifies the logging behaviour for each of the categories at the console instance of an application.
**Levels**

All HPX logging output has seven different logging levels. These levels can be set explicitly or through environmental variables in the main HPX ini file as shown below. The logging levels and their associated integral values are shown in the table below, ordered from most verbose to least verbose. By default, all HPX logs are set to 0, e.g. all logging output is disabled by default.

<table>
<thead>
<tr>
<th>Logging level</th>
<th>Integral value</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;debug&gt;</td>
<td>5</td>
</tr>
<tr>
<td>&lt;info&gt;</td>
<td>4</td>
</tr>
<tr>
<td>&lt;warning&gt;</td>
<td>3</td>
</tr>
<tr>
<td>&lt;error&gt;</td>
<td>2</td>
</tr>
<tr>
<td>&lt;fatal&gt;</td>
<td>1</td>
</tr>
<tr>
<td>No logging</td>
<td>0</td>
</tr>
</tbody>
</table>

**Tip:** The easiest way to enable logging output is to set the environment variable corresponding to the logging category to an integral value as described in the table above. For instance, setting `HPX_LOGLEVEL=5` will enable full logging output for the general category. Please note that the syntax and means of setting environment variables varies between operating systems.

**Configuration**

Logs will be saved to destinations as configured by the user. By default, logging output is saved on the console instance of an application to `hpx.<CATEGORY>.<PID>.lo` (where `CATEGORY` and `PID` are placeholders for the category shortcut and the OS process id). The output for the general logging category is saved to `hpx.<PID>.log`. The default settings for the general logging category are shown here (the syntax is described in the section *The HPX INI File Format*:)

```
[hpx.logging]
level = ${HPX_LOGLEVEL:0}
destination = ${HPX_LOGDESTINATION:console}
format = ${HPX_LOGFORMAT:(T%locality%/%hpxthread%.%hpxphase%/%hpxcomponent%) P →%parentloc%/%hpxparent%.%hpxparentphase% %time%($hh:$mm.$ss.$mili) [%idx%]|\n}
```

The logging level is taken from the environment variable `HPX_LOGLEVEL` and defaults to zero, e.g. no logging. The default logging destination is read from the environment variable `HPX_LOGDESTINATION` On any of the localities it defaults to `console` which redirects all generated logging output to the console instance of an application. The following table lists the possible destinations for any logging output. It is possible to specify more than one destination separated by whitespace.

<table>
<thead>
<tr>
<th>Logging destination</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file:&lt;filename&gt;</td>
<td>Direct all output to a file with the given <code>&lt;filename&gt;</code>.</td>
</tr>
<tr>
<td>cout</td>
<td>Direct all output to the local standard output of the application instance on this <em>locality</em>.</td>
</tr>
<tr>
<td>cerr</td>
<td>Direct all output to the local standard error output of the application instance on this <em>locality</em>.</td>
</tr>
<tr>
<td>console</td>
<td>Direct all output to the console instance of the application. The console instance has its logging destinations configured separately.</td>
</tr>
<tr>
<td>android_log</td>
<td>Direct all output to the (Android) system log (available on Android systems only).</td>
</tr>
</tbody>
</table>
The logging format is read from the environment variable `HPX_LOGFORMAT` and it defaults to a complex format description. This format consists of several placeholder fields (for instance `%locality%` which will be replaced by concrete values when the logging output is generated. All other information is transferred verbatim to the output. The table below describes the available field placeholders. The separator character `|` separates the logging message prefix formatted as shown and the actual log message which will replace the separator.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>locality</td>
<td>The id of the <code>locality</code> on which the logging message was generated.</td>
</tr>
<tr>
<td>hpxthread</td>
<td>The id of the <code>HPX</code>-thread generating this logging output.</td>
</tr>
<tr>
<td>hpxphase</td>
<td>The phase(^98) of the <code>HPX</code>-thread generating this logging output.</td>
</tr>
<tr>
<td>hpxcomponent</td>
<td>The local virtual address of the component which the current <code>HPX</code>-thread is accessing.</td>
</tr>
<tr>
<td>parentloc</td>
<td>The id of the <code>locality</code> where the <code>HPX</code> thread was running which initiated the current <code>HPX</code>-thread. The current <code>HPX</code>-thread is generating this logging output.</td>
</tr>
<tr>
<td>hpxparent</td>
<td>The id of the <code>HPX</code>-thread which initiated the current <code>HPX</code>-thread. The current <code>HPX</code>-thread is generating this logging output.</td>
</tr>
<tr>
<td>hpxparentphase</td>
<td>The phase of the <code>HPX</code>-thread when it initiated the current <code>HPX</code>-thread. The current <code>HPX</code>-thread is generating this logging output.</td>
</tr>
<tr>
<td>time</td>
<td>The time stamp for this logging output line as generated by the source <code>locality</code>.</td>
</tr>
<tr>
<td>idx</td>
<td>The sequence number of the logging output line as generated on the source <code>locality</code>.</td>
</tr>
<tr>
<td>osthread</td>
<td>The sequence number of the OS-thread which executes the current <code>HPX</code>-thread.</td>
</tr>
</tbody>
</table>

**Note:** Not all of the field placeholder may be expanded for all generated logging output. If no value is available for a particular field it is replaced with a sequence of `'-` characters.

Here is an example line from a logging output generated by one of the `HPX` examples (please note that this is generated on a single line, without line break):

```
(T00000000/0000000002d46f90.01/00000000009ebc10) P--------/0000000002d46f80.02 17:49.
→37.320 [000000000000004d] <info> [RT] successfully created component {00000000100ff001, 0000000000030002},
→of type: component_barrier[7(3)]
```

The default settings for the general logging category on the console is shown here:

```
[hpx.logging.console]
level = ${HPX_LOGLEVEL:${hpx.logging.level}}
destination = ${HPX_CONSOLE_LOGDESTINATION:file(hpx.${system.pid}.log)}
format = ${HPX_CONSOLE_LOGFORMAT:}||
```

These settings define how the logging is customized once the logging output is received by the console instance of an application. The logging level is read from the environment variable `HPX_LOGLEVEL` (as set for the console instance of the application). The level defaults to the same values as the corresponding settings in the general logging configuration shown before. The destination on the console instance is set to be a file which name is generated based from its OS process id. Setting the environment variable `HPX_CONSOLE_LOGDESTINATION` allows customization of the naming scheme for the output file. The logging format is set to leave the original logging output unchanged, as received from one of the localities the application runs on.

\(^{98}\) The phase of a `HPX`-thread counts how often this thread has been activated.
**HPX Command Line Options**

The predefined command line options for any application using `hpx::init` are described in the following subsections.

**HPX options (allowed on command line only)**

```
--hpx:help
    print out program usage (default: this message), possible values: full (additionally prints options from components)

--hpx:version
    print out HPX version and copyright information

--hpx:info
    print out HPX configuration information

--hpx:options-file arg
    specify a file containing command line options (alternatively: @filepath)
```

**HPX options (additionally allowed in an options file)**

```
--hpx:worker
    run this instance in worker mode

--hpx:console
    run this instance in console mode

--hpx:connect
    run this instance in worker mode, but connecting late

--hpx:run-agas-server
    run AGAS server as part of this runtime instance

--hpx:run-hpx-main
    run the hpx_main function, regardless of locality mode

--hpx:hp arg
    the IP address the HPX parcelport is listening on, expected format: address:port (default: 127.0.0.1:7910)

--hpx:agas arg
    the IP address the AGAS root server is running on, expected format: address:port (default: 127.0.0.1:7910)

--hpx:run-agas-server-only
    run only the AGAS server

--hpx:nodefile arg
    the file name of a node file to use (list of nodes, one node name per line and core)

--hpx:nodes arg
    the (space separated) list of the nodes to use (usually this is extracted from a node file)

--hpx:endnodes
    this can be used to end the list of nodes specified using the option --hpx:nodes

--hpx:ifsuffix arg
    suffix to append to host names in order to resolve them to the proper network interconnect
```
--hpx:ifprefix arg
prefix to prepend to host names in order to resolve them to the proper network interconnect

--hpx:iftransform arg
sed-style search and replace (s/search/replace/) used to transform host names to the proper network interconnect

--hpx:localities arg
the number of localities to wait for at application startup (default: 1)

--hpx:node arg
number of the node this locality is run on (must be unique)

--hpx:ignore-batch-env
ignore batch environment variables

--hpx:expect-connecting-localities
this locality expects other localities to dynamically connect (this is implied if the number of initial localities is larger than 1)

--hpx:pu-offset
the first processing unit this instance of HPX should be run on (default: 0)

--hpx:pu-step
the step between used processing unit numbers for this instance of HPX (default: 1)

--hpx:threads arg
the number of operating system threads to spawn for this HPX locality. Possible values are: numeric values 1, 2, 3 and so on, all (which spawns one thread per processing unit, includes hyperthreads), or cores (which spawns one thread per core) (default: cores).

--hpx:cores arg
the number of cores to utilize for this HPX locality (default: all, i.e. the number of cores is based on the number of threads --hpx:threads assuming --hpx:bind=compact

--hpx:affinity arg
the affinity domain the OS threads will be confined to, possible values: pu, core, numa, machine (default: pu)

--hpx:bind arg
the detailed affinity description for the OS threads, see More details about HPX command line options for a detailed description of possible values. Do not use with --hpx:pu-step, --hpx:pu-offset or --hpx:affinity options. Implies --hpx:numa-sensitive (--hpx:bind=none) disables defining thread affinities).

--hpx:use-process-mask
use the process mask to restrict available hardware resources (implies --hpx:ignore-batch-env)

--hpx:print-bind
print to the console the bit masks calculated from the arguments specified to all --hpx:bind options.

--hpx:queuing arg
the queue scheduling policy to use, options are local, local-priority-fifo, local-priority-lifo, static, static-priority, abp-priority-fifo and abp-priority-lifo (default: local-priority-fifo)

--hpx:high-priority-threads arg
the number of operating system threads maintaining a high priority queue (default: number of OS threads), valid for --hpx:queuing=abp-priority, --hpx:queuing=static-priority and --hpx:queuing=local-priority only
--hpx:numa-sensitive
  makes the scheduler NUMA sensitive

**HPX configuration options**

--hpx:app-config arg
  load the specified application configuration (ini) file

--hpx:config arg
  load the specified hpx configuration (ini) file

--hpx:ini arg
  add a configuration definition to the default runtime configuration

--hpx:exit
  exit after configuring the runtime

**HPX debugging options**

--hpx:list-symbolic-names
  list all registered symbolic names after startup

--hpx:list-component-types
  list all dynamic component types after startup

--hpx:dump-config-initial
  print the initial runtime configuration

--hpx:dump-config
  print the final runtime configuration

--hpx:debug-hpx-log [arg]
  enable all messages on the HPX log channel and send all HPX logs to the target destination (default: cout)

--hpx:debug-agas-log [arg]
  enable all messages on the AGAS log channel and send all AGAS logs to the target destination (default: cout)

--hpx:debug-parcel-log [arg]
  enable all messages on the parcel transport log channel and send all parcel transport logs to the target destination (default: cout)

--hpx:debug-timing-log [arg]
  enable all messages on the timing log channel and send all timing logs to the target destination (default: cout)

--hpx:debug-app-log [arg]
  enable all messages on the application log channel and send all application logs to the target destination (default: cout)

--hpx:debug-clp
  debug command line processing

--hpx:attach-debugger arg
  wait for a debugger to be attached, possible arg values: startup or exception (default: startup)
**HPX** options related to performance counters

```
--hpx:print-counter
  print the specified performance counter either repeatedly and/or at the times specified by
  --hpx:print-counter-at (see also option --hpx:print-counter-interval)

--hpx:print-counter-reset
  print the specified performance counter either repeatedly and/or at the times specified by
  --hpx:print-counter-at reset the counter after the value is queried. (see also option
  --hpx:print-counter-interval)

--hpx:print-counter-interval
  print the performance counter(s) specified with --hpx:print-counter repeatedly after the time interval
  (specified in milliseconds), (default: 0, which means print once at shutdown)

--hpx:print-counter-destination
  print the performance counter(s) specified with --hpx:print-counter to the given file (default: console)

--hpx:list-counters
  list the names of all registered performance counters, possible values: minimal (prints counter name skele-
  tons), full (prints all available counter names)

--hpx:list-counter-infos
  list the description of all registered performance counters, possible values: minimal (prints info for counter
  name skeletons), full (prints all available counter infos)

--hpx:print-counter-format
  print the performance counter(s) specified with --hpx:print-counter possible formats in csv format
  with header or without any header (see option --hpx:no-csv-header, possible values: csv (prints
  counter values in CSV format with full names as header), csv-short (prints counter values in CSV for-
  mat with shortnames provided with --hpx:print-counter as --hpx:print-counter shortname, full-countername

--hpx:no-csv-header
  print the performance counter(s) specified with --hpx:print-counter and csv or csv-short format
  specified with --hpx:print-counter-format without header

--hpx:print-counter-at arg
  print the performance counter(s) specified with --hpx:print-counter (or
  --hpx:print-counter-reset at the given point in time, possible argument values: startup,
  shutdown (default), noshutdown

--hpx:reset-counters
  reset all performance counter(s) specified with --hpx:print-counter after they have been evaluated.

--hpx:print-counters-locally
  Each locality prints only its own local counters. If this is used with
  --hpx:print-counter-destination=<file>, the code will append a ",<locality_id>" to the file name in order to avoid clashes between localities.
```
Command line argument shortcuts

Additionally, the following shortcuts are available from every HPX application.

<table>
<thead>
<tr>
<th>Shortcut option</th>
<th>Equivalent long option</th>

</tbody>
</table>

It is possible to define your own shortcut options. In fact, all of the shortcuts listed above are pre-defined using the technique described here. Also, it is possible to redefine any of the pre-defined shortcuts to expand differently as well.

Shortcut options are obtained from the internal configuration database. They are stored as key-value properties in a special properties section named hpx.commandline. You can define your own shortcuts by adding the corresponding definitions to one of the ini configuration files as described in the section Configuring HPX applications. For instance, in order to define a command line shortcut --p which should expand to -hpx:print-counter, the following configuration information needs to be added to one of the ini configuration files:

```ini
[hpx.commandline.aliases]
--pc = --hpx:print-counter
```

**Note:** Any arguments for shortcut options passed on the command line are retained and passed as arguments to the corresponding expanded option. For instance, given the definition above, the command line option:

```
--pc=/threads{locality#0/total}/count/cumulative
```

would be expanded to:

```
--hpx:print-counter=/threads{locality#0/total}/count/cumulative
```

**Important:** Any shortcut option should either start with a single ‘-’ or with two ‘--’ characters. Shortcuts
starting with a single '-' are interpreted as short options (i.e. everything after the first character following the '-' is treated as the argument). Shortcuts starting with '--' are interpreted as long options. No other shortcut formats are supported.

### Specifying options for single localities only

For runs involving more than one *locality* it is sometimes desirable to supply specific command line options to single localities only. When the *HPX* application is launched using a scheduler (like PBS, for more details see section *How to use HPX applications with PBS*), specifying dedicated command line options for single localities may be desirable. For this reason all of the command line options which have the general format `--hpx:<some_key>` can be used in a more general form: `--hpx:<N>:<some_key>`, where `<N>` is the number of the *locality* this command line options will be applied to, all other localities will simply ignore the option. For instance, the following PBS script passes the option `--hpx:pu-offset=4` to the *locality* '1' only.

```bash
#!/bin/bash

APP_PATH=~/packages/hpx/bin/hello_world_distributed
APP_OPTIONS=

pbsdsh -u $APP_PATH $APP_OPTIONS --hpx:1:pu-offset=4 --hpx:nodes=`cat $PBS_NODEFILE`
```

Caution:  If the first application specific argument (inside `$APP_OPTIONS` is a non-option (i.e. does not start with a '-' or a '--'), then it must be placed before the option `--hpx:nodes`, which, in this case, should be the last option on the command line.

Alternatively, use the option `--hpx:endnodes` to explicitly mark the end of the list of node names:

```bash
pbsdsh -u $APP_PATH $APP_OPTIONS --hpx:1:pu-offset=4 --hpx:nodes=`cat $PBS_NODEFILE` --
  --hpx:endnodes $APP_OPTIONS
```

### More details about *HPX* command line options

This section documents the following list of the command line options in more detail:

- *The command line option* `--hpx:bind`

#### The command line option `--hpx:bind`

This command line option allows one to specify the required affinity of the *HPX* worker threads to the underlying processing units. As a result the worker threads will run only on the processing units identified by the corresponding bind specification. The affinity settings are to be specified using `--hpx:bind=<BINDINGS>`, where `<BINDINGS>` have to be formatted as described below.

In addition to the syntax described below one can use `--hpx:bind=none` to disable all binding of any threads to a particular core. This is mostly supported for debugging purposes.

The specified affinities refer to specific regions within a machine hardware topology. In order to understand the hardware topology of a particular machine it may be useful to run the lstopo tool which is part of Portable Hardware
Locality (HWLOC) to see the reported topology tree. Seeing and understanding a topology tree will definitely help in understanding the concepts that are discussed below.

Affinities can be specified using HWLOC (Portable Hardware Locality (HWLOC)) tuples. Tuples of HWLOC objects and associated indexes can be specified in the form object:index, object:index-index or object:index,...,index. HWLOC objects represent types of mapped items in a topology tree. Possible values for objects are socket, numanode, core and pu (processing unit). Indexes are non-negative integers that specify a unique physical object in a topology tree using its logical sequence number.

Chaining multiple tuples together in the more general form object1:index1[.object2:index2[...]] is permissible. While the first tuple’s object may appear anywhere in the topology, the Nth tuple’s object must have a shallower topology depth than the (N+1)th tuple’s object. Put simply: as you move right in a tuple chain, objects must go deeper in the topology tree. Indexes specified in chained tuples are relative to the scope of the parent object. For example, socket:0.core:1 refers to the second core in the first socket (all indices are zero based).

Multiple affinities can be specified using several --hpx:bind command line options or by appending several affinities separated by a ';' By default, if multiple affinities are specified, they are added. "all" is a special affinity consisting in the entire current topology.

Note: All ‘names’ in an affinity specification, such as thread, socket, numanode, pu or all can be abbreviated. Thus the affinity specification threads:0-3=socket:0.core:1.pu:1 is fully equivalent to its shortened form t:0-3=s:0.c:1.p:1.

Here is a full grammar describing the possible format of mappings:

```
mappings ::= distribution | mapping (";" mapping)*
distribution ::= "compact" | "scatter" | "balanced" | "numa-balanced"
mapping ::= thread_spec "=" pu_specs
thread_spec ::= "thread:" range_specs
pu_specs ::= pu_spec ("." pu_spec)*
pu_spec ::= type ":" range_specs | ":" pu_spec
range_specs ::= range_spec ("," range_spec)*
range_spec ::= int | int ":" int | "all"
type ::= "socket" | "numanode" | "core" | "pu"
```

The following example assumes a system with at least 4 cores, where each core has more than 1 processing unit (hardware threads). Running hello_world_distributed with 4 OS-threads (on 4 processing units), where each of those threads is bound to the first processing unit of each of the cores, can be achieved by invoking:

```
hello_world_distributed -t4 --hpx:bind=thread:0-3=core:0-3.pu:0
```

Here thread:0-3 specifies the OS threads for which to define affinity bindings, and core:0-3.pu: defines that for each of the cores (core:0-3) only their first processing unit pu:0 should be used.

Note: The command line option --hpx:print-bind can be used to print the bitmasks generated from the affinity mappings as specified with --hpx:bind. For instance, on a system with hyperthreading enabled (i.e. 2 processing units per core), the command line:

```
hello_world_distributed -t4 --hpx:bind=thread:0-3=core:0-3.pu:0 --hpx:print-bind
```

will cause this output to be printed:
where each bit in the bitmasks corresponds to a processing unit the listed worker thread will be bound to run on.

The difference between the four possible predefined distribution schemes (compact, scatter, balanced and numa-balanced) is best explained with an example. Imagine that we have a system with 4 cores and 4 hardware threads per core on 2 sockets. If we place 8 threads the assignments produced by the compact, scatter, balanced and numa-balanced types are shown in the figure below. Notice that compact does not fully utilize all the cores in the system. For this reason it is recommended that applications are run using the scatter or balanced/numa-balanced options in most cases.

Fig. 2.7: Schematic of thread affinity type distributions.

In addition to the predefined distributions it is possible to restrict the resources used by HPX to the process CPU
mask. The CPU mask is typically set by e.g. MPI\cite{MPIT} and batch environments. Using the command line option
\texttt{--hpx:use-process-mask} makes \texttt{HPX} act as if only the processing units in the CPU mask are available for use
by \texttt{HPX}. The number of threads is automatically determined from the CPU mask. The number of threads can still be
changed manually using this option, but only to a number less than or equal to the number of processing units in
the CPU mask. The option \texttt{--hpx:print-bind} is useful in conjunction with \texttt{--hpx:use-process-mask} to
make sure threads are placed as expected.

\subsection*{2.5.6 Writing single-node \texttt{HPX} applications}

\texttt{HPX} is a C++ Standard Library for Concurrency and Parallelism. This means that it implements all of the corre-
sponding facilities as defined by the C++ Standard. Additionally, \texttt{HPX} implements functionalities proposed as part
of the ongoing C++ standardization process. This section focuses on the features available in \texttt{HPX} for parallel and
concurrent computation on a single node, although many of the features presented here are also implemented to work
in the distributed case.

\subsubsection*{Using LCOs}

\textit{Lightweight Control Objects} (LCOs) provide synchronization for \texttt{HPX} applications. Most of them are familiar from
other frameworks, but a few of them work in slightly different ways adapted to \texttt{HPX}. The following synchronization
objects are available in \texttt{HPX}:

1. future
2. queue
3. object_semaphore
4. barrier

\subsubsection*{Channels}

Channels combine communication (the exchange of a value) with synchronization (guaranteeing that two calculations
(tasks) are in a known state). A channel can transport any number of values of a given type from a sender to a receiver:

\begin{verbatim}
hpxCC{}::lcos::local::channel<int> c;
hpxCC{}::future<int> f = c.get();
HPX_ASSERT(!f.is_ready());
c.set(42);
HPX_ASSERT(f.is_ready());
hpxCC{}::cout << f.get() << hpxCC{}::endl;
\end{verbatim}

Channels can be handed to another thread (or in case of channel components, to other localities), thus establishing a
communication channel between two independent places in the program:

\begin{verbatim}
void do_something(hpxCC{}::lcos::local::receive_channel<int> c,
hpxCC{}::lcos::local::send_channel<> done)
{
  // prints 43
  hpxCC{}::cout << c.get(hpxCC{}::launch::sync) << hpxCC{}::endl;
  // signal back
  done.set();
}
\end{verbatim}

\footnote{\url{https://en.wikipedia.org/wiki/Message_Passing_Interface}}
```cpp
void send_receive_channel()
{
    hpx::lcos::local::channel<int> c;
    hpx::lcos::local::channel<> done;

    hpx::apply(&do_something, c, done);

    // send some value
    c.set(43);
    // wait for thread to be done
    done.get().wait();
}
```

Note how `hpx::lcos::local::channel::get` without any arguments returns a future which is ready when a value has been set on the channel. The launch policy `hpx::launch::sync` can be used to make `hpx::lcos::local::channel::get` block until a value is set and return the value directly.

A channel component is created on one locality and can be sent to another locality using an action. This example also demonstrates how a channel can be used as a range of values:

```cpp
// channel components need to be registered for each used type (not needed
// for hpx::lcos::local::channel)
HPX_REGISTER_CHANNEL(double);

void channel_sender(hpx::lcos::channel<double> c)
{
    for (double d : c)
        hpx::cout << d << std::endl;
} HPXPLAIN_ACTION(channel_sender);

void channel()
{
    // create the channel on this locality
    hpx::lcos::channel<double> c(hpx::find_here());

    // pass the channel to a (possibly remote invoked) action
    hpx::apply(channel_sender_action(), hpx::find_here(), c);

    // send some values to the receiver
    std::vector<double> v = {1.2, 3.4, 5.0};
    for (double d : v)
        c.set(d);

    // explicitly close the communication channel (implicit at destruction)
    c.close();
}
```
Composable guards

Composable guards operate in a manner similar to locks, but are applied only to asynchronous functions. The guard (or guards) is automatically locked at the beginning of a specified task and automatically unlocked at the end. Because guards are never added to an existing task’s execution context, the calling of guards is freely composable and can never deadlock.

To call an application with a single guard, simply declare the guard and call run_guarded() with a function (task):

```cpp
hpx::lcos::local::guard gu;
run_guarded(gu, task);
```

If a single method needs to run with multiple guards, use a guard set:

```cpp
boost::shared<hpx::lcos::local::guard> gu1(new hpx::lcos::local::guard());
boost::shared<hpx::lcos::local::guard> gu2(new hpx::lcos::local::guard());
gs.add(*gu1);
gs.add(*gu2);
run_guarded(gs, task);
```

Guards use two atomic operations (which are not called repeatedly) to manage what they do, so overhead should be extremely low. The following guards are available in HPX:

1. conditional_trigger
2. counting_semaphore
3. dataflow
4. event
5. mutex
6. once
7. recursive_mutex
8. spinlock
9. spinlock_no_backoff
10. trigger

Extended facilities for futures

Concurrency is about both decomposing and composing the program from the parts that work well individually and together. It is in the composition of connected and multicore components where today’s C++ libraries are still lacking.

The functionality of std::future offers a partial solution. It allows for the separation of the initiation of an operation and the act of waiting for its result; however, the act of waiting is synchronous. In communication-intensive code this act of waiting can be unpredictable, inefficient and simply frustrating. The example below illustrates a possible synchronous wait using futures:

```cpp
#include <future>
using namespace std;
int main()
{
    future<int> f = async([]() { return 123; });
    int result = f.get(); // might block
}
```
For this reason, *HPX* implements a set of extensions to `std::future` (as proposed by `__cpp11_n4107__). This proposal introduces the following key asynchronous operations to `hpx::future`, `hpx::shared_future` and `hpx::async`, which enhance and enrich these facilities.

### Table 2.13: Facilities extending `std::future`

<table>
<thead>
<tr>
<th>Facility</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>hpx::future::then</code></td>
<td>In asynchronous programming, it is very common for one asynchronous operation, on completion, to invoke a second operation and pass data to it. The current C++ standard does not allow one to register a continuation to a future. With <code>then</code>, instead of waiting for the result, a continuation is “attached” to the asynchronous operation, which is invoked when the result is ready. Continuations registered using <code>then</code> function will help to avoid blocking waits or wasting threads on polling, greatly improving the responsiveness and scalability of an application.</td>
</tr>
<tr>
<td><code>unwrapping constructor for hpx::future</code></td>
<td>In some scenarios, you might want to create a future that returns another future, resulting in nested futures. Although it is possible to write code to unwrap the outer future and retrieve the nested future and its result, such code is not easy to write because users must handle exceptions and it may cause a blocking call. Unwrapping can allow users to mitigate this problem by doing an asynchronous call to unwrap the outermost future.</td>
</tr>
<tr>
<td><code>hpx::future::is_ready</code></td>
<td>There are often situations where a <code>get()</code> call on a future may not be a blocking call, or is only a blocking call under certain circumstances. This function gives the ability to test for early completion and allows us to avoid associating a continuation, which needs to be scheduled with some non-trivial overhead and near-certain loss of cache efficiency.</td>
</tr>
<tr>
<td><code>hpx::make_ready_future</code></td>
<td>Some functions may know the value at the point of construction. In these cases the value is immediately available, but needs to be returned as a future. By using <code>hpx::make_ready_future</code> a future can be created that holds a pre-computed result in its shared state. In the current standard it is non-trivial to create a future directly from a value. First a promise must be created, then the promise is set, and lastly the future is retrieved from the promise. This can now be done with one operation.</td>
</tr>
</tbody>
</table>

The standard also omits the ability to compose multiple futures. This is a common pattern that is ubiquitous in other asynchronous frameworks and is absolutely necessary in order to make C++ a powerful asynchronous programming language. Not including these functions is synonymous to Boolean algebra without AND/OR.

In addition to the extensions proposed by [N4313](http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2014/n4313.html), *HPX* adds functions allowing users to compose several futures in a more flexible way.

</tbody>
</table>

**High level parallel facilities**

In preparation for the upcoming C++ Standards, there are currently several proposals targeting different facilities supporting parallel programming. HPX implements (and extends) some of those proposals. This is well aligned with our strategy to align the APIs exposed from HPX with current and future C++ Standards.

At this point, HPX implements several of the C++ Standardization working papers, most notably N4409[^102] (Working Draft, Technical Specification for C++ Extensions for Parallelism), N4411[^103] (Task Blocks), and N4406[^104] (Parallel Algorithms Need Executors).

**Using parallel algorithms**

A parallel algorithm is a function template described by this document which is declared in the (inline) namespace `hpx::parallel::v1`.

**Note:** For compilers that do not support inline namespaces, all of the namespace v1 is imported into the namespace `hpx::parallel`. The effect is similar to what inline namespaces would do, namely all names defined in `hpx::parallel::v1` are accessible from the namespace `hpx::parallel` as well.

All parallel algorithms are very similar in semantics to their sequential counterparts (as defined in the namespace `std`) with an additional formal template parameter named `ExecutionPolicy`. The execution policy is generally

[^100]: http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2014/n4313.html
[^101]: http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2014/n4313.html
passed as the first argument to any of the parallel algorithms and describes the manner in which the execution of these algorithms may be parallelized and the manner in which they apply user-provided function objects.

The applications of function objects in parallel algorithms invoked with an execution policy object of type `hpx::execution::sequenced_policy` or `hpx::execution::sequenced_task_policy` execute in sequential order. For `hpx::execution::sequenced_policy` the execution happens in the calling thread.

The applications of function objects in parallel algorithms invoked with an execution policy object of type `hpx::execution::parallel_policy` or `hpx::execution::parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and are indeterminately sequenced within each thread.

**Important:** It is the caller’s responsibility to ensure correctness, such as making sure that the invocation does not introduce data races or deadlocks.

The applications of function objects in parallel algorithms invoked with an execution policy of type `hpx::execution::parallel_unsequenced_policy` is, in HPX, equivalent to the use of the execution policy `hpx::execution::parallel_policy`.

Algorithms invoked with an execution policy object of type `hpx::parallel::v1::execution_policy` execute internally as if invoked with the contained execution policy object. No exception is thrown when an `hpx::parallel::v1::execution_policy` contains an execution policy of type `hpx::execution::sequenced_task_policy` or `hpx::execution::parallel_task_policy` (which normally turn the algorithm into its asynchronous version). In this case the execution is semantically equivalent to the case of passing a `hpx::execution::sequenced_policy` or `hpx::execution::parallel_policy` contained in the `hpx::parallel::v1::execution_policy` object respectively.

### Parallel exceptions

During the execution of a standard parallel algorithm, if temporary memory resources are required by any of the algorithms and no memory is available, the algorithm throws a `std::bad_alloc` exception.

During the execution of any of the parallel algorithms, if the application of a function object terminates with an uncaught exception, the behavior of the program is determined by the type of execution policy used to invoke the algorithm:

- If the execution policy object is of type `hpx::execution::parallel_unsequenced_policy`, `hpx::terminate` shall be called.

- If the execution policy object is of type `hpx::execution::sequenced_policy`, `hpx::execution::sequenced_task_policy`, `hpx::execution::parallel_policy`, or `hpx::execution::parallel_task_policy`, the execution of the algorithm terminates with an `hpx::exception_list` exception. All uncaught exceptions thrown during the application of user-provided function objects shall be contained in the `hpx::exception_list` object.

For example, the number of invocations of the user-provided function object in `for_each` is unspecified. When `hpx::parallel::v1::for_each` is executed sequentially, only one exception will be contained in the `hpx::exception_list` object.

These guarantees imply that, unless the algorithm has failed to allocate memory and terminated with `std::bad_alloc`, all exceptions thrown during the execution of the algorithm are communicated to the caller. It is unspecified whether an algorithm implementation will “forge ahead” after encountering and capturing a user exception.

The algorithm may terminate with the `std::bad_alloc` exception even if one or more user-provided function objects have terminated with an exception. For example, this can happen when an algorithm fails to allocate memory...
while creating or adding elements to the `hpx::exception_list` object.

**Parallel algorithms**

*HPX* provides implementations of the following parallel algorithms:
<table>
<thead>
<tr>

Executor parameters and executor parameter traits

HPX introduces the notion of execution parameters and execution parameter traits. At this point, the only parameter that can be customized is the size of the chunks of work executed on a single HPX thread (such as the number of loop iterations combined to run as a single task).

An executor parameter object is responsible for exposing the calculation of the size of the chunks scheduled. It abstracts the (potentially platform-specific) algorithms of determining those chunk sizes.

The way executor parameters are implemented is aligned with the way executors are implemented. All functionalities of concrete executor parameter types are exposed and accessible through a corresponding `hpx::parallel::executor_parameter_traits` type.

With `executor_parameter_traits`, clients access all types of executor parameters uniformly:

```cpp
std::size_t chunk_size =
    executor_parameter_traits<my_parameter_t>::get_chunk_size(my_parameter,
    my_executor, [](auto &&) { return 0; }, num_tasks);
```

This call synchronously retrieves the size of a single chunk of loop iterations (or similar) to combine for execution on a single HPX thread if the overall number of tasks to schedule is given by `num_tasks`. The lambda function exposes a means of test-probing the execution of a single iteration for performance measurement purposes. The execution parameter type might dynamically determine the execution time of one or more tasks in order to calculate the chunk size; see `hpx::execution::auto_chunk_size` for an example of this executor parameter type.

Other functions in the interface exist to discover whether an executor parameter type should be invoked once (i.e., it returns a static chunk size; see `hpx::execution::static_chunk_size`) or whether it should be invoked for each scheduled chunk of work (i.e., it returns a variable chunk size; for an example, see `hpx::execution::guided_chunk_size`).

Although this interface appears to require executor parameter type authors to implement all different basic operations, none are required. In practice, all operations have sensible defaults. However, some executor parameter types will naturally specialize all operations for maximum efficiency.

HPX implements the following executor parameter types:

- `hpx::execution::auto_chunk_size`: Loop iterations are divided into pieces and then assigned to threads. The number of loop iterations combined is determined based on measurements of how long the execution of 1% of the overall number of iterations takes. This executor parameter type makes sure that as many loop iterations are combined as necessary to run for the amount of time specified.

- `hpx::execution::static_chunk_size`: Loop iterations are divided into pieces of a given size and then assigned to threads. If the size is not specified, the iterations are, if possible, evenly divided contiguously among the threads. This executor parameters type is equivalent to OpenMP’s STATIC scheduling directive.
• `hpx::execution::dynamic_chunk_size`: Loop iterations are divided into pieces of a given size and then dynamically scheduled among the cores; when a core finishes one chunk, it is dynamically assigned another. If the size is not specified, the default chunk size is 1. This executor parameter type is equivalent to OpenMP’s DYNAMIC scheduling directive.

• `hpx::execution::guided_chunk_size`: Iterations are dynamically assigned to cores in blocks as cores request them until no blocks remain to be assigned. This is similar to `dynamic_chunk_size` except that the block size decreases each time a number of loop iterations is given to a thread. The size of the initial block is proportional to `number_of_iterations / number_of_cores`. Subsequent blocks are proportional to `number_of_iterations_remaining / number_of_cores`. The optional chunk size parameter defines the minimum block size. The default minimal chunk size is 1. This executor parameter type is equivalent to OpenMP’s GUIDED scheduling directive.

Using task blocks

The `define_task_block`, `run` and the `wait` functions implemented based on N4411 are based on the `task_block` concept that is a part of the common subset of the Microsoft Parallel Patterns Library (PPL) and the Intel Threading Building Blocks (TBB) libraries.

These implementations adopt a simpler syntax than exposed by those libraries—one that is influenced by language-based concepts, such as spawn and sync from Cilk++ and async and finish from X10. They improve on existing practice in the following ways:

• The exception handling model is simplified and more consistent with normal C++ exceptions.

• Most violations of strict fork-join parallelism can be enforced at compile time (with compiler assistance, in some cases).

• The syntax allows scheduling approaches other than child stealing.

Consider an example of a parallel traversal of a tree, where a user-provided function `compute` is applied to each node of the tree, returning the sum of the results:

```cpp
template <typename Func>
int traverse(node& n, Func && compute)
{
    int left = 0, right = 0;
    define_task_block(
        [&](task_block<>& tr) {
            if (n.left)
                tr.run([&] { left = traverse(*n.left, compute); });
            if (n.right)
                tr.run([&] { right = traverse(*n.right, compute); });
        });

    return compute(n) + left + right;
}
```

The example above demonstrates the use of two of the functions, `hpx::parallel::define_task_block` and the `hpx::parallel::task_block::run` member function of `hpx::parallel::task_block`.

The `task_block` function delineates a region in a program code potentially containing invocations of threads spawned by the `run` member function of the `task_block` class. The `run` function spawns an HPX thread, a
unit of work that is allowed to execute in parallel with respect to the caller. Any parallel tasks spawned by `run` within the task block are joined back to a single thread of execution at the end of the `define_task_block.run` takes a user-provided function object `f` and starts it asynchronously—i.e., it may return before the execution of `f` completes. The HPX scheduler may choose to run `f` immediately or delay running `f` until compute resources become available.

A `task_block` can be constructed only by `define_task_block` because it has no public constructors. Thus, `run` can be invoked directly or indirectly only from a user-provided function passed to `define_task_block`:

```
void g();

void f(task_block<> & tr)
{
    tr.run(g); // OK, invoked from within task_block in h
}

void h()
{
    define_task_block(f);
}

int main()
{
    task_block<> tr; // Error: no public constructor
    tr.run(g); // No way to call run outside of a define_task_block
    return 0;
}
```

### Extensions for task blocks

#### Using execution policies with task blocks

HPX implements some extensions for `task_block` beyond the actual standards proposal N4411\(^\text{193}\). The main addition is that a `task_block` can be invoked with an execution policy as its first argument, very similar to the parallel algorithms.

An execution policy is an object that expresses the requirements on the ordering of functions invoked as a consequence of the invocation of a task block. Enabling passing an execution policy to `define_task_block` gives the user control over the amount of parallelism employed by the created `task_block`. In the following example the use of an explicit `par` execution policy makes the user’s intent explicit:

```
template <typename Func>
int traverse(node *n, Func&& compute)
{
    int left = 0, right = 0;

    define_task_block(
        execution::par, // execution::parallel_policy
        [ & ](task_block<> & tb) {
            if (n->left)
                tb.run([ & ] { left = traverse(n->left, compute); });
            if (n->right)
                tb.run([ & ] { right = traverse(n->right, compute); });
        });

    return left + right;
}
```

This also causes the hpx::parallel::v2::task_block object to be a template in our implementation. The template argument is the type of the execution policy used to create the task block. The template argument defaults to hpx::execution::parallel_policy.

HPX still supports calling hpx::parallel::v2::define_task_block without an explicit execution policy. In this case the task block will run using the hpx::execution::parallel_policy.

HPX also adds the ability to access the execution policy that was used to create a given task_block.

Using executors to run tasks

Often, users want to be able to not only define an execution policy to use by default for all spawned tasks inside the task block, but also to customize the execution context for one of the tasks executed by task_block::run. Adding an optionally passed executor instance to that function enables this use case:

```cpp
template <typename Func>
int traverse(node *n, Func&& compute)
{
    int left = 0, right = 0;

    define_task_block(
        execution::par, // execution::parallel_policy
        [&](auto & tb) {
            if (n->left)
            {
                // use explicitly specified executor to run this task
                tb.run(my_executor(), [&] { left = traverse(n->left, compute); });
            }
            if (n->right)
            {
                // use the executor associated with the par execution policy
                tb.run([&] { right = traverse(n->right, compute); });
            }
        });

    return compute(n) + left + right;
}
```

HPX still supports calling hpx::parallel::v2::task_block::run without an explicit executor object. In this case the task will be run using the executor associated with the execution policy that was used to call hpx::parallel::v2::define_task_block.
2.5.7 Writing distributed HPX applications

This section focuses on the features of HPX needed to write distributed applications, namely the Active Global Address Space (AGAS), remotely executable functions (i.e. actions), and distributed objects (i.e. components).

Global names

HPX implements an Active Global Address Space (AGAS) which is exposing a single uniform address space spanning all localities an application runs on. AGAS is a fundamental component of the ParalleX execution model. Conceptually, there is no rigid demarcation of local or global memory in AGAS; all available memory is a part of the same address space. AGAS enables named objects to be moved (migrated) across localities without having to change the object’s name, i.e., no references to migrated objects have to be ever updated. This feature has significance for dynamic load balancing and in applications where the workflow is highly dynamic, allowing work to be migrated from heavily loaded nodes to less loaded nodes. In addition, immutability of names ensures that AGAS does not have to keep extra indirections (“bread crumbs”) when objects move, hence minimizing complexity of code management for system developers as well as minimizing overheads in maintaining and managing aliases.

The AGAS implementation in HPX does not automatically expose every local address to the global address space. It is the responsibility of the programmer to explicitly define which of the objects have to be globally visible and which of the objects are purely local.

In HPX global addresses (global names) are represented using the hpx::id_type data type. This data type is conceptually very similar to void* pointers as it does not expose any type information of the object it is referring to.

The only predefined global addresses are assigned to all localities. The following HPX API functions allow one to retrieve the global addresses of localities:

- hpx::find_here: retrieve the global address of the locality this function is called on.
- hpx::find_all_localities: retrieve the global addresses of all localities available to this application (including the locality the function is being called on).
- hpx::find_remote_localities: retrieve the global addresses of all remote localities available to this application (not including the locality the function is being called on)
- hpx::get_num_localities: retrieve the number of localities available to this application.
- hpx::find_locality: retrieve the global address of any locality supporting the given component type.
- hpx::get_colocation_id: retrieve the global address of the locality currently hosting the object with the given global address.

Additionally, the global addresses of localities can be used to create new instances of components using the following HPX API function:

- hpx::components::new_: Create a new instance of the given Component type on the specified locality.

Note: HPX does not expose any functionality to delete component instances. All global addresses (as represented using hpx::id_type) are automatically garbage collected. When the last (global) reference to a particular component instance goes out of scope the corresponding component instance is automatically deleted.
Applying actions

Action type definition

Actions are special types we use to describe possibly remote operations. For every global function and every member function which has to be invoked distantly, a special type must be defined. For any global function the special macro `HPX_PLAIN_ACTION` can be used to define the action type. Here is an example demonstrating this:

```cpp
namespace app
{
    void some_global_function(double d)
    {
        cout << d;
    }
}

// This will define the action type 'some_global_action' which represents
// the function 'app::some_global_function'.
HPX_PLAIN_ACTION(app::some_global_function, some_global_action);
```

**Important:** The macro `HPX_PLAIN_ACTION` has to be placed in global namespace, even if the wrapped function is located in some other namespace. The newly defined action type is placed in the global namespace as well.

If the action type should be defined somewhere not in global namespace, the action type definition has to be split into two macro invocations (`HPX_DEFINE_PLAIN_ACTION` and `HPX_REGISTER_ACTION`) as shown in the next example:

```cpp
namespace app
{
    void some_global_function(double d)
    {
        cout << d;
    }

    // On conforming compilers the following macro expands to:
    //
    // typedef hpx::actions::make_action<
    //    decltype(&some_global_function), &some_global_function
    // >::type some_global_action;
    //
    // This will define the action type 'some_global_action' which represents
    // the function 'some_global_function'.
    HPX_DEFINE_PLAIN_ACTION(some_global_function, some_global_action);
}

// The following macro expands to a series of definitions of global objects
// which are needed for proper serialization and initialization support
// enabling the remote invocation of the function''some_global_function''
HPX_REGISTER_ACTION(app::some_global_action, app_some_global_action);
```

The shown code defines an action type `some_global_action` inside the namespace `app`.

**Important:** If the action type definition is split between two macros as shown above, the name of the action type to create has to be the same for both macro invocations (here `some_global_action`).
**Important:** The second argument passed to `HPX_REGISTER_ACTION` (app_some_global_action) has to comprise a globally unique C++ identifier representing the action. This is used for serialization purposes.

For member functions of objects which have been registered with AGAS (e.g. ‘components’) a different registration macro `HPX_DEFINE_COMPONENT_ACTION` has to be utilized. Any component needs to be declared in a header file and have some special support macros defined in a source file. Here is an example demonstrating this. The first snippet has to go into the header file:

```cpp
namespace app {
    struct some_component :
        hpx::components::component_base<some_component> {
        int some_member_function(std::string s) {
            return boost::lexical_cast<int>(s);
        }

        // This will define the action type 'some_member_action' which
        // represents the member function 'some_member_function' of the
        // object type 'some_component'.
        HPX_DEFINE_COMPONENT_ACTION(some_component, some_member_function,
                                    some_member_action);
    }

    // Note: The second argument to the macro below has to be systemwide-unique
    // C++ identifiers
    HPX_REGISTER_ACTION_DECLARATION(app::some_component::some_member_action, some_˓
                                      component_some_action);
}
```

The next snippet belongs into a source file (e.g. the main application source file) in the simplest case:

```cpp
typedef hpx::components::component<app::some_component> component_type;
typedef app::some_component some_component;

HPX_REGISTER_COMPONENT(component_type, some_component);

// The parameters for this macro have to be the same as used in the corresponding
// HPX_REGISTER_ACTION_DECLARATION() macro invocation above
typedef some_component::some_member_action some_component_some_action;
HPX_REGISTER_ACTION(some_component_some_action);
```

Granted, these macro invocations are a bit more complex than for simple global functions, however we believe they are still manageable.

The most important macro invocation is the `HPX_DEFINE_COMPONENT_ACTION` in the header file as this defines the action type we need to invoke the member function. For a complete example of a simple component action see [hpx_link examples/quickstart/component_in_executable.cpp..component_in_executable.cpp]
### Action invocation

The process of invoking a global function (or a member function of an object) with the help of the associated action is called ‘applying the action’. Actions can have arguments, which will be supplied while the action is applied. At the minimum, one parameter is required to apply any action - the id of the locality the associated function should be invoked on (for global functions), or the id of the component instance (for member functions). Generally, HPX provides several ways to apply an action, all of which are described in the following sections.

Generally, HPX actions are very similar to ‘normal’ C++ functions except that actions can be invoked remotely. Fig. ?? below shows an overview of the main API exposed by HPX. This shows the function invocation syntax as defined by the C++ language (dark gray), the additional invocation syntax as provided through C++ Standard Library features (medium gray), and the extensions added by HPX (light gray) where:

- f function to invoke,
- p..: (optional) arguments,
- R: return type of f,
- action: action type defined by, `HPX_DEFINE_PLAIN_ACTION` or `HPX_DEFINE_COMPONENT_ACTION` encapsulating f,
- a: an instance of the type ‘action,
- id: the global address the action is applied to.

![Overview of the main API exposed by HPX.](image)

This figure shows that HPX allows the user to apply actions with a syntax similar to the C++ standard. In fact, all action types have an overloaded function operator allowing to synchronously apply the action. Further, HPX implements `hpx::async` which semantically works similar to the way `std::async` works for plain C++ function.

**Note:** The similarity of applying an action to conventional function invocations extends even further. HPX implements `hpx::bind` and `hpx::function` two facilities which are semantically equivalent to the `std::bind` and `std::function` types as defined by the C++11 Standard. While `hpx::async` extends beyond the conventional semantics by supporting actions and conventional C++ functions, the HPX facilities `hpx::bind` and `hpx::function` extend beyond the conventional standard facilities too. The HPX facilities not only support conventional functions, but can be used for actions as well.
Additionally, HPX exposes `hpx::apply` and `hpx::async_continue` both of which refine and extend the standard C++ facilities.

The different ways to invoke a function in HPX will be explained in more detail in the following sections.

**Applying an action asynchronously without any synchronization**

This method (‘fire and forget’) will make sure the function associated with the action is scheduled to run on the target locality. Applying the action does not wait for the function to start running, instead it is a fully asynchronous operation. The following example shows how to apply the action as defined in the previous section on the local locality (the locality this code runs on):

```cpp
some_global_action act;  // define an instance of some_global_action
hpx::apply(act, hpx::find_here(), 2.0);
```

(the function `hpx::find_here()` returns the id of the local locality, i.e. the locality this code executes on).

Any component member function can be invoked using the same syntactic construct. Given that `id` is the global address for a component instance created earlier, this invocation looks like:

```cpp
some_component_action act;  // define an instance of some_component_action
hpx::apply(act, id, "42");
```

In this case any value returned from this action (e.g. in this case the integer 42 is ignored. Please look at *Action type definition* for the code defining the component action `some_component_action` used.

**Applying an action asynchronously with synchronization**

This method will make sure the action is scheduled to run on the target locality. Applying the action itself does not wait for the function to start running or to complete, instead this is a fully asynchronous operation similar to using `hpx::apply` as described above. The difference is that this method will return an instance of a `hpx::future<>` encapsulating the result of the (possibly remote) execution. The future can be used to synchronize with the asynchronous operation. The following example shows how to apply the action from above on the local locality:

```cpp
some_global_action act;  // define an instance of some_global_action
hpx::future<void> f = hpx::async(act, hpx::find_here(), 2.0);
//
// ... other code can be executed here
//
f.get();  // this will possibly wait for the asynchronous operation to 'return'
```

(as before, the function `hpx::find_here()` returns the id of the local locality (the locality this code is executed on).

**Note:** The use of a `hpx::future<void>` allows the current thread to synchronize with any remote operation not returning any value.

**Note:** Any `std::future<>` returned from `std::async()` is required to block in its destructor if the value has not been set for this future yet. This is not true for `hpx::future<>` which will never block in its destructor, even if the value has not been returned to the future yet. We believe that consistency in the behavior of futures is more important than standards conformance in this case.
Any component member function can be invoked using the same syntactic construct. Given that \texttt{id} is the global address for a component instance created earlier, this invocation looks like:

```cpp
some_component_action act;  // define an instance of some_component_action
hpx::future<int> f = hpx::async(act, id, "42");
// ...
// other code can be executed here
//
cout << f.get();  // this will possibly wait for the asynchronous operation to
                 // 'return' 42
```

\textbf{Note:} The invocation of \texttt{f.get()} will return the result immediately (without suspending the calling thread) if the result from the asynchronous operation has already been returned. Otherwise, the invocation of \texttt{f.get()} will suspend the execution of the calling thread until the asynchronous operation returns its result.

### Applying an action synchronously

This method will schedule the function wrapped in the specified action on the target \textit{locality}. While the invocation appears to be synchronous (as we will see), the calling thread will be suspended while waiting for the function to return. Invoking a plain action (e.g. a global function) synchronously is straightforward:

```cpp
some_global_action act;  // define an instance of some_global_action
act(hpx::find_here(), 2.0);
```

While this call looks just like a normal synchronous function invocation, the function wrapped by the action will be scheduled to run on a new thread and the calling thread will be suspended. After the new thread has executed the wrapped global function, the waiting thread will resume and return from the synchronous call.

Equivalently, any action wrapping a component member function can be invoked synchronously as follows:

```cpp
some_component_action act;  // define an instance of some_component_action
int result = act(id, "42");
```

The action invocation will either schedule a new thread locally to execute the wrapped member function (as before, \texttt{id} is the global address of the component instance the member function should be invoked on), or it will send a parcel to the remote \textit{locality} of the component causing a new thread to be scheduled there. The calling thread will be suspended until the function returns its result. This result will be returned from the synchronous action invocation.

It is very important to understand that this ‘synchronous’ invocation syntax in fact conceals an asynchronous function call. This is beneficial as the calling thread is suspended while waiting for the outcome of a potentially remote operation. The \textit{HPX} thread scheduler will schedule other work in the meantime, allowing the application to make further progress while the remote result is computed. This helps overlapping computation with communication and hiding communication latencies.

\textbf{Note:} The syntax of applying an action is always the same, regardless whether the target \textit{locality} is remote to the invocation \textit{locality} or not. This is a very important feature of \textit{HPX} as it frees the user from the task of keeping track what actions have to be applied locally and which actions are remote. If the target for applying an action is local, a new thread is automatically created and scheduled. Once this thread is scheduled and run, it will execute the function encapsulated by that action. If the target is remote, \textit{HPX} will send a parcel to the remote \textit{locality} which encapsulates the action and its parameters. Once the parcel is received on the remote \textit{locality} \textit{HPX} will create and schedule a new thread there. Once this thread runs on the remote \textit{locality}, it will execute the function encapsulated by the action.
Applying an action with a continuation but without any synchronization

This method is very similar to the method described in section Applying an action asynchronously without any synchronization. The difference is that it allows the user to chain a sequence of asynchronous operations, while handing the (intermediate) results from one step to the next step in the chain. Where `hpx::apply` invokes a single function using ‘fire and forget’ semantics, `hpx::apply_continue` asynchronously triggers a chain of functions without the need for the execution flow ‘to come back’ to the invocation site. Each of the asynchronous functions can be executed on a different locality.

Applying an action with a continuation and with synchronization

This method is very similar to the method described in section Applying an action asynchronously with synchronization. In addition to what `hpx::async` can do, the functions `hpx::async_continue` takes an additional function argument. This function will be called as the continuation of the executed action. It is expected to perform additional operations and to make sure that a result is returned to the original invocation site. This method chains operations asynchronously by providing a continuation operation which is automatically executed once the first action has finished executing.

As an example we chain two actions, where the result of the first action is forwarded to the second action and the result of the second action is sent back to the original invocation site:

```cpp
// first action
std::int32_t action1(std::int32_t i)
{
    return i+1;
}
HPXPLAIN_ACTION(action1); // defines action1_type

// second action
std::int32_t action2(std::int32_t i)
{
    return i*2;
}
HPXPLAIN_ACTION(action2); // defines action2_type

// this code invokes 'action1' above and passes along a continuation
// function which will forward the result returned from 'action1' to
// 'action2'.
action1_type act1;       // define an instance of 'action1_type'
action2_type act2;       // define an instance of 'action2_type'

hpx::future<int> f =
    hpx::async_continue(act1, hpx::make_continuation(act2),
                        hpx::find_here(), 42);

hpx::cout << f.get() << "\n"; // will print: 86 ((42 + 1) * 2)
```

By default, the continuation is executed on the same locality as `hpx::async_continue` is invoked from. If you want to specify the locality where the continuation should be executed, the code above has to be written as:

```cpp
// this code invokes 'action1' above and passes along a continuation
// function which will forward the result returned from 'action1' to
// 'action2'.
action1_type act1;       // define an instance of 'action1_type'
action2_type act2;       // define an instance of 'action2_type'

hpx::future<int> f =
    hpx::async_continue(act1, hpx::make_continuation(act2, hpx::find_here()),
                        hpx::find_here(), 42);
```

(continues on next page)
Similarly, it is possible to chain more than 2 operations:

```
action1_type act1;  // define an instance of 'action1_type'
action2_type act2;  // define an instance of 'action2_type'
hpx::future<int> f =
    hpx::async_continue(act1,
                       hpx::make_continuation(act2, hpx::make_continuation(act1)),
                       hpx::find_here(), 42);
hpx::cout << f.get() << "\n";  // will print: 87 ((42 + 1) * 2 + 1)
```

The function `hpx::make_continuation` creates a special function object which exposes the following prototype:

```
struct continuation
{
    template <typename Result>
    void operator()(hpx::id_type id, Result&& result) const
    {
        ...
    }
};
```

where the parameters passed to the overloaded function operator `operator()` are:

- the `id` is the global id where the final result of the asynchronous chain of operations should be sent to (in most cases this is the id of the `hpx::future` returned from the initial call to `hpx::async_continue`. Any custom continuation function should make sure this `id` is forwarded to the last operation in the chain.
- the `result` is the result value of the current operation in the asynchronous execution chain. This value needs to be forwarded to the next operation.

**Note:** All of those operations are implemented by the predefined continuation function object which is returned from `hpx::make_continuation`. Any (custom) function object used as a continuation should conform to the same interface.

### Action error handling

Like in any other asynchronous invocation scheme it is important to be able to handle error conditions occurring while the asynchronous (and possibly remote) operation is executed. In HPX all error handling is based on standard C++ exception handling. Any exception thrown during the execution of an asynchronous operation will be transferred back to the original invocation `locality`, where it is rethrown during synchronization with the calling thread.

**Important:** Exceptions thrown during asynchronous execution can be transferred back to the invoking thread only for the synchronous and the asynchronous case with synchronization. Like with any other unhandled exception, any exception thrown during the execution of an asynchronous action without synchronization will result in calling `hpx::terminate` causing the running application to exit immediately.

**Note:** Even if error handling internally relies on exceptions, most of the API functions exposed by HPX can be used...
without throwing an exception. Please see Working with exceptions for more information.

As an example, we will assume that the following remote function will be executed:

```cpp
namespace app
{
    void some_function_with_error(int arg)
    {
        if (arg < 0) {
            HPX_THROW_EXCEPTION(bad_parameter, "some_function_with_error",
                                "some really bad error happened");
        }
        // do something else...
    }
}

// This will define the action type 'some_error_action' which represents
// the function 'app::some_function_with_error'.
HPX_PLAIN_ACTION(app::some_function_with_error, some_error_action);
```

The use of `HPX_THROW_EXCEPTION` to report the error encapsulates the creation of a `hpx::exception` which is initialized with the error code `hpx::bad_parameter`. Additionally it carries the passed strings, the information about the file name, line number, and call stack of the point the exception was thrown from.

We invoke this action using the synchronous syntax as described before:

```cpp
// note: wrapped function will throw hpx::exception
some_error_action act; // define an instance of some_error_action
try {
    act(hpx::find_here(), -3); // exception will be rethrown from here
}
catch (hpx::exception const& e) {
    // prints: 'some really bad error happened: HPX(bad parameter)'
    cout << e.what();
}
```

If this action is invoked asynchronously with synchronization, the exception is propagated to the waiting thread as well and is re-thrown from the future’s function `get()`:

```cpp
// note: wrapped function will throw hpx::exception
some_error_action act; // define an instance of some_error_action
hpx::future<void> f = hpx::async(act, hpx::find_here(), -3);
try {
    f.get(); // exception will be rethrown from here
}
catch (hpx::exception const& e) {
    // prints: 'some really bad error happened: HPX(bad parameter)'
    cout << e.what();
}
```

For more information about error handling please refer to the section Working with exceptions. There we also explain how to handle error conditions without having to rely on exception.
**Writing components**

A component in *HPX* is a C++ class which can be created remotely and for which its member functions can be invoked remotely as well. The following sections highlight how components can be defined, created, and used.

**Defining components**

In order for a C++ class type to be managed remotely in *HPX*, the type must be derived from the `hpx::components::component_base` template type. We call such C++ class types ’components’.

Note that the component type itself is passed as a template argument to the base class:

```cpp
// header file some_component.hpp

#include <hpx/include/components.hpp>

namespace app
{
    // Define a new component type 'some_component'
    struct some_component : hpx::components::component_base<some_component>
    {
        // This member function is has to be invoked remotely
        int some_member_function(std::string const & s)
        {
            return boost::lexical_cast<int>(s);
        }

        // This will define the action type 'some_member_action' which
        // represents the member function 'some_member_function' of the
        // object type 'some_component'.
        HPX_DEFINE_COMPONENT_ACTION(some_component, some_member_function, some_member_˓→action);
    };
}

// This will generate the necessary boiler-plate code for the action allowing
// it to be invoked remotely. This declaration macro has to be placed in the
// header file defining the component itself.
//
// Note: The second argument to the macro below has to be systemwide-unique
// C++ identifiers
//
// HPX_REGISTER_ACTION_DECLARATION(app::some_component::some_member_action, some_˓→component_some_action);
```

There is more boiler plate code which has to be placed into a source file in order for the component to be usable. Every component type is required to have macros placed into its source file, one for each component type and one macro for each of the actions defined by the component type.

For instance:

```cpp
// source file some_component.cpp

#include "some_component.hpp"

// The following code generates all necessary boiler plate to enable the
```
Defining client side representation classes

Often it is very convenient to define a separate type for a component which can be used on the client side (from where the component is instantiated and used). This step might seem as unnecessary duplicating code, however it significantly increases the type safety of the code.

A possible implementation of such a client side representation for the component described in the previous section could look like:

```cpp
#include <hpx/include/components.hpp>
namespace app {
    // Define a client side representation type for the component type 'some_component' defined in the previous section.
    //
    struct some_component_client
    : hpx::components::client_base<some_component_client, some_component>
    {
        using base_type = hpx::components::client_base<some_component_client, some_component>;

        some_component_client(hpx::future<hpx::id_type> && id)
        : base_type(std::move(id))
        {
        }

        hpx::future<int> some_member_function(std::string const & s)
        {
            some_component::some_member_action act;
            return hpx::async(act, get_id(), s);
        }
    };
}
```

A client side object stores the global id of the component instance it represents. This global id is accessible by calling the function `client_base<>::get_id()`. The special constructor which is provided in the example allows to...
create this client side object directly using the API function `hpx::new_`.

### Creating component instances

Instances of defined component types can be created in two different ways. If the component to create has a defined client side representation type, then this can be used, otherwise use the server type.

The following examples assume that `some_component_type` is the type of the server side implementation of the component to create. All additional arguments (see , , notation below) are passed through to the corresponding constructor calls of those objects:

```cpp
// create one instance on the given locality
hpx::id_type here = hpx::find_here();
hpx::future<hpx::id_type> f =
    hpx::new_<some_component_type>(here, ...);

// create one instance using the given distribution
// policy (here: hpx::colocating_distribution_policy)
hpx::id_type here = hpx::find_here();
hpx::future<hpx::id_type> f =
    hpx::new_<some_component_type>(hpx::colocated(here), ...);

// create multiple instances on the given locality
hpx::id_type here = hpx::find_here();
hpx::future<std::vector<hpx::id_type>> f =
    hpx::new_<some_component_type[]>(here, num, ...);

// create multiple instances using the given distribution
// policy (here: hpx::binpacking_distribution_policy)
hpx::future<std::vector<hpx::id_type>> f = hpx::new_<some_component_type[]>(
    hpx::binpacking(hpx::find_all_localities()), num, ...);
```

The examples below demonstrate the use of the same API functions for creating client side representation objects (instead of just plain ids). These examples assume that `client_type` is the type of the client side representation of the component type to create. As above, all additional arguments (see , , notation below) are passed through to the corresponding constructor calls of the server side implementation objects corresponding to the `client_type`:

```cpp
// create one instance on the given locality
hpx::id_type here = hpx::find_here();
client_type c = hpx::new_<client_type>(here, ...);

// create one instance using the given distribution
// policy (here: hpx::colocating_distribution_policy)
hpx::id_type here = hpx::find_here();
client_type c = hpx::new_<client_type>(hpx::colocated(here), ...);

// create multiple instances on the given locality
hpx::id_type here = hpx::find_here();
client_type c = hpx::find_here();
client_type c = hpx::new_<client_type[]>(here, num, ...);

// create multiple instances using the given distribution
// policy (here: hpx::binpacking_distribution_policy)
hpx::future<std::vector<hpx::id_type>> f = hpx::new_<client_type[]>(
    hpx::binpacking(hpx::find_all_localities()), num, ...);
```
Using component instances

Segmented containers

In parallel programming, there is now a plethora of solutions aimed at implementing “partially contiguous” or segmented data structures, whether on shared memory systems or distributed memory systems. HPX implements such structures by drawing inspiration from Standard C++ containers.

Using segmented containers

A segmented container is a template class that is described in the namespace hpx. All segmented containers are very similar semantically to their sequential counterpart (defined in namespace std but with an additional template parameter named DistPolicy). The distribution policy is an optional parameter that is passed last to the segmented container constructor (after the container size when no default value is given, after the default value if not). The distribution policy describes the manner in which a container is segmented and the placement of each segment among the available runtime localities.

However, only a part of the std container member functions were reimplemented:

- (constructor), (destructor), operator=
- operator[]
- begin, cbegin, end, cend
- size

An example of how to use the partitioned_vector container would be:

```cpp
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(double);

// By default, the number of segments is equal to the current number of
// localities
//
hpx::partitioned_vector<double> va(50);

hpx::partitioned_vector<double> vb(50, 0.0);
```

An example of how to use the partitioned_vector container with distribution policies would be:

```cpp
#include <hpx/include/partitioned_vector.hpp>
#include <hpx/runtime_distributed/find_localities.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(double);

std::size_t num_segments = 10;
std::vector<hpx::id_type> locs = hpx::find_all_localities()

auto layout =
    hpx::container_layout( num_segments, locs );
```

(continues on next page)
By definition, a segmented container must be accessible from any thread although its construction is synchronous only for the thread who has called its constructor. To overcome this problem, it is possible to assign a symbolic name to the segmented container:

```cpp
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(double);

hpx::future<void> fserver = hpx::async(
    [](){
      hpx::partitioned_vector<double> v(50);
      // Register the 'partitioned_vector' with the name "some_name"
      //
      v.register_as("some_name");
      /* Do some code */
    });

hpx::future<void> fclient = hpx::async(
    [](){
      // Naked 'partitioned_vector'
      //
      hpx::partitioned_vector<double> v;
      // Now the variable v points to the same 'partitioned_vector' that has
      // been registered with the name "some_name"
      //
      v.connect_to("some_name");
      /* Do some code */
    });
```

### Segmented containers

*HPX* provides the following segmented containers:

**Table 2.25: Sequence containers**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>In header</th>
<th>Class page at cppreference.com</th>
</tr>
</thead>
<tbody>
<tr>
<td>hpx::partitioned</td>
<td>Dynamic segmented contiguous array.</td>
<td>&lt;hpx/include/partitioned_vector.hpp&gt;</td>
<td>vector[^14]</td>
</tr>
</tbody>
</table>

[^14]: Refer to [cppreference.com](https://cppreference.com) for more information.
### Segmented iterators and segmented iterator traits

The basic iterator used in the STL library is only suitable for one-dimensional structures. The iterators we use in HPX must adapt to the segmented format of our containers. Our iterators are then able to know when incrementing themselves if the next element of type $T$ is in the same data segment or in another segment. In this second case, the iterator will automatically point to the beginning of the next segment.

**Note:** Note that the dereference operation `operator *` does not directly return a reference of type $T$& but an intermediate object wrapping this reference. When this object is used as an l-value, a remote write operation is performed; When this object is used as an r-value, implicit conversion to $T$ type will take care of performing remote read operation.

It is sometimes useful not only to iterate element by element, but also segment by segment, or simply get a local iterator in order to avoid additional construction costs at each dereferencing operations. To mitigate this need, the `hpx::traits::segmented_iterator_traits` are used.

With `segmented_iterator_traits` users can uniformly get the iterators which specifically iterates over segments (by providing a segmented iterator as a parameter), or get the local begin/end iterators of the nearest local segment (by providing a per-segment iterator as a parameter):

```cpp
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments

HPX_REGISTER_PARTITIONED_VECTOR(double);

using iterator = hpx::partitioned_vector<T>::iterator;
using traits = hpx::traits::segmented_iterator_traits<iterator>;

hpx::partitioned_vector<T> v;
std::size_t count = 0;

auto seg_begin = traits::segment(v.begin());
auto seg_end = traits::segment(v.end());

// Iterate over segments
for (auto seg_it = seg_begin; seg_it != seg_end; ++seg_it) {
    auto loc_begin = traits::begin(seg_it);
    auto loc_end = traits::end(seg_it);

    // Iterate over elements inside segments
    for (auto lit = loc_begin; lit != loc_end; ++lit, ++count)
    {
    // (continues on next page)
    ```

---

Using views

The use of multidimensional arrays is quite common in the numerical field whether to perform dense matrix operations or to process images. It exist many libraries which implement such object classes overloading their basic operators (e.g. `+`, `-`, `*`, `()`, etc.). However, such operation becomes more delicate when the underlying data layout is segmented or when it is mandatory to use optimized linear algebra subroutines (i.e. BLAS subroutines).

Our solution is thus to relax the level of abstraction by allowing the user to work not directly on n-dimensionnal data, but on “n-dimensionnal collections of 1-D arrays”. The use of well-accepted techniques on contiguous data is thus preserved at the segment level, and the composability of the segments is made possible thanks to multidimensional array-inspired access mode.

Preface: Why SPMD?

Although HPX refutes by design this programming model, the locality plays a dominant role when it comes to implement vectorized code. To maximize local computations and avoid unneeded data transfers, a parallel section (or Single Programming Multiple Data section) is required. Because the use of global variables is prohibited, this parallel section is created via the RAII idiom.

To define a parallel section, simply write an action taking a spmd_block variable as a first parameter:

```cpp
#include <hpx/collectives/spmd_block.hpp>

void bulk_function(hpx::lcos::spmd_block block /* , arg0, arg1, ... */) {
    // Parallel section
    /* Do some code */
} HPX.PLAIN_ACTION(bulk_function, bulk_action);
```

Note: In the following paragraphs, we will use the term “image” several times. An image is defined as a lightweight process whose entry point is a function provided by the user. It’s an “image of the function”.

2.5. Manual
The `spmd_block` class contains the following methods:

- [def Team information] `get_num_images`, `this_image`, `images_per_locality`
- [def Control statements] `sync_all`, `sync_images`

Here is a sample code summarizing the features offered by the `spmd_block` class:

```cpp
#include <hpx/collectives/spmd_block.hpp>

void bulk_function(hpx::lcos::spmd_block block /*, arg0, arg1, ... */) {
    std::size_t num_images = block.get_num_images();
    std::size_t this_image = block.this_image();
    std::size_t images_per_locality = block.images_per_locality();

    /* Do some code */

    // Synchronize all images in the team
    block.sync_all();

    /* Do some code */

    // Synchronize image 0 and image 1
    block.sync_images(0,1);

    /* Do some code */

    std::vector<std::size_t> vec_images = {2,3,4};

    // Synchronize images 2, 3 and 4
    block.sync_images(vec_images);

    // Alternative call to synchronize images 2, 3 and 4
    block.sync_images(vec_images.begin(), vec_images.end());

    /* Do some code */

    // Non-blocking version of sync_all()
    hpx::future<void> event =
        block.sync_all(hpx::launch::async);

    // Callback waiting for 'event' to be ready before being scheduled
    hpx::future<void> cb =
        event.then(
            [](hpx::future<void>) {
                /* Do some code */
            });

    // Finally wait for the execution tree to be finished
    cb.get();
}
HPX_PLAIN_ACTION(bulk_test_function, bulk_test_action);
```

Then, in order to invoke the parallel section, call the function `define_spmd_block` specifying an arbitrary symbolic name and indicating the number of images per `locality` to create:
```cpp
void bulk_function(hpx::lcos::spmd_block block, /* , arg0, arg1, ... */)
{
}
HPX_PLAIN_ACTION(bulk_test_function, bulk_test_action);

int main()
{
    /* std::size_t arg0, arg1, ... */

    bulk_action act;
    std::size_t images_per_locality = 4;

    // Instantiate the parallel section
    hpx::lcos::define_spmd_block(
        "some_name", images_per_locality, std::move(act) /*, arg0, arg1, ... */);

    return 0;
}
```

**Note:** In principle, the user should never call the `spmd_block` constructor. The `define_spmd_block` function is responsible of instantiating `spmd_block` objects and broadcasting them to each created image.

### SPMD multidimensional views

Some classes are defined as “container views” when the purpose is to observe and/or modify the values of a container using another perspective than the one that characterizes the container. For example, the values of an `std::vector` object can be accessed via the expression `[i]`. Container views can be used, for example, when it is desired for those values to be “viewed” as a 2D matrix that would have been flattened in a `std::vector`. The values would be possibly accessible via the expression `vv(i,j)` which would call internally the expression `v[k]`.

By default, the `partitioned_vector` class integrates 1-D views of its segments:

```cpp
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(double);

using iterator = hpx::partitioned_vector<double>::iterator;
using traits = hpx::traits::segmented_iterator_traits<iterator>;

hpx::partitioned_vector<double> v;

// Create a 1-D view of the vector of segments
auto vv = traits::segment(v.begin());

// Access segment i
std::vector<double> v = vv[i];
```

Our views are called “multidimensional” in the sense that they generalize to N dimensions the purpose of `segmented_iterator_traits::segment()` in the 1-D case. Note that in a parallel section, the 2-D expression `a(i, j) = b(i, j)` is quite confusing because without convention, each of the images invoked will race
to execute the statement. For this reason, our views are not only multidimensional but also “spmd-aware”.

**Note:** SPMD-awareness: The convention is simple. If an assignment statement contains a view subscript as an l-value, it is only and only the image holding the r-value who is evaluating the statement. (In MPI sense, it is called a Put operation).

### Subscript-based operations

Here are some examples of using subscripts in the 2-D view case:

```cpp
#include <hpx/components/containers/partitioned_vector/partitioned_vector_view.hpp>
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the remote creation of 'partitioned_vector' segments
HPX_REGISTER_PARTITIONED_VECTOR(double);

using Vec = hpx::partitioned_vector<double>;
using View_2D = hpx::partitioned_vector_view<double, 2>;

/* Do some code */

Vec v;

// Parallel section (suppose 'block' an spmd_block instance)
{
    std::size_t height, width;

    // Instantiate the view
    View_2D vv(block, v.begin(), v.end(), {height, width});

    // The l-value is a view subscript, the image that owns vv(1,0) evaluates the assignment.
    vv(0,1) = vv(1,0);

    // The l-value is a view subscript, the image that owns the r-value (result of expression 'std::vector<double>(4,1.0)') evaluates the assignment : oops! race between all participating images.
    vv(2,3) = std::vector<double>(4,1.0);
}
```

### Iterator-based operations

Here are some examples of using iterators in the 3-D view case:

```cpp
#include <hpx/components/containers/partitioned_vector/partitioned_vector_view.hpp>
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the remote creation of 'partitioned_vector' segments
HPX_REGISTER_PARTITIONED_VECTOR(int);
```

(continues on next page)
using Vec = hpx::partitioned_vector<int>;
using View_3D = hpx::partitioned_vector_view<int, 3>;

/* Do some code */

Vec v1, v2;

// Parallel section (suppose 'block' an spmd_block instance)
{
    std::size_t size_x, size_y, size_z;

    // Instantiate the views
    View_3D vv1(block, v1.begin(), v1.end(), {size_x, size_y, size_z});
    View_3D vv2(block, v2.begin(), v2.end(), {size_x, size_y, size_z});

    // Save previous segments covered by vv1 into segments covered by vv2
    auto vv2_it = vv2.begin();
    auto vv1_it = vv1.cbegin();
    for (; vv2_it != vv2.end(); vv2_it++, vv1_it++)
    {
        // It's a Put operation
        *vv2_it = *vv1_it;
    }

    // Ensure that all images have performed their Put operations
    block.sync_all();

    // Ensure that only one image is putting updated data into the different
    // segments covered by vv1
    if (block.this_image() == 0)
    {
        int idx = 0;

        // Update all the segments covered by vv1
        for (auto i = vv1.begin(); i != vv1.end(); i++)
        {
            // It's a Put operation
            *i = std::vector<float>(elt_size, idx++);
        }
    }
}

Here is an example that shows how to iterate only over segments owned by the current image:

#include <hpx/components/containers/partitioned_vector/partitioned_vector_view.hpp>
#include <hpx/components/containers/partitioned_vector/partitioned_vector_local_view.hpp>
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(float);

using Vec = hpx::partitioned_vector<float>;
using View_1D = hpx::partitioned_vector_view<float,1>;

/* Do some code */

Vec v;

// Parallel section (suppose 'block' an spmd_block instance)
{
    std::size_t num_segments;

    // Instantiate the view
    View_1D vv(block, v.begin(), v.end(), {num_segments});

    // Instantiate the local view from the view
    auto local_vv = hpx::local_view(vv);

    for ( auto i = local_vv.begin(); i != local_vv.end(); i++ )
    {
        std::vector<float> & segment = *i;

        /* Do some code */
    }
}

Instantiating sub-views

It is possible to construct views from other views: we call it sub-views. The constraint nevertheless for the subviews is to retain the dimension and the value type of the input view. Here is an example showing how to create a sub-view:

#include <hpx/components/containers/partitioned_vector/partitioned_vector_view.hpp>
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments

HPX_REGISTER_PARTITIONED_VECTOR(float);

using Vec = hpx::partitioned_vector<float>;
using View_2D = hpx::partitioned_vector_view<float,2>;

/* Do some code */

Vec v;

// Parallel section (suppose 'block' an spmd_block instance)
{
    std::size_t N = 20;
    std::size_t tilesize = 5;

    // Instantiate the view
    View_2D vv(block, v.begin(), v.end(), {N,N});

    // Instantiate the subview
    View_2D svv
block, &vv(tilesize, 0), &vv(2*tilesize-1, tilesize-1), {tilesize, tilesize}, {N, N});

if (block.this_image() == 0)
{
    // Equivalent to 'vv(tilesize, 0) = 2.0f'
    svv(0, 0) = 2.0f;
    // Equivalent to 'vv(2*tilesize-1, tilesize-1) = 3.0f'
    svv(tilesize-1, tilesize-1) = 3.0f;
}

Note: The last parameter of the subview constructor is the size of the original view. If one would like to create a subview of the subview and so on, this parameter should stay unchanged. (N, N) for the above example.

C++ co-arrays

Fortran has extended its scalar element indexing approach to reference each segment of a distributed array. In this extension, a segment is attributed a co-index and lives in a specific locality. A co-index provides the application with enough information to retrieve the corresponding data reference. In C++, containers present themselves as a smarter alternative of Fortran arrays but there are still no corresponding standardized features similar to the Fortran co-indexing approach. We present here an implementation of such features in HPX.

Preface: co-array, a segmented container tied to a SPMD multidimensional views

As mentioned before, a co-array is a distributed array whose segments are accessible through an array-inspired access mode. We have previously seen that it is possible to reproduce such access mode using the concept of views. Nevertheless, the user must pre-create a segmented container to instantiate this view. We illustrate below how a single constructor call can perform those two operations:

```c++
#include <hpx/components/containers/coarray/coarray.hpp>
#include <hpx/collectives/spmd_block.hpp>

// The following code generates all necessary boiler plate to enable the
// co-creation of 'coarray'

HPX_REGISTER_COARRAY(double);

// Parallel section (suppose 'block' an spmd_block instance)
{
    using hpx::container::placeholders::_;

    std::size_t height=32, width=4, segment_size=10;

    hpx::coarray<double, 3> a(block, "a", {height, width, _}, segment_size);

    /* Do some code */
}
```

Unlike segmented containers, a co-array object can only be instantiated within a parallel section. Here is the description of the parameters to provide to the coarray constructor:
Table 2.27: Parameters of coarray constructor

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>block</td>
<td>Reference to a spmd_block object</td>
</tr>
<tr>
<td>&quot;a&quot;</td>
<td>Symbolic name of type std::string</td>
</tr>
<tr>
<td>{height,width, _}</td>
<td>Dimensions of the coarray object</td>
</tr>
<tr>
<td>segment_size</td>
<td>Size of a co-indexed element (i.e. size of the object referenced by the expression a(i, j,k))</td>
</tr>
</tbody>
</table>

Note that the “last dimension size” cannot be set by the user. It only accepts the constexpr variable hpx::container::placeholders::_. This size, which is considered private, is equal to the number of current images (value returned by block.get_num_images()).

Note: An important constraint to remember about coarray objects is that all segments sharing the same “last dimension index” are located in the same image.

**Using co-arrays**

The member functions owned by the coarray objects are exactly the same as those of spmd multidimensional views. These are:

- Subscript-based operations
- Iterator-based operations

However, one additional functionality is provided. Knowing that the element a(i, j, k) is in the memory of the kth image, the use of local subscripts is possible.

Note: For spmd multidimensional views, subscripts are only global as it still involves potential remote data transfers.

Here is an example of using local subscripts:

```
#include <hpx/components/containers/coarray/coarray.hpp>
#include <hpx/collectives/spmd_block.hpp>

// The following code generates all necessary boiler plate to enable the
// co-creation of 'coarray'

HPX_REGISTER_COARRAY(double);

// Parallel section (suppose 'block' an spmd_block instance)
{
    using hpx::container::placeholders::_
;

    std::size_t height=32, width=4, segment_size=10;

    hpx::coarray<double,3> a(block, "a", {height,width, _}, segment_size);

    double idx = block.this_image()*height*width;

    for (std::size_t j = 0; j<width; j++)
    for (std::size_t i = 0; i<height; i++)
```

(continues on next page)
{  
   // Local write operation performed via the use of local subscript
   a(i,j,_) = std::vector<double>(elt_size,idx);
   idx++;
}

block.sync_all();

Note: When the “last dimension index” of a subscript is equal to hpx::container::placeholders::_, local subscript (and not global subscript) is used. It is equivalent to a global subscript used with a “last dimension index” equal to the value returned by block.this_image().

2.5.8 Running on batch systems

This section walks you through launching HPX applications on various batch systems.

How to use HPX applications with PBS

Most HPX applications are executed on parallel computers. These platforms typically provide integrated job management services that facilitate the allocation of computing resources for each parallel program. HPX includes support for one of the most common job management systems, the Portable Batch System (PBS).

All PBS jobs require a script to specify the resource requirements and other parameters associated with a parallel job. The PBS script is basically a shell script with PBS directives placed within commented sections at the beginning of the file. The remaining (not commented-out) portions of the file executes just like any other regular shell script. While the description of all available PBS options is outside the scope of this tutorial (the interested reader may refer to in-depth documentation for more information), below is a minimal example to illustrate the approach. The following test application will use the multithreaded hello_world_distributed program, explained in the section Remote execution with actions: Hello world.

#!/bin/bash
#
#PBS -l nodes=2:ppn=4
APP_PATH=~/packages/hpx/bin/hello_world_distributed
APP_OPTIONS=

pbsdsh -u $APP_PATH $APP_OPTIONS --hpx:nodes=`cat $PBS_NODEFILE`

Caution: If the first application specific argument (inside $APP_OPTIONS) is a non-option (i.e., does not start with a - or a --), then the argument has to be placed before the option --hpx:nodes, which, in this case, should be the last option on the command line.

Alternatively, use the option --hpx:endnodes to explicitly mark the end of the list of node names:

```bash
pbsdsh -u $APP_PATH --hpx:nodes=`cat $PBS_NODEFILE` --hpx:endnodes $APP_OPTIONS
```

196 http://www.clusterresources.com/torquedocs21/
The \texttt{#PBS -l nodes=2:ppn=4} directive will cause two compute nodes to be allocated for the application, as specified in the option \texttt{nodes}. Each of the nodes will dedicate four cores to the program, as per the option \texttt{ppn}, short for “processors per node” (PBS does not distinguish between processors and cores). Note that requesting more cores per node than physically available is pointless and may prevent PBS from accepting the script.

On newer PBS versions the PBS command syntax might be different. For instance, the PBS script above would look like:

```
#!/bin/bash
#
#PBS -l select=2:ncpus=4
APP_PATH=~/.packages/hpx/bin/hello_world_distributed
APP_OPTIONS=
pbsdsh -u $APP_PATH $APP_OPTIONS --hpx:nodes=`cat $PBS_NODEFILE`
```

\texttt{APP\_PATH} and \texttt{APP\_OPTIONS} are shell variables that respectively specify the correct path to the executable (\texttt{hello\_world\_distributed} in this case) and the command line options. Since the \texttt{hello\_world\_distributed} application doesn’t need any command line options, \texttt{APP\_OPTIONS} has been left empty. Unlike in other execution environments, there is no need to use the \texttt{--hpx:threads} option to indicate the required number of OS threads per node; the \textit{HPX} library will derive this parameter automatically from PBS.

Finally, pbsdsh is a PBS command that starts tasks to the resources allocated to the current job. It is recommended to leave this line as shown and modify only the PBS options and shell variables as needed for a specific application.

\textbf{Important:} A script invoked by pbsdsh starts in a very basic environment: the user’s \$\texttt{HOME} directory is defined and is the current directory, the \texttt{LANG} variable is set to \texttt{C} and the \texttt{PATH} is set to the basic \texttt{/usr/local/bin:/usr/bin:/bin} as defined in a system-wide file \texttt{pbs\_environment}. Nothing that would normally be set up by a system shell profile or user shell profile is defined, unlike the environment for the main job script.

Another choice is for the pbsdsh command in your main job script to invoke your program via a shell, like \texttt{sh} or \texttt{bash}, so that it gives an initialized environment for each instance. Users can create a small script \texttt{runme.sh}, which is used to invoke the program:

```
#!/bin/bash
# Small script which invokes the program based on what was passed on its
# command line.
#
# This script is executed by the bash shell which will initialize all
# environment variables as usual.
$@
```

Now, the script is invoked using the pbsdsh tool:

```
#!/bin/bash
#
#PBS -l nodes=2:ppn=4
APP_PATH=~/.packages/hpx/bin/hello_world_distributed
APP_OPTIONS=
pbsdsh -u runme.sh $APP_PATH $APP_OPTIONS --hpx:node="cat $PBS_NODEFILE"
```

All that remains now is submitting the job to the queuing system. Assuming that the contents of the PBS script were saved in the file \texttt{pbs\_hello\_world.sh} in the current directory, this is accomplished by typing:
If the job is accepted, qsub will print out the assigned job ID, which may look like:

```
$ 42.supercomputer.some.university.edu
```

To check the status of your job, issue the following command:

```
qstat 42.supercomputer.some.university.edu
```

and look for a single-letter job status symbol. The common cases include:

- **Q** - signifies that the job is queued and awaiting its turn to be executed.
- **R** - indicates that the job is currently running.
- **C** - means that the job has completed.

The example qstat output below shows a job waiting for execution resources to become available:

<table>
<thead>
<tr>
<th>Job id</th>
<th>Name</th>
<th>User</th>
<th>Time</th>
<th>Use</th>
<th>S</th>
<th>Queue</th>
</tr>
</thead>
<tbody>
<tr>
<td>42.supercomputer...ello_world.sh</td>
<td>joe_user</td>
<td></td>
<td></td>
<td>Q</td>
<td></td>
<td>batch</td>
</tr>
</tbody>
</table>

After the job completes, PBS will place two files, `pbs_hello_world.sh.o42` and `pbs_hello_world.sh.e42`, in the directory where the job was submitted. The first contains the standard output and the second contains the standard error from all the nodes on which the application executed. In our example, the error output file should be empty and the standard output file should contain something similar to:

```
hello world from OS-thread 3 on locality 0
hello world from OS-thread 2 on locality 0
hello world from OS-thread 1 on locality 1
hello world from OS-thread 0 on locality 0
hello world from OS-thread 3 on locality 1
hello world from OS-thread 2 on locality 1
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 1
```

Congratulations! You have just run your first distributed HPX application!

### How to use HPX applications with SLURM

Just like PBS (described in section *How to use HPX applications with PBS*), SLURM is a job management system which is widely used on large supercomputing systems. Any HPX application can easily be run using SLURM. This section describes how this can be done.

The easiest way to run an HPX application using SLURM is to utilize the command line tool `srun`, which interacts with the SLURM batch scheduling system:

```
srun -p <partition> -N <number-of-nodes> hpx-application <application-arguments>
```

Here, `<partition>` is one of the node partitions existing on the target machine (consult the machine’s documentation to get a list of existing partitions) and `<number-of-nodes>` is the number of compute nodes that should be used. By default, the HPX application is started with one `locality` per node and uses all available cores on a node. You can change the number of localities started per node (for example, to account for NUMA effects) by specifying the `-n` option of `srun`. The number of cores per `locality` can be set by `-c`. The `<application-arguments>` are any application specific arguments that need to be passed on to the application.
**Note:** There is no need to use any of the HPX command line options related to the number of localities, number of threads, or related to networking ports. All of this information is automatically extracted from the SLURM environment by the HPX startup code.

**Important:** The srun documentation explicitly states: “If -c is specified without -n, as many tasks will be allocated per node as possible while satisfying the -c restriction. For instance on a cluster with 8 CPUs per node, a job request for 4 nodes and 3 CPUs per task may be allocated 3 or 6 CPUs per node (1 or 2 tasks per node) depending upon resource consumption by other jobs.” For this reason, it’s recommended to always specify -n <number-of-instances>, even if <number-of-instances> is equal to one (1).

### Interactive shells

To get an interactive development shell on one of the nodes, users can issue the following command:

```bash
srun -p <node-type> -N <number-of-nodes> --pty /bin/bash -l
```

After the shell has been opened, users can run their HPX application. By default, it uses all available cores. Note that if you requested one node, you don’t need to do srun again. However, if you requested more than one node, and want to run your distributed application, you can use srun again to start up the distributed HPX application. It will use the resources that have been requested for the interactive shell.

### Scheduling batch jobs

The above mentioned method of running HPX applications is fine for development purposes. The disadvantage that comes with srun is that it only returns once the application is finished. This might not be appropriate for longer-running applications (for example, benchmarks or larger scale simulations). In order to cope with that limitation, users can use the sbatch command.

The sbatch command expects a script that it can run once the requested resources are available. In order to request resources, users need to add #SBATCH comments in their script or provide the necessary parameters to sbatch directly. The parameters are the same as with run. The commands you need to execute are the same as if you were in an interactive shell.

### 2.5.9 Debugging HPX applications

#### Using a debugger with HPX applications

Using a debugger such as gdb with HPX applications is no problem. However, there are some things to keep in mind to make the experience somewhat more productive.

Call stacks in HPX can often be quite unwieldy as the library is heavily templated and the call stacks can be very deep. For this reason it is sometimes a good idea compile HPX in RelWithDebInfo mode, which applies some optimizations but keeps debugging symbols. This can often compress call stacks significantly. On the other hand, stepping through the code can also be more difficult because of statements being reordered and variables being optimized away. Also, note that because HPX implements user-space threads and context switching, call stacks may not always be complete in a debugger.

HPX launches not only worker threads but also a few helper threads. The first thread is the main thread, which typically does no work in an HPX application, except at startup and shutdown. If using the default settings, HPX will spawn six
additional threads (used for service thread pools). The first worker thread is usually the eighth thread, and most user
codes will be run on these worker threads. The last thread is a helper thread used for HPX shutdown.

Finally, since HPX is a multi-threaded runtime, the following gdb options can be helpful:

```
set pagination off
set non-stop on
```

Non-stop mode allows users to have a single thread stop on a breakpoint without stopping all other threads as well.

Using sanitizers with HPX applications

**Warning:** Not all parts of HPX are sanitizer clean. This means that users may end up with false positives from
HPX itself when using sanitizers for their applications.

To use sanitizers with HPX, turn on HPX_WITH_SANITIZERS and turn off
HPX_WITH_STACKOVERFLOW_DETECTION during CMake configuration. It’s recommended to also build
Boost with the same sanitizers that will be used for HPX. The appropriate sanitizers can then be enabled using
CMake by appending `-fsanitize=address -fno-omit-frame-pointer` to CMAKE_CXX_FLAGS and
 `-fsanitize=address` to CMAKE_EXE_LINKER_FLAGS. Replace address with the sanitizer that you want
to use.

2.5.10 Optimizing HPX applications

Performance counters

Performance counters in HPX are used to provide information as to how well the runtime system or an application
is performing. The counter data can help determine system bottlenecks, and fine-tune system and application performance. The HPX runtime system, its networking, and other layers provide counter data that an application can consume to provide users with information about how well the application is performing.

Applications can also use counter data to determine how much system resources to consume. For example, an application that transfers data over the network could consume counter data from a network switch to determine how much data to transfer without competing for network bandwidth with other network traffic. The application could use the counter data to adjust its transfer rate as the bandwidth usage from other network traffic increases or decreases.

Performance counters are HPX parallel processes that expose a predefined interface. HPX exposes special API functions that allow one to create, manage, and read the counter data, and release instances of performance counters. Performance Counter instances are accessed by name, and these names have a predefined structure which is described in the section Performance counter names. The advantage of this is that any Performance Counter can be accessed remotely (from a different locality) or locally (from the same locality). Moreover, since all counters expose their data using the same API, any code consuming counter data can be utilized to access arbitrary system information with minimal effort.

Counter data may be accessed in real time. More information about how to consume counter data can be found in the section Consuming performance counter data.

All HPX applications provide command line options related to performance counters, such as the ability to list available counter types, or periodically query specific counters to be printed to the screen or save them in a file. For more information, please refer to the section HPX Command Line Options.
Performance counter names

All Performance Counter instances have a name uniquely identifying each instance. This name can be used to access
the counter, retrieve all related meta data, and to query the counter data (as described in the section Consuming
performance counter data). Counter names are strings with a predefined structure. The general form of a countername
is:

```
/objectname{full_instancename}/countername@parameters
```

where `full_instancename` could be either another (full) counter name or a string formatted as:

```
parentinstancename#parentindex/instancename#instanceindex
```

Each separate part of a countername (e.g., `objectname`, `countername parentinstancename`,
`instancename`, and `parameters`) should start with a letter ('`a'...'z'`, 'A'...'Z') or an underscore character ('`_`'), optionally followed by letters, digits ('`0'...'9''), hyphen ('`-''), or underscore characters. Whitespace
is not allowed inside a counter name. The characters `/`, `{`, `}`, `#` and `@` have a special meaning and are
used to delimit the different parts of the counter name.

The parts `parentinstanceindex` and `instanceindex` are integers. If an index is not specified, HPX will
assume a default of `~1`.

Two counter name examples

This section gives examples of both simple counter names and aggregate counter names. For more information on
simple and aggregate counter names, please see Performance counter instances.

An example of a well-formed (and meaningful) simple counter name would be:

```
/threads{locality#0/total}/count/cumulative
```

This counter returns the current cumulative number of executed (retired) HPX threads for the locality 0. The counter
type of this counter is `/threads/count/cumulative` and the full instance name is `locality#0/total`. This counter type does not require an `instanceindex` or `parameters` to be specified.

In this case, the `parentindex` (the '0') designates the locality for which the counter instance is created. The
counter will return the number of HPX threads retired on that particular locality.

Another example for a well formed (aggregate) counter name is:

```
/statistics{/threads{locality#0/total}/count/cumulative}/average@500
```

This counter takes the simple counter from the first example, samples its values every 500 milliseconds, and returns the
average of the value samples whenever it is queried. The counter type of this counter is `/statistics/average` and the instance name is the full name of the counter for which the values have to be averaged. In this case, the `parameters` (the '500') specify the sampling interval for the averaging to take place (in milliseconds).
Performance counter types

Every performance counter belongs to a specific performance counter type which classifies the counters into groups of common semantics. The type of a counter is identified by the objectname and the countername parts of the name.

/objectname/countername

When an application starts HPX will register all available counter types on each of the localities. These counter types are held in a special performance counter registration database, which can be used to retrieve the meta data related to a counter type and to create counter instances based on a given counter instance name.

Performance counter instances

The fullinstancename distinguishes different counter instances of the same counter type. The formatting of the fullinstancename depends on the counter type. There are two types of counters: simple counters, which usually generate the counter values based on direct measurements, and aggregate counters, which take another counter and transform its values before generating their own counter values. An example for a simple counter is given above: counting retired HPX threads. An aggregate counter is shown as an example above as well: calculating the average of the underlying counter values sampled at constant time intervals.

While simple counters use instance names formatted as parentinstancename#parentindex/instancename#instanceindex, most aggregate counters have the full counter name of the embedded counter as their instance name.

Not all simple counter types require specifying all four elements of a full counter instance name; some of the parts (parentinstancename, parentindex, instancename, and instanceindex) are optional for specific counters. Please refer to the documentation of a particular counter for more information about the formatting requirements for the name of this counter (see Existing HPX performance counters).

The parameters are used to pass additional information to a counter at creation time. They are optional, and they fully depend on the concrete counter. Even if a specific counter type allows additional parameters to be given, those usually are not required as sensible defaults will be chosen. Please refer to the documentation of a particular counter for more information about what parameters are supported, how to specify them, and what default values are assumed (see also Existing HPX performance counters).

Every locality of an application exposes its own set of performance counter types and performance counter instances. The set of exposed counters is determined dynamically at application start based on the execution environment of the application. For instance, this set is influenced by the current hardware environment for the locality (such as whether the locality has access to accelerators), and the software environment of the application (such as the number of OS threads used to execute HPX threads).

Using wildcards in performance counter names

It is possible to use wildcard characters when specifying performance counter names. Performance counter names can contain two types of wildcard characters:

- Wildcard characters in the performance counter type
- Wildcard characters in the performance counter instance name

A wildcard character has a meaning which is very close to usual file name wildcard matching rules implemented by common shells (like bash).
Table 2.28: Wildcard characters in the performance counter type

<table>
<thead>
<tr>
<th>Wildcard</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>This wildcard character matches any number (zero or more) of arbitrary characters.</td>
</tr>
<tr>
<td>?</td>
<td>This wildcard character matches any single arbitrary character.</td>
</tr>
<tr>
<td>[...]</td>
<td>This wildcard character matches any single character from the list of specified within the square brackets.</td>
</tr>
</tbody>
</table>

Table 2.29: Wildcard characters in the performance counter instance name

<table>
<thead>
<tr>
<th>Wildcard</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>This wildcard character matches any locality or any thread, depending on whether it is used for locality#* or worker-thread#*. No other wildcards are allowed in counter instance names.</td>
</tr>
</tbody>
</table>

Consuming performance counter data

You can consume performance data using either the command line interface, the HPX application or the HPX API. The command line interface is easier to use, but it is less flexible and does not allow one to adjust the behaviour of your application at runtime. The command line interface provides a convenience abstraction but simplified abstraction for querying and logging performance counter data for a set of performance counters.

Consuming performance counter data from the command line

HPX provides a set of predefined command line options for every application that uses hpx::init for its initialization. While there are many more command line options available (see HPX Command Line Options), the set of options related to performance counters allows one to list existing counters, and query existing counters once at application termination or repeatedly after a constant time interval.

The following table summarizes the available command line options:
### Table 2.30: HPX Command Line Options Related to Performance Counters

<table>
<thead>
<tr>
<th>Command line option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--hpx:print-counter</td>
<td>Prints the specified performance counter either repeatedly and/or at the times specified by --hpx:print-counter-at (see also option --hpx:print-counter-interval).</td>
</tr>
<tr>
<td>--hpx:print-counter-reset</td>
<td>Prints the specified performance counter either repeatedly and/or at the times specified by --hpx:print-counter-at. Reset the counter after the value is queried (see also option --hpx:print-counter-interval).</td>
</tr>
<tr>
<td>--hpx:print-counter-interval</td>
<td>Prints the performance counter(s) specified with --hpx:print-counter repeatedly after the time interval (specified in milliseconds) (default: 0 which means print once at shutdown).</td>
</tr>
<tr>
<td>--hpx:print-counter-destination</td>
<td>Prints the performance counter(s) specified with --hpx:print-counter to the given file (default: console).</td>
</tr>
<tr>
<td>--hpx:list-counters</td>
<td>Lists the names of all registered performance counters.</td>
</tr>
<tr>
<td>--hpx:list-counter-infos</td>
<td>Lists the description of all registered performance counters.</td>
</tr>
<tr>
<td>--hpx:print-counter-format</td>
<td>Prints the performance counter(s) specified with --hpx:print-counter. Possible formats in CVS format with header or without any header (see option --hpx:no-csv-header). Possible values: csv (prints counter values in CSV format with full names as header) csv-short (prints counter values in CSV format with shortnames provided with --hpx:print-counter-shortname,full-countername).</td>
</tr>
<tr>
<td>--hpx:no-csv-header</td>
<td>Prints the performance counter(s) specified with --hpx:print-counter and csv or csv-short format specified with --hpx:print-counter-format without header.</td>
</tr>
<tr>
<td>--hpx:print-counter-at arg</td>
<td>Prints the performance counter(s) specified with --hpx:print-counter (or --hpx:print-counter-reset) at the given point in time. Possible argument values: startup, shutdown (default), noshutdown.</td>
</tr>
<tr>
<td>--hpx:reset</td>
<td>Resets all performance counter(s) specified with --hpx:print-counter after they have been evaluated.</td>
</tr>
<tr>
<td>--hpx:print-counter-types</td>
<td>Appends counter type description to generated output.</td>
</tr>
<tr>
<td>--hpx:print-counters-locally</td>
<td>Each locality prints only its own local counters.</td>
</tr>
</tbody>
</table>

While the options --hpx:list-counters and --hpx:list-counter-infos give a short list of all available counters, the full documentation for those can be found in the section *Existing HPX performance counters*.

**A simple example**

All of the commandline options mentioned above can be tested using the `hello_world_distributed` example.

Listing all available counters `hello_world_distributed --hpx:list-counters` yields:

```
List of available counter instances (replace * below with the appropriate sequence number)
-----------------------------------------------
/agas/count/allocate /agas/count/bind /agas/count/bind_gid
/agas/count/bind_name ... /threads{locality#*/allocator#*}/count/objects
/threads{locality#*/total}/count/stack-recycles
/threads{locality#*/total}/idle-rate
/threads{locality#*/worker-thread#*}/idle-rate
```

Providing more information about all available counters, `hello_world_distributed --hpx:list-counter-infos` yields:
Information about available counter instances (replace * below with the appropriate sequence number)

fullname: /agas/count/allocate helptext: returns the number of invocations of the AGAS service 'allocate' type: counter_raw version: 1.0.0

fullname: /agas/count/bind helptext: returns the number of invocations of the AGAS service 'bind' type: counter_raw version: 1.0.0

fullname: /agas/count/bind_gid helptext: returns the number of invocations of the AGAS service 'bind_gid' type: counter_raw version: 1.0.0

This command will not only list the counter names but also a short description of the data exposed by this counter.

Note: The list of available counters may differ depending on the concrete execution environment (hardware or software) of your application.

Requesting the counter data for one or more performance counters can be achieved by invoking hello_world_distributed with a list of counter names:

```
hello_world_distributed
  --hpx:print-counter=/threads{locality#0/total}/count/cumulative
  --hpx:print-counter=/agas{locality#0/total}/count/bind
```

which yields for instance:

```
hello world from OS-thread 0 on locality 0
/threads{locality#0/total}/count/cumulative,1,0.212527,[s],33
/agas{locality#0/total}/count/bind,1,0.212790,[s],11
```

The first line is the normal output generated by hello_world_distributed and has no relation to the counter data listed. The last two lines contain the counter data as gathered at application shutdown. These lines have six fields, the counter name, the sequence number of the counter invocation, the time stamp at which this information has been sampled, the unit of measure for the time stamp, the actual counter value and an optional unit of measure for the counter value.

Note: The command line option --hpx:print-counter-types will append a seventh field to the generated output. This field will hold an abbreviated counter type.

The actual counter value can be represented by a single number (for counters returning singular values) or a list of numbers separated by ':' (for counters returning an array of values, like for instance a histogram).

Note: The name of the performance counter will be enclosed in double quotes if it contains one or more commas.

Requesting to query the counter data once after a constant time interval with this command line:
yields for instance (leaving off the actual console output of the `hello_world_distributed` example for brevity):

```
threads{locality#0/total}/count/cumulative,1,0.002409,[s],22
agas{locality#0/total}/count/bind,1,0.002542,[s],9
threads{locality#0/total}/count/cumulative,2,0.023002,[s],41
agas{locality#0/total}/count/bind,2,0.023557,[s],10
threads{locality#0/total}/count/cumulative,3,0.037514,[s],46
agas{locality#0/total}/count/bind,3,0.038679,[s],10
```

The command `--hpx:print-counter-destination=<file>` will redirect all counter data gathered to the specified file name, which avoids cluttering the console output of your application.

The command line option `--hpx:print-counter` supports using a limited set of wildcards for a (very limited) set of use cases. In particular, all occurrences of `#*` as in `locality#*` and in `worker-thread#*` will be automatically expanded to the proper set of performance counter names representing the actual environment for the executed program. For instance, if your program is utilizing four worker threads for the execution of HPX threads (see command line option `--hpx:threads`) the following command line

```
hello_world_distributed \
  --hpx:threads=4 \
  --hpx:print-counter=/threads{locality#0/worker-thread#*}/count/cumulative
```

will print the value of the performance counters monitoring each of the worker threads:

```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 2 on locality 0
hello world from OS-thread 3 on locality 0
hello world from OS-thread 4 on locality 0
/threads{locality#0/worker-thread#0}/count/cumulative,1,0.0025214,[s],27
/threads{locality#0/worker-thread#1}/count/cumulative,1,0.0025453,[s],33
/threads{locality#0/worker-thread#2}/count/cumulative,1,0.0025683,[s],29
/threads{locality#0/worker-thread#3}/count/cumulative,1,0.0025904,[s],33
```

The command `--hpx:print-counter-format` takes values `csv` and `csv-short` to generate CSV formatted counter values with a header.

With format as `csv`:

```
hello_world_distributed \
  --hpx:threads=2 \
  --hpx:print-counter-format csv \
  --hpx:print-counter /threads{locality#*/total}/count/cumulative \
  --hpx:print-counter /threads{locality#*/total}/count/cumulative-phases
```

will print the values of performance counters in CSV format with the full countername as a header:

```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 0
/threads{locality#*/total}/count/cumulative,/threads{locality#*/total}/count/cumulative-phases
  39,93
```

With format `csv-short`:  

2.5. Manual
will print the values of performance counters in CSV format with the short countername as a header:

```
hello world from OS-thread 1 on locality 0
cumulative,phases
39,93
```

With format csv and csv-short when used with `--hpx:print-counter-interval`:

```
hello_world_distributed \
--hpx:threads 2 \
--hpx:print-counter-format csv-short \
--hpx:print-counter cumulative,/threads{locality#*/total}/count/cumulative \
--hpx:print-counter phases,/threads{locality#*/total}/count/cumulative-phases 
--hpx:print-counter-interval 5
```

will print the header only once repeating the performance counter value(s) repeatedly:

```
cum,phases
25,42
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 0
44,95
```

The command `--hpx:no-csv-header` can be used with `--hpx:print-counter-format` to print performance counter values in CSV format without any header:

```
hello_world_distributed \
--hpx:threads 2 \
--hpx:print-counter-format csv-short \
--hpx:print-counter cumulative,/threads{locality#*/total}/count/cumulative \
--hpx:print-counter phases,/threads{locality#*/total}/count/cumulative-phases \
--hpx:no-csv-header
```

will print:

```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 0
37,91
```

**Consuming performance counter data using the HPX API**

*HPX* provides an API that allows users to discover performance counters and to retrieve the current value of any existing performance counter from any application.
Discover existing performance counters

Retrieve the current value of any performance counter

Performance counters are specialized HPX components. In order to retrieve a counter value, the performance counter needs to be instantiated. HPX exposes a client component object for this purpose:

```cpp
hpx::performance_counters::performance_counter counter(std::string const & name);
```

Instantiating an instance of this type will create the performance counter identified by the given name. Only the first invocation for any given counter name will create a new instance of that counter. All following invocations for a given counter name will reference the initially created instance. This ensures that at any point in time there is never more than one active instance of any of the existing performance counters.

In order to access the counter value (or to invoke any of the other functionality related to a performance counter, like start, stop or reset) member functions of the created client component instance should be called:

```cpp
// print the current number of threads created on locality 0
hpx::performance_counters::performance_counter count("/threads{locality#0/total}/count/cumulative");
hpx::cout << count.get_value<int>().get() << hpx::endl;
```

For more information about the client component type, see `hpx::performance_counters::performance_counter`

**Note:** In the above example `count.get_value()` returns a future. In order to print the result we must append `.get()` to retrieve the value. You could write the above example like this for more clarity:

```cpp
// print the current number of threads created on locality 0
hpx::performance_counters::performance_counter count("/threads{locality#0/total}/count/cumulative");
hpx::future<int> result = count.get_value<int>();
hpx::cout << result.get() << hpx::endl;
```

Providing performance counter data

HPX offers several ways by which you may provide your own data as a performance counter. This has the benefit of exposing additional, possibly application-specific information using the existing Performance Counter framework, unifying the process of gathering data about your application.

An application that wants to provide counter data can implement a performance counter to provide the data. When a consumer queries performance data, the HPX runtime system calls the provider to collect the data. The runtime system uses an internal registry to determine which provider to call.

Generally, there are two ways of exposing your own performance counter data: a simple, function-based way and a more complex, but more powerful way of implementing a full performance counter. Both alternatives are described in the following sections.
Exposing performance counter data using a simple function

The simplest way to expose arbitrary numeric data is to write a function which will then be called whenever a consumer queries this counter. Currently, this type of performance counter can only be used to expose integer values. The expected signature of this function is:

```cpp
std::int64_t some_performance_data(bool reset);
```

The argument `bool reset` (which is supplied by the runtime system when the function is invoked) specifies whether the counter value should be reset after evaluating the current value (if applicable).

For instance, here is such a function returning how often it was invoked:

```cpp
// The atomic variable 'counter' ensures the thread safety of the counter.
boost::atomic<std::int64_t> counter(0);

std::int64_t some_performance_data(bool reset)
{
    std::int64_t result = ++counter;
    if (reset)
        counter = 0;
    return result;
}
```

This example function exposes a linearly-increasing value as our performance data. The value is incremented on each invocation, i.e., each time a consumer requests the counter data of this performance counter.

The next step in exposing this counter to the runtime system is to register the function as a new raw counter type using the `HPX` API function `hpx::performance_counters::install_counter_type`. A counter type represents certain common characteristics of counters, like their counter type name and any associated description information. The following snippet shows an example of how to register the function `some_performance_data`, which is shown above, for a counter type named "/test/data". This registration has to be executed before any consumer instantiates, and queries an instance of this counter type:

```cpp
#include <hpx/include/performance_counters.hpp>

void register_counter_type()
{
    // Call the HPX API function to register the counter type.
    hpx::performance_counters::install_counter_type(
        "/test/data",
        &some_performance_data, /*function providing counter*/
        "returns a linearly increasing counter value" /*description text (optional)
        "int"
        /*unit of measure (optional)*/
    );
}
```

Now it is possible to instantiate a new counter instance based on the naming scheme "/test{locality#*/total}/data" where * is a zero-based integer index identifying the `locality` for which the counter instance should be accessed. The function `hpx::performance_counters::install_counter_type` enables users to instantiate exactly one counter instance for each `locality`. Repeated requests to instantiate such a counter will return the same instance, i.e., the instance created for the first request.

If this counter needs to be accessed using the standard `HPX` command line options, the registration has to be performed during application startup, before `hpx::main` is executed. The best way to achieve this is to register an `HPX` startup function using the API function `hpx::register_startup_function` before calling `hpx::init` to initialize the runtime system:
int main(int argc, char* argv[])
{
    // By registering the counter type we make it available to any consumer
    // who creates and queries an instance of the type "/test/data".
    //
    // This registration should be performed during startup. The
    // function 'register_counter_type' should be executed as an HPX thread right
    // before hpx_main is executed.
    hpx::register_startup_function(register_counter_type);

    // Initialize and run HPX.
    return hpx::init(argc, argv);
}

Please see the code in simplest_performance_counter.cpp for a full example demonstrating this functionality.

Implementing a full performance counter

Sometimes, the simple way of exposing a single value as a performance counter is not sufficient. For that reason, HPX provides a means of implementing full performance counters which support:

- Retrieving the descriptive information about the performance counter
- Retrieving the current counter value
- Resetting the performance counter (value)
- Starting the performance counter
- Stopping the performance counter
- Setting the (initial) value of the performance counter

Every full performance counter will implement a predefined interface:

```cpp

void reinit(
    launch::sync_policy, bool reset = true, error_code& ec = throws);

///////////////////////////////////////////////////////////////////////
future<std::string> get_name() const;

std::string get_name(
    launch::sync_policy, error_code& ec = throws) const;

private:
    template<typename T>
        static T extract_value(future<counter_value>&& value)
        {
            return value.get().get_value<T>();
        }

public:
    template<typename T>
        future<T> get_value(bool reset = false)
        {
            return get_counter_value(reset).then(hpx::launch::sync,
                util::bind_front(&performance_counter::extract_value<T>));
        }

    template<typename T>
        T get_value(
            launch::sync_policy, bool reset = false, error_code& ec = throws)
        {
            return get_counter_value(launch::sync, reset).get_value<T>(ec);
        }

    template<typename T>
        future<T> get_value() const
        {
            return get_counter_value().then(hpx::launch::sync,
                util::bind_front(&performance_counter::extract_value<T>));
        }

    template<typename T>
        T get_value(launch::sync_policy, error_code& ec = throws) const
        {
            return get_counter_value(launch::sync).get_value<T>(ec);
        }

};

// Return all counters matching the given name (with optional wild cards).
HPX_EXPORT std::vector<performance_counter> discover_counters(
    std::string const& name, error_code& ec = throws);
}

// namespace hpx::performance_counters

In order to implement a full performance counter, you have to create an HPX component exposing this interface. To
simplify this task, *HPX* provides a ready-made base class which handles all the boiler plate of creating a component for you. The remainder of this section will explain the process of creating a full performance counter based on the Sine example, which you can find in the directory `examples/performance_counters/sine/`.

The base class is defined in the header file `hpx/performance_counters/base_performance_counter.hpp` as:

```cpp
// Copyright (c) 2007-2018 Hartmut Kaiser
// SPDX-License-Identifier: BSL-1.0
// Distributed under the Boost Software License, Version 1.0. (See accompanying
// file LICENSE_1_0.txt or copy at http://www.boost.org/LICENSE_1_0.txt)

#pragma once
#include <hpx/config.hpp>
#include <hpx/actions_base/component_action.hpp>
#include <hpx/components_base/component_type.hpp>
#include <hpx/components_base/server/component_base.hpp>
#include <hpx/performance_counters/counters.hpp>
#include <hpx/performance_counters/server/base_performance_counter.hpp>

namespace hpx { namespace performance_counters {

```
The single template parameter is expected to receive the type of the derived class implementing the performance counter. In the Sine example this looks like:

```cpp
namespace performance_counters { namespace sine { namespace server {

  class sine_counter :
  public hpx::performance_counters::base_performance_counter<sine_counter> {
  public:
    sine_counter() : current_value_(0), evaluated_at_(0) {}
    explicit sine_counter(
      hpx::performance_counters::counter_info const& info);

    /// This function will be called in order to query the current value of
    /// this performance counter
    hpx::performance_counters::counter_value get_counter_value(bool reset); 

    /// The functions below will be called to start and stop collecting
    /// counter values from this counter.
    bool start();
    bool stop();

    /// finalize() will be called just before the instance gets destructed
    void finalize();

  protected:
    bool evaluate();

  private:
    typedef hpx::lcos::local::spinlock mutex_type;
    mutable mutex_type mtx_; 
  }
}} // namespace hpx::performance_counters

```

(continues on next page)
i.e., the type `sine_counter` is derived from the base class passing the type as a template argument (please see `simplest_performance_counter.cpp` for the full source code of the counter definition). For more information about this technique (called Curiously Recurring Template Pattern - CRTP), please see for instance the corresponding Wikipedia article\(^{197}\). This base class itself is derived from the `performance_counter` interface described above.

Additionally, a full performance counter implementation not only exposes the actual value but also provides information about:

- The point in time a particular value was retrieved.
- A (sequential) invocation count.
- The actual counter value.
- An optional scaling coefficient.
- Information about the counter status.

**Existing HPX performance counters**

The HPX runtime system exposes a wide variety of predefined performance counters. These counters expose critical information about different modules of the runtime system. They can help determine system bottlenecks and fine-tune system and application performance.

</tbody>
</table>
Table 2.37: Performance counters for elementary arithmetic operations

<table>
<thead>
<tr>
<th>Counter type</th>
<th>Counter instance formatting</th>
<th>Description</th>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>/arithmetics/add</td>
<td>None</td>
<td>Returns the sum calculated based on the values queried from the underlying counters (the ones specified as the parameters).</td>
<td>The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wild-cards in the counter names will be expanded.</td>
</tr>
<tr>
<td>/arithmetics/subtract</td>
<td>None</td>
<td>Returns the difference calculated based on the values queried from the underlying counters (the ones specified as the parameters).</td>
<td>The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wild-cards in the counter names will be expanded.</td>
</tr>
<tr>
<td>/arithmetics/multiply</td>
<td>None</td>
<td>Returns the product calculated based on the values queried from the underlying counters (the ones specified as the parameters).</td>
<td>The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wild-cards in the counter names will be expanded.</td>
</tr>
<tr>
<td>/arithmetics/divide</td>
<td>None</td>
<td>Returns the result of division of the values queried from the underlying counters (the ones specified as the parameters).</td>
<td>The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wild-cards in the counter names will be expanded.</td>
</tr>
<tr>
<td>/arithmetics/mean</td>
<td>None</td>
<td>Returns the average value of all values queried from the underlying counters (the ones specified as the parameters).</td>
<td>The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wild-cards in the counter names will be expanded.</td>
</tr>
<tr>
<td>/arithmetics/variance</td>
<td>None</td>
<td>Returns the standard deviation of all values queried from the underlying counters (the ones specified as the parameters).</td>
<td>The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wild-cards in the counter names will be expanded.</td>
</tr>
<tr>
<td>/arithmetics/median</td>
<td>None</td>
<td>Returns the median value of all values queried from the underlying counters (the ones specified as the parameters).</td>
<td>The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wild-cards in the counter names will be expanded.</td>
</tr>
<tr>
<td>/arithmetics/min</td>
<td>None</td>
<td>Returns the minimum value of all values queried from the underlying counters (the ones specified as the parameters).</td>
<td>The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wild-cards in the counter names will be expanded.</td>
</tr>
<tr>
<td>/arithmetics/max</td>
<td>None</td>
<td>Returns the maximum value of all values queried from the underlying counters (the ones specified as the parameters).</td>
<td>The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wild-cards in the counter names will be expanded.</td>
</tr>
<tr>
<td>/arithmetics/count</td>
<td>None</td>
<td>Returns the count value of all values queried from the underlying counters (the ones specified as the parameters).</td>
<td>The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wild-cards in the counter names will be expanded.</td>
</tr>
</tbody>
</table>

**Note:** The /arithmetics counters can consume an arbitrary number of other counters. For this reason those have to be specified as parameters (a comma separated list of counters appended after a '@'). For instance:

```
./bin/hello_world_distributed -t2 \
```
Since all wildcards in the parameters are expanded, this example is fully equivalent to specifying both counters separately to `/arithmetics/add`:

```
./bin/hello_world_distributed -t 2 \
   --hpx:print-counter=/threads{locality#0/worker-thread#*}/count/cumulative \ 
   --hpx:print-counter=/arithmetics/add@/threads{locality#0/worker-thread#*}/count/ 
   --cumulative
```

<td></td>
<td>Returns the number of messages generated by the message handler associated with the action which is given by the counter parameter.</td>
<td>The action type. This is the string which has been used while registering the action with HPX, e.g. which has been passed as the second parameter to the macro HPX_REGISTER_ACTION or HPX_REGISTER_ACTION_ID.</td>
</tr>
<tr>
<td>/coalescing/average-parcels-per-message/locality##</td>
<td></td>
<td>Returns the average number of parcels sent in a message generated by the message handler associated with the action which is given by the counter parameter.</td>
<td>The action type. This is the string which has been used while registering the action with HPX, e.g. which has been passed as the second parameter to the macro HPX_REGISTER_ACTION or HPX_REGISTER_ACTION_ID.</td>
</tr>
<tr>
<td>/coalescing/average-parcel-arrival-time/locality##</td>
<td></td>
<td>Returns the average time between arriving parcels for the action which is given by the counter parameter.</td>
<td>The action type. This is the string which has been used while registering the action with HPX, e.g. which has been passed as the second parameter to the macro HPX_REGISTER_ACTION or HPX_REGISTER_ACTION_ID.</td>
</tr>
</tbody>
</table>
Note: The performance counters related to parcel coalescing are available only if the configuration time constant `HPX_WITH_PARCEL_COALESCING` is set to ON (default: ON). However, even in this case it will be available only for actions that are enabled for parcel coalescing (see the macros `HPX_ACTION_USES_MESSAGE_COALESCING` and `HPX_ACTION_USES_MESSAGE_COALESCING_NOTHROW`).

AEPX integration

HPX provides integration with AEPX\(^{199}\), which is a framework for application profiling using task timers and various performance counters. It can be added as a git submodule by turning on the option `HPX_WITH_APEX:BOOL` during CMake configuration. TAU\(^{200}\) is an optional dependency when using AEPX.

To build HPX with AEPX, add `HPX_WITH_APEX=ON`, and, optionally, `TAU_ROOT=$PATH_TO_TAU` to your CMake configuration. In addition, you can override the tag used for AEPX with the `HPX_WITH_APEX_TAG` option. Please see the AEPX HPX documentation\(^{201}\) for detailed instructions on using AEPX with HPX.

2.5.11 HPX runtime and resources

HPX thread scheduling policies

The HPX runtime has five thread scheduling policies: local-priority, static-priority, local, static and abp-priority. These policies can be specified from the command line using the command line option `--hpx:queuing`. In order to use a particular scheduling policy, the runtime system must be built with the appropriate scheduler flag turned on (e.g. `cmake -DHPX_THREAD_SCHEDULERS=local`, see CMake variables used to configure HPX for more information).

Priority local scheduling policy (default policy)

- default or invoke using: `--hpx:queuing local-priority-fifo`

The priority local scheduling policy maintains one queue per operating system (OS) thread. The OS thread pulls its work from this queue. By default the number of high priority queues is equal to the number of OS threads; the number of high priority queues can be specified on the command line using `--hpx:high-priority-threads`. High priority threads are executed by any of the OS threads before any other work is executed. When a queue is empty work will be taken from high priority queues first. There is one low priority queue from which threads will be scheduled only when there is no other work.

For this scheduling policy there is an option to turn on NUMA sensitivity using the command line option `--hpx:numa-sensitive`. When NUMA sensitivity is turned on work stealing is done from queues associated with the same NUMA domain first, only after that work is stolen from other NUMA domains.

This scheduler is enabled at build time by default and will be available always.

This scheduler can be used with two underlying queuing policies (FIFO: first-in-first-out, and LIFO: last-in-first-out). The default is FIFO. In order to use the LIFO policy use the command line option `--hpx:queuing local-priority-lifo`.

---

199 https://khuck.github.io/xpress-apex/
200 https://www.cs.uoregon.edu/research/tau/home.php
201 https://khuck.github.io/xpress-apex/usage/#hpx-louisiana-state-university
Static priority scheduling policy

- invoke using: `--hpx:queuing=static-priority` (or `-qs`)
- flag to turn on for build: `HPX_THREAD_SCHEDULERS=all` or `HPX_THREAD_SCHEDULERS=static-priority`

The static scheduling policy maintains one queue per OS thread from which each OS thread pulls its tasks (user threads). Threads are distributed in a round robin fashion. There is no thread stealing in this policy.

Local scheduling policy

- invoke using: `--hpx:queuing=local` (or `-ql`)
- flag to turn on for build: `HPX_THREAD_SCHEDULERS=all` or `HPX_THREAD_SCHEDULERS=local`

The local scheduling policy maintains one queue per OS thread from which each OS thread pulls its tasks (user threads).

Static scheduling policy

- invoke using: `--hpx:queuing=static`
- flag to turn on for build: `HPX_THREAD_SCHEDULERS=all` or `HPX_THREAD_SCHEDULERS=static`

The static scheduling policy maintains one queue per OS thread from which each OS thread pulls its tasks (user threads). Threads are distributed in a round robin fashion. There is no thread stealing in this policy.

Priority ABP scheduling policy

- invoke using: `--hpx:queuing=abp-priority-fifo`
- flag to turn on for build: `HPX_THREAD_SCHEDULERS=all` or `HPX_THREAD_SCHEDULERS=abp-priority`

Priority ABP policy maintains a double ended lock free queue for each OS thread. By default the number of high priority queues is equal to the number of OS threads; the number of high priority queues can be specified on the command line using `--hpx:high-priority-threads`. High priority threads are executed by the first OS threads before any other work is executed. When a queue is empty work will be taken from high priority queues first. There is one low priority queue from which threads will be scheduled only when there is no other work. For this scheduling policy there is an option to turn on NUMA sensitivity using the command line option `--hpx:numa-sensitive`. When NUMA sensitivity is turned on work stealing is done from queues associated with the same NUMA domain first, only after that work is stolen from other NUMA domains.

This scheduler can be used with two underlying queuing policies (FIFO: first-in-first-out, and LIFO: last-in-first-out). In order to use the LIFO policy use the command line option `--hpx:queuing=abp-priority-lifo`. 
The HPX resource partitioner

The HPX resource partitioner lets you take the execution resources available on a system—processing units, cores, and numa domains—and assign them to thread pools. By default HPX creates a single thread pool name `default`. While this is good for most use cases, the resource partitioner lets you create multiple thread pools with custom resources and options.

Creating custom thread pools is useful for cases where you have tasks which absolutely need to run without interference from other tasks. An example of this is when using MPI for distribution instead of the built-in mechanisms in HPX (useful in legacy applications). In this case one can create a thread pool containing a single thread for MPI communication. MPI tasks will then always run on the same thread, instead of potentially being stuck in a queue behind other threads.

Note that HPX thread pools are completely independent from each other in the sense that task stealing will never happen between different thread pools. However, tasks running on a particular thread pool can schedule tasks on another thread pool.

Note: It is simpler in some situations to schedule important tasks with high priority instead of using a separate thread pool.

Using the resource partitioner

The `hpx::resource::partitioner` is now created during HPX runtime initialization without explicit action needed from the user. To specify some of the initialization parameters you can use the `hpx::init_params`.

```c++
#include <hpx/hpx_init.hpp>
#include <hpx/resource_partitioner/partitioner.hpp>

int hpx_main()
{
    return hpx::finalize();
}

int main(int argc, char** argv)
{
    // Setup the init parameters
    hpx::init_params init_args;
    hpx::init(argc, argv, init_args);
}
```

The resource partitioner callback is the interface to add thread pools to the HPX runtime and to assign resources to the thread pools. In order to create custom thread pools you can specify the resource partitioner callback `hpx::init_params::rp_callback` which will be called once the resource partitioner will be created, see the example below. You can also specify other parameters, see `hpx::init_params`.

To add a thread pool use the `hpx::resource::partitioner::create_thread_pool` method. If you simply want to use the default scheduler and scheduler options it is enough to call `rp.create_thread_pool("my-thread-pool")`.

Then, to add resources to the thread pool you can use the `hpx::resource::partitioner::add_resource` method. The resource partitioner exposes the hardware topology retrieved using Portable Hardware Locality.

---

203 https://en.wikipedia.org/wiki/Message_Passing_Interface
204 https://en.wikipedia.org/wiki/Message_Passing_Interface
and lets you iterate through the topology to add the wanted processing units to the thread pool. Below is an example of adding all processing units from the first NUMA domain to a custom thread pool, unless there is only one NUMA domain in which case we leave the first processing unit for the default thread pool:

```cpp
#include <hpx/hpx_init.hpp>
#include <hpx/resource_partitioner/partitioner.hpp>
#include <iostream>

int hpx_main()
{
    return hpx::finalize();
}

void init_resource_partitioner_handler(hpx::resource::partitioner& rp,
                                       hpx::program_options::variables_map const& /*vm*/)
{
    rp.create_thread_pool("my-thread-pool");

    bool one_numa_domain = rp.numa_domains().size() == 1;
    bool skipped_first_pu = false;

    hpx::resource::numa_domain const& d = rp.numa_domains()[0];

    for (hpx::resource::core const& c : d.cores())
    {
        for (hpx::resource::pu const& p : c.pus())
        {
            if (one_numa_domain && !skipped_first_pu)
            {
                skipped_first_pu = true;
                continue;
            }

            rp.add_resource(p, "my-thread-pool");
        }
    }
}

int main(int argc, char* argv[])
{
    // Set the callback to init the thread pools
    hpx::init_params init_args;
    init_args.rp_callback = &init_resource_partitioner_handler;

    hpx::init(argc, argv, init_args);
}
```

**Note:** Whatever processing units not assigned to a thread pool by the time `hpx::init` is called will be added to the default thread pool. It is also possible to explicitly add processing units to the default thread pool, and to create the default thread pool manually (in order to e.g. set the scheduler type).

**Tip:** The command line option `--hpx:print-bind` is useful for checking that the thread pools have been set up.

---

205 [https://www.open-mpi.org/projects/hwloc/]
the way you expect.

**Difference between the old and new version**

In the old version, you had to create an instance of the `resource_partitioner` with `argc` and `argv`.

```cpp
int main(int argc, char** argv)
{
    hpx::resource::partitioner rp(argc, argv);
    hpx::init();
}
```

From *HPX* 1.5.0 onwards, you just pass `argc` and `argv` to `hpx::init()` or `hpx::start()` for the binding options to be parsed by the resource partitioner.

```cpp
int main(int argc, char** argv)
{
    hpx::init_params init_args;
    hpx::init(argc, argv, init_args);
}
```

In the old version, when creating a custom thread pool, you just called the utilities on the resource partitioner instantiated previously.

```cpp
int main(int argc, char** argv)
{
    hpx::resource::partitioner rp(argc, argv);
    rp.create_thread_pool("my-thread-pool");

    bool one_numa_domain = rp.numa_domains().size() == 1;
    bool skipped_first_pu = false;
    hpx::resource::numa_domain const& d = rp.numa_domains()[0];

    for (const hpx::resource::core& c : d.cores())
    {
        for (const hpx::resource::pu& p : c.pus())
        {
            if (one_numa_domain && !skipped_first_pu)
            {
                skipped_first_pu = true;
                continue;
            }

            rp.add_resource(p, "my-thread-pool");
        }
    }
    hpx::init();
}
```

You now specify the resource partitioner callback which will tie the resources to the resource partitioner created during runtime initialization.
```cpp
void init_resource_partitioner_handler(hpx::resource::partitioner& rp)
{
    rp.create_thread_pool("my-thread-pool");

    bool one_numa_domain = rp.numa_domains().size() == 1;
    bool skipped_first_pu = false;

    hpx::resource::numa_domain const& d = rp.numa_domains()[0];

    for (const hpx::resource::core& c : d.cores())
    {
        for (const hpx::resource::pu& p : c.pus())
        {
            if (one_numa_domain && !skipped_first_pu)
            {
                skipped_first_pu = true;
                continue;
            }
            rp.add_resource(p, "my-thread-pool");
        }
    }
}

int main(int argc, char* argv[])
{
    hpx::init_params init_args;
    init_args.rp_callback = &init_resource_partitioner_handler;
    hpx::init(argc, argv, init_args);
}
```

### Advanced usage

It is possible to customize the built-in schedulers by passing scheduler options to `hpx::resource::partitioner::create_thread_pool`. It is also possible to create and use custom schedulers.

**Note:** It is not recommended to create your own scheduler. The HPX developers use this to experiment with new scheduler designs before making them available to users via the standard mechanisms of choosing a scheduler (command line options). If you would like to experiment with a custom scheduler the resource partitioner example `shared_priority_queue_scheduler.cpp` contains a fully implemented scheduler with logging etc. to make exploration easier.

To choose a scheduler and custom mode for a thread pool, pass additional options when creating the thread pool like this:

```cpp
rp.create_thread_pool("my-thread-pool",
    hpx::resource::policies::local_priority_lifo,
    hpx::policies::scheduler_mode(
        hpx::policies::scheduler_mode::default |
        hpx::policies::scheduler_mode::enable_elasticity));
```

The available schedulers are documented here: `hpx::resource::scheduling_policy`, and the avail-
able scheduler modes here: `hpx::threads::policies::scheduler_mode`. Also see the examples folder for examples of advanced resource partitioner usage: `simple_resource_partitioner.cpp` and `oversubscribing_resource_partitioner.cpp`.

### 2.5.12 Miscellaneous

#### Error handling

Like in any other asynchronous invocation scheme, it is important to be able to handle error conditions occurring while the asynchronous (and possibly remote) operation is executed. In HPX all error handling is based on standard C++ exception handling. Any exception thrown during the execution of an asynchronous operation will be transferred back to the original invocation `locality`, where it will be rethrown during synchronization with the calling thread.

The source code for this example can be found here: `error_handling.cpp`.

#### Working with exceptions

For the following description assume that the function `raise_exception()` is executed by invoking the plain action `raise_exception_type`.

```cpp
#include <hpx/iostream.hpp>
#include <hpx/modules/runtime_local.hpp>

// error_handling_raise_exception
void raise_exception()
```

The exception is thrown using the macro `HPX_THROW_EXCEPTION`. The type of the thrown exception is `hpx::exception`. This associates additional diagnostic information with the exception, such as file name and line number, `locality` id and thread id, and stack backtrace from the point where the exception was thrown.

Any exception thrown during the execution of an action is transferred back to the (asynchronous) invocation site. It will be rethrown in this context when the calling thread tries to wait for the result of the action by invoking either `future<>::get()` or the synchronous action invocation wrapper as shown here:

```cpp

    // Error reporting using exceptions
    hpx::cout << "Error reporting using exceptions\n";
    try {
        // invoke raise_exception() which throws an exception
        raise_exception_action do_it;
        do_it(hpx::find_here());
    } catch (hpx::exception const & e) {
        // Print just the essential error information.
        hpx::cout << "caught exception: " << e.what() << "\n";

        // Print all of the available diagnostic information as stored with
        // the exception.
    }
```

**Note:** The exception is transferred back to the invocation site even if it is executed on a different `locality`. 
Additionally, this example demonstrates how an exception thrown by an (possibly remote) action can be handled. It shows the use of `hpx::diagnostic_information`, which retrieves all available diagnostic information from the exception as a formatted string. This includes, for instance, the name of the source file and line number, the sequence number of the OS thread and the `HPX` thread id, the `locality` id and the stack backtrace of the point where the original exception was thrown.

Under certain circumstances it is desirable to output only some of the diagnostics, or to output those using different formatting. For this case, `HPX` exposes a set of lower-level functions as demonstrated in the following code snippet:

```cpp
// Detailed error reporting using exceptions
hpx::cout << "Detailed error reporting using exceptions\n";
try {
    // Invoke raise_exception() which throws an exception.
    raise_exception_action do_it;
    do_it(hpx::find_here());
} catch (hpx::exception const & e) {

    // Print the elements of the diagnostic information separately.
    hpx::cout << "{what}: " << hpx::get_error_what(e) << "\n";
    hpx::cout << "{locality-id}: " << hpx::get_error_locality_id(e) << "\n";
    hpx::cout << "{hostname}: " << hpx::get_error_host_name(e) << "\n";
    hpx::cout << "{pid}: " << hpx::get_error_process_id(e) << "\n";
    hpx::cout << "{function}: " << hpx::get_error_function_name(e) << "\n";
    hpx::cout << "{file}: " << hpx::get_error_file_name(e) << "\n";
    hpx::cout << "{line}: " << hpx::get_error_line_number(e) << "\n";
    hpx::cout << "{os-thread}: " << hpx::get_error_os_thread(e) << "\n";
    hpx::cout << "{thread-id}: " << std::hex << hpx::get_error_thread_id(e) << "\n";
    hpx::cout << "{thread-description}: " << hpx::get_error_thread_description(e) << "\n";
    hpx::cout << "{state}: " << std::hex << hpx::get_error_state(e) << "\n";
}
```

### Working with error codes

Most of the API functions exposed by `HPX` can be invoked in two different modes. By default those will throw an exception on error as described above. However, sometimes it is desirable not to throw an exception in case of an error condition. In this case an object instance of the `hpx::error_code` type can be passed as the last argument to the API function. In case of an error, the error condition will be returned in that `hpx::error_code` instance. The following example demonstrates extracting the full diagnostic information without exception handling:

```cpp
///////////////////////////////////////////////////////////////////////
// Error reporting using error code
hpx::cout << "Error reporting using error code\n";

// Create a new error_code instance.
hpx::error_code ec;

// If an instance of an error_code is passed as the last argument while
// invoking the action, the function will not throw in case of an error
// but store the error information in this error_code instance instead.
```

(continues on next page)
raise_exception_action do_it;
do_it(hpx::find_here(), ec);

if (ec) {
    // Print just the essential error information.
    hpx::cout << "returned error: " << ec.get_message() << "\n";

    // Print all of the available diagnostic information as stored with
    // the exception.
    hpx::cout << "diagnostic information:"
}

Note: The error information is transferred back to the invocation site even if it is executed on a different locality.

This example shows how an error can be handled without having to resolve to exceptions and that the returned hpx::error_code instance can be used in a very similar way as the hpx::exception type above. Simply pass it to the hpx::diagnostic_information, which retrieves all available diagnostic information from the error code instance as a formatted string.

As for handling exceptions, when working with error codes, under certain circumstances it is desirable to output only some of the diagnostics, or to output those using different formatting. For this case, HPX exposes a set of lower-level functions usable with error codes as demonstrated in the following code snippet:

```cpp
// Detailed error reporting using error code
{
    // Print the elements of the diagnostic information separately.
    hpx::cout << "{what}: " << hpx::get_error_what(ec) << "\n";
    hpx::cout << "{locality-id}: " << hpx::get_error_locality_id(ec) << "\n";
    hpx::cout << "{hostname}: " << hpx::get_error_host_name(ec) << "\n";
    hpx::cout << "{pid}: " << hpx::get_error_process_id(ec) << "\n";
    hpx::cout << "{function}: " << hpx::get_error_function_name(ec) << "\n";
    hpx::cout << "{file}: " << hpx::get_error_file_name(ec) << "\n";
    hpx::cout << "{line}: " << hpx::get_error_line_number(ec) << "\n";
    hpx::cout << "{os-thread}: " << hpx::get_error_os_thread(ec) << "\n";
    hpx::cout << "{thread-id}: " << std::hex << hpx::get_error_thread_id(ec) << "\n";
```
hpx::cout << "\{thread-description\}: \n" << hpx::get_error_thread_description(ec) "\n\n";
hpx::cout << "\{state\}: " << std::hex << hpx::get_error_state(ec) "\n";
hpx::cout << "\{stack-trace\}: " << hpx::get_error_backtrace(ec) "\n";

For more information please refer to the documentation of hpx::get_error_what, hpx::get_error_locality_id, hpx::get_error_host_name, hpx::get_error_process_id, hpx::get_error_function_name, hpx::get_error_file_name, hpx::get_error_line_number, hpx::get_error_os_thread, hpx::get_error_thread_id, hpx::get_error_thread_description, hpx::get_error_backtrace, hpx::get_error_env, and hpx::get_error_state.

### Lightweight error codes

Sometimes it is not desirable to collect all the ambient information about the error at the point where it happened as this might impose too much overhead for simple scenarios. In this case, HPX provides a lightweight error code facility that will hold the error code only. The following snippet demonstrates its use:

```cpp
// Error reporting using lightweight error code
{
    //\{lightweight_error_handling_diagnostic_information
    hpx::cout << "Error reporting using a lightweight error code\n";

    // Create a new error_code instance.
    hpx::error_code ec(hpx::lightweight);

    // If an instance of an error_code is passed as the last argument while
    // invoking the action, the function will not throw in case of an error
    // but store the error information in this error_code instance instead.
    raise_exception_action do_it;
    do_it(hpx::find_here(), ec);

    if (ec) { // Print just the essential error information.
        hpx::cout << "returned error: " << ec.get_message() "\n";

    } // Print all of the available diagnostic information as stored with
    // the exception.
```

All functions that retrieve other diagnostic elements from the hpx::error_code will fail if called with a lightweight error_code instance.

### Utilities in HPX

In order to ease the burden of programming, HPX provides several utilities to users. The following section documents those facilities.
Checkpoint

See checkpoint.

The HPX I/O-streams component

The HPX I/O-streams subsystem extends the standard C++ output streams `std::cout` and `std::cerr` to work in the distributed setting of an HPX application. All of the output streamed to `hpx::cout` will be dispatched to `std::cout` on the console locality. Likewise, all output generated from `hpx::cerr` will be dispatched to `std::cerr` on the console locality.

Note: All existing standard manipulators can be used in conjunction with `hpx::cout` and `hpx::cerr`. Historically, HPX also defines `hpx::endl` and `hpx::flush` but those are just aliases for the corresponding standard manipulators.

In order to use either `hpx::cout` or `hpx::cerr`, application codes need to `#include <hpx/include/iostreams.hpp>`. For an example, please see the following ‘Hello world’ program:

```cpp
// Copyright (c) 2007-2012 Hartmut Kaiser
//
// SPDX-License-Identifier: BSL-1.0
// Distributed under the Boost Software License, Version 1.0. (See accompanying
// file LICENSE_1_0.txt or copy at http://www.boost.org/LICENSE_1_0.txt)

// The purpose of this example is to execute a HPX-thread printing
// "Hello World!" once. That's all.

#include <hpx/hpx_main.hpp>
#include <hpx/iostream.hpp>

int main()
{
    // Say hello to the world!
    hpx::cout << "Hello World!\n" << hpx::flush;
    return 0;
}
```

Additionally, those applications need to link with the iostreams component. When using CMake this can be achieved by using the `COMPONENT_DEPENDENCIES` parameter; for instance:

```cmake
include(HPX_AddExecutable)
add_hpx_executable(
    hello_world
    SOURCES hello_world.cpp
    COMPONENT_DEPENDENCIES iostreams
)
```

Note: The `hpx::cout` and `hpx::cerr` streams buffer all output locally until a `std::endl` or `std::flush` is
encountered. That means that no output will appear on the console as long as either of these is explicitly used.

2.5.13 Troubleshooting

This section contains commonly encountered problems when compiling or using HPX.

Undefined reference to boost::program_options

Boost::ProgramOptions is not ABI compatible between all C++ versions and compilers. Because of this you may see linker errors similar to this:

```
...: undefined reference to `boost::program_options::operator<<(std::ostream&,
    boost::program_options::options_description const&)
```

if you are not linking to a compatible version of Boost::ProgramOptions. We recommend that you use hpx::program_options, which is part of HPX, as a replacement for boost::program_options (see program_options). Until you have migrated to use hpx::program_options we recommend that you always build Boost libraries and HPX with the same compiler and C++ standard.

Undefined reference to hpx::cout

You may see an linker error message that looks a bit like this:

```
hello_world.cpp:(.text+0x5aa): undefined reference to `hpx::cout'
hello_world.cpp:(.text+0x5c3): undefined reference to `hpx::iostreams::flush'
```

This usually happens if you are trying to use HPX iostreams functionality such as hpx::cout but are not linking against it. The iostreams functionality is not part of the core HPX library, and must be linked to explicitly. Typically this can be solved by adding COMPONENT_DEPENDENCIES iostreams to a call to add_hpx_library/add_hpx_executable/hpx_setup_target if using CMake. See Creating HPX projects for more details.

2.6 Additional material

2.7 Overview

HPX is organized into different sub-libraries and those in turn into modules. The libraries and modules are independent, with clear dependencies and no cycles. As an end-user, the use of these libraries is completely transparent. If you use e.g. `add_hpx_executable` to create a target in your project you will automatically get all modules as dependencies. See below for a list of the available libraries and modules. Currently these are nothing more than an internal grouping and do not affect usage. They cannot be consumed individually at the moment.

2.7.1 Core modules

affinity

The affinity module contains helper functionality for mapping worker threads to hardware resources. See the API reference of the module for more details.

allocator_support

This module provides utilities for allocators. It contains `hpx::util::internal_allocator` which directly forwards allocation calls to `jemalloc`. This utility is mainly useful on Windows. See the API reference of the module for more details.

asio

The asio module is a thin wrapper around the Boost.ASIO library, providing a few additional helper functions. See the API reference of the module for more details.

assertion

The assertion library implements the macros `HPX_ASSERT` and `HPX_ASSERT_MSG`. Those two macros can be used to implement assertions which are turned off during a release build.

By default, the location and function where the assert has been called from are displayed when the assertion fires. This behavior can be modified by using `hpx::assertion::set_assertion_handler`. When HPX initializes, it uses this function to specify a more elaborate assertion handler. If your application needs to customize this, it needs to do so before calling `hpx::hpx_init`, `hpx::hpx_main` or using the C-main wrappers. See the API reference of the module for more details.

cache

This module provides two cache data structures:

- `hpx::util::cache::local_cache`
- `hpx::util::cache::lru_cache`

See the API reference of the module for more details.
concepts

This module provides helpers for emulating concepts. It provides the following macros:

- `HPX_CONCEPT_REQUIRES`
- `HPX_HAS_MEMBER_XXX_TRAIT_DEF`
- `HPX_HAS_XXX_TRAIT_DEF`

See the API reference of the module for more details.

concurrency

This module provides concurrency primitives useful for multi-threaded programming such as:

- `hpx::util::barrier`
- `hpx::util::cache_line_data` and `hpx::util::cache_aligned_data`: wrappers for aligning and padding data to cache lines.
- various lockfree queue data structures

See the API reference of the module for more details.

config

The config module contains various configuration options, typically hidden behind macros that choose the correct implementation based on the compiler and other available options.

See the API reference of the module for more details.

config_registry

The config_registry module is a low level module providing helper functionality for registering configuration entries to a global registry from other modules. The `hpx::config_registry::add_module_config` function is used to add configuration options, and `hpx::config_registry::get_module_configs` can be used to retrieve configuration entries registered so far. `add_module_config_helper` can be used to register configuration entries through static global options.

See the API reference of this module for more details.

coroutines

The coroutines module provides coroutine (user-space thread) implementations for different platforms.

See the API reference of the module for more details.
datastructures

The datastructures module provides basic data structures (typically provided for compatibility with older C++ standards):

- `hpx::util::basic_any`
- `hpx::util::optional`
- `hpx::util::tuple`

See the API reference of the module for more details.

debugging

This module provides helpers for demangling symbol names.

See the API reference of the module for more details.

tools

This module provides support for exceptions and error codes:

- `hpx::exception`
- `hpx::error_code`
- `hpx::error`

See the API reference of the module for more details.

execution_base

The basic execution module is the main entry point to implement parallel and concurrent operations. It is modeled after P0443\textsuperscript{211} with some additions and implementations for the described concepts. Most notably, it provides an abstraction for execution resources, execution contexts and execution agents in such a way, that it provides customization points that those aforementioned concepts can be replaced and combined with ease.

For that purpose, three virtual base classes are provided to be able to provide implementations with different properties:

- `resource_base`: This is the abstraction for execution resources, that is for example CPU cores or an accelerator.
- `context_base`: An execution context uses execution resources and is able to spawn new execution agents, as new threads of executions on the available resources.
- `agent_base`: The execution agent represents the thread of execution, and can be used to yield, suspend, resume or abort a thread of execution.

\textsuperscript{211} \url{http://wg21.link/p0443}
filesystem

This module provides a compatibility layer for the C++17 filesystem library. If the filesystem library is available this module will simply forward its contents into the \texttt{hpx::filesystem} namespace. If the library is not available it will fall back to Boost.Filesystem instead.

See the \textit{API reference} of the module for more details.

format

The format module exposes the \texttt{format} and \texttt{format\_to} functions for formatting strings.

See the \textit{API reference} of the module for more details.

functional

This module provides function wrappers and helpers for managing functions and their arguments.

- \texttt{hpx::util::function}
- \texttt{hpx::util::function\_ref}
- \texttt{hpx::util::unique\_function}
- \texttt{hpx::util::bind}
- \texttt{hpx::util::bind\_back}
- \texttt{hpx::util::bind\_front}
- \texttt{hpx::util::deferred\_call}
- \texttt{hpx::util::invoke}
- \texttt{hpx::util::invoke\_fused}
- \texttt{hpx::util::mem\_fn}
- \texttt{hpx::util::one\_shot}
- \texttt{hpx::util::protect}
- \texttt{hpx::util::result\_of}

See the \textit{API reference} of the module for more details.

hardware

The hardware module abstracts away hardware specific details of timestamps and CPU features.

See the \textit{API reference} of the module for more details.
hashing

The hashing module provides two hashing implementations:

- `hpx::util::fibhash`
- `hpx::util::jenkins_hash`

See the API reference of the module for more details.

io_service

This module provides an abstraction over Boost.ASIO, combining multiple `asio::io_context`s into a single pool. `hpx::util::io_service_pool` provides a simple pool of `asio::io_context`s with an API similar to `asio::io_context`. `hpx::threads::detail::io_service_thread_pool` wraps `hpx::util::io_service_pool` into an interface derived from `hpx::threads::detail::thread_pool_base`.

See the API reference of this module for more details.

iterator_support

This module provides helpers for iterators. It provides `hpx::util::iterator_facade` and `hpx::util::iterator_adaptor` for creating new iterators, and the trait `hpx::util::is_iterator` along with more specific iterator traits.

See the API reference of the module for more details.

itt_notify

This module provides support for profiling with Intel VTune\textsuperscript{212}.

See the API reference of this module for more details.

logging

This module provides useful macros for logging information.

See the API reference of the module for more details.

memory

Part of this module is a forked version of `boost::intrusive_ptr` from Boost.SmartPtr.

See the API reference of the module for more details.

\textsuperscript{212} https://software.intel.com/content/www/us/en/develop/tools/vtune-profiler.html
**plugin**

This module provides base utilities for creating plugins.
See the *API reference* of the module for more details.

**prefix**

This module provides utilities for handling the prefix of an HPX application, i.e. the paths used for searching components and plugins.
See the *API reference* of this module for more details.

**preprocessor**

This library contains useful preprocessor macros:

- `HPX_PP_CAT`
- `HPX_PP_EXPAND`
- `HPX_PP_NARGS`
- `HPX_PP_STRINGIZE`
- `HPX_PP_STRIP_PARENS`

See the *API reference* of the module for more details.

**properties**

This module implements the `prefer` customization point for properties in terms of P2220\(^\text{213}\). This differs from P1393\(^\text{214}\) in that it relies fully on `tag_invoke` overloads and fewer base customization points. Actual properties are defined in modules. All functionality is experimental and can be accessed through the `hpx::experimental` namespace.

See the *API reference* of this module for more details.

**schedulers**

This module provides schedulers used by thread pools in the *thread_pools* module. There are currently three main schedulers:

- `hpx::threads::policies::local_priority_queue_scheduler`
- `hpx::threads::policies::static_priority_queue_scheduler`
- `hpx::threads::policies::shared_priority_queue_scheduler`

Other schedulers are specializations or variations of the above schedulers. See the examples of the *resource_partitioner* module for examples of specifying a custom scheduler for a thread pool.

See the *API reference* of this module for more details.

\(^{213}\) http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2020/p2220r0.pdf

\(^{214}\) http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2019/p1393r0.html
serialization

This module provides serialization primitives and support for all built-in types as well as all C++ Standard Library collection and utility types. This list is extended by HPX vocabulary types with proper support for global reference counting. HPX’s mode of serialization is derived from Boost’s serialization model\(^\text{215}\) and, as such, is mostly interface compatible with its Boost counterpart.

The purest form of serializing data is to copy the content of the payload bit by bit; however, this method is impractical for generic C++ types, which might be composed of more than just regular built-in types. Instead, HPX’s approach to serialization is derived from the Boost Serialization library, and is geared towards allowing the programmer of a given class explicit control and syntax of what to serialize. It is based on operator overloading of two special archive types that hold a buffer or stream to store the serialized data and is responsible for dispatching the serialization mechanism to the intrusive or non-intrusive version. The serialization process is recursive. Each member that needs to be serialized must be specified explicitly. The advantage of this approach is that the serialization code is written in C++ and leverages all necessary programming techniques. The generic, user-facing interface allows for effective application of the serialization process without obstructing the algorithms that need special code for packing and unpacking. It also allows for optimizations in the implementation of the archives.

See the API reference of the module for more details.

static_reinit

This module provides a simple wrapper around static variables that can be reinitialized.

See the API reference of this module for more details.

statistics

This module provides some statistics utilities like rolling min/max and histogram.

See the API reference of the module for more details.

string_util

This module contains string utilities inspired by the Boost string algorithms library.

See the API reference of this module for more details.

synchronization

This module provides synchronization primitives which should be used rather than the C++ standard ones in HPX threads:

- `hpx::lcos::local::barrier`
- `hpx::lcos::local::condition_variable`
- `hpx::lcos::local::counting_semaphore`
- `hpx::lcos::local::event`
- `hpx::lcos::local::latch`
- `hpx::lcos::local::mutex`
- `hpx::lcos::local::no_mutex`

\(^\text{215}\) https://www.boost.org/doc/libs/1_72_0/libs/serialization/doc/index.html
• `hpx::lcos::local::once_flag`
• `hpx::lcos::local::recursive_mutex`
• `hpx::lcos::local::shared_mutex`
• `hpx::lcos::local::sliding_semaphore`
• `hpx::lcos::local::spinlock (std::mutex compatible spinlock)`
• `hpx::lcos::local::spinlock_no_backoff (boost::mutex compatible spinlock)`
• `hpx::lcos::local::spinlock_pool`

See `lcos_local`, `async_combinators`, and `async` for higher level synchronization facilities.

See the API reference of this module for more details.

testing

The testing module contains useful macros for testing. The results of tests can be printed with `hpx::util::report_errors`. The following macros are provided:

• `HPX_TEST`
• `HPX_TEST_MSG`
• `HPX_TEST_EQ`
• `HPX_TEST_NEQ`
• `HPX_TEST_LT`
• `HPX_TEST_LTE`
• `HPX_TEST_RANGE`
• `HPX_TEST_EQ_MSG`
• `HPX_TEST_NEQ_MSG`
• `HPX_SANITY`
• `HPX_SANITY_MSG`
• `HPX_SANITY_EQ`
• `HPX_SANITY_NEQ`
• `HPX_SANITY_LT`
• `HPX_SANITY_LTE`
• `HPX_SANITY_RANGE`
• `HPX_SANITY_EQ_MSG`

See the API reference of the module for more details.
thread_pools

This module defines the thread pools and utilities used by the HPX runtime. The only thread pool implementation provided by this module is `hpx::threads::detail::scheduled_thread_pool`, which is derived from `hpx::threads::detail::thread_pool_base` defined in the `threading_base` module.

See the API reference of this module for more details.

thread_support

This module provides miscellaneous utilities for threading and concurrency.

See the API reference of the module for more details.

threading_base

This module contains the base class definition required for threads. The base class `hpx::threads::thread_data` is inherited by two specializations for stackful and stackless threads: `hpx::threads::thread_data_stackful` and `hpx::threads::thread_data_stackless`. In addition, the module defines the base classes for schedulers and thread pools: `hpx::threads::policies::scheduler_base` and `hpx::threads::thread_pool_base`.

See the API reference of this module for more details.

timing

This module provides the timing utilities (clocks and timers).

See the API reference of the module for more details.

topology

This module provides the class `hpx::threads::topology` which represents the hardware resources available on a node. The class is a light wrapper around the Portable Hardware Locality (HWLOC) library. The `hpx::threads::cpu_mask` is a small companion class that represents a set of resources on a node.

See the API reference of the module for more details.

type_support

This module provides helper facilities related to types.

See the API reference of the module for more details.
The `util` module provides miscellaneous standalone utilities.
See the API reference of the module for more details.

The `version` module contains macros and functions for accessing version information about HPX and its dependencies.
See the API reference of this module for more details.

### 2.7.2 Parallelism modules

The `algorithms` module exposes the full set of algorithms defined by the C++ standard. There is also partial support for C++ ranges.
See the API reference of the module for more details.

The `async_base` module defines the basic functionality for spawning tasks on thread pools. This module does not implement any functionality on its own, but is extended by `async_local` and `modules_async_distributed` with implementations for the local and distributed cases.
See the API reference of this module for more details.

This module contains combinators for futures. The `when_*` functions allow you to turn multiple futures into a single future which is ready when all, any, some, or each of the given futures are ready. The `wait_*` combinators are equivalent to the `when_*` functions except that they do not return a future.
The `split_future` combinator takes a single future of a container (e.g. `tuple`) and turns it into a container of futures.
See `lcos_local`, `synchronization`, and `async` for other synchronization facilities.
See the API reference of this module for more details.

This module extends `async_base` to provide local implementations of `hpx::async`, `hpx::apply`, `hpx::sync`, and `hpx::dataflow`.
See the API reference of this module for more details.
execution

This library implements executors and execution policies for use with parallel algorithms and other facilities related to managing the execution of tasks.

See the API reference of the module for more details.

executors

The executors module exposes executors and execution policies. Most importantly, it exposes the following classes and constants:

- \texttt{hpx::execution::sequenced\_executor}
- \texttt{hpx::execution::parallel\_executor}
- \texttt{hpx::execution::sequenced\_policy}
- \texttt{hpx::execution::parallel\_policy}
- \texttt{hpx::execution::parallel\_unsequenced\_policy}
- \texttt{hpx::execution::sequenced\_task\_policy}
- \texttt{hpx::execution::parallel\_task\_policy}
- \texttt{hpx::execution::seq}
- \texttt{hpx::execution::par}
- \texttt{hpx::execution::par\_unseq}
- \texttt{hpx::execution::task}

See the API reference of this module for more details.

futures

This module defines the \texttt{hpx:lcos::future} and \texttt{hpx:lcos::shared\_future} classes corresponding to the C++ standard library classes \texttt{std::future} and \texttt{std::shared\_future}. Note that the specializations of \texttt{hpx:lcos::future::then} for executors and execution policies are defined in the \texttt{execution} module.

See the API reference of this module for more details.

lcos\_local

This module provides the following local LCOs:

- \texttt{hpx:lcos::local::and\_gate}
- \texttt{hpx:lcos::local::channel}
- \texttt{hpx:lcos::local::one\_element\_channel}
- \texttt{hpx:lcos::local::receive\_channel}
- \texttt{hpx:lcos::local::send\_channel}
- \texttt{hpx:lcos::local::guard}
- \texttt{hpx:lcos::local::guard\_set}
- \texttt{hpx:lcos::local::run\_guarded}
• `hpx::lcos::local::conditional_trigger`
• `hpx::lcos::local::packaged_task`
• `hpx::lcos::local::promise`
• `hpx::lcos::local::receive_buffer`
• `hpx::lcos::local::trigger`

See `lcos_distributed` for distributed LCOs. Basic synchronization primitives for use in `HPX` threads can be found in `synchronization`. `async_combinators` contains useful utility functions for combining futures.

See the API reference of this module for more details.

**pack_traversal**

This module exposes the basic functionality for traversing various packs, both synchronously and asynchronously: `hpx::util::traverse_pack` and `hpx::util::traverse_pack_async`. It also exposes the higher level functionality of unwrapping nested futures: `hpx::util::unwrap` and its function object form `hpx::util::functional::unwrap`.

See the API reference of this module for more details.

**resiliency**

In `HPX`, a program failure is a manifestation of a failing task. This module exposes several APIs that allow users to manage failing tasks in a convenient way by either replaying a failed task or by replicating a specific task.

Task replay is analogous to the Checkpoint/Restart mechanism found in conventional execution models. The key difference being localized fault detection. When the runtime detects an error, it replays the failing task as opposed to completely rolling back the entire program to the previous checkpoint.

Task replication is designed to provide reliability enhancements by replicating a set of tasks and evaluating their results to determine a consensus among them. This technique is most effective in situations where there are few tasks in the critical path of the DAG which leaves the system underutilized or where hardware or software failures may result in an incorrect result instead of an error. However, the drawback of this method is the additional computational cost incurred by repeating a task multiple times.

The following API functions are exposed:

• `hpx::resiliency::experimental::async_replay`: This version of task replay will catch user-defined exceptions and automatically reschedule the task N times before throwing an `hpx::resiliency::experimental::abort_replay_exception` if no task is able to complete execution without an exception.

• `hpx::resiliency::experimental::async_replay_validate`: This version of replay adds an argument to async replay which receives a user-provided validation function to test the result of the task against. If the task’s output is validated, the result is returned. If the output fails the check or an exception is thrown, the task is replayed until no errors are encountered or the number of specified retries has been exceeded.

• `hpx::resiliency::experimental::async_replicate`: This is the most basic implementation of the task replication. The API returns the first result that runs without detecting any errors.

• `hpx::resiliency::experimental::async_replicate_validate`: This API additionally takes a validation function which evaluates the return values produced by the threads. The first task to compute a valid result is returned.
• **hpx::resiliency::experimental::async_replicate_vote**: This API adds a vote function to the basic replicate function. Many hardware or software failures are silent errors which do not interrupt program flow. In order to detect errors of this kind, it is necessary to run the task several times and compare the values returned by every version of the task. In order to determine which return value is “correct”, the API allows the user to provide a custom consensus function to properly form a consensus. This voting function then returns the “correct” answer.

• **hpx::resiliency::experimental::async_replicate_vote_validate**: This combines the features of the previously discussed replicate set. Replicate vote validate allows a user to provide a validation function to filter results. Additionally, as described in replicate vote, the user can provide a “voting function” which returns the consensus formed by the voting logic.

• **hpx::resiliency::experimental::dataflow_replay**: This version of dataflow replay will catch user-defined exceptions and automatically reschedules the task N times before throwing an exception if no task is able to complete execution without an exception. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.

• **hpx::resiliency::experimental::dataflow_replay_validate**: This version of replay adds an argument to dataflow replay which receives a user-provided validation function to test the result of the task against. If the task’s output is validated, the result is returned. If the output fails the check or an exception is thrown, the task is replayed until no errors are encountered or the number of specified retries have been exceeded. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.

• **hpx::resiliency::experimental::dataflow_replicate**: This is the most basic implementation of the task replication. The API returns the first result that runs without detecting any errors. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.

• **hpx::resiliency::experimental::dataflow_replicate_validate**: This API additionally takes a validation function which evaluates the return values produced by the threads. The first task to compute a valid result is returned. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.

• **hpx::resiliency::experimental::dataflow_replicate_vote**: This API adds a vote function to the basic replicate function. Many hardware or software failures are silent errors which do not interrupt program flow. In order to detect errors of this kind, it is necessary to run the task several times and compare the values returned by every version of the task. In order to determine which return value is “correct”, the API allows the user to provide a custom consensus function to properly form a consensus. This voting function then returns the “correct” answer. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.

• **hpx::resiliency::experimental::dataflow_replicate_vote_validate**: This combines the features of the previously discussed replicate set. Replicate vote validate allows a user to provide a validation function to filter results. Additionally, as described in replicate vote, the user can provide a “voting function” which returns the consensus formed by the voting logic. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.

See the API reference of the module for more details.
thread_pool_util

This module contains helper functions for asynchronously suspending and resuming thread pools and their worker
threads.
See the API reference of this module for more details.

threading

This module provides the equivalents of std::thread and std::jthread for lightweight HPX threads:
- hpx::thread
- hpx::jthread
See the API reference of this module for more details.

timed_execution

This module provides extensions to the executor interfaces defined in the execution module that allow timed submission of tasks on thread pools (at or after a specified time).
See the API reference of this module for more details.

2.7.3 Main HPX modules

actions

TODO: High-level description of the library.
See the API reference of this module for more details.

actions_base

TODO: High-level description of the library.
See the API reference of this module for more details.

agas

TODO: High-level description of the module.
See the API reference of this module for more details.
agas_base

This module holds the implementation of the four AGAS services: primary namespace, locality namespace, component namespace, and symbol namespace.

See the API reference of this module for more details.

async_colocated

TODO: High-level description of the module.

See the API reference of this module for more details.

async_cuda

This library adds a simple API that enables the user to retrieve a future from a cuda stream. Typically, a user may launch one or more kernels and then get a future from the stream that will become ready when those kernels have completed. The act of getting a future from the cuda_stream_helper object in this library hides the creation of a cuda stream event and the attachment of this event to the promise that is backing the future returned.

The usage is best illustrated by looking at an example

```cpp
// create a cuda target using device number 0,1,2...
hp::cuda::experimental::target target(device);
// create a stream helper object
hp::cuda::experimental::cuda_future_helper helper(device);

// launch a kernel and return a future
auto fn = &cuda_trivial_kernel<double>;
double d = 3.1415;
auto f = helper.async(fn, d);

// attach a continuation to the future
f.then([](hp::future<void> &f) {
    std::cout << "trivial kernel completed \n";
}).get();
```

Kernels and CPU work may be freely intermixed/overlapped and synchronized with futures.

It is important to note that multiple kernels may be launched without fetching a future, and multiple futures may be obtained from the helper. Please refer to the unit tests and examples for further examples.

CMake variables

HPX_WITH_CUDA - this is a general option that will enable both HPX_WITH_ASYNC_CUDA and HPX_WITH_CUDA_COMPUTE when turned ON.

HPX_WITH_ASYNC_CUDA=ON enables the building of this module which requires only the presence of CUDA on the system and only exposes cuda+futures support (HPX_WITH_ASYNC_CUDA may be used when HPX_WITH_CUDA_COMPUTE=OFF).

HPX_WITH_CUDA_COMPUTE=ON enables building HPX compute features that allow parallel algorithms to be passed through to the GPU/CUDA backend.

See the API reference of this module for more details.
async

This module contains functionality for asynchronously launching work on remote localities: \texttt{hpx::async}, \texttt{hpx::apply}. This module extends the local-only functions in \texttt{libs_async_local}.

See the API reference of this module for more details.

async mpi

The MPI library is intended to simplify the process of integrating MPI based codes with the HPX runtime. Any MPI function that is asynchronous and uses an MPI Request may be converted into an \texttt{hpx::future}. The syntax is designed to allow a simple replacement of the MPI call with a futurized async version that accepts an executor instead of a communicator, and returns a future instead of assigning a request. Typically, an MPI call of the form

\begin{verbatim}
int MPI_Isend(buf, count, datatype, rank, tag, comm, request);
\end{verbatim}

becomes

\begin{verbatim}
hpx::future\lt\texttt{int}\gt f = hpx::async(executor, MPI_Isend, buf, count, datatype, rank, tag);
\end{verbatim}

When the MPI operation is complete, the future will become ready. This allows communication to integrated cleanly with the rest of HPX, in particular the continuation style of programming may be used to build up more complex code. Consider the following example, that chains user processing, sends and receives using continuations...

\begin{verbatim}
// create an executor for MPI dispatch
hpx::mpi::experimental::executor exec(MPI_COMM_WORLD);

// post an asynchronous receive using MPI_Irecv
hpx::future\lt\texttt{int}\gt f_recv = hpx::async(
  exec, MPI_Irecv, \&data, rank, MPI_INT, rank_from, i);

// attach a continuation to run when the recv completes,
// f_recv.then([\texttt{\&}, \&tokens, \&counter](\texttt{auto}&&)
// { // call an application specific function
//   msg_recv(rank, size, rank_to, rank_from, tokens[i], i);
//   // send a new message
//   hpx::future\lt\texttt{int}\gt f_send = hpx::async(
//     exec, MPI_Isend, \&tokens[i], 1, MPI_INT, rank_to, i);
//   // when that send completes
//   f_send.then([\texttt{\&}, \&tokens, \&counter](\texttt{auto}&&)
//     { // call an application specific function
//       msg_send(rank, size, rank_to, rank_from, tokens[i], i);
//     });
// });
\end{verbatim}

The example above makes use of \texttt{MPI_Isend} and \texttt{MPI_Irecv}, but any MPI function that uses requests may be futurized in this manner. The following is a (non exhaustive) list of MPI functions that \textit{should} be supported, though not all have been tested at the time of writing (please report any problems to the issue tracker).

\begin{verbatim}
int MPI_Isend(...);
int MPI_Ibsend(...);
int MPI_Issend(...);
\end{verbatim}

(continues on next page)
Note that the HPX mpi futurization wrapper should work with any asynchronous MPI call, as long as the function signature has the last two arguments `MPI_xxx(..., MPI_Comm comm, MPI_Request *request)` - internally these two parameters will be substituted by the executor and future data parameters that are supplied by template instantiations inside the `hpx::mpi` code.

See the API reference of this module for more details.

### batch_environments

This module allows for the detection of execution as batch jobs, a series of programs executed without user intervention. All data is preselected and will be executed according to preset parameters, such as date or completion of another task. Batch environments are especially useful for executing repetitive tasks.

HPX supports the creation of batch jobs through the Portable Batch System (PBS) and SLURM.

For more information on batch environments, see Running on batch systems and the API reference for the module.

### checkpoint

A common need of users is to periodically backup an application. This practice provides resiliency and potential restart points in code. HPX utilizes the concept of a checkpoint to support this use case.

Found in `hpx/util/checkpoint.hpp`, checkpoints are defined as objects that hold a serialized version of an object or set of objects at a particular moment in time. This representation can be stored in memory for later use or it can be written to disk for storage and/or recovery at a later point. In order to create and fill this object with data, users must use a function called `save_checkpoint`. In code the function looks like this:

```cpp
hpx::future<hpx::util::checkpoint> hpx::util::save_checkpoint(a, b, c, ...);
```
save_checkpoint takes arbitrary data containers, such as `int`, `double`, `float`, `vector`, and `future`, and serializes them into a newly created checkpoint object. This function returns a future to a checkpoint containing the data. Here’s an example of a simple use case:

```cpp
using hpx::util::checkpoint;
using hpx::util::save_checkpoint;

std::vector<int> vec{1,2,3,4,5};
hpx::future<checkpoint> save_checkpoint(vec);
```

Once the future is ready, the checkpoint object will contain the `vector vec` and its five elements.

prepare_checkpoint takes arbitrary data containers (same as for `save_checkpoint`), such as `int`, `double`, `float`, `vector`, and `future`, and calculates the necessary buffer space for the checkpoint that would be created if `save_checkpoint` was called with the same arguments. This function returns a future to a checkpoint that is appropriately initialized. Here’s an example of a simple use case:

```cpp
using hpx::util::checkpoint;
using hpx::util::prepare_checkpoint;

std::vector<int> vec{1,2,3,4,5};
hpx::future<checkpoint> prepare_checkpoint(vec);
```

Once the future is ready, the checkpoint object will be initialized with an appropriately sized internal buffer.

It is also possible to modify the launch policy used by `save_checkpoint`. This is accomplished by passing a launch policy as the first argument. It is important to note that passing `hpx::launch::sync` will cause `save_checkpoint` to return a checkpoint instead of a future to a checkpoint. All other policies passed to `save_checkpoint` will return a future to a checkpoint.

Sometimes checkpoints must be declared before they are used. `save_checkpoint` allows users to move pre-created checkpoints into the function as long as they are the first container passing into the function (In the case where a launch policy is used, the checkpoint will immediately follow the launch policy). An example of these features can be found below:

```cpp
char character = 'd';
int integer = 10;
float flt = 10.01f;
bool boolean = true;
std::string str = "I am a string of characters";
std::vector<char> vec(str.begin(), str.end());
checkpoint archive;

// Test 1
// test basic functionality
hpx::shared_future<checkpoint> f_archive = save_checkpoint(
    std::move(archive), character, integer, flt, boolean, str, vec);
```

Once users can create checkpoints they must now be able to restore the objects they contain into memory. This is accomplished by the function `restore_checkpoint`. This function takes a checkpoint and fills its data into the containers it is provided. It is important to remember that the containers must be ordered in the same way they were placed into the checkpoint. For clarity see the example below:

```cpp
char character2;
int integer2;
float flt2;
bool boolean2;
std::string str2;
```
std::vector<char> vec2;
restore_checkpoint(data, character2, integer2, flt2, boolean2, str2, vec2);

The core utility of checkpoint is in its ability to make certain data persistent. Often, this means that the data needs to be stored in an object, such as a file, for later use. HPX has two solutions for these issues: stream operator overloads and access iterators.

HPX contains two stream overloads, operator<< and operator>>, to stream data out of and into checkpoint. Here is an example of the overloads in use below:

double a9 = 1.0, b9 = 1.1, c9 = 1.2;
std::ofstream test_file_9("test_file_9.txt");
hx::future<checkpoint> f_9 = save_checkpoint(a9, b9, c9);
test_file_9 << f_9.get();
test_file_9.close();

double a9_1, b9_1, c9_1;
std::ifstream test_file_9_1("test_file_9.txt");
checkpoint archive9;
test_file_9_1 >> archive9;
restore_checkpoint(archive9, a9_1, b9_1, c9_1);

This is the primary way to move data into and out of a checkpoint. It is important to note, however, that users should be cautious when using a stream operator to load data and another function to remove it (or vice versa). Both operator<< and operator>> rely on a .write() and a .read() function respectively. In order to know how much data to read from the std::istream, the operator<< will write the size of the checkpoint before writing the checkpoint data. Correspondingly, the operator>> will read the size of the stored data before reading the data into a new instance of checkpoint. As long as the user employs the operator<< and operator>> to stream the data, this detail can be ignored.

Important: Be careful when mixing operator<< and operator>> with other facilities to read and write to a checkpoint. operator<< writes an extra variable, and operator>> reads this variable back separately. Used together the user will not encounter any issues and can safely ignore this detail.

Users may also move the data into and out of a checkpoint using the exposed .begin() and .end() iterators. An example of this use case is illustrated below.

std::ofstream test_file_7("checkpoint_test_file.txt");
std::vector<float> vec7{1.02f, 1.03f, 1.04f, 1.05f};
hx::future<checkpoint> fut_7 = save_checkpoint(vec7);
checkpoint archive7 = fut_7.get();
std::copy(archive7.begin(), // Write data to ofstream
    archive7.end(), // ie. the file
    std::ostream_iterator<char>(test_file_7));
test_file_7.close();

std::vector<float> vec7_1;
std::vector<char> char_vec;
std::ifstream test_file_7_1("checkpoint_test_file.txt");
if (test_file_7_1)
{
    test_file_7_1.seekg(0, test_file_7_1.end);
    auto length = test_file_7_1.tellg();
}
Checkpointing components

save_checkpoint and restore_checkpoint are also able to store components inside checkpoints. This can be done in one of two ways. First a client of the component can be passed to save_checkpoint. When the user wishes to resurrect the component she can pass a client instance to restore_checkpoint.

This technique is demonstrated below:

```cpp
// Try to checkpoint and restore a component with a client
std::vector<int> vec3{10, 10, 10, 10, 10};

// Create a component instance through client constructor
data_client D(hpx::find_here(), std::move(vec3));
hpx::future<checkpoint> f3 = save_checkpoint(D);

// Create a new client
data_client E;

// Restore server inside client instance
restore_checkpoint(f3.get(), E);
```

The second way a user can save a component is by passing a shared_ptr to the component to save_checkpoint. This component can be resurrected by creating a new instance of the component type and passing a shared_ptr to the new instance to restore_checkpoint.

This technique is demonstrated below:

```cpp
// test checkpoint a component using a shared_ptr
std::vector<int> vec{1, 2, 3, 4, 5};
data_client A(hpx::find_here(), std::move(vec));

// Checkpoint Server
hpx::id_type old_id = A.get_id();

hpx::future<std::shared_ptr<data_server>> f_a_ptr =
  hpx::get_ptr<data_server>(A.get_id());
std::shared_ptr<data_server> a_ptr = f_a_ptr.get();
hpx::future<checkpoint> f = save_checkpoint(a_ptr);
auto&& data = f.get();

// test prepare_checkpoint API
checkpoint c = prepare_checkpoint(hpx::launch::sync, a_ptr);
HPX_TEST(c.size() == data.size());

// Restore Server
// Create a new server instance
std::shared_ptr<data_server> b_server;
restore_checkpoint(data, b_server);
```
checkpoint_base

The checkpoint_base module contains lower level facilities that wrap simple check-pointing capabilities. This module does not implement special handling for futures or components, but simply serializes all arguments to or from a given container.

This module exposes the `hpx::util::save_checkpoint_data`, `hpx::util::restore_checkpoint_data`, and `hpx::util::prepare_checkpoint_data` APIs. These functions encapsulate the basic serialization functionalities necessary to save/restore a variadic list of arguments to/from a given data container.

See the API reference of this module for more details.

collectives

The collectives module exposes a set of distributed collective operations. Those can be used to exchange data between participating sites in a coordinated way. At this point the module exposes the following collective primitives:

- `hpx::collectives::all_reduce`: performs a reduction on data from each participating site to each participating site.
- `hpx::collectives::all_to_all`: each participating site provides its element of the data to collect while all participating sites receive the data from every other site.
- `hpx::lcos::barrier`: distributed barrier.
- `hpx::lcos::broadcast`: performs a given action on all given global identifiers.
- `hpx::lcos::fold`: performs a fold with a given action on all given global identifiers.
- `hpx::lcos::gather`: gathers values from all participating sites.
- `hpx::lcos::latch`: distributed latch.
- `hpx::lcos::reduce`: performs a reduction on data from each participating site to a root site.
- `hpx::lcos::spmd_block`: performs the same operation on a local image while providing handles to the other images.

See the API reference of the module for more details.

command_line_handling

The command_line_handling module defines and handles the command-line options required by the HPX runtime, combining them with configuration options defined by the runtime_configuration module. The actual parsing of command line options is handled by the program_options module.

See the API reference of the module for more details.

components

TODO: High-level description of the module.

See the API reference of this module for more details.
components_base

TODO: High-level description of the library.
See the API reference of this module for more details.

compute

The compute module provides utilities for handling task and memory affinity on host systems. The compute_cude for extensions to CUDA programmable GPU devices.
See the API reference of the module for more details.

compute_cude

This module extends the compute module to handle CUDA programmable GPU devices.
See the API reference of the module for more details.

distribution_policies

TODO: High-level description of the module.
See the API reference of this module for more details.

executors_distributed

This module provides the executor hpx::parallel::execution::distribution_policy_executor. It allows one to create work that is implicitly distributed over multiple localities.
See the API reference of this module for more details.

include

This module provides no functionality in itself. Instead it provides headers that group together other headers that often appear together. The grouping is similar to that provided by modules. We intend to deprecate these headers in favor of hpx/<modulename>.hpp headers.
See the API reference of this module for more details.

init_runtime

TODO: High-level description of the library.
See the API reference of this module for more details.
lcos_distributed

This module contains distributed LCOs. Currently the only LCO provided is :cpp:class:`hpx::lcos::channel`, a construct for sending values from one locality to another. See libs_lcos_local for local LCOs.

See the API reference of this module for more details.

mpi_base

This module provides helper functionality for detecting MPI environments.

See the API reference of this module for more details.

naming

TODO: High-level description of the module.

See the API reference of this module for more details.

naming_base

This module provides a forward declaration of address_type, component_type and invalid_locality_id.

See the API reference of this module for more details.

performance_counters

This module provides the basic functionality required for defining performance counters. See Performance counters for more information about performance counters.

See the API reference of this module for more details.

program_options

The module program_options is a direct fork of the Boost.ProgramOptions library (Boost V1.70.0). For more information about this library please see here\(^\text{217}\). In order to be included as an HPX module, the Boost.ProgramOptions library has been moved to the namespace hpx::program_options. We have also replaced all Boost facilities the library depends on with either the equivalent facilities from the standard library or from HPX. As a result, the HPX program_options module is fully interface compatible with Boost.ProgramOptions (sans the hpx namespace and the \#include <hpx/modules/program_options.hpp> changes that need to be applied to all code relying on this library).

All credit goes to Vladimir Prus, the author of the excellent Boost.ProgramOptions library. All bugs have been introduced by us.

See the API reference of the module for more details.

\(^{217}\) https://www.boost.org/doc/libs/1_70_0/doc/html/program_options.html
resiliency_distributed

Software resiliency features of HPX were introduced in the resiliency module. This module extends the APIs to run on distributed-memory systems allowing the user to invoke the failing task on other localities at runtime. This is useful in cases where a node is identified to fail more often (e.g., for certain ALU computes) as the task can now be replayed or replicated among different localities. The API exposed allows for an easy integration with the local only resiliency APIs as well.

Distributed software resilience APIs have a similar function signature and lives under the same namespace of \texttt{hpx::resiliency::experimental}. The difference arises in the formal parameters where distributed APIs takes the localities as the first argument, and an action as opposed to a function or a function object. The localities signify the order in which the API will either schedule (in case of Task Replay) tasks in a round robin fashion or replicate the tasks onto the list of localities.

The list of APIs exposed by distributed resiliency modules is the same as those defined in local resiliency module.

See the API reference of this module for more details.

resource_partitioner

The resource_partitioner module defines \texttt{hpx::resource::partitioner}, the class used by the runtime and users to partition available hardware resources into thread pools. See Using the resource partitioner for more details on using the resource partitioner in applications.

See the API reference of this module for more details.

runtime_components

TODO: High-level description of the module.

See the API reference of this module for more details.

runtime_components_base

TODO: High-level description of the module.

See the API reference of this module for more details.

runtime_configuration

This module handles the configuration options required by the runtime.

See the API reference of this module for more details.

runtime_distributed

TODO: High-level description of the module.

See the API reference of this module for more details.
runtime_local

TODO: High-level description of the library.
See the API reference of this module for more details.

segmented_algorithms

Segmented algorithms extend the usual parallel algorithms by providing overloads that work with distributed containers, such as partitioned vectors.
See the API reference of the module for more details.

thread_executors

This module provides executors implementing the executor interface proposed in N3562\(^ {218}\). These executors are deprecated.
See the API reference of this module for more details.

thread_manager

This module defines the hpx::threads::threadmanager class. This is used by the runtime to manage the creation and destruction of thread pools. The resource_partitioner module handles the partitioning of resources into thread pools, but not the creation of thread pools.
See the API reference of this module for more details.

2.8 API reference

HPX follows a versioning scheme with three numbers: major.minor.patch. We guarantee no breaking changes in the API for patch releases. Minor releases may remove or break existing APIs, but only after a deprecation period of at least two minor releases. In rare cases do we outright remove old and unused functionality without a deprecation period.

We do not provide any ABI compatibility guarantees between any versions, debug and release builds, and builds with different C++ standards.

The public API of HPX is presented below. Clicking on a name brings you to the full documentation for the class or function. Including the header specified in a heading brings in the features listed under that heading.

Note: Names listed here are guaranteed stable with respect to semantic versioning. However, at the moment the list is incomplete and certain unlisted features are intended to be in the public API. While we work on completing the list, if you’re unsure about whether a particular unlisted name is part of the public API you can get into contact with us or open an issue and we’ll clarify the situation.

\(^{218}\) http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2013/n3562.pdf
2.8.1 Public API

All names below are also available in the top-level hpx namespace unless otherwise noted. The names in hpx should be preferred. The names in sub-namespaces will eventually be removed.

Header hpx/algorithm.hpp

Corresponds to the C++ standard library header algorithm\(^{219}\). See *Using parallel algorithms* for more information about the parallel algorithms.

Classes

- hpx::parallel::v2::reduction
- hpx::parallel::v2::induction

Functions

- hpx::adjacent_find

**Header hpx/any.hpp**

Corresponds to the C++ standard library header any\(^{220}\). `hpx::any` is compatible with `std::any`.

**Classes**

• `hpx::any`
• `hpx::any_nonser`
• `hpx::bad_any_cast`
• `hpx::unique_any_nonser`

**Functions**

• `hpx::any_cast`
• `hpx::make_any`
• `hpx::make_any_nonser`
• `hpx::make_unique_any_nonser`

**Header hpx/assert.hpp**

Corresponds to the C++ standard library header cassert\(^{221}\). HPX_ASSERT is the HPX equivalent to assert in cassert. HPX_ASSERT can also be used in CUDA device code.

Macros

- `HPX_ASSERT`
- `HPX_ASSERT_MSG`

Header `hpx/barrier.hpp`

This header includes `Header hpx/local/barrier.hpp` and `Header hpx/distributed/barrier.hpp`.

Header `hpx/local/barrier.hpp`

Corresponds to the C++ standard library header `barrier`.222

Classes

- `hpx::lcos::local::cpp20_barrier`

Header `hpx/distributed/barrier.hpp`

Contains a distributed barrier implementation. This functionality is also exposed through the `hpx::distributed` namespace. The name in `hpx::distributed` should be preferred.

Classes

- `hpx::lcos::barrier`

Header `hpx/channel.hpp`

This header includes `Header hpx/local/channel.hpp` and `Header hpx/distributed/channel.hpp`.

Header `hpx/local/channel.hpp`

Contains a local channel implementation.

Classes

- `hpx::lcos::local::channel`

**Header hpx/distributed/channel.hpp**

Contains a distributed channel implementation. This functionality is also exposed through the hpx::distributed namespace. The name in hpx::distributed should be preferred.

**Classes**

- hpx::lcos::channel

**Header hpx/chrono.hpp**

Corresponds to the C++ standard library header chrono\(^{223}\). The following replacements and extensions are provided compared to chrono\(^{224}\). The classes below are also available in the hpx::chrono namespace, not in the top-level hpx namespace.

**Classes**

- hpx::chrono::high_resolution_clock
- hpx::chrono::high_resolution_timer
- hpx::chrono::steady_time_point

**Header hpx/condition_variable.hpp**

Corresponds to the C++ standard library header condition_variable\(^{225}\).

**Classes**

- hpx::lcos::local::condition_variable
- hpx::lcos::local::condition_variable_any
- hpx::lcos::local::cv_status

**Header hpx/exception.hpp**

Corresponds to the C++ standard library header exception\(^{226}\). hpx::exception extends std::exception and is the base class for all exceptions thrown in HPX. `HPX_THROW_EXCEPTION` can be used to throw HPX exceptions with file and line information attached to the exception.

            return pi * r * r;
        })
        .get() << std::endl;
```

(continues on next page)
// Easier continuations with dataflow; it waits for all future or
// shared_future arguments before executing the continuation, and also
// accepts non-future arguments
hpx::future<double> f8 = hpx::async([]() { return 3.14; });
hpx::future<double> f9 = hpx::make_ready_future(42.0);
hpx::shared_future<double> f10 = hpx::async([]() { return 123.45; });
hpx::future<hpx::tuple<double, double>> f11 = hpx::dataflow(
    [](hpx::future<double> a, hpx::future<double> b,
        hpx::shared_future<double> c, double d) {
        return hpx::make_tuple<>(a.get() + b.get(), c.get() / d);
    },
    f8, f9, f10, -3.9);

// split_future gives a tuple of futures from a future of tuple
hpx::tuple<hpx::future<double>, hpx::future<double>> f12 =
    hpx::split_future(std::move(f11));
std::cout << hpx::get<1>(f12).get() << std::endl;
    return 0;
}

**Header hpx/distributed/future.hpp**

Contains overloads of `hpx::async`, `hpx::apply`, `hpx::sync`, and `hpx::dataflow` that can be used with actions. See *Action invocation* for more information about invoking actions.

**Note:** The alias from `hpx::promise` to `hpx::lcos::promise` is deprecated and will be removed in a future release. The alias `hpx::distributed::promise` should be used in new applications.

**Classes**

- `hpx::lcos::promise`

**Functions**

- `hpx::async`
- `hpx::apply`
- `hpx::sync`
- `hpx::dataflow`
Header hpx/init.hpp

This header contains functionality for starting, stopping, suspending, and resuming the HPX runtime. This is the main way to explicitly start the HPX runtime. See Starting the HPX runtime for more details on starting the HPX runtime.

Classes

- hpx::init_params
- hpx::runtime_mode

Functions

- hpx::init
- hpx::start
- hpx::finalize
- hpx::disconnect
- hpx::suspend
- hpx::resume

Header hpx/latch.hpp

This header includes Header hpx/local/latch.hpp and Header hpx/distributed/latch.hpp.

Header hpx/local/latch.hpp

Corresponds to the C++ standard library header latch\textsuperscript{230}.

Classes

- hpx::lcos::local::cpp20_latch

Header hpx/distributed/latch.hpp

Contains a distributed latch implementation. This functionality is also exposed through the hpx::distributed namespace. The name in hpx::distributed should be preferred.

\textsuperscript{230} http://en.cppreference.com/w/cpp/header/latch
Classes

- `hpx::lcos::latch`

Header `hpx/mutex.hpp`

Corresponds to the C++ standard library header `mutex`\(^{231}\).

Classes

- `hpx::lcos::local::mutex`
- `hpx::lcos::local::no_mutex`
- `hpx::lcos::local::once_flag`
- `hpx::lcos::local::recursive_mutex`
- `hpx::lcos::local::spinlock`
- `hpx::lcos::local::timed_mutex`
- `hpx::lcos::local::unlock_guard`

Functions

- `hpx::lcos::local::call_once`

Header `hpx/memory.hpp`

Corresponds to the C++ standard library header `memory`\(^{232}\). It contains parallel versions of the copy, fill, move, and construct helper functions in `memory`\(^{233}\). See *Using parallel algorithms* for more information about the parallel algorithms.

Functions

- `hpx::parallel::v1::uninitialized_copy`
- `hpx::parallel::v1::uninitialized_copy_n`
- `hpx::parallel::v1::uninitialized_default_construct`
- `hpx::parallel::v1::uninitialized_default_construct_n`
- `hpx::parallel::v1::uninitialized_fill`
- `hpx::parallel::v1::uninitialized_fill_n`
- `hpx::parallel::v1::uninitialized_move`
- `hpx::parallel::v1::uninitialized_move_n`
- `hpx::parallel::v1::uninitialized_value_construct`

\(^{231}\) [http://en.cppreference.com/w/cpp/header/mutex]
\(^{232}\) [http://en.cppreference.com/w/cpp/header/memory]
\(^{233}\) [http://en.cppreference.com/w/cpp/header/memory]
- `hpx::parallel::v1::uninitialized_value_construct_n`

**Header hpx/numeric.hpp**

Corresponds to the C++ standard library header `numeric`. See *Using parallel algorithms* for more information about the parallel algorithms.

**Functions**

- `hpx::parallel::v1::adjacent_difference`
- `hpx::parallel::v1::exclusive_scan`
- `hpx::parallel::v1::inclusive_scan`
- `hpx::reduce`
- `hpx::parallel::v1::transform_exclusive_scan`
- `hpx::parallel::v1::transform_inclusive_scan`
- `hpx::transform_reduce`

**Header hpx/optional.hpp**

Corresponds to the C++ standard library header `optional`. `hpx::util::optional` is compatible with `std::optional`.

**Constants**

- `hpx::util::nullopt`

**Classes**

- `hpx::util::optional`
- `hpx::util::nullopt_t`
- `hpx::util::bad_optional_access`

**Functions**

- `hpx::util::make_optional`

---

Header `hpx/runtime.hpp`

This header includes `Header hpx/local/runtime.hpp` and `Header hpx/distributed/runtime.hpp`.

Header `hpx/local/runtime.hpp`

This header contains functions for accessing local runtime information.

**Typedefs**

- `hpx::startup_function_type`
- `hpx::shutdown_function_type`

**Functions**

- `hpx::get_num_worker_threads`
- `hpx::get_worker_thread_num`
- `hpx::get_thread_name`
- `hpx::register_pre_startup_function`
- `hpx::register_startup_function`
- `hpx::register_pre_shutdown_function`
- `hpx::register_shutdown_function`
- `hpx::get_num_localities`
- `hpx::get_locality_name`

Header `hpx/distributed/runtime.hpp`

This header contains functions for accessing distributed runtime information.

**Functions**

- `hpx::find_root_locality`
- `hpx::find_all_localities`
- `hpx::find_remote_localities`
- `hpx::find_locality`
- `hpx::get_colocation_id`
- `hpx::get_locality_id`
Header `hpx/system_error.hpp`

Corresponds to the C++ standard library header `system_error`\textsuperscript{236}.

**Classes**

- `hpx::error_code`

Header `hpx/task_block.hpp`

Corresponds to the `task_block` feature in N4411\textsuperscript{237}. See *Using task blocks* for more details on using task blocks.

**Classes**

- `hpx::parallel::v2::task_canceled_exception`
- `hpx::parallel::v2::task_block`

**Functions**

- `hpx::parallel::v2::define_task_block`
- `hpx::parallel::v2::define_task_block_restore_thread`

Header `hpx/thread.hpp`

Corresponds to the C++ standard library header `thread`\textsuperscript{238}. The functionality in this header is equivalent to the standard library thread functionality, with the exception that the \textit{HPX} equivalents are implemented on top of lightweight threads and the \textit{HPX} runtime.

**Classes**

- `hpx::thread`
- `hpx::jthread`

**Functions**

- `hpx::this_thread::yield`
- `hpx::this_thread::get_id`
- `hpx::this_thread::sleep_for`
- `hpx::this_thread::sleep_until`

\textsuperscript{236} http://en.cppreference.com/w/cpp/header/system_error
\textsuperscript{237} http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2015/n4411.pdf
\textsuperscript{238} http://en.cppreference.com/w/cpp/header/thread
Header `hpx/seaphore.hpp`

Corresponds to the C++ standard library header `semaphore`\(^{239}\).

Classes

- `hpx::lcos::local::cpp20_binary_semaphore`
- `hpx::lcos::local::cpp20_counting_semaphore`

Header `hpx/shared_mutex.hpp`

Corresponds to the C++ standard library header `shared_mutex`\(^{240}\).

Classes

- `hpx::lcos::local::shared_mutex`

Header `hpx/stop_token.hpp`

Corresponds to the C++ standard library header `stop_token`\(^{241}\).

Constants

- `hpx::nostopstate`

Classes

- `hpx::stop_callback`
- `hpx::stop_source`
- `hpx::stop_token`
- `hpx::nostopstate_t`

Header `hpx/tuple.hpp`

Corresponds to the C++ standard library header `tuple`\(^{242}\). `hpx::tuple` can be used in CUDA device code, unlike `std::tuple`.

Constants

• hpx::ignore

Classes

• hpx::tuple
  • hpx::tuple_size
  • hpx::tuple_element

Functions

• hpx::make_tuple
• hpx::tie
• hpx::forward_as_tuple
• hpx::tuple_cat
• hpx::get

Header hpx/type_traits.hpp

Corresponds to the C++ standard library header type_traits243.

Classes

• hpx::is_invocable
• hpx::is_invocable_r

Header hpx/version.hpp

This header provides version information about HPX.

Macros

• HPX_VERSION_MAJOR
• HPX_VERSION_MINOR
• HPX_VERSION_SUBMINOR
• HPX_VERSION_FULL
• HPX_VERSION_DATE
• HPX_VERSION_TAG
• HPX_AGAS_VERSION

243 http://en.cppreference.com/w/cpp/header/type_traits
Functions

- `hpx::major_version`
- `hpx::minor_version`
- `hpx::subminor_version`
- `hpx::full_version`
- `hpx::full_version_as_string`
- `hpx::tag`
- `hpx::agas_version`
- `hpx::build_type`
- `hpx::build_date_time`

Header `hpx/wrap_main.hpp`

This header does not provide any direct functionality but is used for implicitly using `main` as the runtime entry point. See Re-use the main() function as the main HPX entry point for more details on implicitly starting the HPX runtime.

### 2.8.2 Full API

The full API of HPX is presented below. The listings for the public API above refer to the full documentation below.

**Note:** Most names listed in the full API reference are implementation details or considered unstable. They are listed mostly for completeness. If there is a particular feature you think deserves being in the public API we may consider promoting it. In general we prioritize making sure features corresponding to C++ standard library features are stable and complete.

Main HPX library

This lists functionality in the main HPX library that has not been moved to modules yet.

**namespace hpx**

Functions

```cpp
naming::id_type find_here(error_code &ec = throws)
```

Return the global id representing this locality.

The function `find_here()` can be used to retrieve the global id usable to refer to the current locality.

**Note** Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global actions).

**Return** The global id representing the locality this function has been called on.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.
Note This function will return meaningful results only if called from an HPX-thread. It will return `hpx::naming::invalid_id` otherwise.

See `hpx::find_all_localities(), hpx::find_locality()`

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
naming::id_type find_root_locality (error_code &ec = throws)
```

Return the global id representing the root locality.

The function `find_root_locality()` can be used to retrieve the global id usable to refer to the root locality. The root locality is the locality where the main AGAS service is hosted.

Note Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

Return The global id representing the root locality for this application.

Note As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

Note This function will return meaningful results only if called from an HPX-thread. It will return `hpx::naming::invalid_id` otherwise.

See `hpx::find_all_localities(), hpx::find_locality()`

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
std::vector<naming::id_type> find_all_localities (error_code &ec = throws)
```

Return the list of global ids representing all localities available to this application.

The function `find_all_localities()` can be used to retrieve the global ids of all localities currently available to this application.

Note Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

Return The global ids representing the localities currently available to this application.

Note As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

Note This function will return meaningful results only if called from an HPX-thread. It will return an empty vector otherwise.

See `hpx::find_here(), hpx::find_locality()`

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
std::vector<naming::id_type> find_remote_localities (error_code &ec = throws)
```

Return the list of locality ids of remote localities supporting the given component type. By default this function will return the list of all remote localities (all but the current locality).
The function `find_remote_localities()` can be used to retrieve the global ids of all remote localities currently available to this application (i.e. all localities except the current one).

**Note** Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

**Return** The global ids representing the remote localities currently available to this application.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Note** This function will return meaningful results only if called from an HPX-thread. It will return an empty vector otherwise.

**See** `hpx::find_here()`, `hpx::find_locality()`

**Parameters**

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
std::string get_locality_name()
```

Return the name of the locality this function is called on.

This function returns the name for the locality on which this function is called.

**Return** This function returns the name for the locality on which the function is called. The name is retrieved from the underlying networking layer and may be different for different parcelports.

**See** `future<std::string> get_locality_name(naming::id_type const& id)`

```cpp
future<std::string> get_locality_name(naming::id_type const& id)
```

Return the name of the referenced locality.

This function returns a future referring to the name for the locality of the given id.

**Return** This function returns the name for the locality of the given id. The name is retrieved from the underlying networking layer and may be different for different parcel ports.

**See** `std::string get_locality_name()`

**Parameters**

- `id`: [in] The global id of the locality for which the name should be retrieved

**namespace components**

**Functions**

```cpp
template<typename Component>
future<naming::id_type> migrate_from_storage(naming::id_type const &to_resurrect,
                                          naming::id_type const &target = naming::invalid_id)
```

Migrate the component with the given id from the specified target storage (resurrect the object)

The function `migrate_from_storage<Component>` will migrate the component referenced by `to_resurrect` from the storage facility specified where the object is currently stored on. It returns a future referring
to the migrated component instance. The component instance is resurrected on the locality specified by `target_locality`.

**Return** A future representing the global id of the migrated component instance. This should be the same as `to_resurrect`.

**Parameters**
- `to_resurrect`: [in] The global id of the component to migrate.
- `target`: [in] The optional locality to resurrect the object on. By default the object is resurrected on the locality it was located on last.

**Template Parameters**
- The: only template argument specifies the component type of the component to migrate from the given storage facility.

```cpp
template<typename Component>
future<naming::id_type> migrate_to_storage(naming::id_type const &to_migrate, naming::id_type const &target_storage)
```

Migrate the component with the given id to the specified target storage.

The function `migrate_to_storage<Component>` will migrate the component referenced by `to_migrate` to the storage facility specified with `target_storage`. It returns a future referring to the migrated component instance.

**Return** A future representing the global id of the migrated component instance. This should be the same as `migrate_to`.

**Parameters**
- `to_migrate`: [in] The global id of the component to migrate.
- `target_storage`: [in] The id of the storage facility to migrate this object to.

**Template Parameters**
- The: only template argument specifies the component type of the component to migrate to the given storage facility.

```cpp
template<typename Derived, typename Stub>
Derived migrate_to_storage(client_base<Derived, Stub> const &to_migrate,
                           hpx::components::component_storage const &target_storage)
```

Migrate the given component to the specified target storage.

The function `migrate_to_storage<Derived>` will migrate the component referenced by `to_migrate` to the storage facility specified with `target_storage`. It returns a future referring to the migrated component instance.

**Return** A client side representation of representing of the migrated component instance. This should be the same as `migrate_to`.

**Parameters**
- `to_migrate`: [in] The client side representation of the component to migrate.
- `target_storage`: [in] The id of the storage facility to migrate this object to.

assertion

The contents of this module can be included with the header hpx/modules/assertion.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/assertion.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

Defines

HPX_ASSERT_CURRENT_FUNCTION

namespace hpx

namespace assertion

Functions

std::ostream &operator<<(std::ostream &os, source_location const &loc)

struct source_location

#include <source_location.hpp> This contains the location information where HPX_ASSERT has been called
Public Members

```cpp
const char *file_name
unsigned line_number
const char *function_name
```

Defines

**HPX_ASSERT**(*expr*)

This macro asserts that *expr* evaluates to true.

If *expr* evaluates to false, the source location and msg is being printed along with the expression and additional. Afterwards the program is being aborted. The assertion handler can be customized by calling hpx::assertion::set_assertion_handler().

**Parameters**

- **expr**: The expression to assert on. This can either be an expression that’s convertible to bool or a callable which returns bool
- **msg**: The optional message that is used to give further information if the assert fails. This should be convertible to a std::string

Asserts are enabled if **HPX_DEBUG** is set. This is the default for CMAKE_BUILD_TYPE=Debug

**HPX_ASSERT_MSG**(*expr*, *msg*)

See **HPX_ASSERT**

```cpp
namespace hpx
```

```cpp
namespace assertion
```

Typedefs

```cpp
using assertion_handler = void (*)(source_location const &loc, const char *expr, std::string const &msg)
```

The signature for an assertion handler.

Functions

```cpp
void set_assertion_handler(assertion_handler handler)
```

Set the assertion handler to be used within a program. If the handler has been set already once, the call to this function will be ignored.

**Note** This function is not thread safe
cache

The contents of this module can be included with the header `hpx/modules/cache.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/cache.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

```cpp
namespace hpx

namespace util

namespace cache

template<typename Key, typename Entry, typename UpdatePolicy = std::less<Entry>, typename InsertPolicy = policies::always, typename CacheStorage = std::map<Key, Entry>, typename Statistics = statistics::no_statistics>
class local_cache
#include <hpx/cache/local_cache.hpp> The local_cache implements the basic functionality needed for a local (non-distributed) cache.

Template Parameters
• Key: The type of the keys to use to identify the entries stored in the cache
• Entry: The type of the items to be held in the cache, must model the CacheEntry concept
• UpdatePolicy: A (optional) type specifying a (binary) function object used to sort the cache entries based on their ‘age’. The ‘oldest’ entries (according to this sorting criteria) will be discarded first if the maximum capacity of the cache is reached. The default is std::less<Entry>. The function object will be invoked using 2 entry instances of the type Entry. This type must model the UpdatePolicy model.
• InsertPolicy: A (optional) type specifying a (unary) function object used to allow global decisions whether a particular entry should be added to the cache or not. The default is policies::always, imposing no global insert related criteria on the cache. The function object will be invoked using the entry instance to be inserted into the cache. This type must model the InsertPolicy model.
• CacheStorage: A (optional) container type used to store the cache items. The container must be an associative and STL compatible container. The default is a std::map<Key, Entry>.
• Statistics: A (optional) type allowing to collect some basic statistics about the operation of the cache instance. The type must conform to the CacheStatistics concept. The default value is the type statistics::no_statistics which does not collect any numbers, but provides empty stubs allowing the code to compile.

Public Types

typedef Key key_type

typedef Entry entry_type

typedef UpdatePolicy update_policy_type

typedef InsertPolicy insert_policy_type

typedef CacheStorage storage_type

typedef Statistics statistics_type

typedef entry_type::value_type value_type
```
typedef storage_type::size_type size_type
typedef storage_type::value_type storage_value_type

Public Functions

local_cache(size_type max_size = 0, update_policy_type const &up = update_policy_type(), insert_policy_type const &ip = insert_policy_type())
Construct an instance of a local_cache.

Parameters
- max_size: [in] The maximal size this cache is allowed to reach any time. The default is zero (no size limitation). The unit of this value is usually determined by the unit of the values returned by the entry’s get_size function.
- up: [in] An instance of the UpdatePolicy to use for this cache. The default is to use a default constructed instance of the type as defined by the UpdatePolicy template parameter.
- ip: [in] An instance of the InsertPolicy to use for this cache. The default is to use a default constructed instance of the type as defined by the InsertPolicy template parameter.

local_cache(local_cache &&other)

size_type size() const
Return current size of the cache.

Return The current size of this cache instance.

size_type capacity() const
Access the maximum size the cache is allowed to grow to.

Note The unit of this value is usually determined by the unit of the return values of the entry’s function entry::get_size.
Return The maximum size this cache instance is currently allowed to reach. If this number is zero the cache has no limitation with regard to a maximum size.

bool reserve(size_type max_size)
Change the maximum size this cache can grow to.

Return This function returns true if successful. It returns false if the new max_size is smaller than the current limit and the cache could not be shrunk to the new maximum size.
Parameters
- max_size: [in] The new maximum size this cache will be allowed to grow to.

bool holds_key(key_type const &k) const
Check whether the cache currently holds an entry identified by the given key.

Note This function does not call the entry’s function entry::touch. It just checks if the cache contains an entry corresponding to the given key.
Return This function returns true if the cache holds the referenced entry, otherwise it returns false.
Parameters
- k: [in] The key for the entry which should be looked up in the cache.
bool get_entry (key_type const &k, key_type &realkey, entry_type &val)
Get a specific entry identified by the given key.

**Note** The function will call the entry’s entry::touch function if the value corresponding to the provided key is found in the cache.

**Return** This function returns true if the cache holds the referenced entry, otherwise it returns false.

**Parameters**
- k: [in] The key for the entry which should be retrieved from the cache.
- val: [out] If the entry indexed by the key is found in the cache this value on successful return will be a copy of the corresponding entry.

bool get_entry (key_type const &k, entry_type &val)
Get a specific entry identified by the given key.

**Note** The function will call the entry’s entry::touch function if the value corresponding to the provided key is found in the cache.

**Return** This function returns true if the cache holds the referenced entry, otherwise it returns false.

**Parameters**
- k: [in] The key for the entry which should be retrieved from the cache.
- val: [out] If the entry indexed by the key is found in the cache this value on successful return will be a copy of the corresponding entry.

bool get_entry (key_type const &k, value_type &val)
Get a specific entry identified by the given key.

**Note** The function will call the entry’s entry::touch function if the value corresponding to the provided is found in the cache.

**Return** This function returns true if the cache holds the referenced entry, otherwise it returns false.

**Parameters**
- k: [in] The key for the entry which should be retrieved from the cache.
- val: [out] If the entry indexed by the key is found in the cache this value on successful return will be a copy of the corresponding value.

bool insert (key_type const &k, value_type const &val)
Insert a new element into this cache.

**Note** This function invokes both, the insert policy as provided to the constructor and the function entry::insert of the newly constructed entry instance. If either of these functions returns false the key/value pair doesn’t get inserted into the cache and the insert function will return false. Other reasons for this function to fail (return false) are a) the key/value pair is already held in the cache or b) inserting the new value into the cache maxed out its capacity and it was not possible to free any of the existing entries.

**Return** This function returns true if the entry has been successfully added to the cache, otherwise it returns false.

**Parameters**
- k: [in] The key for the entry which should be added to the cache.
- value: [in] The value which should be added to the cache.

bool insert (key_type const &k, entry_type &e)
Insert a new entry into this cache.
**Note** This function invokes both, the insert policy as provided to the constructor and the function `entry::insert` of the provided entry instance. If either of these functions returns false the key/value pair doesn’t get inserted into the cache and the `insert` function will return `false`. Other reasons for this function to fail (return `false`) are a) the key/value pair is already held in the cache or b) inserting the new value into the cache maxed out its capacity and it was not possible to free any of the existing entries.

**Return** This function returns `true` if the entry has been successfully added to the cache, otherwise it returns `false`.

**Parameters**
- `k`: [in] The key for the entry which should be added to the cache.
- `value`: [in] The entry which should be added to the cache.

```cpp
bool update(key_type const &k, value_type const &val)
```
Update an existing element in this cache.

**Note** The function will call the entry’s `entry::touch` function if the indexed value is found in the cache.

**Note** The difference to the other overload of the `insert` function is that this overload replaces the cached value only, while the other overload replaces the whole cache entry, updating the cache entry properties.

**Return** This function returns `true` if the entry has been successfully updated, otherwise it returns `false`. If the entry currently is not held by the cache it is added and the return value reflects the outcome of the corresponding insert operation.

**Parameters**
- `k`: [in] The key for the value which should be updated in the cache.
- `value`: [in] The value which should be used as a replacement for the existing value in the cache. Any existing cache entry is not changed except for its value.

```cpp
template<typename F>
bool update_if(key_type const &k, value_type const &val, F f)
```
Update an existing element in this cache.

**Note** The function will call the entry’s `entry::touch` function if the indexed value is found in the cache.

**Note** The difference to the other overload of the `insert` function is that this overload replaces the cached value only, while the other overload replaces the whole cache entry, updating the cache entry properties.

**Return** This function returns `true` if the entry has been successfully updated, otherwise it returns `false`. If the entry currently is not held by the cache it is added and the return value reflects the outcome of the corresponding insert operation.

**Parameters**
- `k`: [in] The key for the value which should be updated in the cache.
- `value`: [in] The value which should be used as a replacement for the existing value in the cache. Any existing cache entry is not changed except for its value.
- `f`: [in] A callable taking two arguments, `k` and the key found in the cache (in that order). If `f` returns true, then the update will continue. If `f` returns false, then the update will not succeed.

```cpp
bool update(key_type const &k, entry_type &e)
```
Update an existing entry in this cache.
**Note** The function will call the entry’s `entry::touch` function if the indexed value is found in the cache.

**Note** The difference to the other overload of the `insert` function is that this overload replaces the whole cache entry, while the other overload replaces the cached value only, leaving the cache entry properties untouched.

**Return** This function returns `true` if the entry has been successfully updated, otherwise it returns `false`. If the entry currently is not held by the cache it is added and the return value reflects the outcome of the corresponding insert operation.

**Parameters**
- `k`: [in] The key for the entry which should be updated in the cache.
- `value`: [in] The entry which should be used as a replacement for the existing entry in the cache. Any existing entry is first removed and then this entry is added.

```cpp
template<typename Func>
size_type erase(Func const &ep = policies::always<storage_value_type>())
```

Remove stored entries from the cache for which the supplied function object returns true.

**Return** This function returns the overall size of the removed entries (which is the sum of the values returned by the `entry::get_size` functions of the removed entries).

**Parameters**
- `ep`: [in] This parameter has to be a (unary) function object. It is invoked for each of the entries currently held in the cache. An entry is considered for removal from the cache whenever the value returned from this invocation is `true`. Even then the entry might not be removed from the cache as its `entry::remove` function might return `false`.

```cpp
size_type erase()
```

Remove all stored entries from the cache.

**Note** All entries are considered for removal, but in the end an entry might not be removed from the cache as its `entry::remove` function might return false. This function is very useful for instance in conjunction with an entry’s `entry::remove` function enforcing additional criteria like entry expiration, etc.

**Return** This function returns the overall size of the removed entries (which is the sum of the values returned by the `entry::get_size` functions of the removed entries).

```cpp
void clear()
```

Clear the cache.

Unconditionally removes all stored entries from the cache.

```cpp
statistics_type const &get_statistics() const
```

Allow to access the embedded statistics instance.

**Return** This function returns a reference to the statistics instance embedded inside this cache.

namespace hpx

namespace util

namespace cache
template<typename Key, typename Entry, typename Statistics = statistics::no_statistics>
class lru_cache
#include <hpx/cache/lru_cache.hpp> The lru_cache implements the basic functionality needed for a local (non-distributed) LRU cache.

Template Parameters
- **Key**: The type of the keys to use to identify the entries stored in the cache
- **Entry**: The type of the items to be held in the cache.
- **Statistics**: A (optional) type allowing to collect some basic statistics about the operation of the cache instance. The type must conform to the CacheStatistics concept. The default value is the type statistics::no_statistics which does not collect any numbers, but provides empty stubs allowing the code to compile.

Public Types
- **typedef Key key_type**
- **typedef Entry entry_type**
- **typedef Statistics statistics_type**
- **typedef std::pair<Key, entry_type> entry_pair**
- **typedef std::list<entry_pair> storage_type**
- **typedef std::map<Key, typename storage_type::iterator> map_type**
- **typedef std::size_t size_type**

Public Functions

lru_cache(size_type max_size = 0)
Construct an instance of a lru_cache.

Parameters
- **max_size**: [in] The maximal size this cache is allowed to reach any time. The default is zero (no size limitation). The unit of this value is usually determined by the unit of the values returned by the entry’s get_size function.

lru_cache(lru_cache &&other)

size_type size() const
Return current size of the cache.

Return The current size of this cache instance.

size_type capacity() const
Access the maximum size the cache is allowed to grow to.

Note The unit of this value is usually determined by the unit of the return values of the entry’s function entry::get_size.

Return The maximum size this cache instance is currently allowed to reach. If this number is zero the cache has no limitation with regard to a maximum size.
void reserve(size_type max_size)

Change the maximum size this cache can grow to.

Parameters

• max_size: [in] The new maximum size this cache will be allowed to grow to.

bool holds_key(key_type const &key)

Check whether the cache currently holds an entry identified by the given key.

Note This function does not call the entry’s function entry::touch. It just checks if the cache contains an entry corresponding to the given key.

Return This function returns true if the cache holds the referenced entry, otherwise it returns false.

Parameters

• k: [in] The key for the entry which should be looked up in the cache.

bool get_entry(key_type const &key, key_type &realkey, entry_type &entry)

Get a specific entry identified by the given key.

Note The function will “touch” the entry and mark it as recently used if the key was found in the cache.

Return This function returns true if the cache holds the referenced entry, otherwise it returns false.

Parameters

• key: [in] The key for the entry which should be retrieved from the cache.
• entry: [out] If the entry indexed by the key is found in the cache this value on successful return will be a copy of the corresponding entry.

bool get_entry(key_type const &key, entry_type &entry)

Get a specific entry identified by the given key.

Note The function will “touch” the entry and mark it as recently used if the key was found in the cache.

Return This function returns true if the cache holds the referenced entry, otherwise it returns false.

Parameters

• key: [in] The key for the entry which should be retrieved from the cache.
• entry: [out] If the entry indexed by the key is found in the cache this value on successful return will be a copy of the corresponding entry.

bool insert(key_type const &key, entry_type const &entry)

Insert a new entry into this cache.

Note This function assumes that the entry is not in the cache already. Inserting an already existing entry is considered undefined behavior.

Parameters

• key: [in] The key for the entry which should be added to the cache.
• entry: [in] The entry which should be added to the cache.

void insert_nonexist(key_type const &key, entry_type const &entry)

void update(key_type const &key, entry_type const &entry)

Update an existing element in this cache.
**Note** The function will “touch” the entry and mark it as recently used if the key was found in the cache.

**Note** The difference to the other overload of the *insert* function is that this overload replaces the cached value only, while the other overload replaces the whole cache entry, updating the cache entry properties.

**Parameters**
- **key**: [in] The key for the value which should be updated in the cache.
- **entry**: [in] The entry which should be used as a replacement for the existing value in the cache. Any existing cache entry is not changed except for its value.

```cpp
template<typename F>
bool update_if (key_type const &key, entry_type const &entry, F &&f)
```

Update an existing element in this cache.

**Note** The function will “touch” the entry and mark it as recently used if the key was found in the cache.

**Note** The difference to the other overload of the *insert* function is that this overload replaces the cached value only, while the other overload replaces the whole cache entry, updating the cache entry properties.

**Return** This function returns true if the entry has been successfully updated, otherwise it returns false. If the entry currently is not held by the cache it is added and the return value reflects the outcome of the corresponding insert operation.

**Parameters**
- **key**: [in] The key for the value which should be updated in the cache.
- **entry**: [in] The value which should be used as a replacement for the existing value in the cache. Any existing cache entry is not changed except for its value.
- **f**: [in] A callable taking two arguments, *k* and the key found in the cache (in that order). If *f* returns true, then the update will continue. If *f* returns false, then the update will not succeed.

```cpp
template<typename Func>
size_type erase (Func const &ep)
```

Remove stored entries from the cache for which the supplied function object returns true.

**Return** This function returns the overall size of the removed entries (which is the sum of the values returned by the *entry::get_size* functions of the removed entries).

**Parameters**
- **ep**: [in] This parameter has to be a (unary) function object. It is invoked for each of the entries currently held in the cache. An entry is considered for removal from the cache whenever the value returned from this invocation is true.

```cpp
size_type erase ()
```

Remove all stored entries from the cache.

**Return** This function returns the overall size of the removed entries (which is the sum of the values returned by the *entry::get_size* functions of the removed entries).

```cpp
size_type clear ()
```

Clear the cache.

Unconditionally removes all stored entries from the cache.

```cpp
statistics_type const &get_statistics () const
```

Allow to access the embedded statistics instance.
Return This function returns a reference to the statistics instance embedded inside this cache

namespace \text{cache}

namespace \text{entries}

class entry

#include <hpx/cache/entries/entry.hpp>

Template Parameters

- \text{Value}: The data type to be stored in a cache. It has to be default constructible, copy constructible and less_than_comparable.
- \text{Derived}: The (optional) type for which this type is used as a base class.
Public Types

typedef Value value_type

Public Functions

entry ()
Any cache entry has to be default constructible.

entry (value_type const &val)
Construct a new instance of a cache entry holding the given value.

bool touch ()
The function touch is called by a cache holding this instance whenever it has been requested (touched).

Note It is possible to change the entry in a way influencing the sort criteria mandated by the UpdatePolicy. In this case the function should return true to indicate this to the cache, forcing to reorder the cache entries.
Note This function is part of the CacheEntry concept
Return This function should return true if the cache needs to update it’s internal heap. Usually this is needed if the entry has been changed by touch() in a way influencing the sort order as mandated by the cache’s UpdatePolicy

bool insert ()
The function insert is called by a cache whenever it is about to be inserted into the cache.

Note This function is part of the CacheEntry concept
Return This function should return true if the entry should be added to the cache, otherwise it should return false.

bool remove ()
The function remove is called by a cache holding this instance whenever it is about to be removed from the cache.

Note This function is part of the CacheEntry concept
Return The return value can be used to avoid removing this instance from the cache. If the value is true it is ok to remove the entry, other wise it will stay in the cache.

std::size_t get_size () const
Return the ‘size’ of this entry. By default the size of each entry is just one (1), which is sensible if the cache has a limit (capacity) measured in number of entries.

value_type &get ()
Get a reference to the stored data value.

Note This function is part of the CacheEntry concept

value_type const &get () const
Private Members

value_type value_

Friends

bool operator< (entry const &lhs, entry const &rhs)
Forwarding operator< allowing to compare entries instead of the values.

namespace hpx

namespace util

namespace entries

template<typename Value>
class fifo_entry: public hpx::util::cache::entries::entry<Value, fifo_entry<Value>>
#include <hpx/cache/entries/fifo_entry.hpp> The fifo_entry type can be used to store arbitrary values in a cache. Using this type as the cache’s entry type makes sure that the least recently inserted entries are discarded from the cache first.

Note The fifo_entry conforms to the CacheEntry concept.
Note This type can be used to model a ‘last in first out’ cache policy if it is used with a std::greater as the caches’ UpdatePolicy (instead of the default std::less).

Template Parameters
  • Value: The data type to be stored in a cache. It has to be default constructible, copy constructible and less_than_comparable.

Public Functions

fifo_entry ()
Any cache entry has to be default constructible.

fifo_entry (Value const &val)
Construct a new instance of a cache entry holding the given value.

bool insert ()
The function insert is called by a cache whenever it is about to be inserted into the cache.

Note This function is part of the CacheEntry concept
Return This function should return true if the entry should be added to the cache, otherwise it should return false.

std::chrono::steady_clock::time_point const &get_creation_time () const

namespace cache

namespace entries

template<typename Value>
class lfu_entry : public hpx::util::cache::entries::entry<Value, lfu_entry<Value>>

#include <hpx/cache/entries/lfu_entry.hpp>
The lfu_entry type can be used to store arbitrary values in a cache. Using this type as the cache’s entry type makes sure that the least frequently used entries are discarded from the cache first.

Note The lfu_entry conforms to the CacheEntry concept.

Note This type can be used to model a ‘most frequently used’ cache policy if it is used with a std::greater as the caches’ UpdatePolicy (instead of the default std::less).

Template Parameters

- **Value**: The data type to be stored in a cache. It has to be default constructible, copy constructible and less_than_comparable.

Public Functions

```cpp
lfu_entry ()

Any cache entry has to be default constructible.
```

```cpp
lfu_entry (Value const &val)

Construct a new instance of a cache entry holding the given value.
```

```cpp
bool touch ()

The function touch is called by a cache holding this instance whenever it has been requested (touched).

In the case of the LFU entry we store the reference count tracking the number of times this entry has been requested. This which will be used to compare the age of an entry during the invocation of the operator<().
```
Return This function should return true if the cache needs to update its internal heap. Usually this is needed if the entry has been changed by touch() in a way influencing the sort order as mandated by the cache’s UpdatePolicy.

namespace cache

namespace entries

template<typename Value>
class lru_entry : public hpx::util::cache::entries::entry<Value, lru_entry<Value>>
#include <hpx/cache/entries/lru_entry.hpp> The lru_entry type can be used to store arbitrary values in a cache. Using this type as the cache’s entry type makes sure that the least recently used entries are discarded from the cache first.

Note The lru_entry conforms to the CacheEntry concept.

Note This type can be used to model a ‘most recently used’ cache policy if it is used with a std::greater as the caches’ UpdatePolicy (instead of the default std::less).

Template Parameters

• Value: The data type to be stored in a cache. It has to be default constructible, copy constructible and less_than_comparable.
Public Functions

**lru_entry()**
Any cache entry has to be default constructible.

**lru_entry(Value const &val)**
Construct a new instance of a cache entry holding the given value.

**bool touch()**
The function *touch* is called by a cache holding this instance whenever it has been requested (touched).

In the case of the LRU entry we store the time of the last access which will be used to compare the age of an entry during the invocation of the *operator<()*.

**Return** This function should return true if the cache needs to update its internal heap. Usually this is needed if the entry has been changed by *touch()* in a way influencing the sort order as mandated by the cache’s UpdatePolicy.

**std::chrono::steady_clock::time_point const &get_access_time() const**
Returns the last access time of the entry.

Private Types

Private Members

**std::chrono::steady_clock::time_point access_time_**

Friends

**bool operator< (lru_entry const &lhs, lru_entry const &rhs)**
Compare the ‘age’ of two entries. An entry is ‘older’ than another entry if it has been accessed less recently (LRU).

namespace hpx

namespace util

namespace cache

namespace entries

**class size_entry**
#include <hpx/cache/entries/size_entry.hpp> The size_entry type can be used to store values in a cache which have a size associated (such as files, etc.). Using this type as the cache’s entry type makes sure that the entries with the biggest size are discarded from the cache first.
Note The size_entry conforms to the CacheEntry concept.
Note This type can be used to model a ‘discard smallest first’ cache policy if it is used with a std::greater as the caches’ UpdatePolicy (instead of the default std::less).

Template Parameters
- **Value**: The data type to be stored in a cache. It has to be default constructible, copy constructible and less_than_comparable.
- **Derived**: The (optional) type for which this type is used as a base class.

Public Functions

size_entry()
   Any cache entry has to be default constructible.

size_entry (Value const &val, std::size_t size)
   Construct a new instance of a cache entry holding the given value.

std::size_t get_size () const
   Return the 'size' of this entry.

Private Types

typedef detail::size-derived<Value, Derived>::type derived_type

typedef entry<Value, derived_type> base_type

Private Members

std::size_t size_

Friends

bool operator< (size_entry const &lhs, size_entry const &rhs)
   Compare the ‘age’ of two entries. An entry is ‘older’ than another entry if it has a bigger size.
Public Functions

bool operator() (Entry const&)

namespace hpx

namespace util

namespace cache

namespace statistics

class local_full_statistics : public hpx::util::cache::statistics::local_statistics

Public Functions

std::int64_t get_get_entry_count (bool reset)
    The function get_get_entry_count returns the number of invocations of the get_entry() API function of the cache.

std::int64_t get_insert_entry_count (bool reset)
    The function get_insert_entry_count returns the number of invocations of the insert_entry() API function of the cache.

std::int64_t get_update_entry_count (bool reset)
    The function get_update_entry_count returns the number of invocations of the update_entry() API function of the cache.

std::int64_t get_erase_entry_count (bool reset)
    The function get_erase_entry_count returns the number of invocations of the erase() API function of the cache.

std::int64_t get_get_entry_time (bool reset)
    The function get_get_entry_time returns the overall time spent executing of the get_entry() API function of the cache.

std::int64_t get_insert_entry_time (bool reset)
    The function get_insert_entry_time returns the overall time spent executing of the insert_entry() API function of the cache.

std::int64_t get_update_entry_time (bool reset)
    The function get_update_entry_time returns the overall time spent executing of the update_entry() API function of the cache.

std::int64_t get_erase_entry_time (bool reset)
    The function get_erase_entry_time returns the overall time spent executing of the erase() API function of the cache.

    The function get_erase_entry_time returns the overall time spent executing of the erase() API function of the cache.

struct update_on_exit
    #include <no_statistics.hpp> Helper class to update timings and counts on function exit.

Public Functions

update_on_exit (no_statistics const&, method)

concepts

The contents of this module can be included with the header hpx/modules/concepts.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/concepts.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.
Defines

HPX_CONCEPT_REQUIRES_(...)  
HPX_CONCEPT_REQUIRES(...)  
HPX_CONCEPT_ASSERT(...)  

Defines

HPX_HAS_MEMBER_XXX_TRAIT_DEF (MEMBER)  
This macro creates a boolean unary metafunction which result is true if and only if its parameter type has member function with MEMBER name (no matter static it is or not). The generated trait ends up in a namespace where the macro itself has been placed.

Defines

HPX_HAS_XXX_TRAIT_DEF (Name)  
This macro creates a boolean unary metafunction such that for any type X, has_name<X>::value == true if and only if X is a class type and has a nested type member x::name. The generated trait ends up in a namespace where the macro itself has been placed.

concurrency

The contents of this module can be included with the header hpx/modules/concurrency.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/concurrency.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

\textbf{config}

The contents of this module can be included with the header \texttt{hpx/modules/config.hpp}. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we \textit{strongly} suggest only including the module header \texttt{hpx/modules/config.hpp}, not the particular header in which the functionality you would like to use is defined. See \textit{Public API} for a list of names that are part of the public \textit{HPX} API.

\textit{Defines}

\textbf{HPX\_INITIAL\_IP\_PORT}
This is the default ip/port number used by the parcel subsystem.

\textbf{HPX\_CONNECTING\_IP\_PORT}

\textbf{HPX\_INITIAL\_IP\_ADDRESS}

\textbf{HPX\_RUNTIME\_INSTANCE\_LIMIT}
This defines the maximum number of possible runtime instances in one executable

\textbf{HPX\_PARCEL\_BOOTSTRAP}
This defines the type of the parcelport to be used during application bootstrap. This value can be changed at runtime by the configuration parameter:

\texttt{hpx.parcel.bootstrap = \ldots}

(or by setting the corresponding environment variable \texttt{HPX\_PARCEL\_BOOTSTRAP}).

\textbf{HPX\_PARCEL\_MAX\_CONNECTIONS}
This defines the number of outgoing (parcel-) connections kept alive (to all other localities). This value can be changed at runtime by setting the configuration parameter:

\texttt{hpx.parcel.max_connections = \ldots}

(or by setting the corresponding environment variable \texttt{HPX\_PARCEL\_MAX\_CONNECTIONS}).
HPX_PARCEL_IPC_DATA_BUFFER_CACHE_SIZE
This defines the number of outgoing ipc (parcel-) connections kept alive (to each of the other localities on the same node). This value can be changed at runtime by setting the configuration parameter:

`hpx.parcel.ipc.data_buffer_cache_size = ...`
(or by setting the corresponding environment variable `HPX_PARCEL_IPC_DATA_BUFFER_CACHE_SIZE`).

HPX_PARCEL_MPI_MAX_REQUESTS
This defines the number of MPI requests in flight. This value can be changed at runtime by setting the configuration parameter:

`hpx.parcel.mpi.max_requests = ...`
(or by setting the corresponding environment variable `HPX_PARCEL_MPI_MAX_REQUESTS`).

HPX_PARCEL_MAX_CONNECTIONS_PER_LOCALITY
This defines the number of outgoing ( parcel- ) connections kept alive (to each of the other localities). This value can be changed at runtime by setting the configuration parameter:

`hpx.parcel.max_connections_per_locality = ...`
(or by setting the corresponding environment variable `HPX_PARCEL_MAX_CONNECTIONS_PER_LOCALITY`).

HPX_PARCEL_MAX_MESSAGE_SIZE
This defines the maximally allowed message size for messages transferred between localities. This value can be changed at runtime by setting the configuration parameter:

`hpx.parcel.max_message_size = ...`
(or by setting the corresponding environment variable `HPX_PARCEL_MAX_MESSAGE_SIZE`).

HPX_PARCEL_MAX_OUTBOUND_MESSAGE_SIZE
This defines the maximally allowed outbound message size for coalescing messages transferred between localities. This value can be changed at runtime by setting the configuration parameter:

`hpx.parcel.max_outbound_message_size = ...`
(or by setting the corresponding environment variable `HPX_PARCEL_MAX_OUTBOUND_MESSAGE_SIZE`).

HPX_PARCEL.Serialization_OVERHEAD
HPX_AGAS_LOCAL_CACHE_SIZE
This defines the number of AGAS address translations kept in the local cache. This is just the initial size which may be adjusted depending on the load of the system (not implemented yet), etc. It must be a minimum of 3 for AGAS v3 bootstrapping.

This value can be changed at runtime by setting the configuration parameter:

`hpx.agas.local_cache_size = ...`
(or by setting the corresponding environment variable `HPX_AGAS_LOCAL_CACHE_SIZE`).

HPX_INITIAL_AGAS_MAX_PENDING_REFCNT_REQUESTS
HPX_GLOBALCREDIT_INITIAL
This defines the initial global reference count associated with any created object.

HPX_NUM_IO_POOL_SIZE
This defines the default number of OS-threads created for the different internal thread pools.

HPX_NUM_PARCEL_POOL_SIZE
HPX_NUM_TIMER_POOL_SIZE

2.8. API reference
HPX_SPINLOCK_DEADLOCK_DETECTION_LIMIT
By default, enable minimal thread deadlock detection in debug builds only.

HPX_COROUTINE_NUM_HEAPS
This defines the default number of coroutine heaps.

HPX_HAVE_THREAD_BACKTRACE_DEPTH
By default, enable storing the thread phase in debug builds only.
By default, enable storing the parent thread information in debug builds only. By default, enable storing the thread description in debug builds only. By default, enable storing the target address of the data the thread is accessing in debug builds only. By default we do not maintain stack back-traces on suspension. This is a pure debugging aid to be able to see in the debugger where a suspended thread got stuck. By default we capture only 20 levels of stack back trace on suspension.

HPX_MAX_NETWORK_RETRIES
HPX_NETWORK_RETRIES_SLEEP

Defines

HPX_NOINLINE
Function attribute to tell compiler not to inline the function.

HPX_NORETURN
Function attribute to tell compiler that the function does not return.

HPX_DEPRECATED (x)
Marks an entity as deprecated. The argument x specifies a custom message that is included in the compiler warning. For more details see <>__.

HPX_FALLTHROUGH
Indicates that the fall through from the previous case label is intentional and should not be diagnosed by a compiler that warns on fallthrough. For more details see <>__.

HPX_NODISCARD
If a function declared nodiscard or a function returning an enumeration or class declared nodiscard by value is called from a discarded-value expression other than a cast to void, the compiler is encouraged to issue a warning. For more details see __.

HPX_NO_UNIQUE_ADDRESS
Indicates that this data member need not have an address distinct from all other non-static data members of its class. For more details see __.

Defines

HPX_LIKELY (expr)
Hint at the compiler that expr is likely to be true.

HPX_UNLIKELY (expr)
Hint at the compiler that expr is likely to be false.

Defines

HPX_COMPILER_FENCE
Generates assembly that serves as a fence to the compiler CPU to disable optimization. Usually implemented in the form of a memory barrier.

HPX_SMT_PAUSE
Generates assembly the executes a “pause” instruction. Useful in spinning loops.
Defines

**HPX_NATIVE_TLS**
This macro is replaced with the compiler specific keyword attribute to mark a variable as thread local. For more details see <__>. This macro is deprecated. It is always replaced with the `thread_local` keyword. Prefer using `thread_local` directly instead.

Defines

**HPX_GCC_VERSION**
Returns the GCC version HPX is compiled with. Only set if compiled with GCC.

**HPX_CLANG_VERSION**
Returns the Clang version HPX is compiled with. Only set if compiled with Clang.

**HPX_INTEL_VERSION**
Returns the Intel Compiler version HPX is compiled with. Only set if compiled with the Intel Compiler.

**HPX_MSVC**
This macro is set if the compilation is with MSVC.

**HPX_MINGW**
This macro is set if the compilation is with Mingw.

**HPX_WINDOWS**
This macro is set if the compilation is for Windows.

**HPX_NATIVE_MIC**
This macro is set if the compilation is for Intel Knights Landing.

Defines

**HPX_CONSTEXPR**
This macro evaluates to `constexpr` if the compiler supports it. This macro is deprecated. It is always replaced with the `constexpr` keyword. Prefer using `constexpr` directly instead.

**HPX_CONSTEXPR_OR_CONST**
This macro evaluates to `constexpr` if the compiler supports it, `const` otherwise. This macro is deprecated. It is always replaced with the `constexpr` keyword. Prefer using `constexpr` directly instead.

**HPX_INLINE_CONSTEXPR_VARIABLE**
This macro evaluates to `inline constexpr` if the compiler supports it, `constexpr` otherwise.

**HPX_STATIC_CONSTEXPR**
This macro evaluates to `static constexpr` if the compiler supports it, `static const` otherwise. This macro is deprecated. It is always replaced with the `static constexpr` keyword. Prefer using `static constexpr` directly instead.
Defines

**HPX_DEBUG**
Defined if HPX is compiled in debug mode.

**HPX_BUILD_TYPE**
Evaluates to debug if compiled in debug mode, release otherwise.

Defines

**HPX_HAVE_DEPRECATED_WARNINGS_V1_4**
**HPX_DEPRECATED_V1_4** *(x)*

**HPX_HAVE_DEPRECATED_WARNINGS_V1_5**
**HPX_DEPRECATED_V1_5** *(x)*

**HPX_HAVE_DEPRECATED_WARNINGS_V1_6**
**HPX_DEPRECATED_V1_6** *(x)*

**HPX_HAVE_DEPRECATED_WARNINGS_V1_7**
**HPX_DEPRECATED_V1_7** *(x)*

**HPX_DEPRECATED_V** *(major, minor, x)*

Defines

**HPX_NON_COPYABLE**(cls)
Marks a class as non-copyable and non-movable.

Defines

**HPX_EXPORT**
Marks a class or function to be exported from HPX or imported if it is consumed.

Defines

**HPX_FORCEINLINE**
Marks a function to be forced inline.

Defines

**HPX_CAPTURE_FORWARD**(var)
Evaluates to \( \text{var} = \text{std::forward<decltype}(\text{var})>(\text{var}) \) if the compiler supports C++14 Lambdas. Defaults to \( \text{var} \).
This macro is deprecated. Prefer using \( \text{var} = \text{std::forward<decltype((\text{var})>}(\text{var}) \) directly instead.

**HPX_CAPTURE_MOVE**(var)
Evaluates to \( \text{var} = \text{std::move}(\text{var}) \) if the compiler supports C++14 Lambdas. Defaults to \( \text{var} \).
This macro is deprecated. Prefer using \( \text{var} = \text{std::move}(\text{var}) \) directly instead.

HPX_THREAD_STACKSIZE_UNSCOPED_ENUM_DEPRECATED_MSG
HPX_THREAD_SCHEDULE_HINT_UNSCOPED_ENUM_DEPRECATED_MSG
```

namespace hpx

```cpp
namespace threads
```

 Enums

```cpp
enum thread_schedule_state
  The thread_schedule_state enumerator encodes the current state of a thread instance
  Values:
  unknown = 0
  active = 1
    thread is currently active (running, has resources)
  pending = 2
    thread is pending (ready to run, but no hardware resource available)
  suspended = 3
    thread has been suspended (waiting for synchronization event, but still known and under control
    of the thread-manager)
```
depleted = 4
  thread has been depleted (deeply suspended, it is not known to the thread-manager)

terminated = 5
  thread has been stopped and may be garbage collected

staged = 6
  this is not a real thread state, but allows to reference staged task descriptions, which eventually
  will be converted into thread objects

pending_do_not_schedule = 7

pending_boost = 8

enum thread_priority
  This enumeration lists all possible thread-priorities for HPX threads.
  
  Values:

  unknown = -1
  default_ = 0
    Will assign the priority of the task to the default (normal) priority.

  low = 1
    Task goes onto a special low priority queue and will not be executed until all high/normal priority
    tasks are done, even if they are added after the low priority task.

  normal = 2
    Task will be executed when it is taken from the normal priority queue, this is usually a first in-
    first-out ordering of tasks (depending on scheduler choice). This is the default priority.

  high_recursive = 3
    The task is a high priority task and any child tasks spawned by this task will be made high priority
    as well - unless they are specifically flagged as non default priority.

  boost = 4
    Same as thread_priority_high except that the thread will fall back to thread_priority_normal if
    resumed after being suspended.

  high = 5
    Task goes onto a special high priority queue and will be executed before normal/low priority tasks
    are taken (some schedulers modify the behavior slightly and the documentation for those should
    be consulted).

  bound = 6
    Task goes onto a special high priority queue and will never be stolen by another thread after initial
    assignment. This should be used for thread placement tasks such as OpenMP type for loops.

enum thread_restart_state
  The thread_restart_state enumerator encodes the reason why a thread is being restarted
  
  Values:

  unknown = 0

  signaled = 1
    The thread has been signaled.

  timeout = 2
    The thread has been reactivated after a timeout

  terminate = 3
    The thread needs to be terminated.
abort = 4
   The thread needs to be aborted.

enum thread_stacksize
   A thread_stacksize references any of the possible stack-sizes for HPX threads.
   Values:
   unknown = -1
   small_ = 1
      use small stack size (the underscore is to work around small being defined to char on Windows)
   medium = 2
      use medium sized stack size
   large = 3
      use large stack size
   huge = 4
      use very large stack size
   nostack = 5
      this thread does not suspend (does not need a stack)
   current = 6
      use size of current thread’s stack
   default_ = small_
      use default stack size
   minimal = small_
      use minimally stack size
   maximal = huge
      use maximally stack size

enum thread_schedule_hint_mode
   The type of hint given when creating new tasks.
   Values:
   none = 0
      A hint that leaves the choice of scheduling entirely up to the scheduler.
   thread = 1
      A hint that tells the scheduler to prefer scheduling a task on the local thread number associated with this hint. Local thread numbers are indexed from zero. It is up to the scheduler to decide how to interpret thread numbers that are larger than the number of threads available to the scheduler. Typically thread numbers will wrap around when too large.
   numa = 2
      A hint that tells the scheduler to prefer scheduling a task on the NUMA domain associated with this hint. NUMA domains are indexed from zero. It is up to the scheduler to decide how to interpret NUMA domain indices that are larger than the number of available NUMA domains to the scheduler. Typically indices will wrap around when too large.
Functions

```cpp
std::ostream &operator<<(std::ostream &os, thread_schedule_state const t)
```

`char const *get_thread_state_name(thread_schedule_state state)`

Get the readable string representing the name of the given thread_state constant.

**Parameters**
- `state`: this represents the thread state.

```cpp
std::ostream &operator<<(std::ostream &os, thread_priority const t)
```

`char const *get_thread_priority_name(thread_priority priority)`

Get the readable string representing the name of the given thread_priority constant.

**Parameters**
- `this`: represents the thread priority.

```cpp
std::ostream &operator<<(std::ostream &os, thread_restart_state const t)
```

`char const *get_thread_state_ex_name(thread_restart_state state)`

Get the readable string representing the name of the given thread_restart_state constant.

```cpp
std::ostream &operator<<(std::ostream &os, thread_stacksize const t)
```

`char const *get_stack_size_enum_name(thread_stacksize size)`

Returns the stack size name.

**Parameters**
- `size`: this represents the stack size

```cpp```

struct thread_schedule_hint
#include <thread_enums.hpp> A hint given to a scheduler to guide where a task should be scheduled.
A scheduler is free to ignore the hint, or modify the hint to suit the resources available to the scheduler.

Public Functions

constexpr thread_schedule_hint ()
Construct a default hint with mode thread_schedule_hint_mode::none.

constexpr thread_schedule_hint (std::int16_t thread_hint)
Construct a hint with mode thread_schedule_hint_mode::thread and the given hint as the local thread number.
constexpr thread_schedule_hint (thread_schedule_hint_mode mode, std::int16_t hint)

Construct a hint with the given mode and hint. The numerical hint is unused when the mode is thread_schedule_hint_mode::none.

Public Members

thread_schedule_hint_mode mode
The mode of the scheduling hint.

std::int16_t hint
The hint associated with the mode. The interpretation of this hint depends on the given mode.

datastructures

The contents of this module can be included with the header hpx/modules/datastructures.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/datastructures.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

debugging

The contents of this module can be included with the header `hpx/modules/debugging.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/debugging.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

```cpp
namespace hpx

namespace util

Functions

void attach_debugger()
    Tries to break an attached debugger, if not supported a loop is invoked which gives enough time to attach a debugger manually.

errors

The contents of this module can be included with the header hpx/modules/errors.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/errors.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

namespace hpx

Enums

enum error

Possible error conditions.

This enumeration lists all possible error conditions which can be reported from any of the API functions.

Values:

success = 0
  The operation was successful.

no_success = 1
  The operation did failed, but not in an unexpected manner.

not_implemented = 2
  The operation is not implemented.

out_of_memory = 3
  The operation caused an out of memory condition.

bad_action_code = 4

bad_component_type = 5
  The specified component type is not known or otherwise invalid.

network_error = 6
  A generic network error occurred.

version_too_new = 7
  The version of the network representation for this object is too new.
version_too_old = 8
   The version of the network representation for this object is too old.

version_unknown = 9
   The version of the network representation for this object is unknown.

unknown_component_address = 10

duplicate_component_address = 11
   The given global id has already been registered.

invalid_status = 12
   The operation was executed in an invalid status.

bad_parameter = 13
   One of the supplied parameters is invalid.

internal_server_error = 14

service_unavailable = 15

bad_request = 16

repeated_request = 17

lock_error = 18

duplicate_console = 19
   There is more than one console locality.

no_registered_console = 20
   There is no registered console locality available.

startup_timed_out = 21

uninitialized_value = 22

bad_response_type = 23

deadlock = 24

assertion_failure = 25

null_thread_id = 26
   Attempt to invoke a API function from a non-HPX thread.

invalid_data = 27

yield_aborted = 28
   The yield operation was aborted.

dynamic_link_failure = 29

commandline_option_error = 30
   One of the options given on the command line is erroneous.

serialization_error = 31
   There was an error during serialization of this object.

unhandled_exception = 32
   An unhandled exception has been caught.

kernel_error = 33
   The OS kernel reported an error.

broken_task = 34
   The task associated with this future object is not available anymore.
The task associated with this future object has been moved.

The task associated with this future object has already been started.

The future object has already been retrieved.

The value for this future object has already been set.

The future object does not support cancellation.

The future can’t be canceled at this time.

The future object has no valid shared state.

The promise has been deleted.

The promise has been deleted.

The component type has already been registered.

An unknown error occurred.

The specified plugin type is not known or otherwise invalid.

The specified file does not exist or other filesystem related error.

The equivalent of std::bad_function_call.

The parallel::v2::task_canceled_exception.

The task region is not active.

Equivalent to std::out_of_range.

Equivalent to std::length_error.

migration failed because of global race, retry

namespace hpx
Unnamed Group

```cpp
error_code make_error_code (error e, throwmode mode = plain)
   Returns a new error_code constructed from the given parameters.
```

```cpp
error_code make_error_code (error e, char const *func, char const *file, long line, throwmode mode = plain)
error_code make_error_code (error e, char const *msg, throwmode mode = plain)
```

```cpp
error_code make_error_code (error e, char const *msg, char const *func, char const *file, long line, throwmode mode = plain)
error_code make_error_code (error e, std::string const &msg, throwmode mode = plain)
```

```cpp
error_code make_error_code (error e, std::string const &msg, char const *func, char const *file, long line, throwmode mode = plain)
```

```cpp
error_code make_error_code (std::exception_ptr const &e)
```

Functions

```cpp
std::error_category const &get_hpx_category ()
   Returns generic HPX error category used for new errors.
```

```cpp
std::error_category const &get_hpx_rethrow_category ()
   Returns generic HPX error category used for errors re-thrown after the exception has been de-serialized.
```

```cpp
error_code make_success_code (throwmode mode = plain)
   Returns error_code(hpx::success, "success", mode).
```

class error_code : public error_code
```
#include <error_code.hpp> A hpx::error_code represents an arbitrary error condition.
```

The class hpx::error_code describes an object used to hold error code values, such as those originating from the operating system or other low-level application program interfaces.

Note Class hpx::error_code is an adjunct to error reporting by exception

Public Functions

```cpp
error_code (throwmode mode = plain)
   Construct an object of type error_code.
```

Parameters
- mode: The parameter mode specifies whether the constructed hpx::error_code belongs to the error category hpx_category (if mode is plain, this is the default) or to the category hpx_category_rethrow (if mode is rethrow).

Exceptions
- nothing:
**error_code** (*error e, throwmode mode = plain*)

Construct an object of type *error_code*.

**Parameters**
- *e*: The parameter *e* holds the hpx::error code the new exception should encapsulate.
- *mode*: The parameter *mode* specifies whether the constructed hpx::error_code belongs to the error category *hpx_category* (if mode is *plain*, this is the default) or to the category *hpx_category_rethrow* (if mode is *rethrow*).

**Exceptions**
- nothing:

**error_code** (*error e, char const *func, char const *file, long line, throwmode mode = plain*)

Construct an object of type *error_code*.

**Parameters**
- *e*: The parameter *e* holds the hpx::error code the new exception should encapsulate.
- *func*: The name of the function where the error was raised.
- *file*: The file name of the code where the error was raised.
- *line*: The line number of the code line where the error was raised.
- *mode*: The parameter *mode* specifies whether the constructed hpx::error_code belongs to the error category *hpx_category* (if mode is *plain*, this is the default) or to the category *hpx_category_rethrow* (if mode is *rethrow*).

**Exceptions**
- nothing:

**error_code** (*error e, char const *msg, throwmode mode = plain*)

Construct an object of type *error_code*.

**Parameters**
- *e*: The parameter *e* holds the hpx::error code the new exception should encapsulate.
- *msg*: The parameter *msg* holds the error message the new exception should encapsulate.
- *mode*: The parameter *mode* specifies whether the constructed hpx::error_code belongs to the error category *hpx_category* (if mode is *plain*, this is the default) or to the category *hpx_category_rethrow* (if mode is *rethrow*).

**Exceptions**
- std::bad_alloc: (if allocation of a copy of the passed string fails).

**error_code** (*error e, char const *msg, char const *func, char const *file, long line, throwmode mode = plain*)

Construct an object of type *error_code*.

**Parameters**
- *e*: The parameter *e* holds the hpx::error code the new exception should encapsulate.
- *msg*: The parameter *msg* holds the error message the new exception should encapsulate.
- *func*: The name of the function where the error was raised.
- *file*: The file name of the code where the error was raised.
- *line*: The line number of the code line where the error was raised.
- *mode*: The parameter *mode* specifies whether the constructed hpx::error_code belongs to the error category *hpx_category* (if mode is *plain*, this is the default) or to the category *hpx_category_rethrow* (if mode is *rethrow*).

**Exceptions**
- std::bad_alloc: (if allocation of a copy of the passed string fails).
error_code (error e, std::string const &msg, throwmode mode = plain)
Construct an object of type error_code.

Parameters
- e: The parameter e holds the hpx::error code the new exception should encapsulate.
- msg: The parameter msg holds the error message the new exception should encapsulate.
- mode: The parameter mode specifies whether the constructed hpx::error_code belongs to the error category hpx_category (if mode is plain, this is the default) or to the category hpx_category_rethrow (if mode is rethrow).

Exceptions
- std::bad_alloc: (if allocation of a copy of the passed string fails).

error_code (error e, std::string const &msg, char const *func, char const *file, long line, throwmode mode = plain)
Construct an object of type error_code.

Parameters
- e: The parameter e holds the hpx::error code the new exception should encapsulate.
- msg: The parameter msg holds the error message the new exception should encapsulate.
- func: The name of the function where the error was raised.
- file: The file name of the code where the error was raised.
- line: The line number of the code line where the error was raised.
- mode: The parameter mode specifies whether the constructed hpx::error_code belongs to the error category hpx_category (if mode is plain, this is the default) or to the category hpx_category_rethrow (if mode is rethrow).

Exceptions
- std::bad_alloc: (if allocation of a copy of the passed string fails).

std::string get_message () const
Return a reference to the error message stored in the hpx::error_code.

Exceptions
- nothing: void clear ()
Clear this error_code object. The postconditions of invoking this method are.

- value() == hpx::success and category() == hpx::get_hpx_category()

error_code (error_code const &rhs)
Copy constructor for error_code

Note This function maintains the error category of the left hand side if the right hand side is a success code.

error_code &operator= (error_code const &rhs)
Assignment operator for error_code

Note This function maintains the error category of the left hand side if the right hand side is a success code.

Typedefs

\texttt{using custom\_exception\_info\_handler\_type} = std::function<hpx::exception\_info (std::string \texttt{const} \&\textit{msg}, std::string \texttt{const} \&\textit{file}, long, std::string \texttt{const} \&\textit{func})>

\texttt{using pre\_exception\_handler\_type} = std::function<void ()>

Functions

\texttt{void set\_custom\_exception\_info\_handler} (custom\_exception\_info\_handler\_type \texttt{f})

\texttt{void set\_pre\_exception\_handler} (pre\_exception\_handler\_type \texttt{f})

\texttt{std::string get\_error\_what} (exception\_info \texttt{const} \&\textit{xi})

Return The error message of the thrown exception.

The function \texttt{hpx::get\_error\_what} can be used to extract the diagnostic information element representing the error message as stored in the given exception instance.

Return The error message stored in the exception If the exception instance does not hold this information, the function will return an empty string.

See \texttt{hpx::diagnostic\_information()}, \texttt{hpx::get\_error\_host\_name()}, \texttt{hpx::get\_error\_process\_id()}, \texttt{hpx::get\_error\_function\_name()}, \texttt{hpx::get\_error\_file\_name()}, \texttt{hpx::get\_error\_line\_number()}, \texttt{hpx::get\_error\_os\_thread()}, \texttt{hpx::get\_error\_thread\_id()}, \texttt{hpx::get\_error\_thread\_description()}, \texttt{hpx::get\_error()}, \texttt{hpx::get\_error\_backtrace()}, \texttt{hpx::get\_error\_env()}, \texttt{hpx::get\_error\_config()}, \texttt{hpx::get\_error\_state()}

Parameters
• \texttt{xi}: The parameter \texttt{e} will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: \texttt{hpx::exception\_info}, \texttt{hpx::error\_code}, \texttt{std::exception}, or \texttt{std::exception\_ptr}.

**Exceptions**
• \texttt{std::bad\_alloc}: (if one of the required allocations fails)

\texttt{error get\_error (hpx::exception const &e)}

Return the error code value of the exception thrown.

The function \texttt{hpx::get\_error} can be used to extract the diagnostic information element representing the error value code as stored in the given exception instance.

\textbf{Return} The error value code of the locality where the exception was thrown. If the exception instance does not hold this information, the function will return \texttt{hpx::naming::invalid\_locality\_id}.

\textbf{See} \texttt{hpx::diagnostic\_information()}, \texttt{hpx::get\_error\_host\_name()}, \texttt{hpx::get\_error\_process\_id()}, \texttt{hpx::get\_error\_function\_name()}, \texttt{hpx::get\_error\_file\_name()}, \texttt{hpx::get\_error\_line\_number()}, \texttt{hpx::get\_error\_os\_thread()}, \texttt{hpx::get\_error\_thread\_id()}, \texttt{hpx::get\_error\_thread\_description()}, \texttt{hpx::get\_error\_backtrace()}, \texttt{hpx::get\_error\_env()}, \texttt{hpx::get\_error\_what()}, \texttt{hpx::get\_error\_config()}, \texttt{hpx::get\_error\_state()}

\textbf{Parameters}
• \texttt{e}: The parameter \texttt{e} will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: \texttt{hpx::exception}, \texttt{hpx::error\_code}, or \texttt{std::exception\_ptr}.

**Exceptions**
• nothing:

\texttt{error get\_error (hpx::error\_code const &e)}

\textbf{See} \texttt{hpx::diagnostic\_information()}, \texttt{hpx::get\_error\_host\_name()}, \texttt{hpx::get\_error\_process\_id()}, \texttt{hpx::get\_error\_function\_name()}, \texttt{hpx::get\_error\_file\_name()}, \texttt{hpx::get\_error\_line\_number()}, \texttt{hpx::get\_error\_os\_thread()}, \texttt{hpx::get\_error\_thread\_id()}, \texttt{hpx::get\_error\_thread\_description()}, \texttt{hpx::get\_error\_backtrace()}, \texttt{hpx::get\_error\_env()}, \texttt{hpx::get\_error\_what()}, \texttt{hpx::get\_error\_config()}, \texttt{hpx::get\_error\_state()}

\textbf{Parameters}
• \texttt{xi}: The parameter \texttt{e} will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: \texttt{hpx::exception\_info}, \texttt{hpx::error\_code}, \texttt{std::exception}, or \texttt{std::exception\_ptr}.

**Exceptions**
• \texttt{std::bad\_alloc}: (if one of the required allocations fails)
std::string get_error_file_name (hpx::exception_info const &xi)

Return the (source code) file name of the function from which the exception was thrown.

The function hpx::get_error_file_name can be used to extract the diagnostic information element representing the name of the source file as stored in the given exception instance.

Return The name of the source file of the function from which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

See hpx::diagnostic_information(), hpx::get_error_host_name(), hpx::get_error_process_id(), hpx::get_error_function_name(), hpx::get_error_line_number(), hpx::get_error_os_thread(), hpx::get_error_thread_id(), hpx::get_error_thread_description(), hpx::get_error_backtrace(), hpx::get_error_env(), hpx::get_error_what(), hpx::get_error_config(), hpx::get_error_state()

Parameters
• xi: The parameter e will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: hpx::exception_info, hpx::error_code, std::exception, or std::exception_ptr.

Exceptions
• std::bad_alloc: (if one of the required allocations fails)

long get_error_line_number (hpx::exception_info const &xi)

Return the line number in the (source code) file of the function from which the exception was thrown.

The function hpx::get_error_line_number can be used to extract the diagnostic information element representing the line number as stored in the given exception instance.

Return The line number of the place where the exception was thrown. If the exception instance does not hold this information, the function will return -1.

See hpx::diagnostic_information(), hpx::get_error_host_name(), hpx::get_error_process_id(), hpx::get_error_function_name(), hpx::get_error_line_number(), hpx::get_error_os_thread(), hpx::get_error_thread_id(), hpx::get_error_thread_description(), hpx::get_error_backtrace(), hpx::get_error_env(), hpx::get_error_what(), hpx::get_error_config(), hpx::get_error_state()

Parameters
• xi: The parameter e will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: hpx::exception_info, hpx::error_code, std::exception, or std::exception_ptr.

Exceptions
• nothing:

class exception : public system_error
#include <exception.hpp> A hpx::exception is the main exception type used by HPX to report errors.

The hpx::exception type is the main exception type used by HPX to report errors. Any exceptions thrown by functions in the HPX library are either of this type or of a type derived from it. This implies that it is always safe to use this type only in catch statements guarding HPX library calls.

Subclassed by hpx::exception_list
Public Functions

exception (error e = success)

Construct a `hpx::exception` from a `hpx::error`.

Parameters

• e: The parameter e holds the `hpx::error` code the new exception should encapsulate.

exception (std::system_error const &e)

Construct a `hpx::exception` from a `boost::system_error`.

exception (std::error_code const &e)

Construct a `hpx::exception` from a `boost::system::error_code` (this is new for Boost V1.69). This constructor is required to compensate for the changes introduced as a resolution to LWG3162 (https://cplusplus.github.io/LWG/issue3162).

exception (error e, char const *msg, throwmode mode = plain)

Construct a `hpx::exception` from a `hpx::error` and an error message.

Parameters

• e: The parameter e holds the `hpx::error` code the new exception should encapsulate.
• msg: The parameter msg holds the error message the new exception should encapsulate.
• mode: The parameter mode specifies whether the returned `hpx::error_code` belongs to the error category `hpx_category` (if mode is plain, this is the default) or to the category `hpx_category_rethrow` (if mode is rethrow).

exception (error e, std::string const &msg, throwmode mode = plain)

Construct a `hpx::exception` from a `hpx::error` and an error message.

Parameters

• e: The parameter e holds the `hpx::error` code the new exception should encapsulate.
• msg: The parameter msg holds the error message the new exception should encapsulate.
• mode: The parameter mode specifies whether the returned `hpx::error_code` belongs to the error category `hpx_category` (if mode is plain, this is the default) or to the category `hpx_category_rethrow` (if mode is rethrow).

~exception ()

Destruct a `hpx::exception`

Exceptions

• nothing:

error get_error () const

The function get_error() returns the `hpx::error` code stored in the referenced instance of a `hpx::exception`. It returns the `hpx::error` code this exception instance was constructed from.

Exceptions

• nothing:

error_code get_error_code (throwmode mode = plain) const

The function get_error_code() returns a `hpx::error_code` which represents the same error condition as this `hpx::exception` instance.
Parameters

• mode: The parameter mode specifies whether the returned `hpx::error_code` belongs to the error category `hpx_category` (if mode is `plain`, this is the default) or to the category `hpx_category_rethrow` (if mode is `rethrow`).

```plaintext
struct thread_interrupted: public exception

#include <exception.hpp> A hpx::thread_interrupted is the exception type used by HPX to interrupt a running HPX thread.

The hpx::thread_interrupted type is the exception type used by HPX to interrupt a running thread.

A running thread can be interrupted by invoking the interrupt() member function of the corresponding hpx::thread object. When the interrupted thread next executes one of the specified interruption points (or if it is currently blocked whilst executing one) with interruption enabled, then a hpx::thread_interrupted exception will be thrown in the interrupted thread. If not caught, this will cause the execution of the interrupted thread to terminate. As with any other exception, the stack will be unwound, and destructors for objects of automatic storage duration will be executed.

If a thread wishes to avoid being interrupted, it can create an instance of hpx::this_thread::disable_interruption. Objects of this class disable interruption for the thread that created them on construction, and restore the interruption state to whatever it was before on destruction.

```plaintext

```plaintext
void f()
{
    // interruption enabled here
    {
        hpx::this_thread::disable_interruption di;
        // interruption disabled
        {
            hpx::this_thread::disable_interruption di2;
            // interruption still disabled
        } // di2 destroyed, interruption state restored
        // interruption still disabled
    } // di destroyed, interruption state restored
    // interruption now enabled
}
```

The effects of an instance of hpx::this_thread::disable_interruption can be temporarily reversed by constructing an instance of hpx::this_thread::restore_interruption, passing in the hpx::this_thread::disable_interruption object in question. This will restore the interruption state to what it was when the hpx::this_thread::disable_interruption object was constructed, and then disable interruption again when the hpx::this_thread::restore_interruption object is destroyed.

```plaintext
void g()
{
    // interruption enabled here
    {
        hpx::this_thread::disable_interruption di;
        // interruption disabled
        {
            hpx::this_thread::restore_interruption ri(di);
            // interruption now enabled
        } // ri destroyed, interruption disable again
        // di destroyed, interruption state restored
    }
} // g()

(continues on next page)
// interruption now enabled
}

At any point, the interruption state for the current thread can be queried by calling `hpx::this_thread::interruption_enabled()`.

**namespace hpx**

** Enums**

**enum throwmode**

Encode error category for new `error_code`.

Values:

- `plain` = 0
- `rethrow` = 1
- `lightweight` = 0x80

**Variables**

**error_code throws**

Predefined `error_code` object used as “throw on error” tag.

The predefined `hpx::error_code` object `hpx::throws` is supplied for use as a “throw on error” tag.

Functions that specify an argument in the form ‘`error_code& ec=throws`’ (with appropriate namespace qualified), have the following error handling semantics:

- If `&ec` != `&throws` and an error occurred: `ec.value()` returns the implementation specific error number for the particular error that occurred and `ec.category()` returns the error_category for `ec.value()`.
- If `&ec` != `&throws` and an error did not occur, `ec.clear()`.
- If an error occurs and `&ec` == `&throws`, the function throws an exception of type `hpx::exception` or of a type derived from it. The exception’s `get_errorcode()` member function returns a reference to an `hpx::error_code` object with the behavior as specified above.

Defines

HPX_THROW_EXCEPTION (errcode, f, msg)

Throw a hpx::exception initialized from the given parameters.

The macro HPX_THROW_EXCEPTION can be used to throw a hpx::exception. The purpose of this macro is to prepend the source file name and line number of the position where the exception is thrown to the error message. Moreover, this associates additional diagnostic information with the exception, such as file name and line number, locality id and thread id, and stack backtrace from the point where the exception was thrown.

The parameter errcode holds the hpx::error code the new exception should encapsulate. The parameter f is expected to hold the name of the function exception is thrown from and the parameter msg holds the error message the new exception should encapsulate.

void raise_exception()
{
   // Throw a hpx::exception initialized from the given parameters.
   // Additionally associate with this exception some detailed
   // diagnostic information about the throw-site.
   HPX_THROW_EXCEPTION(hpx::no_success, "raise_exception", "simulated error");
}

Example:

HPX_THROWS_IF (ec, errcode, f, msg)

Either throw a hpx::exception or initialize hpx::error_code from the given parameters.

The macro HPX_THROWS_IF can be used to either throw a hpx::exception or to initialize a hpx::error_code from the given parameters. If &ec == &hpx::throws, the semantics of this macro are equivalent to HPX_THROW_EXCEPTION. If &ec != &hpx::throws, the hpx::error_code instance ec is initialized instead.

The parameter errcode holds the hpx::error code from which the new exception should be initialized. The parameter f is expected to hold the name of the function exception is thrown from and the parameter msg holds the error message the new exception should encapsulate.
The contents of this module can be included with the header hpx/modules/execution_base.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/execution_base.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

namespace experimental

Functions

template<typename O>
void start(O && o)

start is a customization point object. The expression
hpx::execution::experimental::start(r) is equivalent to:
• r.start(), if that expression is valid. If the function selected does not signal the receiver
r’s done channel, the program is ill-formed (no diagnostic required).
• Otherwise, `start(r), if that expression is valid, with overload resolution performed in a context
that include the declaration void start();
• Otherwise, the expression is ill-formed.
The customization is implemented in terms of hpx::functional::tag_invoke.

Variables

hpx::execution::experimental::start_t start

template<typename O>
constexpr bool is_operation_state_v = is_operation_state<O>::value

template<typename O>
struct is_operation_state

#include <operation_state.hpp> An operation_state is an object rep-
representing the asynchronous operation that has been returned from calling
hpx::execution::experimental::connect with a sender and a receiver.
The only operation on an operation_state is:
• hpx::execution::experimental::start
hpx::execution::experimental::start can be called exactly once. Once it
has been invoked, the caller needs to ensure that the receiver’s completion signaling
operations strongly happen before the destructor of the state is called. The call to
hpx::basic_exeuction::start needs to happen strongly before the completion signal-
ing operations.

Functions

template<
typename R, typename ...As>
void set_value (R &&r, As &&... as)

set_value is a customization point object. The expression hpx::execution::set_value(r, as...) is equivalent to:
  • r.set_value(as...), if that expression is valid. If the function selected does not send the value(s) as... to the Receiver r’s value channel, the program is ill-formed (no diagnostic required).
  • Otherwise, `set_value(r, as...), if that expression is valid, with overload resolution performed in a context that include the declaration void set_value();
  • Otherwise, the expression is ill-formed.

The customization is implemented in terms of hpx::functional::tag_invoke.

template<
typename R>
void set_done (R &&r)

set_done is a customization point object. The expression hpx::execution::set_done(r) is equivalent to:
  • r.set_done(), if that expression is valid. If the function selected does not signal the Receiver r’s done channel, the program is ill-formed (no diagnostic required).
  • Otherwise, `set_done(r), if that expression is valid, with overload resolution performed in a context that include the declaration void set_done();
  • Otherwise, the expression is ill-formed.

The customization is implemented in terms of hpx::functional::tag_invoke.

template<
typename R, typename E>
void set_error (R &&r, E &&e)

set_error is a customization point object. The expression hpx::execution::set_error(r, e) is equivalent to:
  • r.set_done(e), if that expression is valid. If the function selected does not send the error e the Receiver r’s error channel, the program is ill-formed (no diagnostic required).
  • Otherwise, `set_error(r, e), if that expression is valid, with overload resolution performed in a context that include the declaration void set_error();
  • Otherwise, the expression is ill-formed.

The customization is implemented in terms of hpx::functional::tag_invoke.
Variables

```cpp
hpx::execution::experimental::set_value_t set_value
hpx::execution::experimental::set_error_t set_error
hpx::execution::experimental::set_done_t set_done
```

template<typename T, typename E = std::exception_ptr>
```cpp
constexpr bool is_receiver_v = is_receiver<T, E>::value
```

template<typename T, typename ...As>
```cpp
constexpr bool is_receiver_of_v = is_receiver_of<T, As...>::value
```

template<typename T, typename ...As>
```cpp
constexpr bool is_nothrow_receiver_of_v = is_nothrow_receiver_of<T, As...>::value
```

```cpp
template<typename T, typename E>
struct is_receiver
#include <receiver.hpp>
```

Receiving values from asynchronous computations is handled by the Receiver concept. A Receiver needs to be able to receive an error or be marked as being canceled. As such, the Receiver concept is defined by having the following two customization points defined, which form the completion-signal operations:

- `hpx::execution::experimental::set_done`
- `hpx::execution::experimental::set_error`

Those two functions denote the completion-signal operations. The Receiver contract is as follows:

- None of a Receiver’s completion-signal operation shall be invoked before `hpx::execution::experimental::start` has been called on the operation state object that was returned by connecting a Receiver to a sender `hpx::execution::experimental::connect`.
- Once `hpx::execution::start` has been called on the operation state object, exactly one of the Receiver’s completion-signal operation shall complete without an exception before the Receiver is destroyed.

Once one of the Receiver’s completion-signal operation has been completed without throwing an exception, the Receiver contract has been satisfied. In other words: The asynchronous operation has been completed.

See `hpx::execution::experimental::is_receiver_of`

```cpp
template<typename T, typename ...As>
struct is_receiver_of
#include <receiver.hpp>
```

The `is_receiver_of` concept is a refinement of the Receiver concept by requiring one additional completion-signal operation:

- `hpx::execution::set_value`

This completion-signal operation adds the following to the Receiver’s contract:

- If `hpx::execution::set_value` exits with an exception, it is still valid to call `hpx::execution::set_error` or `hpx::execution::set_done`

See `hpx::execution::traits::is_receiver`

Functions

template<typename E, typename F>
void execute(E &e, F &f)
execute is a customization point object. For some subexpression e and f, let E be
decltype((e)) and let F be decltype((F)). The expression execute(e, f) is ill-
formed if F does not model invocable, or if E does not model either executor or sender.
The result of the expression hpx::execution::experimental::execute(e, f) is
then equivalent to:
• e.execute(f), if that expression is valid. If the function selected does not execute the
  function object f on the executor e, the program is ill-formed with no diagnostic required.
• Otherwise, execute(e, f), if that expression is valid, with overload resolution performed
  in a context that includes the declaration void execute(); and that does not include a
  declaration of hpx::execution::experimental::execute. If the function selected
  by overload resolution does not execute the function object f on the executor e, the program is
  ill-formed with no diagnostic required.
• Otherwise, execution::submit(e, as-receiver<remove_cvref_t<F>, E>{forward<F>(f)}) if
  – F is not an instance of as-invocable<R,E’> for some type R where E and E’ name the same
    type ignoring cv and reference qualifiers, and
  – invocable<remove_cvref_t<F>>& & sender_to<E, as-receiver<remove_cvref_t<F>, E>>&
    is true
where as-receiver is some implementation-defined class template equivalent to:

```cpp
template<class F, class>
struct as-receiver {
    F f_;  
    void set_value() noexcept(is_nothrow_invocable_v<F&>) {
        invoke(f_);  
    }
    template<class E>
    [[noreturn]] void set_error(E&&) noexcept {
        terminate();  
    }
    void set_done() noexcept {}  
};
```

The customization is implemented in terms of `hpx::functional::tag_invoke`.

```cpp
template<typename S, typename R>
void connect (S &s, R &r)  
connect is a customization point object. For some subexpression s and r, let S be the type such that `decltype((s))` is S and let R be the type such that `decltype((r))` is R. The result of the expression `hpx::execution::experimental::connect(s, r)` is then equivalent to:

- s.connect(r), if that expression is valid and returns a type satisfying the `operation_state`
  See `hpx::execution::experimental::traits::is_operation_state` and if S satisfies the `sender` concept.
- s.connect(r), if that expression is valid and returns a type satisfying the `operation_state`
  See `hpx::execution::experimental::traits::is_operation_state` and if S satisfies the `sender` concept. Overload resolution is performed in a context that include the declaration `void connect();`
- Otherwise, as-operation{s, r}, if
  - r is not an instance of as-receiver<F, S'> for some type F where S and S' name the same type ignoring cv and reference qualifiers, and
  - receiver_of<R> & executor-of-impl<remove_cvref_t

```

```cpp
template<typename S, typename R>
auto submit (S &s, R &r)  
The name submit denotes a customization point object.
For some subexpressions s and r, let S be `decltype((s))` and let R be `decltype((r))`. The expression `submit(s, r)` is ill-formed if sender_to<S, R> is not true. Otherwise, it is expression-equivalent to:

- s.submit(r), if that expression is valid and S models sender. If the function selected does not submit the receiver object r via the sender s, the program is ill-formed with no diagnostic required.
- Otherwise, submit(s, r), if that expression is valid and S models sender, with overload resolution performed in a context that includes the declaration
```

(continues on next page)
void submit();

and that does not include a declaration of execution::submit. If
the function selected by overload resolution does not submit the
receiver object r via the sender s, the program is ill-formed with
no diagnostic required.

* Otherwise, start({(new submit-state<S, R>{s, r})->state_}),
where submit-state is an implementation-defined class template
equivalent to

```cpp
template<class S, class R>
struct submit-state {
    struct submit-receiver {
        submit-state * p_;
        template<class...As>
        requires receiver_of<R, As...>
        void set_value(As&&... as) &&
        noexcept(is_nothrow_receiver_<
            of_v<R, As...>){
            set_value(std::move(p_->r_), (As&&) as...);
            delete p_;}
    };
    template<class E>
    requires receiver<R, E>
    void set_error(E&& e) &&
    noexcept{
        set_error(std::move(p_->r_), (E&&) e);
        delete p_;}
    void set_done() &&
    noexcept{
        set_done(std::move(p_->r_));
        delete p_;}
};
remove_cvref_t<R> r_;  
connect_result_t<S, submit-receiver> state_;  
submit-state(S&& s, R&& r)  
: r_((R&&) r),
  state_(connect(({S&&} s, submit-receiver{this}))) {}
};
```

The customization is implemented in terms of hpx::functional::tag_invoke.

```cpp
template<
    typename Executor, typename F,  
    typename = std::enable_if_t<hpx::is_invocable<std::decay_t<F>>&>&>::value
constexpr auto tag_fallback_invoke(execute_t, Executor &&executor, F &&f)
```

Variables

struct invocable_archetype

Public Functions

void operator() ()

template<typename Sender>
struct is_sender

#include <sender.hpp> The name schedule denotes a customization point object. For some subexpression s, let S be decltype((s)). The expression schedule(s) is expression-equivalent to:

* s.schedule(), if that expression is valid and its type models sender.
* Otherwise, schedule(s), if that expression is valid and its type models sender with overload resolution performed in a context that includes the declaration

    void schedule();

and that does not include a declaration of schedule.

* Otherwise, as_sender<remove_cvref_t<S>>(s) if S satisfies executor, where as_sender is an implementation-defined class

template equivalent to

    template<class E>
    struct as_sender {
    private:
    E ex_{;
    public:

(continues on next page)
template<template<class...> class Tuple, template<class...> class Variant>
    using value_types = Variant<Tuple<>>

template<template<class...> class Variant>
    using error_types = Variant<std::exception_ptr>

static constexpr bool sends_done = true;

explicit as_sender(E e) noexcept : ex_((E&&) e) {}  

template<class R>
    requires receiver_of<R>  
    connect_result_t<E, R> connect(R&& r) && {
        return connect((E&&) ex_, (R&&) r);
    }

template<class R>
    requires receiver_of<R>  
    connect_result_t<const E &, R> connect(R&& r) const & {
        return connect(ex_, (R&&) r);
    }

* Otherwise, schedule(s) is ill-formed.

The customization is implemented in terms of `hpx::functional::tag_invoke`. A sender is a type that is describing an asynchronous operation. The operation itself might not have started yet. In order to get the result of this asynchronous operation, a sender needs to be connected to a receiver with the corresponding value, error and done channels:

- `hpx::execution::experimental::connect`

In addition, `hpx::execution::experimental::sender_traits` needs to be specialized in some form.

A sender’s destructor shall not block pending completion of submitted operations.

```
template<typename Sender, typename Receiver>
struct is_sender_to
    #include <sender.hpp>

    friend constexpr auto tag_fallback_invoke(schedule_t, S &&s)  

    template<typename Sender>  
    struct sender_traits
        #include <sender.hpp> sender_traits expose the different value and error types exposed by a sender. This can be either specialized directly for user defined sender types or embedded value_types, error_types and sends_done inside the sender type can be provided.

        Subclassed by hpx::execution::experimental::sender_traits<
            Sender & &>
```

namespace functional

Typedefs

template<typename Tag, typename ...Args>
using tag fallback invoke result = invoke_result<decltype(tag fallback invoke(Tag, Args...)), Tag, Args...>
hpx::functional::tag fallback invoke result<Tag, Args...> is the trait returning the result type of the call hpx::functional::tag fallback invoke. This can be used in a SFINAE context.

template<typename Tag, typename ...Args>
using tag fallback invoke result_t = typename tag fallback invoke result<Tag, Args...>::type
hpx::functional::tag fallback invoke result_t<Tag, Args...> evaluates to hpx::functional::tag fallback invoke result_t<Tag, Args...>::type
Variables

constexpr unspecified **tag_fallback_invoke** = unspecified

The `hpx::functional::tag_fallback_invoke` name defines a constexpr object that is invocable with one or more arguments. The first argument is a ‘tag’ (typically a CPO). It is only invocable if an overload of `tag_fallback_invoke()` that accepts the same arguments could be found via ADL.

The evaluation of the expression `hpx::functional::tag_fallback_invoke(tag, args...)` is equivalent to evaluating the unqualified call to `tag_fallback_invoke(decay-copy(tag), std::forward<Args>(args)...)`.

`hpx::functional::tag_fallback_invoke` is implemented against P1895.

Example: Defining a new customization point `foo`:

```cpp
namespace mylib {
    inline constexpr struct foo_fn final : hpx::functional::tag_fallback<foo_fn>
    {
        foo{};
    }
}
```

Defining an object `bar` which customizes `foo`:

```cpp
struct bar
{
    int x = 42;

    friend constexpr int tag_fallback_invoke(mylib::foo_fn, bar const& x)
    {
        return b.x;
    }
};
```

Using the customization point:

```cpp
static_assert(42 == mylib::foo(bar{}), "The answer is 42");
```

```cpp
template<typename Tag, typename ...Args>
constexpr bool is_tag_fallback_invocable_v = is_tag_fallback_invocable<Tag, Args...>::value
hpx::functional::is_tag_fallback_invocable_v<Tag, Args...> evaluates to
hpx::functional::is_tag_fallback_invocable<Tag, Args...>::value
```

```cpp
template<typename Tag, typename ...Args>
constexpr bool is_nothrow_tag_fallback_invocable_v = is_nothrow_tag_fallback_invocable<Tag, Args...>
    hpx::functional::is_nothrow_tag_fallback_invocable_v<Tag, Args...> evaluates to
hpx::functional::is_nothrow_tag_fallback_invocable<Tag, Args...>::value
```

```cpp
template<typename Tag, typename ...Args>
struct is_nothrow_tag_fallback_invocable
#include <tag_fallback_invoke.hpp>
    hpx::functional::is_nothrow_tag_fallback_invocable<Tag, Args...> is std::true_type if an overload of `tag_fallback_invoke(tag, args...)` can be found via ADL and is noexcept.
```

```cpp
template<typename Tag, typename ...Args>
```
struct is_tag_fallback_invocable
#include <tag_fallback_invoke.hpp>  hpx::functional::is_tag_fallback_invocable<Tag, Args...> is std::true_type if an overload of tag_fallback_invoke(tag, args...) can be found via ADL.

template<typename Tag>
struct tag_fallback
#include <tag_fallback_invoke.hpp>  hpx::functional::tag_fallback<Tag> defines a base class that implements the necessary tag dispatching functionality for a given type Tag

template<typename Tag>
struct tag_fallback_noexcept
#include <tag_fallback_invoke.hpp>  hpx::functional::tag_fallback_noexcept<Tag> defines a base class that implements the necessary tag dispatching functionality for a given type Tag where the implementation is required to be noexcept

namespace hpx

namespace functional

Typedefs

template< typename Tag, typename ... Args >
using tag_invoke_result_t = typename tag_invoke_result<Tag, Args...>::type
  hpx::functional::tag_invoke_result_t<Tag, Args...>::type evaluates to

Variables

cconstexpr unspecified tag_invoke = unspecified
The hpx::functional::tag_invoke name defines a constexpr object that is invocable with one or more arguments. The first argument is a ‘tag’ (typically a CPO). It is only invocable if an overload of tag_invoke() that accepts the same arguments could be found via ADL.

The evaluation of the expression hpx::tag_invoke(tag, args...) is equivalent to evaluating the unqualified call to tag_invoke(decay-copy(tag), std::forward<Args>(args)...).

hpx::functional::tag_invoke is implemented against P1895.

Example: Defining a new customization point foo:

```cpp
namespace mylib {
  inline constexpr struct foo_fn final : hpx::functional::tag<foo_fn> {
    } foo{};
}
```

Defining an object bar which customizes foo:
```cpp
struct bar
{
    int x = 42;

    friend constexpr int tag_invoke(mylib::foo_fn, bar const& x)
    {
        return b.x;
    }
};
```

Using the customization point:

```cpp
static_assert(42 == mylib::foo(bar{}), "The answer is 42");
```

```cpp
template<typename Tag, typename ...Args>
constexpr bool is_tag_invocable_v = is_tag_invocable<Tag, Args...>::value
hpx::functional::is_tag_invocable_v<Tag, Args...> evaluates to
hpx::functional::is_tag_invocable<Tag, Args...>::value
```

```cpp
template<typename Tag, typename ...Args>
constexpr bool is_nothrow_tag_invocable_v = is_nothrow_tag_invocable<Tag, Args...>::value
hpx::functional::is_nothrow_tag_invocable_v<Tag, Args...> evaluates to
hpx::functional::is_nothrow_tag_invocable<Tag, Args...>::value
```

```cpp
template<typename Tag, typename ...Args>
struct is_nothrow_tag_invocable
#include <tag_invoke.hpp>
hpx::functional::is_nothrow_tag_invocable_v<Tag, Args...> is std::true_type if an overload of tag_invoke(tag, args...) can be found via ADL and is noexcept.
```

```cpp
template<typename Tag, typename ...Args>
struct is_tag_invocable
#include <tag_invoke.hpp>
hpx::functional::is_tag_invocable_v<Tag, Args...> is std::true_type if an overload of tag_invoke(tag, args...) can be found via ADL.
```

```cpp
template<typename Tag>
struct tag
#include <tag_invoke.hpp> hpx::functional::tag<Tag> defines a base class that implements the necessary tag dispatching functionality for a given type Tag
```

```cpp
template<typename Tag>
struct tag_noexcept
#include <tag_invoke.hpp> hpx::functional::tag_noexcept<Tag> defines a base class that implements the necessary tag dispatching functionality for a given type Tag The implementation has to be noexcept
```

namespace hpx
```
Typedefs

```cpp
template<typename Tag, typename ...Args>
using tag_override_invoke_result = invoke_result<decltype(tag_override_invoke(Tag, Args...)), Tag, Args...> 

hpx::functional::tag_override_invoke_result<Tag, Args...> is the trait returning the result type of the call hpx::functional::tag_override_invoke. This can be used in a SFINAE context.
```

```cpp
template<typename Tag, typename ...Args>
using tag_override_invoke_result_t = typename tag_override_invoke_result<Tag, Args...>::type 

hpx::functional::tag_override_invoke_result_t<Tag, Args...> evaluates to hpx::functional::tag_override_invoke_result<Tag, Args...>::type
```

Variables

```cpp
constexpr unspecified tag_override_invoke = unspecified 
```

The hpx::functional::tag_override_invoke name defines a constexpr object that is invocable with one or more arguments. The first argument is a ‘tag’ (typically a CPO). It is only invocable if an overload of tag_override_invoke() that accepts the same arguments could be found via ADL.

The evaluation of the expression hpx::functional::tag_override_invoke(tag, args...) is equivalent to evaluating the unqualified call to tag_override_invoke(decay-copy(tag), std::forward<Args>(args)...).

hpx::functional::tag_override_invoke is implemented against P1895.

Example: Defining a new customization point foo:

```cpp
namespace mylib {
    inline constexpr struct foo_fn final : hpx::functional::tag_override<foo_fn> {
        } foo{};
}
```

Defining an object bar which customizes foo:

```cpp
struct bar {
    int x = 42;

    friend constexpr int tag_override_invoke(mylib::foo_fn, bar const & x) {
        return b.x;
    }
};
```

Using the customization point:

```cpp
static_assert(42 == mylib::foo(bar{}), "The answer is 42");
```

```cpp
template<typename Tag, typename ...Args>
constexpr bool is_tag_override_invocable_v = is_tag_override_invocable<Tag, Args...>::value 
```

hpx::functional::is_tag_override_invocable_v<Tag, Args...> evaluates to hpx::functional::is_tag_override_invocable<Tag, Args...>::value
template<
    typename Tag,
    typename ... Args
>
constexpr bool is_nothrow_tag_override_invocable_v =
    is_nothrow_tag_override_invocable<Tag, Args...>::value

hpx::functional::is_tag_override_invocable_v<Tag, Args...>::value evaluates to

template<
    typename Tag,
    typename ... Args
>
struct is_nothrow_tag_override_invocable
    #include <tag_priority_invoke.hpp>
    hpx::functional::is_nothrow_tag_override_invocable<Tag, Args...>
    is std::true_type if an overload of tag_override_invoke(tag, args...) can
    be found via ADL and is noexcept.

template<
    typename Tag,
    typename ... Args
>
struct is_tag_override_invocable
    #include <tag_priority_invoke.hpp>
    hpx::functional::is_tag_override_invocable<Tag, Args...>
    is std::true_type if an overload of tag_override_invoke(tag, args...) can
    be found via ADL.

template<
    typename Tag
>
struct tag_override
    #include <tag_priority_invoke.hpp>
    hpx::functional::tag_override<Tag>
    defines a
    base class that implements the necessary tag dispatching functionality for a given type Tag

template<
    typename Tag
>
struct tag_override_noexcept
    #include <tag_priority_invoke.hpp>
    hpx::functional::tag_override_noexcept<Tag>
    defines a base class that implements the necessary tag dispatching functionality for a given type Tag
    where the implementation is required to be noexcept

**io_service**

The contents of this module can be included with the header hpx/modules/io_service.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/io_service.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

**namespace hpx**
namespace util

class io_service_pool
#include <io_service_pool.hpp> A pool of io_service objects.

Public Functions

HPX_NON_COPYABLE (io_service_pool)
io_service_pool (std::size_t pool_size = 2, threads::policies::callback_notifier const &notifier = threads::policies::callback_notifier(), char const *pool_name = "", char const *name_postfix = "")
Construct the io_service pool.

Parameters

• pool_size: [in] The number of threads to run to serve incoming requests
• start_thread: [in]

io_service_pool (threads::policies::callback_notifier const &notifier, char const *pool_name = "", char const *name_postfix = "")
Construct the io_service pool.

Parameters

• start_thread: [in]

~io_service_pool ()

bool run (bool join_threads = true, barrier *startup = nullptr)
Run all io_service objects in the pool. If join_threads is true this will also wait for all threads to complete

bool run (std::size_t num_threads, bool join_threads = true, barrier *startup = nullptr)
Run all io_service objects in the pool. If join_threads is true this will also wait for all threads to complete

void stop ()
Stop all io_service objects in the pool.

void join ()
Join all io_service threads in the pool.

void clear ()
Clear all internal data structures.

void wait ()
Wait for all work to be done.

bool stopped ()

asio::io_context &get_io_service (int index = -1)
Get an io_service to use.

std::thread &get_os_thread_handle (std::size_t thread_num)
access underlying thread handle
\textit{std::size_t} \textbf{size()} \textbf{const}

Get number of threads associated with this I/O service.

\textbf{void} \textbf{thread_run} (\textit{std::size_t \textit{index}, barrier \textit{*\textit{startup} = nullptr})

Activate the thread \textit{index} for this thread pool.

\textbf{char \textit{const}} \textbf{*get_name()} \textbf{const}

Return name of this pool.

\section*{Protected Functions}

\textbf{bool} \textbf{run_locked} (\textit{std::size_t \textit{num_threads}, bool \textit{join_threads}, barrier \textit{*\textit{startup}})

\textbf{void} \textbf{stop_locked}()

\section*{Private Members}

\textbf{std::mutex mtx_}

\textbf{std::vector<io_service_ptr>} \textbf{io_services_}

The pool of \textbf{io_services}.

\textbf{std::vector<\textit{std::thread}> threads_}

\textbf{std::vector<\textit{work_type}> work_}

The work that keeps the \textbf{io_services} running.

\textbf{std::size_t next_io_service_}

The next \textbf{io_service} to use for a connection.

\textbf{bool} \textbf{stopped_}

set to true if stopped

\textbf{std::size_t} \textbf{pool_size_}

initial number of OS threads to execute in this pool

\textit{threads::policies::callback_notifier \textbf{const &notifier_}

call this for each thread start/stop

\textbf{char \textit{const}} \textbf{*pool_name_}
char const * pool_name_postfix_
bool waiting_
    Set to true if waiting for work to finish.
barrier wait_barrier_
barrier continue_barrier_

iterator_support

logging

The contents of this module can be included with the header hpx/modules/logging.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/logging.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

namespace hpx

namespace util

namespace logging

Enums

enum level
Handling levels - classes that can hold and/or deal with levels.

- filters and level holders
By default we have these levels:

- debug (smallest level),
- info,
- warning ,
- error ,
- fatal (highest level)

Depending on which level is enabled for your application, some messages will reach the log: those messages having at least that level. For instance, if info level is enabled, all logged messages will reach the log. If warning level is enabled, all messages are logged, but the warnings. If debug level is enabled, messages that have levels debug, error, fatal will be logged.

Values:

disable_all = static_cast<unsigned int>(-1)
enable_all = 0
debug = 1000
info = 2000
warning = 3000
error = 4000
fatal = 5000
always = 6000
Functions

void format_value (std::ostream &os, boost::string_ref spec, level value)

Include this file when you’re using the logging lib, but don’t necessarily want to use formatters and destinations. If you want to use formatters and destinations, then you can include this one instead:

```cpp
#include <hpx/logging/format.hpp>
```

namespace hpx

namespace util

namespace logging

namespace destination

Destination is a manipulator. It contains a place where the message, after being formatted, is to be written to.

Some viable destinations are: the console, a file, a socket, etc.

struct manipulator
    #include <manipulator.hpp> What to use as base class, for your destination classes.

    Subclassed by hpx::util::logging::destination::cerr, hpx::util::logging::destination::cout,
    hpx::util::logging::destination::dbg_window, hpx::util::logging::destination::file,
    hpx::util::logging::destination::stream

Public Functions

template virtual void operator() (message const &val) = 0

template virtual void configure (std::string const &)
    Override this if you want to allow configuration through scripting.

    That is, this allows configuration of your manipulator at run-time.

virtual ~manipulator ()

Protected Functions

manipulator ()

namespace formatter

Formatter is a manipulator. It allows you to format the message before writing it to the destination(s)

Examples of formatters are: prepend the time, prepend high-precision time, prepend the index of the message, etc.
struct manipulator
#include <manipulator.hpp> What to use as base class, for your formatter classes.
Subclassed by hpx::util::logging::formatter::high_precision_time, hpx::util::logging::formatter::idx, hpx::util::logging::formatter::thread_id

Public Functions

virtual void operator() (std::ostream &to) const = 0
virtual void configure (std::string const&) 
   Override this if you want to allow configuration through scripting.
   That is, this allows configuration of your manipulator at run-time.
virtual ~manipulator ()

Protected Functions

manipulator ()

Friends

void format_value (std::ostream &os, boost::string_ref, manipulator const &value)

namespace hpx

namespace util

namespace logging

class message
#include <message.hpp> Optimizes the formatting for prepending and/or appending strings to the original message.
It keeps all the modified message in one string. Useful if some formatter needs to access the whole string at once.
reserve() - the size that is reserved for prepending (similar to string::reserve function)
Note: as strings are prepended, reserve() shrinks.

Public Functions

message ()
message (std::stringstream msg)
Parameters
   • msg: - the message that is originally cached
message (message &&other)
template<typename T>
message &operator<<(T &&v)

template<typename ...Args>
message &format(boost::string_ref format_str, Args const &... args)

std::string const &full_string() const
returns the full string

bool empty() const

Private Members

std::stringstream m_str
bool m_full_msg_computed
std::string m_full_msg

Friends

std::ostream &operator<<(std::ostream &os, message const &value)

namespace hpx

namespace util

namespace logging

namespace destination

Destination is a manipulator. It contains a place where the message, after being formatted, is to be written to.

Some viable destinations are: the console, a file, a socket, etc.

struct cerr : public hpx::util::logging::destination::manipulator
#include <destinations.hpp> Writes the string to cerr.

Public Functions

~cerr()

Public Static Functions

static std::unique_ptr<cerr> make()
Protected Functions

cerr()

struct cout : public hpx::util::logging::destination::manipulator
#include <destinations.hpp> Writes the string to console.

Public Functions

~cout()

Public Static Functions

static std::unique_ptr<cout> make()

Protected Functions

cout()

struct dbg_window : public hpx::util::logging::destination::manipulator
#include <destinations.hpp> Writes the string to output debug window.

For non-Windows systems, this is the console.

Public Functions

~dbg_window()

Public Static Functions

static std::unique_ptr<dbg_window> make()

Protected Functions

dbg_window()

struct file : public hpx::util::logging::destination::manipulator
#include <destinations.hpp> Writes the string to a file.

Public Functions

~file()
Public Static Functions

```cpp
static std::unique_ptr<file> make (std::string const &file_name, file_settings set = {}) constructs the file destination
```

Parameters
- `file_name`: name of the file
- `set`: [optional] file settings - see `file_settings` class, and dealing_with_flags

Protected Functions

```cpp
file (std::string const &file_name, file_settings set)
```

Protected Attributes

```cpp
std::string name
file_settings settings
```

```cpp
struct file_settings
#include <destinations.hpp> settings for when constructing a file class. To see how it’s used, see dealing_with_flags.
```

Public Functions

```cpp
file_settings()
```

Public Members

```cpp
bool flush_each_time : 1
if true (default), flushes after each write
```

```cpp
bool initial_overwrite : 1
```

```cpp
bool do_append : 1
```

```cpp
std::ios_base::openmode extra_flags
just in case you have some extra flags to pass, when opening the file
```

```cpp
struct stream: public hpx::util::logging::destination::manipulator
#include <destinations.hpp> writes to stream.
```

Note: The stream must outlive this object! Or, `clear()` the stream, before the stream is deleted.

**Public Functions**

~`stream`()

```cpp
void set_stream (std::ostream *stream_ptr)
```

resets the stream. Further output will be written to this stream

```cpp
void clear()
```

clears the stream. Further output will be ignored

**Public Static Functions**

```cpp
static std::unique_ptr<stream> make (std::ostream *stream_ptr)
```

**Protected Functions**

```cpp
stream (std::ostream *stream_ptr)
```

**Protected Attributes**

```cpp
std::ostream *ptr
```

namespace hpx

namespace util

namespace logging

namespace formatter

Formatter is a manipulator. It allows you to format the message before writing it to the destination(s)

Examples of formatters are: prepend the time, prepend high-precision time, prepend the index of the message, etc.

```cpp
struct high_precision_time : public hpx::util::logging::formatter::manipulator
```

```cpp
#include <formatters.hpp>
```

Prefixes the message with a high-precision time (. You pass the format string at construction.

```cpp
#include <hpx/logging/format/formatter/high_precision_time.hpp>
```

Internally, it uses hpx::util::date_time::microsec_time_clock. So, our precision matches this class.

The format can contain escape sequences: $dd - day, 2 digits $MM - month, 2 digits $yy - year, 2 digits $yyyy - year, 4 digits $hh - hour, 2 digits $mm - minute, 2 digits $ss - second, 2 digits $mili - milliseconds $micro - microseconds (if the high precision clock allows; otherwise, it pads zeros) $nano - nanoseconds (if the high precision clock allows; otherwise, it pads zeros)

Example:
Parameters
• `convert`: [optional] In case there needs to be a conversion between `std::(w)string` and the string that holds your logged message. See `convert_format`.

Public Functions

~`high_precision_time`()  

Public Static Functions

`static std::unique_ptr<high_precision_time> make (std::string const &format)`  

Protected Functions

`high_precision_time (std::string const &format)`  

`struct idx : public hpx::util::logging::formatter::manipulator`  

#include <formatters.hpp> prefixes each message with an index.

Example:

```
L_ << "my message";
L_ << "my 2nd message";
```

This will output something similar to:

```
[1] my message
[2] my 2nd message
```
Protected Functions

idx()

struct thread_id: public hpx::util::logging::formatter::manipulator
#include <formatters.hpp> Writes the thread_id to the log.

Parameters
  • convert: [optional] In case there needs to be a conversion between std::(w)string and the string that holds your logged message. See convert_format.

Public Functions

~thread_id()

Public Static Functions

static std::unique_ptr<thread_id> make()

Protected Functions

namespace hpx

namespace util

namespace logging

namespace writer

struct named_write
#include <named_write.hpp> Composed of a named formatter and a named destinations. Thus, you can specify the formatting and destinations as strings.

#include <hpx/logging/format/named_write.hpp>

Contains a very easy interface for using formatters and destinations:
  • at construction, specify 2 params: the formatter string and the destinations string
Setting the formatters and destinations to write to is extremely simple:

// Set the formatters (first param) and destinations (second step) in one step
   g_l()->writer().write("%time%($hh:$mm.$ss.$mili) [%idx%] |\n", "cout file(out.txt) debug");

(continues on next page)
// set the formatter(s)
g_l()->writer().format("%time%($hh:$mm:$ss.$mili) [%idx%] |\n");

// set the destination(s)
g_l()->writer().destination("cout file(out.txt) debug");

Public Functions

named_write()

void format (std::string const &format_str)
    sets the format string: what should be before, and what after the original message, separated
    by “|”
    
    Example: “[%idx%] \n” - this writes “[%idx%] ” before the message, and “\n” after the
    message
    
    If “|” is not present, the whole message is prepended to the message

void destination (std::string const &destination_str)
    sets the destinations string - where should logged messages be outputted

void write (std::string const &format_str, std::string const &destination_str)
    Specifies the formats and destinations in one step.

void operator () (message const &msg) const

template<typename Formatter>
void set_formatter (std::string const &name, Formatter fmt)
    Replaces a formatter from the named formatter.
    
    You can use this, for instance, when you want to share a formatter between multiple named
    writers.

template<
    typename Formatter,
    typename ...Args>
void set_formatter (std::string const &name, Args&&... args)

template<typename Destination>
void set_destination (std::string const &name, Destination dest)
    Replaces a destination from the named destination.
    
    You can use this, for instance, when you want to share a destination between multiple named
    writers.

template<
    typename Destination,
    typename ...Args>
void set_destination (std::string const &name, Args&&... args)
Private Functions

void configure_formatter (std::string const &format)
void configure_destination (std::string const &format)

Private Members

detail::named_formatters m_format
detail::named_destinations m_destination
std::string m_format_str
std::string m_destination_str

preprocessor

The contents of this module can be included with the header hpx/modules/preprocessor.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/preprocessor.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.
Defines

**HPX_PP_CAT** (*A*, *B*)

Concatenates the tokens *A* and *B* into a single token. Evaluates to *AB*

Parameters

- *A*: First token
- *B*: Second token

Defines

**HPX_PP_EXPAND** (*X*)

The HPX_PP_EXPAND macro performs a double macro-expansion on its argument. This macro can be used to produce a delayed preprocessor expansion.

Parameters

- *X*: Token to be expanded twice

Example:

```c
#define MACRO(a, b, c) (a)(b)(c)
#define ARGS() (1, 2, 3)
HPX_PP_EXPAND(MACRO ARGS())) // expands to (1)(2)(3)
```

Defines

**HPX_PP_NARGS** (...)

Expands to the number of arguments passed in

Example Usage:

```c
HPX_PP_NARGS(hpx, pp, nargs)
HPX_PP_NARGS(hpx, pp)
HPX_PP_NARGS(hpx)
```

Parameters

- . . . : The variadic number of arguments

Expands to:

```
3
2
1
```
**Defines**

**HPX_PP_STRINGIZE** (*X*)

The **HPX_PP_STRINGIZE** macro stringizes its argument after it has been expanded.

The passed argument *X* will expand to "*X*". Note that the stringizing operator (#) prevents arguments from expanding. This macro circumvents this shortcoming.

**Parameters**

- *X*: The text to be converted to a string literal

**Defines**

**HPX_PP_STRIP_PARENS** (*X*)

For any symbol *X*, this macro returns the same symbol from which potential outer parens have been removed. If no outer parens are found, this macro evaluates to *X* itself without error.

The original implementation of this macro is from Steven Watanabe as shown in [http://boost.2283326.n4.nabble.com/preprocessor-removing-parentheses-td2591973.html#a2591976](http://boost.2283326.n4.nabble.com/preprocessor-removing-parentheses-td2591973.html#a2591976)

```
HPX_PP_STRIP_PARENS(no_parens)
HPX_PP_STRIP_PARENS((with_parens))
```

**Example Usage:**

**Parameters**

- *X*: Symbol to strip parens from

This produces the following output

```
no_parens
with_parens
```

**properties**

The contents of this module can be included with the header `hpx/modules/properties.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/properties.hpp`, not the particular header in which the functionality you would like to use is defined. template-typename Mutex = std::mutex, typename PendingQueuing = concurrentqueue_fifo, typename TerminatedQueuing = default_shared_priority_queue_scheduler_terminated_queue>
class shared_priority_queue_scheduler : public scheduler_base

#include <shared_priority_queue_scheduler.hpp> The shared_priority_queue_scheduler maintains a set of high, normal, and low priority queues. For each priority level there is a core/queue ratio which determines how many cores share a single queue. If the high priority core/queue ratio is 4 the first 4 cores will share a single high priority queue, the next 4 will share another one and so on. In addition, the shared_priority_queue_scheduler is NUMA-aware and takes NUMA scheduling hints into account when creating and scheduling work.

Warning: PendingQueuing lifo causes lockup on termination

namespace hpx
namespace threads
namespace policies

Typedefs

using default_static_priority_queue_scheduler_terminated_queue = lockfree_fifo
template<typename Mutex = std::mutex, typename PendingQueuing = lockfree_fifo, typename StagedQueuing = lockfree_fifo, typename TerminatedQueuing = default_static_priority_queue_scheduler_terminated_queue>
class static_priority_queue_scheduler : public hpx::threads::policies::local_priority_queue_scheduler

#include <static_priority_queue_scheduler.hpp> The static_priority_queue_scheduler maintains exactly one queue of work items (threads) per OS thread, where this OS thread pulls its next work from. Additionally it maintains separate queues: several for high priority threads and one for low priority threads. High priority threads are executed by the first N OS threads before any other work is executed. Low priority threads are executed by the last OS thread whenever no other work is available. This scheduler does not do any work stealing.
Public Types

```cpp
template<>
using base_type = local_priority_queue_scheduler<Mutex, PendingQueuing, StagedQueuing, TerminatedQueuing>
```

```cpp
template<>
using init_parameter_type = typename base_type::init_parameter_type
```

Public Functions

```cpp
static_priority_queue_scheduler (init_parameter_type const &init, bool deferred_initialization = true)
```

```cpp
void set_scheduler_mode (scheduler_mode mode)
```

Public Static Functions

```cpp
static std::string get_scheduler_name ()
```

```cpp
namespace hpx
```

```cpp
namespace threads
```

```cpp
namespace policies
```

**Typedefs**

```cpp
using default_static_queue_scheduler_terminated_queue = lockfree_fifo
```

```cpp
template<typename Mutex = std::mutex, typename PendingQueuing = lockfree_fifo, typename StagedQueuing = lockfree_fifo, typename TerminatedQueuing = default_static_queue_scheduler_terminated_queue>
class static_queue_scheduler : public hpx::threads::policies::local_queue_scheduler<Mutex, lockfree_fifo, lockfree_fifo, default_static_queue_scheduler_terminated_queue>
```

#include <static_queue_scheduler.hpp>

The `local_queue_scheduler` maintains exactly one queue of work items (threads) per OS thread, where this OS thread pulls its next work from.

Public Types

```cpp
typedef local_queue_scheduler<Mutex, PendingQueuing, StagedQueuing, TerminatedQueuing> base_type
```

Public Functions

```cpp
static_queue_scheduler (typename base_type::init_parameter_type const &init, bool deferred_initialization = true)
```

```cpp
void set_scheduler_mode (scheduler_mode mode)
```

```cpp
bool get_next_thread (std::size_t num_thread, bool threads::thread_data *&thr, bool)
```

Return the next thread to be executed, return false if none is available
bool wait_or_add_new(std::size_t num_thread, bool running, std::int64_t &idle_loop_count, bool, std::size_t &added)

This is a function which gets called periodically by the thread manager to allow for maintenance tasks to be executed in the scheduler. Returns true if the OS thread calling this function has to be terminated (i.e. no more work has to be done).

Public Static Functions

static std::string get_scheduler_name ()

### serialization

The contents of this module can be included with the header hpx/modules/serialization.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/serialization.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

synchronization

The contents of this module can be included with the header `hpx/modules/synchronization.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/synchronization.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

```cpp
namespace hpx

Typedefs

template<std::ptrdiff_t LeastMaxValue = PTRDIFF_MAX>
using counting_semaphore = hpx::lcos::local::cpp20_counting_semaphore<LeastMaxValue>

using binary_semaphore = hpx::lcos::local::cpp20_binary_semaphore<>

namespace hpx

Typedefs

template<typename OnCompletion = lcos::local::detail::empty_oncompletion>
using barrier = lcos::local::cpp20_barrier<OnCompletion>

namespace hpx

Typedefs

using latch = hpx::lcos::local::cpp20_latch

namespace hpx

namespace lcos

namespace local

class barrier

#include <barrier.hpp> A barrier can be used to synchronize a specific number of threads, blocking all of the entering threads until all of the threads have entered the barrier.

Note A barrier is not a LCO in the sense that it has no global id and it can’t be triggered using the action (parcel) mechanism. It is just a low level synchronization primitive allowing to synchronize a given number of threads.
Public Functions

`barrier (std::size_t number_of_threads)`

`~barrier ()`

void `wait ()`
   The function `wait` will block the number of entering threads (as given by the constructor parameter `number_of_threads`), releasing all waiting threads as soon as the last thread entered this function.

void `count_up ()`
   The function `count_up` will increase the number of threads to be waited in `wait` function.

void `reset (std::size_t number_of_threads)`
   The function `reset` will reset the number of threads as given by the function parameter `number_of_threads`. The newer coming threads executing the function `wait` will be waiting until `total_` is equal to `barrier_flag`. The last thread exiting the `wait` function will notify the newer threads waiting and the newer threads will get the reset `number_of_threads`. The function `reset` can be executed while previous threads executing waiting after they have been waken up. Thus `total_` can not be reset to `barrier_flag` which will break the comparison condition under the function `wait`.

namespace hpx

namespace lcos

namespace local

class cpp20_latch
#include <latch.hpp> Latches are a thread coordination mechanism that allow one or more threads to block until an operation is completed. An individual latch is a singleuse object; once the operation has been completed, the latch cannot be reused.

Subclassed by hpx::lcos::local::latch
Public Functions

**HPX_NON_COPYABLE** (cpp20_latch)

`cpp20_latch (std::ptrdiff_t count)`

Initialize the latch

Requires: count >= 0. Synchronization: None Postconditions: counter_ == count.

`~cpp20_latch ()`

Requires: No threads are blocked at the synchronization point.

**Note** May be called even if some threads have not yet returned from `wait()` or `count_down_and_wait()`, provided that counter_ is 0.

**Note** The destructor might not return until all threads have exited `wait()` or `count_down_and_wait()`.

**Note** It is the caller’s responsibility to ensure that no other thread enters `wait()` after one thread has called the destructor. This may require additional coordination.

`void count_down (std::ptrdiff_t update)`

Decrement counter_ by n. Does not block.

Requires: counter_ >= n and n >= 0.

Synchronization: Synchronizes with all calls that block on this latch and with all try_wait calls on this latch that return true.

**Exceptions**

• Nothing.

`bool try_wait () const`

Returns: With very low probability false. Otherwise counter == 0.

`void wait () const`

If counter_ is 0, returns immediately. Otherwise, blocks the calling thread at the synchronization point until counter_ reaches 0.

**Exceptions**

• Nothing.

`void arrive_and_wait (std::ptrdiff_t update = 1)`

Effects: Equivalent to: count_down(update); wait();

Public Static Functions

`static constexpr std::ptrdiff_t() hpx::lcos::local::cpp20_latch::max()`

Returns: The maximum value of counter that the implementation supports.
**Protected Types**

typedef lcos::local::spinlock mutex_type

**Protected Attributes**

class latch : public hpx::lcos::local::cpp20_latch
#include <latch.hpp> A latch maintains an internal counter_ that is initialized when the latch is created. Threads may block at a synchronization point waiting for counter_ to be decremented to 0. When counter_ reaches 0, all such blocked threads are released.

Calls to countdown_and_wait() , count_down() , wait() , is_ready() , count_up() , and reset() behave as atomic operations.

**Note** A local::latch is not an LCO in the sense that it has no global id and it can’t be triggered using the action (parcel) mechanism. Use lcos::latch instead if this is required. It is just a low level synchronization primitive allowing to synchronize a given number of threads.

**Public Functions**

HPX_NON_COPYABLE (latch)
latch (std::ptrdiff_t count)
Initialize the latch

Requires: count >= 0. Synchronization: None Postconditions: counter_ == count.

~latch ()
Requires: No threads are blocked at the synchronization point.

**Note** May be called even if some threads have not yet returned from wait() or count_down_and_wait(), provided that counter_ is 0.
**Note** The destructor might not return until all threads have exited wait() or count_down_and_wait().
**Note** It is the caller’s responsibility to ensure that no other thread enters wait() after one thread has called the destructor. This may require additional coordination.

void count_down_and_wait ()
Decrement counter_ by 1. Blocks at the synchronization point until counter_ reaches 0.

Requires: counter_ > 0.

Synchronization: Synchronizes with all calls that block on this latch and with all is_ready calls on this latch that return true.

**Exceptions**

• Nothing:
bool is_ready() const
   Returns: counter_ == 0. Does not block.

   Exceptions
   • Nothing.

void abort_all()

void count_up(std::ptrdiff_t n)
   Increments counter_ by n. Does not block.
   Requires: n >= 0.

   Exceptions
   • Nothing.

void reset(std::ptrdiff_t n)
   Reset counter_ to n. Does not block.
   Requires: n >= 0.

   Exceptions
   • Nothing.

A semaphore is a protected variable (an entity storing a value) or abstract data type (an entity grouping several variables that may or may not be numerical) which constitutes the classic method for restricting access to shared resources, such as shared memory, in a multiprogramming environment. Semaphores exist in many variants, though usually the term refers to a counting semaphore, since a binary semaphore is better known as a mutex. A counting semaphore is a counter for a set of available resources, rather than a locked/unlocked flag of a single resource. It was invented by Edsger Dijkstra. Semaphores are the classic solution to preventing race conditions in the dining philosophers problem, although they do not prevent resource deadlocks.

Sliding semaphores can be used for synchronizing multiple threads as well: one thread waiting for several other threads to touch (signal) the semaphore, or several threads waiting for one other thread to touch this semaphore. The difference to a counting semaphore is that a sliding semaphore will not limit the number of threads which are allowed to proceed, but will make sure that the difference between the (arbitrary) number passed to set and wait does not exceed a given threshold.

**Public Functions**

`sliding_semaphore_var (std::int64_t max_difference, std::int64_t lower_limit = 0)`
Construct a new sliding semaphore.

**Parameters**
- `max_difference`: [in] The max difference between the upper limit (as set by `wait()`) and the lower limit (as set by `signal()`) which is allowed without suspending any thread calling `wait()`.
- `lower_limit`: [in] The initial lower limit.

`void set_max_difference (std::int64_t max_difference, std::int64_t lower_limit = 0)`
Set/Change the difference that will cause the semaphore to trigger.

**Parameters**
- `max_difference`: [in] The max difference between the upper limit (as set by `wait()`) and the lower limit (as set by `signal()`) which is allowed without suspending any thread calling `wait()`.
HPX Documentation,  master

• lower_limit: [in] The initial lower limit.

void wait (std::int64_t upper_limit)

Wait for the semaphore to be signaled.

Parameters
• upper_limit: [in] The new upper limit. The calling thread will be suspended if the
difference between this value and the largest lower_limit which was set by signal() is
larger than the max_difference.

bool try_wait (std::int64_t upper_limit = 1)

Try to wait for the semaphore to be signaled.

Return The function returns true if the calling thread would not block if it was calling wait().
Parameters
• upper_limit: [in] The new upper limit. The calling thread will be suspended if the
difference between this value and the largest lower_limit which was set by signal() is
larger than the max_difference.

void signal (std::int64_t lower_limit)

Signal the semaphore.

Parameters
• lower_limit: [in] The new lower limit. This will update the current lower limit of this
semaphore. It will also re-schedule all suspended threads for which their associated upper
limit is not larger than the lower limit plus the max_difference.

std::int64_t signal_all ()

namespace threads

Functions

```cpp
template<typename F>
thread_function_type make_thread_function(F &&f)

template<typename F>
thread_function_type make_thread_function_nullary(F &&f)

threads::thread_id_type register_thread(threads::thread_init_data &data,
    threads::thread_pool_base *pool,
    error_code &ec = throws)
```

Create a new thread using the given data.

Return This function will return the internal id of the newly created HPX-thread.

Note As long as `ec` is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

Parameters

- **data**: [in] The data to use for creating the thread.
- **pool**: [in] The thread pool to use for launching the work.
- **ec**: [in,out] This represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

Exceptions

- `invalid_status`: if the runtime system has not been started yet.

```cpp
threads::thread_id_type register_thread(threads::thread_init_data &data, error_code &ec = throws)
```

Create a new thread using the given data on the same thread pool as the calling thread, or on the default thread pool if not on an HPX thread.

Return This function will return the internal id of the newly created HPX-thread.

Note As long as `ec` is not pre-initialized to `hpx::throws` this function doesn't throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

Parameters

- **data**: [in] The data to use for creating the thread.
- **ec**: [in,out] This represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

Exceptions

- `invalid_status`: if the runtime system has not been started yet.
void register_work(threads::thread_init_data &data, threads::thread_pool_base *pool, error_code &ec = throws)

Create a new work item using the given data.

**Note** As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

**Parameters**
- data: [in] The data to use for creating the thread.
- pool: [in] The thread pool to use for launching the work.
- ec: [in,out] This represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

**Exceptions**
- invalid_status: if the runtime system has not been started yet.

void register_work(threads::thread_init_data &data, error_code &ec = throws)

Create a new work item using the given data on the same thread pool as the calling thread, or on the default thread pool if not on an HPX thread.

**Note** As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

**Parameters**
- data: [in] The data to use for creating the thread.
- ec: [in,out] This represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

**Exceptions**
- invalid_status: if the runtime system has not been started yet.

Enums

enum scheduler_mode
This enumeration describes the possible modes of a scheduler.

Values:

nothing_special = 0x000
As the name suggests, this option can be used to disable all other options.

do_background_work = 0x001
The scheduler will periodically call a provided callback function from a special HPX thread to enable performing background-work, for instance driving networking progress or garbage-collect AGAS.

reduce_thread_priority = 0x002
The kernel priority of the os-thread driving the scheduler will be reduced below normal.

delay_exit = 0x004
The scheduler will wait for some unspecified amount of time before exiting the scheduling loop while being terminated to make sure no other work is being scheduled during processing the shutdown request.

fast_idle_mode = 0x008
Some schedulers have the capability to act as ‘embedded’ schedulers. In this case it needs to periodically invoke a provided callback into the outer scheduler more frequently than normal. This option enables this behavior.

enable_elasticity = 0x010
This option allows for the scheduler to dynamically increase and reduce the number of processing units it runs on. Setting this value not succeed for schedulers that do not support this functionality.

enable_stealing = 0x020
This option allows schedulers that support work thread/stealing to enable/disable it

enable_stealing_numa = 0x040
This option allows schedulers that support it to disallow stealing between numa domains

assign_work_round_robin = 0x080
This option tells schedulers that support it to add tasks round robin to queues on each core

assign_work_thread_parent = 0x100
This option tells schedulers that support it to add tasks round to the same core/queue that the parent task is running on

steal_high_priority_first = 0x200
This option tells schedulers that support it to always (try to) steal high priority tasks from other queues before finishing their own lower priority tasks

steal_after_local = 0x400
This option tells schedulers that support it to steal tasks only when their local queues are empty

enable_idle_backoff = 0x0800
This option allows for certain schedulers to explicitly disable exponential idle-back off

default_mode = do_background_work | reduce_thread_priority | delay_exit | enable_stealing | enable_stealing_numa
This option represents the default mode.

all_flags = do_background_work | reduce_thread_priority | delay_exit | fast_idle_mode | enable_elasticity | enable_stealing | enable_stealing_numa | assign_work_round_robin | assign_work_thread_parent | steal_high_priority_first | steal_after_local | enable_idle_backoff
This enables all available options.

Functions

constexpr thread_data *get_thread_id_data (thread_id_type const &tid)

thread_self &get_self ()
  The function get_self returns a reference to the (OS thread specific) self reference to the current HPX thread.

thread_self *get_self_ptr ()
  The function get_self_ptr returns a pointer to the (OS thread specific) self reference to the current HPX thread.

thread_self_impl_type *get_ctx_ptr ()
  The function get_ctx_ptr returns a pointer to the internal data associated with each coroutine.
The function `get_self_ptr_checked` returns a pointer to the (OS thread specific) self reference to the current HPX thread.

The function `get_self_id` returns the HPX thread id of the current thread (or zero if the current thread is not a HPX thread).

The function `get_self_id_data` returns the data of the HPX thread id associated with the current thread (or nullptr if the current thread is not a HPX thread).

The function `get_parent_id` returns the HPX thread id of the current thread’s parent (or zero if the current thread is not a HPX thread).

Note This function will return a meaningful value only if the code was compiled with HPX_HAVE_THREAD_PARENT_REFERENCE being defined.

The function `get_parent_phase` returns the HPX phase of the current thread’s parent (or zero if the current thread is not a HPX thread).

Note This function will return a meaningful value only if the code was compiled with HPX_HAVE_THREAD_PARENT_REFERENCE being defined.

The function `get_self_stacksize` returns the stack size of the current thread (or zero if the current thread is not a HPX thread).

The function `get_self_stacksize_enum` returns the stack size of the l.

The function `get_parent_locality_id` returns the id of the locality of the current thread’s parent (or zero if the current thread is not a HPX thread).

Note This function will return a meaningful value only if the code was compiled with HPX_HAVE_THREAD_PARENT_REFERENCE being defined.

The function `get_self_component_id` returns the lva of the component the current thread is acting on

Note This function will return a meaningful value only if the code was compiled with HPX_HAVE_THREAD_TARGET_ADDRESS being defined.

A thread encapsulates:
- A thread status word (see the functions `thread::get_state` and `thread::set_state`)
- A function to execute (the thread function)
- A frame (in this implementation this is a block of memory used as the threads stack)
• A block of registers (not implemented yet)
Generally, threads are not created or executed directly. All functionality related to the management of threads is implemented by the thread-manager.

Subclassed by hpx::threads::thread_data_stackful, hpx::threads::thread_data_stackless

Public Types

using spinlock_pool = util::spinlock_pool<thread_data>

Public Functions

thread_data (thread_data const&)
thread_data (thread_data&&)
thread_data &operator= (thread_data const&)
thread_data &operator= (thread_data&&)

thread_state get_state (std::memory_order order = std::memory_order_acquire) const
The get_state function queries the state of this thread instance.

Return This function returns the current state of this thread. It will return one of the values as defined by the thread_state enumeration.

Note This function will be seldom used directly. Most of the time the state of a thread will be retrieved by using the function threadmanager::get_state.

thread_state set_state (thread_schedule_state state, thread_restart_state state_ex = thread_restart_state::unknown, std::memory_order load_order = std::memory_order_acquire, std::memory_order exchange_order = std::memory_order_seq_cst)
The set_state function changes the state of this thread instance.

Note This function will be seldom used directly. Most of the time the state of a thread will have to be changed using the threadmanager. Moreover, changing the thread state using this function does not change its scheduling status. It only sets the thread’s status word. To change the thread’s scheduling status threadmanager::set_state should be used.

Parameters
• newstate: [in] The new state to be set for the thread.

bool set_state_tagged (thread_schedule_state newstate, thread_state &prev_state, thread_state &new_tagged_state, std::memory_order exchange_order = std::memory_order_seq_cst)

bool restore_state (thread_state new_state, thread_state old_state, std::memory_order load_order = std::memory_order_relaxed, std::memory_order load_exchange = std::memory_order_seq_cst)
The restore_state function changes the state of this thread instance depending on its current state. It will change the state atomically only if the current state is still the same as passed as the second parameter. Otherwise it won’t touch the thread state of this instance.
**Note** This function will be seldom used directly. Most of the time the state of a thread will have to be changed using the threadmanager. Moreover, changing the thread state using this function does not change its scheduling status. It only sets the thread’s status word. To change the thread’s scheduling status `threadmanager::set_state` should be used.

**Return** This function returns `true` if the state has been changed successfully

**Parameters**
- `newstate`: [in] The new state to be set for the thread.
- `oldstate`: [in] The old state of the thread which still has to be the current state.

```cpp
bool restore_state(thread_schedule_state new_state,
                    thread_restart_state state_ex,
                    thread_state old_state,
                    std::memory_order load_exchange =
                    std::memory_order_seq_cst)
```

```cpp
constexpr std::uint64_t get_component_id() const
```

Return the id of the component this thread is running in.

```cpp
util::thread_description get_description() const

util::thread_description set_description(util::thread_description)

util::thread_description get_lco_description() const

util::thread_description set_lco_description(util::thread_description)
```

```cpp
constexpr std::uint32_t get_parent_locality_id() const
```

Return the locality of the parent thread.

```cpp
constexpr thread_id_type get_parent_thread_id() const
```

Return the thread id of the parent thread.

```cpp
constexpr std::size_t get_parent_thread_phase() const
```

Return the phase of the parent thread.

```cpp
constexpr util::backtrace const *get_backtrace() const

util::backtrace const *set_backtrace(util::backtrace const*)
```

```cpp
constexpr thread_priority get_priority() const
```

```cpp
void set_priority(thread_priority priority) const
```

```cpp
bool interruption_requested() const
```

```cpp
bool interruption_enabled() const
```

```cpp
bool set_interruption_enabled(bool enable)
```

```cpp
void interrupt (bool flag = true)
```

```cpp
bool interruption_point (bool throw_on_interrupt = true)
```

```cpp
bool add_thread_exit_callback (util::function_nonser<void>
                               > const &f
                               
                               void run_thread_exit_callbacks()
                               
                               void free_thread_exit_callbacks()
                               
                               policies::scheduler_base *get_scheduler_base() const
```
HPX Documentation, master

```cpp
std::size_t get_last_worker_thread_num() const
void set_last_worker_thread_num(std::size_t last_worker_thread_num)
std::ptrdiff_t get_stack_size() const
thread_stacksize get_stack_size_enum() const
template<typename ThreadQueue>
ThreadQueue &get_queue()
coroutine_type::result_type operator()(hpx::execution_base::this_thread::detail::agent_storage *agent_storage)

Execute the thread function.

**Return** This function returns the thread state the thread should be scheduled from this point on. The thread manager will use the returned value to set the thread’s scheduling status.

```cpp
virtual thread_id_type get_thread_id() const
virtual std::size_t get_thread_phase() const

Functions

util::thread_description get_thread_description(thread_id_type const &id, error_code &ec = throws)

The function get_thread_description is part of the thread related API allows to query the description of one of the threads known to the thread-manager.

Return This function returns the description of the thread referenced by the id parameter. If the thread is not known to the thread-manager the return value will be the string "<unknown>".

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters

- id: [in] The thread id of the thread being queried.
- ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

util::thread_description set_thread_description(thread_id_type const &id, util::thread_description const &desc = util::thread_description(), error_code &ec = throws)

Functions

threads::thread_restart_state suspend(threads::thread_schedule_state state, threads::thread_id_type const &id,
util::thread_description const &description =
util::thread_description("this_thread::suspend"),
error_code &ec = throws)

The function suspend will return control to the thread manager (suspends the current thread). It sets
the new state of this thread to the thread state passed as the parameter.

Note  Must be called from within a HPX-thread.

Exceptions
• If: &ec != &throws, never throws, but will set ec to an appropriate value when an error occurs. Otherwise, this function will throw an hpx::exception with an error code of hpx::yield_aborted if it is signaled with wait_aborted. If called outside of a HPX-thread, this function will throw an hpx::exception with an error code of hpx::null_thread_id. If this function is called while the thread-manager is not running, it will throw an hpx::exception with an error code of hpx::invalid_status.

threads::thread_restart_state suspend(threads::thread_schedule_state state =
threads::thread_schedule_state::pending,
util::thread_description const &description =
util::thread_description("this_thread::suspend"),
error_code &ec = throws)

The function suspend will return control to the thread manager (suspends the current thread). It sets
the new state of this thread to suspended and schedules a wakeup for this threads at the given time.

Note  Must be called from within a HPX-thread.

Exceptions
• If: &ec != &throws, never throws, but will set ec to an appropriate value when an error occurs. Otherwise, this function will throw an hpx::exception with an error code of hpx::yield_aborted if it is signaled with wait_aborted. If called outside of a HPX-thread, this function will throw an hpx::exception with an error code of hpx::null_thread_id. If this function is called while the thread-manager is not running, it will throw an hpx::exception with an error code of hpx::invalid_status.

threads::thread_restart_state suspend(hpx::chrono::steady_time_point const &abs_time, threads::thread_id_type const &id,
util::thread_description const &description =
util::thread_description("this_thread::suspend"),
error_code &ec = throws)

The function suspend will return control to the thread manager (suspends the current thread). It sets
the new state of this thread to suspended and schedules a wakeup for this threads at the given time.

Note  Must be called from within a HPX-thread.

Exceptions
• If: &ec != &throws, never throws, but will set ec to an appropriate value when an error occurs. Otherwise, this function will throw an hpx::exception with an error code of hpx::yield_aborted if it is signaled with wait_aborted. If called outside of a HPX-thread, this function will throw an hpx::exception with an error code of hpx::null_thread_id. If this function is called while the thread-manager is not running, it will throw an hpx::exception with an error code of hpx::invalid_status.
threads::thread_restart_state suspend(hpx::chrono::steady_time_point const &abs_time,
util::thread_description const &description =
util::thread_description("this_thread::suspend"),
error_code &ec = throws)

The function suspend will return control to the thread manager (suspends the current thread). It sets
the new state of this thread to suspended and schedules a wakeup for this threads at the given time.

**Note** Must be called from within a HPX-thread.

**Exceptions**
- If: &ec != &throws, never throws, but will set ec to an appropriate value when an er-
or occurs. Otherwise, this function will throw an hpx::exception with an error code of
hpx::yield_aborted if it is signaled with wait_aborted. If called outside of a HPX-thread, this
function will throw an hpx::exception with an error code of hpx::null_thread_id. If this function
is called while the thread-manager is not running, it will throw an hpx::exception with an
error code of hpx::invalid_status.

threads::thread_restart_state suspend(hpx::chrono::steady_duration const &rel_time,
util::thread_description const &description =
util::thread_description("this_thread::suspend"),
error_code &ec = throws)

The function suspend will return control to the thread manager (suspends the current thread). It sets
the new state of this thread to suspended and schedules a wakeup for this threads after the given
duration.

**Note** Must be called from within a HPX-thread.

**Exceptions**
- If: &ec != &throws, never throws, but will set ec to an appropriate value when an er-
or occurs. Otherwise, this function will throw an hpx::exception with an error code of
hpx::yield_aborted if it is signaled with wait_aborted. If called outside of a HPX-thread, this
function will throw an hpx::exception with an error code of hpx::null_thread_id. If this function
is called while the thread-manager is not running, it will throw an hpx::exception with an
error code of hpx::invalid_status.

threads::thread_restart_state suspend(hpx::chrono::steady_duration const &rel_time,
threads::thread_id_type const &id,
util::thread_description const &description =
util::thread_description("this_thread::suspend"),
error_code &ec = throws)

The function suspend will return control to the thread manager (suspends the current thread). It sets
the new state of this thread to suspended and schedules a wakeup for this threads after the given
duration.

**Note** Must be called from within a HPX-thread.

**Exceptions**
- If: &ec != &throws, never throws, but will set ec to an appropriate value when an er-
or occurs. Otherwise, this function will throw an hpx::exception with an error code of
hpx::yield_aborted if it is signaled with wait_aborted. If called outside of a HPX-thread, this
function will throw an hpx::exception with an error code of hpx::null_thread_id. If this function
is called while the thread-manager is not running, it will throw an hpx::exception with an
error code of hpx::invalid_status.

threads::thread_restart_state suspend(std::uint64_t ms,
util::thread_description const &description =
util::thread_description("this_thread::suspend"),
error_code &ec = throws)
The function `suspend` will return control to the thread manager (suspends the current thread). It sets the new state of this thread to `suspended` and schedules a wakeup for this threads after the given time (specified in milliseconds).

**Note** Must be called from within a HPX-thread.

**Exceptions**
- If `ec` != `&throws`, never throws, but will set `ec` to an appropriate value when an error occurs. Otherwise, this function will throw an `hpx::exception` with an error code of `hpx::yield_aborted` if it is signaled with `wait_aborted`. If called outside of a HPX-thread, this function will throw an `hpx::exception` with an error code of `hpx::null_thread_id`. If this function is called while the thread-manager is not running, it will throw an `hpx::exception` with an error code of `hpx::invalid_status`.

```cpp
threads::thread_pool_base *get_pool (error_code &ec = throws)
```

Returns a pointer to the pool that was used to run the current thread.

**Exceptions**
- If `ec` != `&throws`, never throws, but will set `ec` to an appropriate value when an error occurs. Otherwise, this function will throw an `hpx::exception` with an error code of `hpx::yield_aborted` if it is signaled with `wait_aborted`. If called outside of a HPX-thread, this function will throw an `hpx::exception` with an error code of `hpx::null_thread_id`. If this function is called while the thread-manager is not running, it will throw an `hpx::exception` with an error code of `hpx::invalid_status`.

```cpp
namespace threads {
  
  Functions

  thread_state set_thread_state (thread_id_type const &id, thread_schedule_state state = thread_schedule_state::pending, thread_restart_state stateex = thread_restart_state::signaled, thread_priority priority = thread_priority::normal, bool retry_on_active = true, hpx::error_code &ec = throws)
```

Set the thread state of the thread referenced by the thread_id `id`.

**Note** If the thread referenced by the parameter `id` is in `thread_state::active` state this function schedules a new thread which will set the state of the thread as soon as its not active anymore. The function returns `thread_state::active` in this case.

**Return** This function returns the previous state of the thread referenced by the `id` parameter. It will return one of the values as defined by the `thread_state` enumeration. If the thread is not known to the thread-manager the return value will be `thread_state::unknown`.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Parameters**
- `id`: [in] The thread id of the thread the state should be modified for.
- `state`: [in] The new state to be set for the thread referenced by the `id` parameter.
- `stateex`: [in] The new extended state to be set for the thread referenced by the `id` parameter.
- `priority`:
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.
thread_id_type set_thread_state (thread_id_type const &id, hpx::chrono::steady_time_point const &abs_time, std::atomic<bool> *started, thread_schedule_state state = thread_schedule_state::pending, thread_restart_state stateex = thread_restart_state::timeout, thread_priority priority = thread_priority::normal, bool retry_on_active = true, error_code &ec = throws)

Set the thread state of the thread referenced by the thread_id id.

Set a timer to set the state of the given thread to the given new value after it expired (at the given time)

Return

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters

• id: [in] The thread id of the thread the state should be modified for.
• abs_time: [in] Absolute point in time for the new thread to be run.
• started: [in,out] A helper variable allowing to track the state of the timer helper thread.
• state: [in] The new state to be set for the thread referenced by the id parameter.
• stateex: [in] The new extended state to be set for the thread referenced by the id parameter.
• priority:
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

thread_id_type set_thread_state (thread_id_type const &id, hpx::chrono::steady_duration const &rel_time, thread_schedule_state state = thread_schedule_state::pending, thread_restart_state stateex = thread_restart_state::timeout, thread_priority priority = thread_priority::normal, bool retry_on_active = true, error_code &ec = throws)

Set the thread state of the thread referenced by the thread_id id.

Set a timer to set the state of the given thread to the given new value after it expired (after the given duration)

Return

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters

• id: [in] The thread id of the thread the state should be modified for.
• rel_time: [in] Time duration after which the new thread should be run.
• state: [in] The new state to be set for the thread referenced by the id parameter.
• stateex: [in] The new extended state to be set for the thread referenced by the id parameter.
• priority:
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.
thread_state \textbf{get\_thread\_state}(\texttt{thread\_id\_type const \&id, error\_code \&ec = throws})

The function \texttt{get\_thread\_backtrace} is part of the thread related API allows to query the currently stored thread back trace (which is captured during thread suspension).

**Return**
This function returns the currently captured stack back trace of the thread referenced by the \texttt{id} parameter. If the thread is not known to the thread-manager the return value will be the zero.

**Note**
As long as \texttt{ec} is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter \texttt{ec}. Otherwise it throws an instance of hpx::exception. The function \texttt{get\_thread\_state} is part of the thread related API. It queries the state of one of the threads known to the thread-manager.

**Return**
This function returns the thread state of the thread referenced by the \texttt{id} parameter. If the thread is not known to the thread-manager the return value will be \texttt{terminated}.

**Note**
As long as \texttt{ec} is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter \texttt{ec}. Otherwise it throws an instance of hpx::exception.

**Parameters**
- \texttt{id}: [in] The thread id of the thread being queried.
- \texttt{ec}: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

\texttt{std::size\_t \textbf{get\_thread\_phase}(\texttt{thread\_id\_type const \&id, error\_code \&ec = throws})}

The function \texttt{get\_thread\_phase} is part of the thread related API. It queries the phase of one of the threads known to the thread-manager.

**Return**
This function returns the thread phase of the thread referenced by the \texttt{id} parameter. If the thread is not known to the thread-manager the return value will be \texttt{~0}.

**Note**
As long as \texttt{ec} is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter \texttt{ec}. Otherwise it throws an instance of hpx::exception.

**Parameters**
- \texttt{id}: [in] The thread id of the thread the phase should be modified for.
- \texttt{ec}: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

\texttt{bool \textbf{get\_thread\_interruption\_enabled}(\texttt{thread\_id\_type const \&id, error\_code \&ec = throws})}

Returns whether the given thread can be interrupted at this point.

**Return**
This function returns \texttt{true} if the given thread can be interrupted at this point in time. It will return \texttt{false} otherwise.

**Note**
As long as \texttt{ec} is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter \texttt{ec}. Otherwise it throws an instance of hpx::exception.

**Parameters**
- \texttt{id}: [in] The thread id of the thread which should be queried.
- \texttt{ec}: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

\texttt{bool \textbf{set\_thread\_interruption\_enabled}(\texttt{thread\_id\_type const \&id, bool enable, error\_code \&ec = throws})}

Set whether the given thread can be interrupted at this point.
Return  This function returns the previous value of whether the given thread could have been inter-
rupted.

Note  As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the 
result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters  
- id: [in] The thread id of the thread which should receive the new value.
- enable: [in] This value will determine the new interruption enabled status for the given 
  thread.
- ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the 
  function will throw on error instead.

bool get_thread_interruption_requested (thread_id_type const &id, error_code &ec = throws)

Returns whether the given thread has been flagged for interruption.

Return  This function returns true if the given thread was flagged for interruption. It will return false 
otherwise.

Note  As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the 
result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters  
- id: [in] The thread id of the thread which should be queried.
- ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the 
  function will throw on error instead.

void interrupt_thread (thread_id_type const &id, bool flag, error_code &ec = throws)

Flag the given thread for interruption.

Note  As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the 
result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters  
- id: [in] The thread id of the thread which should be interrupted.
- flag: [in] The flag encodes whether the thread should be interrupted (if it is true), or ‘unin- 
  terrupted’ (if it is false).
- ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the 
  function will throw on error instead.

void interrupt_thread (thread_id_type const &id, error_code &ec = throws)

void interruption_point (thread_id_type const &id, error_code &ec = throws)

Interrupt the current thread at this point if it was canceled. This will throw a thread_interrupted 
exception, which will cancel the thread.

Note  As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the 
result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters  
- id: [in] The thread id of the thread which should be interrupted.
- ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the 
  function will throw on error instead.

threads::thread_priority get_thread_priority (thread_id_type const &id, error_code &ec = 
throws)

Return priority of the given thread
**Note**  As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Parameters**
- **id**: [in] The thread id of the thread whose priority is queried.
- **ec**: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
std::ptrdiff_t get_stack_size(thread_id_type const &id, error_code &ec = throws)
```

Return stack size of the given thread

**Note**  As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Parameters**
- **id**: [in] The thread id of the thread whose priority is queried.
- **ec**: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
threads::thread_pool_base *get_pool(thread_id_type const &id, error_code &ec = throws)
```

Returns a pointer to the pool that was used to run the current thread

**Exceptions**
- **If**: `&ec != &throws`, never throws, but will set `ec` to an appropriate value when an error occurs. Otherwise, this function will throw an `hpx::exception` with an error code of `hpx::yield_aborted` if it is signaled with `wait_aborted`. If called outside of a HPX-thread, this function will throw an `hpx::exception` with an error code of `hpx::null_thread_id`. If this function is called while the thread-manager is not running, it will throw an `hpx::exception` with an error code of `hpx::invalid_status`.

```cpp
namespace hpx
namespace threads

class thread_init_data

Public Functions

thread_schedule_state initial_state
bool run_now
policies::scheduler_base *scheduler_base
```

namespace hpx

Functions

```cpp
std::size_t get_worker_thread_num()
```

Return the number of the current OS-thread running in the runtime instance the current HPX-thread is executed with.

This function returns the zero based index of the OS-thread which executes the current HPX-thread.

**Note** The returned value is zero based and its maximum value is smaller than the overall number of OS-threads executed (as returned by `get_os_thread_count()`).

**Note** This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

```cpp
std::size_t get_worker_thread_num(error_code &ec)
```

Return the number of the current OS-thread running in the runtime instance the current HPX-thread is executed with.

This function returns the zero based index of the OS-thread which executes the current HPX-thread.

**Note** The returned value is zero based and its maximum value is smaller than the overall number of OS-threads executed (as returned by `get_os_thread_count()`). It will return -1 if the current thread is not a known thread or if the runtime is not in running state.

**Note** This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

**Parameters**

- `ec`: [in,out] this represents the error status on exit.

```cpp
std::size_t get_local_worker_thread_num()
```

Return the number of the current OS-thread running in the current thread pool the current HPX-thread is executed with.

This function returns the zero based index of the OS-thread on the current thread pool which executes the current HPX-thread.

**Note** The returned value is zero based and its maximum value is smaller than the number of OS-threads executed on the current thread pool. It will return -1 if the current thread is not a known thread or if the runtime is not in running state.
Note This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

```cpp
std::size_t get_local_worker_thread_num(error_code &ec)
```

Return the number of the current OS-thread running in the current thread pool the current HPX-thread is executed with.

This function returns the zero based index of the OS-thread on the current thread pool which executes the current HPX-thread.

Note The returned value is zero based and its maximum value is smaller than the number of OS-threads executed on the current thread pool. It will return -1 if the current thread is not a known thread or if the runtime is not in running state.

Note This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

Parameters

- `ec`: [in,out] this represents the error status on exit.

```cpp
std::size_t get_thread_pool_num()
```

Return the number of the current thread pool the current HPX-thread is executed with.

This function returns the zero based index of the thread pool which executes the current HPX-thread.

Note The returned value is zero based and its maximum value is smaller than the number of thread pools started by the runtime. It will return -1 if the current thread pool is not a known thread pool or if the runtime is not in running state.

Note This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

```cpp
std::size_t get_thread_pool_num(error_code &ec)
```

Return the number of the current thread pool the current HPX-thread is executed with.

This function returns the zero based index of the thread pool which executes the current HPX-thread.

Note The returned value is zero based and its maximum value is smaller than the number of thread pools started by the runtime. It will return -1 if the current thread pool is not a known thread pool or if the runtime is not in running state.

Note This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

Parameters

- `ec`: [in,out] this represents the error status on exit.

```cpp
namespace hpx
```

```cpp
namespace threads
```

```cpp
struct executor_statistics
```

`#include <thread_pool_base.hpp>` Data structure which stores statistics collected by an executor instance.
Public Functions

`executor_statistics()`

`class thread_pool_base`

#include `<thread_pool_base.hpp>` The base class used to manage a pool of OS threads.

Public Functions

`virtual void suspend_processing_unit_direct(std::size_t virt_core, error_code &ec = throws) = 0`
Suspends the given processing unit. Blocks until the processing unit has been suspended.

Parameters

- `virt_core`: [in] The processing unit on the the pool to be suspended. The processing units are indexed starting from 0.

`virtual void resume_processing_unit_direct(std::size_t virt_core, error_code &ec = throws) = 0`
Resumes the given processing unit. Blocks until the processing unit has been resumed.

Parameters

- `virt_core`: [in] The processing unit on the the pool to be resumed. The processing units are indexed starting from 0.

`virtual void resume_direct(error_code &ec = throws) = 0`
Resumes the thread pool. Blocks until all OS threads on the thread pool have been resumed.

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

`virtual void suspend_direct(error_code &ec = throws) = 0`
Suspends the thread pool. Blocks until all OS threads on the thread pool have been suspended.

Note A thread pool cannot be suspended from an HPX thread running on the pool itself.
Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

Exceptions

- `hpx::exception`: if called from an HPX thread which is running on the pool itself.

struct topology

Public Functions

topology()

~topology()

std::size_t get_socket_number (std::size_t num_thread, error_code& = throws) const

Return the Socket number of the processing unit the given thread is running on.

Parameters

• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

std::size_t get_numa_node_number (std::size_t num_thread, error_code& = throws) const

Return the NUMA node number of the processing unit the given thread is running on.

Parameters

• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

mask_cref_type get_machine_affinity_mask (error_code &ec = throws) const

Return a bit mask where each set bit corresponds to a processing unit available to the application.

Parameters

• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.
mask_type get_service_affinity_mask (mask_cref_type used_processing_units, error_code &ec = throws) const

Return a bit mask where each set bit corresponds to a processing unit available to the service threads in the application.

Parameters

• used_processing_units: [in] This is the mask of processing units which are not available for service threads.
• ec: [in,out] This represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

mask_cref_type get_socket_affinity_mask (std::size_t num_thread, error_code &ec = throws) const

Return a bit mask where each set bit corresponds to a processing unit available to the given thread inside the socket it is running on.

Parameters

• ec: [in,out] This represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

mask_cref_type get_numa_node_affinity_mask (std::size_t num_thread, error_code &ec = throws) const

Return a bit mask where each set bit corresponds to a processing unit available to the given thread inside the NUMA domain it is running on.

Parameters

• ec: [in,out] This represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

mask_type get_numa_node_affinity_mask_from_numa_node (std::size_t num_node) const

Return a bit mask where each set bit corresponds to a processing unit associated with the given NUMA node.

Parameters

• ec: [in,out] This represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

mask_cref_type get_core_affinity_mask (std::size_t num_thread, error_code &ec = throws) const

Return a bit mask where each set bit corresponds to a processing unit available to the given thread inside the core it is running on.

Parameters

• ec: [in,out] This represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

mask_cref_type get_thread_affinity_mask (std::size_t num_thread, error_code &ec = throws) const

Return a bit mask where each set bit corresponds to a processing unit available to the given thread.

Parameters

• ec: [in,out] This represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.
void set_thread_affinity_mask(mask_cref_type mask, error_code &ec = throws)
    const
Use the given bit mask to set the affinity of the given thread. Each set bit corresponds to a
processing unit the thread will be allowed to run on.

Note Use this function on systems where the affinity must be set from inside the thread itself.
Parameters
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the
  function will throw on error instead.

mask_type get_thread_affinity_mask_from_lva(void const *lva, error_code &ec = throws) const
Return a bit mask where each set bit corresponds to a processing unit co-located with the memory
the given address is currently allocated on.

Parameters
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the
  function will throw on error instead.

void print_affinity_mask(std::ostream &os, std::size_t num_thread, mask_cref_type m,
    const std::string &pool_name) const
Prints the.

Parameters
• m: to os in a human readable form

bool reduce_thread_priority(error_code &ec = throws) const
Reduce thread priority of the current thread.

Parameters
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the
  function will throw on error instead.

std::size_t get_number_of.Sockets() const
Return the number of available NUMA domains.

std::size_t get_number_of_numa_nodes() const
Return the number of available NUMA domains.

std::size_t get_number_of_cores() const
Return the number of available cores.

std::size_t get_number_of_pushs() const
Return the number of available hardware processing units.

std::size_t get_number_of_numa_node_cores(std::size_t numa) const
Return number of cores in given numa domain.

std::size_t get_number_of_numa_node_pushs(std::size_t numa) const
Return number of processing units in a given numa domain.

std::size_t get_number_of_socket_pushs(std::size_t socket) const
Return number of processing units in a given socket.

std::size_t get_number_of_core_pushs(std::size_t core) const
Return number of processing units in given core.
std::size_t get_number_of_socket_cores (std::size_t socket) const
Return number of cores units in given socket.

std::size_t get_core_number (std::size_t num_thread, error_code& = throws) const

std::size_t get_pu_number (std::size_t num_core, std::size_t num_pu, error_code &ec = throws) const

mask_type get_cpubind_mask (error_code &ec = throws) const

mask_type get_cpubind_mask (std::thread &handle, error_code &ec = throws) const

hwloc_bitmap_ptr cpuset_to_nodeset (mask_cref_type cpuset) const
convert a cpu mask into a numa node mask in hwloc bitmap form

void write_to_log () const

void *allocate (std::size_t len) const
This is equivalent to malloc(), except that it tries to allocate page-aligned memory from the OS.

void *allocate_membind (std::size_t len, hwloc_bitmap_ptr bitmap, hpx_hwloc_membind_policy policy, int flags) const
allocate memory with binding to a numa node set as specified by the policy and flags (see hwloc docs)

threads::mask_type get_area_membind_nodeset (const void *addr, std::size_t len) const

bool set_area_membind_nodeset (const void *addr, std::size_t len, void *nodeset) const

int get_numa_domain (const void *addr) const

void deallocate (void *addr, std::size_t len) const
Free memory that was previously allocated by allocate.

void print_vector (std::ostream &os, std::vector<std::size_t> const &v) const

void print_mask_vector (std::ostream &os, std::vector<mask_type> const &v) const

void print_hwloc (std::ostream&) const

mask_type init_socket_affinity_mask_from_socket (std::size_t num_socket) const

mask_type init_numa_node_affinity_mask_from_numa_node (std::size_t num_numa_node) const

mask_type init_core_affinity_mask_from_core (std::size_t num_core, mask_cref_type default_mask = empty_mask) const

mask_type init_thread_affinity_mask (std::size_t num_thread) const

mask_type init_thread_affinity_mask (std::size_t num_core, std::size_t num_pu) const

hwloc_bitmap_t mask_to_bitmap (mask_cref_type mask, hwloc_obj_type_t htype) const

mask_type bitmap_to_mask (hwloc_bitmap_t bitmap, hwloc_obj_type_t htype) const

Functions

template<typename Iterator>
bool insert_checked (std::pair<Iterator, bool> const &r)
   Helper function for writing predicates that test whether an std::map insertion succeeded. This inline
template function negates the need to explicitly write the sometimes lengthy std::pair<Iterator, bool>
type.

   Return  This function returns r.second.
   Parameters
   • r: [in] The return value of a std::map insert operation.

bool parse_sed_expression(const string& input, string& search, string& replace)

Parse a sed command.

Return true if the parsing was successful, false otherwise.

Note Currently, only supports search and replace syntax (s/search/replace/)

Parameters

• input: [in] The content to parse.
• search: [out] If the parsing is successful, this string is set to the search expression.
• search: [out] If the parsing is successful, this string is set to the replace expression.

struct sed_transform

#include <sed_transform.hpp> An unary function object which applies a sed command to its subject and returns the resulting string.

Note Currently, only supports search and replace syntax (s/search/replace/)

Public Functions

**HPX_REGISTER_ACTION_DECLARATION(...)**

Declare the necessary component action boilerplate code.

The macro `HPX_REGISTER_ACTION_DECLARATION` can be used to declare all the boilerplate code which is required for proper functioning of component actions in the context of HPX.

The parameter `action` is the type of the action to declare the boilerplate for.

This macro can be invoked with an optional second parameter. This parameter specifies a unique name of the action to be used for serialization purposes. The second parameter has to be specified if the first parameter is not usable as a plain (non-qualified) C++ identifier, i.e. the first parameter contains special characters which cannot be part of a C++ identifier, such as `<`, `>`, or ':'.

```cpp
namespace app {

// Define a simple component exposing one action 'print_greeting'
class HPX_COMPONENT_EXPORT server : public hpx::components::component_base<server> {
    void print_greeting () {
        hpx::cout << "Hey, how are you?\n" << hpx::flush;
    }

    // Component actions need to be declared, this also defines the
    // type 'print_greeting_action' representing the action.
    HPX_DEFINE_COMPONENT_ACTION(server, print_greeting, print_greeting_action);
}

// Declare boilerplate code required for each of the component actions.
HPX_REGISTER_ACTION_DECLARATION(app::server::print_greeting_action);
```

**Example:**

```
Note This macro has to be used once for each of the component actions defined using one of the
HPX_DEFINE_COMPONENT_ACTION macros. It has to be visible in all translation units using the
action, thus it is recommended to place it into the header file defining the component.
```

**HPX_REGISTER_ACTION_DECLARATION(...)**

**HPX_REGISTER_ACTION_DECLARATION_1 (action)**

**HPX_REGISTER_ACTION (...)**

Define the necessary component action boilerplate code.
The macro `HPX_REGISTER_ACTION` can be used to define all the boilerplate code which is required for proper functioning of component actions in the context of HPX.

The parameter `action` is the type of the action to define the boilerplate for.

This macro can be invoked with an optional second parameter. This parameter specifies a unique name of the action to be used for serialization purposes. The second parameter has to be specified if the first parameter is not usable as a plain (non-qualified) C++ identifier, i.e. the first parameter contains special characters which cannot be part of a C++ identifier, such as '<', '>', or ':'.

**Note** This macro has to be used once for each of the component actions defined using one of the `HPX_DEFINE_COMPONENT_ACTION` or `HPX_DEFINE_PLAIN_ACTION` macros. It has to occur exactly once for each of the actions, thus it is recommended to place it into the source file defining the component.

**Note** Only one of the forms of this macro `HPX_REGISTER_ACTION` or `HPX_REGISTER_ACTION_ID` should be used for a particular action, never both.

```
HPX_REGISTER_ACTION_ID (action, actionname, actionid)
```

Define the necessary component action boilerplate code and assign a predefined unique id to the action.

The macro `HPX_REGISTER_ACTION` can be used to define all the boilerplate code which is required for proper functioning of component actions in the context of HPX.

The parameter `action` is the type of the action to define the boilerplate for.

The parameter `actionname` specifies an unique name of the action to be used for serialization purposes. The second parameter has to be usable as a plain (non-qualified) C++ identifier, it should not contain special characters which cannot be part of a C++ identifier, such as '<', '>', or ':'.

The parameter `actionid` specifies an unique integer value which will be used to represent the action during serialization.

**Note** This macro has to be used once for each of the component actions defined using one of the `HPX_DEFINE_COMPONENT_ACTION` or global actions `HPX_DEFINE_PLAIN_ACTION` macros. It has to occur exactly once for each of the actions, thus it is recommended to place it into the source file defining the component.

**Note** Only one of the forms of this macro `HPX_REGISTER_ACTION` or `HPX_REGISTER_ACTION_ID` should be used for a particular action, never both.

```cpp
namespace hpx
{
namespace actions
{

template<typename Component, typename Signature, typename Derived>
struct basic_action
{
    #include <basic_action_fwd.hpp>

    Template Parameters
    • Component: component type
    • Signature: return type and arguments
    • Derived: derived action class
}
}
```

2.8. API reference 621
Defines

HPX_DEFINE_COMPONENT_ACTION (...) Registers a member function of a component as an action type with HPX.

The macro `HPX_DEFINE_COMPONENT_ACTION` can be used to register a member function of a component as an action type named `action_type`.

The parameter `component` is the type of the component exposing the member function `func` which should be associated with the newly defined action type. The parameter `action_type` is the name of the action type to register with HPX.

```cpp
namespace app {
    // Define a simple component exposing one action 'print_greeting'
    class HPX_COMPONENT_EXPORT server : public hpx::components::component_base<server> {
        void print_greeting() const {
            hpx::cout << "Hey, how are you?\n" << hpx::flush;
        }

        // Component actions need to be declared, this also defines the
        // type 'print_greeting_action' representing the action.
        HPX_DEFINE_COMPONENT_ACTION(server, print_greeting, print_greeting_action);
    };
}
```

Example:

The first argument must provide the type name of the component the action is defined for.

The second argument must provide the member function name the action should wrap.

The default value for the third argument (the typename of the defined action) is derived from the name of the function (as passed as the second argument) by appending ‘_action’. The third argument can be omitted only if the second argument with an appended suffix ‘_action’ resolves to a valid, unqualified C++ type name.

**Note** The macro `HPX_DEFINE_COMPONENT_ACTION` can be used with 2 or 3 arguments. The third argument is optional.

Defines

HPX_DEFINE_PLAIN_ACTION (...) Defines a plain action type.

```cpp
namespace app {
    void some_global_function(double d) {
    }
}
```
cout << d;
}

// This will define the action type 'app::some_global_action' which
// represents the function 'app::some_global_function'.
HPX_DEFINE_PLAIN_ACTION(some_global_function, some_global_action);

Example:

Note Usually this macro will not be used in user code unless the intent is to avoid defining the action_type in
global namespace. Normally, the use of the macro HPX.PLAIN_ACTION is recommended.

Note The macro HPX.DEFINE.PLAIN_ACTION can be used with 1 or 2 arguments. The second argument is
optional. The default value for the second argument (the typename of the defined action) is derived from
the name of the function (as passed as the first argument) by appending '_action'. The second argument
can be omitted only if the first argument with an appended suffix '_action' resolves to a valid, unqualified
C++ type name.

HPX_DECLARE_PLAIN_ACTION(...)Declares a plain action type.

HPX.PLAIN_ACTION(...) Defines a plain action type based on the given function func and registers it with HPX.

The macro HPX.PLAIN_ACTION can be used to define a plain action (e.g. an action encapsulating a global or
free function) based on the given function func. It defines the action type name representing the given function.
This macro additionally registers the newly define action type with HPX.

The parameter func is a global or free (non-member) function which should be encapsulated into a plain action.
The parameter name is the name of the action type defined by this macro.

namespace app
{
    void some_global_function(double d)
    {
        cout << d;
    }
}

// This will define the action type 'some_global_action' which represents
// the function 'app::some_global_function'.
HPX.PLAIN_ACTION(app::some_global_function, some_global_action);

Example:

Note The macro HPX.PLAIN_ACTION has to be used at global namespace even if the wrapped function is
located in some other namespace. The newly defined action type is placed into the global namespace as
well.

Note The macro HPX.PLAIN_ACTION_ID can be used with 1, 2, or 3 arguments. The second and third
arguments are optional. The default value for the second argument (the typename of the defined action) is
derived from the name of the function (as passed as the first argument) by appending '_action'. The second argument can be omitted only if the first argument with an appended suffix '_action' resolves to a valid, unqualified C++ type name. The default value for the third argument is `hpx::components::factory_check`.

**Note** Only one of the forms of this macro `HPX_PLAIN_ACTION` or `HPX_PLAIN_ACTION_ID` should be used for a particular action, never both.

**HPX_PLAIN_ACTION_ID** (func, name, id)

Defines a plain action type based on the given function `func` and registers it with HPX.

The macro `HPX_PLAIN_ACTION_ID` can be used to define a plain action (e.g. an action encapsulating a global or free function) based on the given function `func`. It defines the action type `actionname` representing the given function. The parameter `actionid`

The parameter `actionid` specifies an unique integer value which will be used to represent the action during serialization.

The parameter `func` is a global or free (non-member) function which should be encapsulated into a plain action. The parameter `name` is the name of the action type defined by this macro.

The second parameter has to be usable as a plain (non-qualified) C++ identifier, it should not contain special characters which cannot be part of a C++ identifier, such as '<', '>', or ':'.

```cpp
namespace app {
    void some_global_function(double d) {
        cout << d;
    }
}

// This will define the action type 'some_global_action' which represents
// the function 'app::some_global_function'.
HPX_PLAIN_ACTION_ID(app::some_global_function, some_global_action,
    some_unique_id);
```

**Example:**

**Note** The macro `HPX_PLAIN_ACTION_ID` has to be used at global namespace even if the wrapped function is located in some other namespace. The newly defined action type is placed into the global namespace as well.

**Note** Only one of the forms of this macro `HPX_PLAIN_ACTION` or `HPX_PLAIN_ACTION_ID` should be used for a particular action, never both.

bool register_locality(parcelset::endpoints_type const &endpoints, naming::gid_type &prefix, std::uint32_t num_threads, error_code &ec = throws)

Add a locality to the runtime.

parcelset::endpoints_type const &resolve_locality(naming::gid_type const &gid, error_code &ec = throws)

Resolve a locality to its prefix.

Return Returns an empty vector if the locality is not registered.

bool has_resolved_locality(naming::gid_type const &gid)

bool unregister_locality(naming::gid_type const &gid, error_code &ec = throws)

Remove a locality from the runtime.

void remove_resolved_locality(naming::gid_type const &gid)

remove given locality from locality cache

bool get_console_locality(naming::gid_type &locality, error_code &ec = throws)

Get locality locality_id of the console locality.

Return This function returns true if a console locality_id exists and returns false otherwise.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters

• locality_id: [out] The locality_id value uniquely identifying the console locality. This is valid only, if the return value of this function is true.
• try_cache: [in] If this is set to true the console is first tried to be found in the local cache. Otherwise this function will always query AGAS, even if the console locality_id is already known locally.
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

bool get_localities (std::vector<naming::gid_type> &locality_ids, components::component_type type, error_code &ec = throws)

Query for the locality_ids of all known localities.

This function returns the locality_ids of all localities known to the AGAS server or all localities having a registered factory for a given component type.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters

• locality_ids: [out] The vector will contain the prefixes of all localities registered with the AGAS server. The returned vector holds the prefixes representing the runtime_support components of these localities.
• type: [in] The component type will be used to determine the set of prefixes having a registered factory for this component. The default value for this parameter is components::component_invalid, which will return prefixes of all localities.
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

bool get_localities (std::vector<naming::gid_type> &locality_ids, error_code &ec = throws)

lcos::future<std::uint32_t> get_num_localities_async (components::component_type type = components::component_invalid) const

Query for the number of all known localities.

This function returns the number of localities known to the AGAS server or the number of localities having a registered factory for a given component type.

Note As long as ec is not pre-initialzed to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters

• type: [in] The component type will be used to determine the set of prefixes having a registered factory for this component. The default value for this parameter is components::component_invalid, which will return prefixes of all localities.
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

std::uint32_t get_num_localities (components::component_type type, error_code &ec = throws) const

std::uint32_t get_num_localities (error_code &ec = throws) const

lcos::future<std::uint32_t> get_num_overall_threads_async () const

std::uint32_t get_num_overall_threads (error_code &ec = throws) const

lcos::future<std::vector<std::uint32_t>> get_num_threads_async () const

std::vector<std::uint32_t> get_num_threads (error_code &ec = throws) const
components::component_type get_component_id (std::string const &name, error_code &ec = throws)

Return a unique id usable as a component type.

This function returns the component type id associated with the given component name. If this is the first request for this component name a new unique id will be created.

Return The function returns the currently associated component type. Any error results in an exception thrown from this function.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters

- name: [in] The component name (string) to get the component type for.
- ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

void iterate_types (iterate_types_function_type const &f, error_code &ec = throws)

std::string get_component_type_name (components::component_type_id, error_code &ec = throws)

components::component_type register_factory (naming::gid_type const &locality_id, std::string const &name, error_code &ec = throws)

Register a factory for a specific component type.

This function allows to register a component factory for a given locality and component type.

Return The function returns the currently associated component type. Any error results in an exception thrown from this function. The returned component type is the same as if the function get_component_id was called using the same component name.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters

- locality_id: [in] The locality value uniquely identifying the given locality the factory needs to be registered for.
- name: [in] The component name (string) to register a factory for the given component type for.
- ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

components::component_type register_factory (std::uint32_t locality_id, std::string const &name, error_code &ec = throws)

bool get_id_range (std::uint64_t count, naming::gid_type &lower_bound, naming::gid_type &upper_bound, error_code &ec = throws)

Get unique range of freely assignable global ids.

Every locality needs to be able to assign global ids to different components without having to consult the AGAS server for every id to generate. This function can be called to preallocate a range of ids usable for this purpose.

Return This function returns true if a new range has been generated (it has been called for the first time for the given locality) and returns false if this locality already got a range assigned in an earlier call. Any error results in an exception thrown from this function.
Note This function assigns a range of global ids usable by the given locality for newly created components. Any of the returned global ids still has to be bound to a local address, either by calling bind or bind_range.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters
• l: [in] The locality the locality id needs to be generated for. Repeating calls using the same locality results in identical locality_id values.
• count: [in] The number of global ids to be generated.
• lower_bound: [out] The lower bound of the assigned id range. The returned value can be used as the first id to assign. This is valid only, if the return value of this function is true.
• upper_bound: [out] The upper bound of the assigned id range. The returned value can be used as the last id to assign. This is valid only, if the return value of this function is true.
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

bool bind_local (naming::gid_type const &id, naming::address const &addr, error_code &ec = throws)
Bind a global address to a local address.

Every element in the HPX namespace has a unique global address (global id). This global address has to be associated with a concrete local address to be able to address an instance of a component using its global address.

Return This function returns true, if this global id got associated with an local address. It returns false otherwise.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters
• id: [in] The global address which has to be bound to the local address.
• addr: [in] The local address to be bound to the global address.
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

hpx::future<bool> bind_async (naming::gid_type const &id, naming::address const &addr, std::uint32_t locality_id)

hpx::future<bool> bind_async (naming::gid_type const &id, naming::address const &addr, naming::gid_type const &locality)

bool bind_range_local (naming::gid_type const &lower_id, std::uint64_t count, naming::address const &baseaddr, std::uint64_t offset, error_code &ec = throws)
Bind unique range of global ids to given base address.

Every locality needs to be able to bind global ids to different components without having to consult the AGAS server for every id to bind. This function can be called to bind a range of consecutive global ids to a range of consecutive local addresses (separated by a given offset).

Return This function returns true, if the given range was successfully bound. It returns false otherwise.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Note Binding a gid to a local address sets its global reference count to one.

Parameters
• **lower_id**: [in] The lower bound of the assigned id range. The value can be used as the first id to assign.
• **count**: [in] The number of consecutive global ids to bind starting at `lower_id`.
• **baseaddr**: [in] The local address to bind to the global id given by `lower_id`. This is the base address for all additional local addresses to bind to the remaining global ids.
• **offset**: [in] The offset to use to calculate the local addresses to be bound to the range of global ids.
• **ec**: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
hpx::future<bool> bind_range_async(naming::gid_type const &lower_id, std::uint64_t count, naming::address const &baseaddr, std::uint64_t offset, naming::gid_type const &locality)
```

```cpp
hpx::future<bool> bind_range_async(naming::gid_type const &lower_id, std::uint64_t count, naming::address const &baseaddr, std::uint64_t offset, std::uint32_t locality_id)
```

**bool unbind_local (naming::gid_type const &id, error_code &ec = throws)**

Unbind a global address.

Remove the association of the given global address with any local address, which was bound to this global address. Additionally it returns the local address which was bound at the time of this call.

**Return**  The function returns `true` if the association has been removed, and it returns `false` if no association existed. Any error results in an exception thrown from this function.

**Note**  You can unbind only global ids bound using the function `bind`. Do not use this function to unbind any of the global ids bound using `bind_range`.

**Note**  As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Note**  This function will raise an error if the global reference count of the given gid is not zero!  
TODO: confirm that this happens.

**Parameters**
• **id**: [in] The global address (id) for which the association has to be removed.
• **ec**: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
bool unbind_local (naming::gid_type const &id, naming::address &addr, error_code &ec = throws)
```

Unbind a global address.

Remove the association of the given global address with any local address, which was bound to this global address. Additionally it returns the local address which was bound at the time of this call.

**Return**  The function returns `true` if the association has been removed, and it returns `false` if no association existed. Any error results in an exception thrown from this function.

**Note**  You can unbind only global ids bound using the function `bind`. Do not use this function to unbind any of the global ids bound using `bind_range`.

**Note**  As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Note**  This function will raise an error if the global reference count of the given gid is not zero!  
TODO: confirm that this happens.

**Parameters**
HPX Documentation, master

- **id**: [in] The global address (id) for which the association has to be removed.
- **addr**: [out] The local address which was associated with the given global address (id). This is valid only if the return value of this function is true.
- **ec**: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

```cpp
bool unbind_range_local(naming::gid_type const &lower_id, std::uint64_t count, error_code &ec = throws)
```

Unbind the given range of global ids.

**Return** This function returns `true` if a new range has been generated (it has been called for the first time for the given locality) and returns `false` if this locality already got a range assigned in an earlier call. Any error results in an exception thrown from this function.

**Note** You can unbind only global ids bound using the function bind_range. Do not use this function to unbind any of the global ids bound using bind.

**Note** As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

**Note** This function will raise an error if the global reference count of the given gid is not zero! TODO: confirm that this happens.

**Parameters**

- **lower_id**: [in] The lower bound of the assigned id range. The value must the first id of the range as specified to the corresponding call to bind_range.
- **count**: [in] The number of consecutive global ids to unbind starting at lower_id. This number must be identical to the number of global ids bound by the corresponding call to bind_range
- **ec**: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

```cpp
bool unbind_range_local(naming::gid_type const &lower_id, std::uint64_t count, naming::address &addr, error_code &ec = throws)
```

Unbind the given range of global ids.

**Return** This function returns `true` if a new range has been generated (it has been called for the first time for the given locality) and returns `false` if this locality already got a range assigned in an earlier call.

**Note** You can unbind only global ids bound using the function bind_range. Do not use this function to unbind any of the global ids bound using bind.

**Note** As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

**Note** This function will raise an error if the global reference count of the given gid is not zero!

**Parameters**

- **lower_id**: [in] The lower bound of the assigned id range. The value must the first id of the range as specified to the corresponding call to bind_range.
- **count**: [in] The number of consecutive global ids to unbind starting at lower_id. This number must be identical to the number of global ids bound by the corresponding call to bind_range
- **addr**: [out] The local address which was associated with the given global address (id). This is valid only if the return value of this function is true.
- **ec**: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

```cpp
hpx::future<naming::address> unbind_range_async(naming::gid_type const &lower_id, std::uint64_t count = 1)
```

634 Chapter 2. What’s so special about HPX?
bool is_local_address_cached(naming::gid_type const &id, error_code &ec = throws)
Test whether the given address refers to a local object.
This function will test whether the given address refers to an object living on the locality of the caller.

**Return** This function returns true if the passed address refers to an object which lives on the locality of the caller.

**Note** As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

**Parameters**
- **addr**: [in] The address to test.
- **ec**: [in,out] This represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

bool is_local_address_cached(naming::gid_type const &id, naming::address &addr, error_code &ec = throws)

bool is_local_lva_encoded_address(std::uint64_t msb)

bool resolve_local(naming::gid_type const &id, naming::address &addr, error_code &ec = throws)
Resolve a given global address (id) to its associated local address.
This function returns the local address which is currently associated with the given global address (id).

**Return** This function returns true if the global address has been resolved successfully (there exists an association to a local address) and the associated local address has been returned. The function returns false if no association exists for the given global address. Any error results in an exception thrown from this function.

**Note** As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

**Parameters**
- **id**: [in] The global address (id) for which the associated local address should be returned.
- **addr**: [out] The local address which currently is associated with the given global address (id), this is valid only if the return value of this function is true.
- **ec**: [in,out] This represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

bool resolve_local(naming::id_type const &id, naming::address &addr, error_code &ec = throws)
naming::address resolve_local(naming::gid_type const &id, error_code &ec = throws)
naming::address resolve_local(naming::id_type const &id, error_code &ec = throws)
hpx::future<naming::address> resolve_async(naming::gid_type const &id)
hpx::future<naming::address> resolve_async(naming::id_type const &id)

bool resolve_full_local(naming::gid_type const &id, naming::address &addr, error_code &ec = throws)
bool resolve_full_local (naming::id_type const &id, naming::address &addr, error_code &ec = throws)
naming::address resolve_full_local (naming::gid_type const &id, error_code &ec = throws)
naming::address resolve_full_local (naming::id_type const &id, error_code &ec = throws)

hpx::future<naming::address> resolve_full_async (naming::gid_type const &id)

hpx::future<naming::address> resolve_full_async (naming::id_type const &id)

bool resolve Cached (naming::gid_type const &id, naming::address &addr, error Code &ec = throws)
bool resolve Cached (naming::id_type const &id, naming::address &addr, error Code &ec = throws)

bool resolve local (naming::gid_type const *gids, naming::address *addrs, std::size_t size, boost::dynamic_bitset<> &locals, error_code &ec = throws)

bool resolve_full_local (naming::gid_type const *gids, naming::address *addrs, std::size_t size, boost::dynamic_bitset<> &locals, error_code &ec = throws)

bool resolve Cached (naming::gid_type const *gids, naming::address *addrs, std::size_t size, boost::dynamic_bitset<> &locals, error_code &ec = throws)

hcos::future<std::int64_t> incref_async (naming::gid_type const &gid, std::int64_t credits = 1, naming::id_type const &keep_alive = naming::invalid_id)

Increment the global reference count for the given id.

Return Whether the operation was successful.
Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters
• id: [in] The global address (id) for which the global reference count has to be incremented.
• credits: [in] The number of reference counts to add for the given id.
• ec: [in,out] This represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

std::int64_t incref (naming::gid_type const &gid, std::int64_t credits = 1, error_code &ec = throws)

void decref (naming::gid_type const &id, std::int64_t credits = 1, error_code &ec = throws)
Decrement the global reference count for the given id.

Return The global reference count after the decrement.
Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters
• id: [in] The global address (id) for which the global reference count has to be decremented.
• t: [out] If this was the last outstanding global reference for the given gid (the return value of this function is zero), t will be set to the component type of the corresponding element. Otherwise t will not be modified.
• credits: [in] The number of reference counts to add for the given id.
• **ec**: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
hpx::future<iterate_names_return_type> iterate_ids (std::string const &pattern)
```

Invoke the supplied `hpx::function` for every registered global name.

This function iterates over all registered global ids and returns every found entry matching the given name pattern. Any error results in an exception thrown (or reported) from this function.

**Parameters**
- `pattern`: [in] pattern (possibly using wildcards) to match all existing entries against

```cpp
bool register_name (std::string const &name, naming::gid_type const &id, error_code &ec = throws)
```

Register a global name with a global address (id)

This function registers an association between a global name (string) and a global address (id) usable with one of the functions above (bind, unbind, and resolve).

**Return** The function returns `true` if the global name was registered. It returns false if the global name is not registered.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Parameters**
- `name`: [in] The global name (string) to be associated with the global address.
- `id`: [in] The global address (id) to be associated with the global address.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
lcos::future<bool> register_name_async (std::string const &name, naming::id_type const &id)
```

```cpp
bool register_name (std::string const &name, naming::id_type const &id, error_code &ec = throws)
```

```cpp
lcos::future<naming::id_type> unregister_name_async (std::string const &name)
```

Unregister a global name (release any existing association)

This function releases any existing association of the given global name with a global address (id).

**Return** The function returns `true` if an association of this global name has been released, and it returns `false`, if no association existed. Any error results in an exception thrown from this function.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Parameters**
- `name`: [in] The global name (string) for which any association with a global address (id) has to be released.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
naming::id_type unregister_name (std::string const &name, error_code &ec = throws)
```

```cpp
lcos::future<naming::id_type> resolve_name_async (std::string const &name)
```

Query for the global address associated with a given global name.
This function returns the global address associated with the given global name.

This function returns true if it returned global address (id), which is currently associated with the given global name, and it returns false, if currently there is no association for this global name. Any error results in an exception thrown from this function.

**Return** [out] The id currently associated with the given global name (valid only if the return value is true).

**Parameters**
- **name**: [in] The global name (string) for which the currently associated global address has to be retrieved.
- **ec**: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

**Note** As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

```cpp
naming::id_type resolve_name (std::string const &name, error_code &ec = throws)
```

```cpp
future<hpx::id_type> on_symbol_namespace_event (std::string const &name, bool call_for_past_events = false)
```

Install a listener for a given symbol namespace event.

This function installs a listener for a given symbol namespace event. It returns a future which becomes ready as a result of the listener being triggered.

**Return** A future instance encapsulating the global id which is causing the registered listener to be triggered.

**Note** The only event type which is currently supported is symbol_ns_bind, i.e. the listener is triggered whenever a global id is registered with the given name.

**Parameters**
- **name**: [in] The global name (string) for which the given event should be triggered.
- **evt**: [in] The event for which a listener should be installed.
- **call_for_past_events**: [in, optional] Trigger the listener even if the given event has already happened in the past. The default for this parameter is false.

```cpp
void update_cache_entry (naming::gid_type const &gid, gva const &gva, error_code &ec = throws)
```

**Warning** This function is for internal use only. It is dangerous and may break your code if you use it.

```cpp
void update_cache_entry (naming::gid_type const &gid, naming::address const &addr, std::uint64_t count = 0, std::uint64_t offset = 0, error_code &ec = throws)
```

**Warning** This function is for internal use only. It is dangerous and may break your code if you use it.

```cpp
bool get_cache_entry (naming::gid_type const &gid, gva &gva, naming::gid_type &id_base, error_code &ec = throws)
```

**Warning** This function is for internal use only. It is dangerous and may break your code if you use it.

```cpp
void remove_cache_entry (naming::gid_type const &id, error_code &ec = throws)
```

**Warning** This function is for internal use only. It is dangerous and may break your code if you use it.

```cpp
void clear_cache (error_code &ec = throws)
```
**Warning**  This function is for internal use only. It is dangerous and may break your code if you use it.

```cpp
void start_shutdown (error_code &ec = throws)
```

```cpp
hpx::future<std::pair<naming::id_type, naming::address>> begin_migration (naming::id_type const &id)
```

Start/stop migration of an object.

**Return**  Current locality and address of the object to migrate

```cpp
bool end_migration (naming::id_type const &id)
```

```cpp
std::pair<bool, components::pinned_ptr> was_object_migrated (naming::gid_type const &gid,  
util::unique_function_nonser<components::pinned_ptr> f)
```

Maintain list of migrated objects.

```cpp
hpx::future<void> mark_as_migrated (naming::gid_type const &gid,  
util::unique_function_nonser<std::pair<bool, hpx::future<void>>> f)
```

Mark the given object as being migrated (if the object is unpinned). Delay migration until the object is unpinned otherwise.

```cpp
void unmark_as_migrated (naming::gid_type const &gid)
```

Remove the given object from the table of migrated objects.

```cpp
void pre_cache_endpoints (std::vector<parcelset::endpoints_type> const &)
```

The contents of this module can be included with the header hpx/modules/agas_base.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/agas_base.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

namespace hpx

AGAS’s primary namespace maps 128-bit global identifiers (GIDs) to resolved addresses.

The following is the canonical description of the partitioning of AGAS’s primary namespace.

|-----MSB------||------LSB-----|
BBBBBBBBBBBBBBBBBBBBBBBBBBBBBBBB
|prefix||RC||----identifier----|
MSB - Most significant bits (bit 64 to bit 127)
LSB - Least significant bits (bit 0 to bit 63)
prefix - Highest 32 bits (bit 96 to bit 127) of the MSB. Each locality is assigned a prefix. This creates a 96-bit address space for each locality.
RC - Bit 88 to bit 92 of the MSB. This is the log2 of the number of reference counting credits on the GID.
Bit 93 is used by the locking scheme for gid_types.
Bit 94 is a flag which is set if the credit value is valid.
Bit 95 is a flag that is set if a GID’s credit count is ever split (e.g. if the GID is ever passed to another locality).
- Bit 87 marks the gid such that it will not be stored in any of the AGAS caches. This is used mainly for ids which represent 'one-shot' objects (like promises).
identifier - Bit 64 to bit 86 of the MSB, and the entire LSB. The content of these bits depends on the component type of

(continues on next page)
the underlying object. For all user-defined components, these bits contain a unique 88-bit number which is assigned sequentially for each locality. For hpx\#components\#component_runtime_support the high 24 bits are zeroed and the low 64 bits hold the LVA of the component.

Note The layout of the address space is implementation defined, and subject to change. Never write application code that relies on the internal layout of GIDs. AGAS only guarantees that all assigned GIDs will be unique.

The following address ranges are reserved. Some are either explicitly or implicitly protected by AGAS. The letter x represents a single-byte wild card.

```
00000000xxxxxxxxxxxxxxxxxxxxxxxx
   Historically unused address space reserved for future use.
xxxxxxxxxxxx0000xxxxxxxxxxxxxxxxxxxx
   Address space for LVA-encoded GIDs.

namespace hpx
AGAS’s primary namespace maps 128-bit global identifiers (GIDs) to resolved addresses.
```

The following is the canonical description of the partitioning of AGAS’s primary namespace.

```
|-----MSB------|------LSB------|
BBB BBB BBB BBB BBB BBB BBB BBB BBB
|prefix||RC||----identifier----|

MSB - Most significant bits (bit 64 to bit 127)
LSB - Least significant bits (bit 0 to bit 63)
prefix - Highest 32 bits (bit 96 to bit 127) of the MSB. Each locality is assigned a prefix. This creates a 96-bit address space for each locality.
RC - Bit 88 to bit 92 of the MSB. This is the log2 of the number of reference counting credits on the GID.
    Bit 93 is used by the locking scheme for gid_types.
    Bit 94 is a flag which is set if the credit value is valid.
    Bit 95 is a flag that is set if a GID's credit count is ever split (e.g. if the GID is ever passed to another locality).
    Bit 87 marks the gid such that it will not be stored in any of the AGAS caches. This is used mainly for ids which represent 'one-shot' objects (like promises).
identifier - Bit 64 to bit 86 of the MSB, and the entire LSB. The content of these bits depends on the component type of the underlying object. For all user-defined components, these bits contain a unique 88-bit number which is assigned sequentially for each locality. For hpx#components#component_runtime_support the high 24 bits are zeroed and the low 64 bits hold the LVA of the component.
```

**Note** The layout of the address space is implementation defined, and subject to change. Never write application code that relies on the internal layout of GIDs. AGAS only guarantees that all assigned GIDs will be unique.
The following address ranges are reserved. Some are either explicitly or implicitly protected by AGAS. The letter x represents a single-byte wildcard.

```
00000000xxxxxxxxxxxxxxxxxxxxxxxxx
Historically unused address space reserved for future use.
xxxxxxxxxxxx0000xxxxxxxxxxxxxxxx
Address space for LVA-encoded GIDs.
00000001xxxxxxxxxxxxxxxxxxxxxxxxx
Prefix of the bootstrap AGAS locality.
00000001000000000000000000000001
Address of the primary_namespace component on the bootstrap AGAS locality.
00000001000000000000000000000002
Address of the component_namespace component on the bootstrap AGAS locality.
00000001000000000000000000000003
Address of the symbol_namespace component on the bootstrap AGAS locality.
00000001000000000000000000000004
Address of the locality_namespace component on the bootstrap AGAS locality.
```

RC - Bit 88 to bit 92 of the MSB. This is the log2 of the number of reference counting credits on the GID. Bit 93 is used by the locking scheme for gid_types. Bit 94 is a flag which is set if the credit value is valid. Bit 95 is a flag that is set if a GID's credit count is ever split (e.g. if the GID is ever passed to another locality). - Bit 87 marks the gid such that it will not be stored in any of the AGAS caches. This is used mainly for ids which represent 'one-shot' objects (like promises).

(continues on next page)
identifier - Bit 64 to bit 86 of the MSB, and the entire LSB. The content of these bits depends on the component type of the underlying object. For all user-defined components, these bits contain a unique 88-bit number which is assigned sequentially for each locality. For component_runtime_support the high 24 bits are zeroed and the low 64 bits hold the LVA of the component.

Note The layout of the address space is implementation defined, and subject to change. Never write application code that relies on the internal layout of GIDs. AGAS only guarantees that all assigned GIDs will be unique.

The following address ranges are reserved. Some are either explicitly or implicitly protected by AGAS. The letter x represents a single-byte wild card.

```
00000000xxxxxxxxxxxxxxxxxxxxxxxxxxxx
   Historically unused address space reserved for future use.
xxxxxxxxxxxxx0000xxxxxxxxxxxxxxxxxxxx
   Address space for LVA-encoded GIDs.
00000001xxxxxxxxxxxxxxxxxxxxxxxxxxxx
   Prefix of the bootstrap AGAS locality.
00000001000000000000000000000001
   Address of the primary_namespace component on the bootstrap AGAS locality.
00000001000000000000000000000002
   Address of the component_namespace component on the bootstrap AGAS locality.
00000001000000000000000000000003
   Address of the symbol_namespace component on the bootstrap AGAS locality.
00000001000000000000000000000004
   Address of the locality_namespace component on the bootstrap AGAS locality.
```

namespace hpx

AGAS's primary namespace maps 128-bit global identifiers (GIDs) to resolved addresses.

The following is the canonical description of the partitioning of AGAS's primary namespace.

```
|-----MSB-----||------LSB-----|
BBBBBBBBBBBBBBBBBBBBBBBBBBBBBBBB
|prefix||RC||----identifier----|
MSB - Most significant bits (bit 64 to bit 127)
LSB - Least significant bits (bit 0 to bit 63)
prefix - Highest 32 bits (bit 96 to bit 127) of the MSB. Each locality is assigned a prefix. This creates a 96-bit address space for each locality.
RC - Bit 88 to bit 92 of the MSB. This is the log2 of the number of reference counting credits on the GID. Bit 93 is used by the locking scheme for gid_types. Bit 94 is a flag which is set if the credit value is valid. Bit 95 is a flag that is set if a GID's credit count is ever split (e.g. if the GID is ever passed to another locality).
identifier - Bit 64 to bit 86 of the MSB, and the entire LSB. The content of these bits depends on the component type of the underlying object. For all user-defined components, these bits contain a unique 88-bit number which is assigned sequentially for each locality. For `hpx#components#component_runtime_support` the high 24 bits are zeroed and the low 64 bits hold the LVA of the component.
```

Note The layout of the address space is implementation defined, and subject to change. Never write application code that relies on the internal layout of GIDs. AGAS only guarantees that all assigned GIDs will be unique.

The following address ranges are reserved. Some are either explicitly or implicitly protected by AGAS. The letter x represents a single-byte wild card.

```
00000000xxxxxxxxxxxxxxxxxxxxxxxxxxxx
  Historically unused address space reserved for future use.
```

async_colocated

The contents of this module can be included with the header hpx/modules/async_colocated.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/async_colocated.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

Defines

HPX_REGISTER_ASYNC_COLOCATED_DECLARATION (Action, Name)
HPX_REGISTER_ASYNC_COLOCATED (Action, Name)

namespace hpx

Functions

naming::id_type get_colocation_id(launch::sync_policy, naming::id_type const &id, error_code &ec = throws)

Return the id of the locality where the object referenced by the given id is currently located on.

The function hpx::get_colocation_id() returns the id of the locality where the given object is currently located.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

See hpx::get_colocation_id()

Parameters

• id: [in] The id of the object to locate.
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

lcos::future<naming::id_type> get_colocation_id(naming::id_type const &id)

Asynchronously return the id of the locality where the object referenced by the given id is currently located on.

See hpx::get_colocation_id(launch::sync_policy)
Parameters

- **id**: [in] The id of the object to locate.

Defines

**HPX_REGISTER_APPLY_COLOCATED_DECLARATION** *(Action, Name)*

**HPX_REGISTER_APPLY_COLOCATED** *(action, name)*

async_distributed

The contents of this module can be included with the header hpx/modules/async_distributed.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/async_distributed.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

namespace hpx

namespace applier

Functions

applier &get_applier()  
The function get_applier returns a reference to the (thread specific) applier instance.

applier *get_applier_ptr()  
The function get_applier returns a pointer to the (thread specific) applier instance. The returned pointer is NULL if the current thread is not known to HPX or if the runtime system is not active.

namespace applier

The namespace applier contains all definitions needed for the class hpx::applier::applier and its related functionality. This namespace is part of the HPX core module.

checkpoint

The contents of this module can be included with the header `hpp/modules/checkpoint.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpp/modules/checkpoint.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

This header defines the save_checkpoint and restore_checkpoint functions. These functions are designed to help HPX application developer’s checkpoint their applications. Save_checkpoint serializes one or more objects and saves them as a byte stream. Restore_checkpoint converts the byte stream back into instances of the objects.

```cpp
namespace hpx

namespace util

Functions

```cpp
std::ostream &operator<< (std::ostream &ost, checkpoint const &ckp)
```

Operator<< Overload

This overload is the main way to write data from a checkpoint to an object such as a file. Inside the function, the size of the checkpoint will be written to the stream before the checkpoint’s data. The `operator>>` overload uses this to read the correct number of bytes. Be mindful of this additional write and read when you use different facilities to write out or read in data to a checkpoint!

Parameters

- **ost**: Output stream to write to.
- **ckp**: Checkpoint to copy from.

Return Operator<< returns the ostream object.
Operator>> Overload

This overload is the main way to read in data from an object such as a file to a checkpoint. It is important to note that inside the function, the first variable to be read is the size of the checkpoint. This size variable is written to the stream before the checkpoint’s data in the operator<< overload. Be mindful of this additional read and write when you use different facilities to read in or write out data from a checkpoint!

**Parameters**
- `ist`: Input stream to write from.
- `ckp`: Checkpoint to write to.

**Return** Operator>> returns the ostream object.

Save checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component’s client instance to save_checkpoint. Additionally the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

**Template Parameters**
- `T`: Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- `Ts`: More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- `U`: This parameter is used to make sure that T is not a launch policy or a checkpoint. This forces the compiler to choose the correct overload.

**Parameters**
- `t`: A container to restore.
- `ts`: Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

**Return** Save_checkpoint returns a future to a checkpoint with one exception: if you pass hpx::launch::sync as the first argument. In this case save_checkpoint will simply return a checkpoint.

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component’s client instance to save_checkpoint. Additionally the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

**Template Parameters**
- `T`: Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- `Ts`: More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
Parameters
- \( c \): Takes a pre-initialized checkpoint to copy data into.
- \( t \): A container to restore.
- \( t_\ldots s \): Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

Return
Save_checkpoint returns a future to a checkpoint with one exception: if you pass `hpx::launch::sync` as the first argument. In this case `save_checkpoint` will simply return a checkpoint.

```cpp
template<typename T, typename ...Ts>
hpx::future<checkpoint> save_checkpoint (hpx::launch p, T &&t, Ts&&... ts)
```

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a `std::shared_ptr` to the component or by passing a component's client instance to `save_checkpoint`. Additionally, the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used `save_checkpoint` will simply return a checkpoint.

Template Parameters
- \( T \): Containers passed to `save_checkpoint` to be serialized and placed into a checkpoint object.
- \( Ts \): More containers passed to `save_checkpoint` to be serialized and placed into a checkpoint object.

Parameters
- \( p \): Takes an HPX launch policy. Allows the user to change the way the function is launched i.e. async, sync, etc.
- \( t \): A container to restore.
- \( t_\ldots s \): Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

Return
Save_checkpoint returns a future to a checkpoint with one exception: if you pass `hpx::launch::sync` as the first argument. In this case `save_checkpoint` will simply return a checkpoint.

```cpp
template<typename T, typename ...Ts>
hpx::future<checkpoint> save_checkpoint (hpx::launch p, checkpoint &&c, T &&t, Ts&&... ts)
```

2.8. API reference
• ts: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

Return Save_checkpoint returns a future to a checkpoint with one exception: if you pass hpx::launch::sync as the first argument. In this case save_checkpoint will simply return a checkpoint.

template<typename T, typename ...Ts, typename U = typename std::enable_if<!std::is_same<typename std::decay<T>::type, checkpoint>::value>::type>
checkpoint save_checkpoint (hpx::launch::sync_policy sync_p, T &t, Ts&... ts)
Save_checkpoint - Sync_policy overload

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component’s client instance to save_checkpoint. Additionally the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

Template Parameters
• T: Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
• Ts: More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
• U: This parameter is used to make sure that T is not a checkpoint. This forces the compiler to choose the correct overload.

Parameters
• sync_p: hpx::launch::sync_policy
• t: A container to restore.
• ts: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

Return Save_checkpoint which is passed hpx::launch::sync_policy will return a checkpoint which contains the serialized values checkpoint.

template<typename T, typename ...Ts>
checkpoint save_checkpoint (hpx::launch::sync_policy sync_p, checkpoint &c, T &t, Ts&... ts)
Save_checkpoint - Sync_policy overload & pre-init. checkpoint

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component’s client instance to save_checkpoint. Additionally the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

Template Parameters
• T: Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
• Ts: More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.

Parameters
• sync_p: hpx::launch::sync_policy
• c: Takes a pre-initialized checkpoint to copy data into.
• t: A container to restore.
• ts: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.
Return  Save_checkpoint which is passed hpx::launch::sync_policy will return a checkpoint which contains the serialized values checkpoint.

template<typename T, typename ... Ts, typename U = typename std::enable_if<!hpx::traits::is_launch_policy<T>::value &
hpx::future<checkpoint> prepare_checkpoint (T const &t, Ts const &... ts)
    prepare_checkpoint
prepare_checkpoint takes the containers which have to be filled from the byte stream by a subsequent restore_checkpoint invocation. prepare_checkpoint will calculate the necessary buffer size and will return an appropriately sized checkpoint object.

Return  prepare_checkpoint returns a properly resized checkpoint object that can be used for a subsequent restore_checkpoint operation.

Template Parameters
• T: A container to restore.
• Ts: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

Parameters
• t: A container to restore.
• ts: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

template<typename T, typename ... Ts>
    hpx::future<checkpoint> prepare_checkpoint (checkpoint &&c, T const &t, Ts const &... ts)
    prepare_checkpoint
prepare_checkpoint takes the containers which have to be filled from the byte stream by a subsequent restore_checkpoint invocation. prepare_checkpoint will calculate the necessary buffer size and will return an appropriately sized checkpoint object.

Return  prepare_checkpoint returns a properly resized checkpoint object that can be used for a subsequent restore_checkpoint operation.

Template Parameters
• T: A container to restore.
• Ts: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

Parameters
• c: Takes a pre-initialized checkpoint to prepare
• t: A container to restore.
• ts: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

template<typename T, typename ... Ts, typename U = typename std::enable_if<!std::is_same<T, checkpoint>::value>::type>
    hpx::future<checkpoint> prepare_checkpoint (hpx::launch p, T const &t, Ts const &... ts)
    prepare_checkpoint
prepare_checkpoint takes the containers which have to be filled from the byte stream by a subsequent restore_checkpoint invocation. prepare_checkpoint will calculate the necessary buffer size and will return an appropriately sized checkpoint object.

Return  prepare_checkpoint returns a properly resized checkpoint object that can be used for a subsequent restore_checkpoint operation.

Template Parameters
• T: A container to restore.
• T/s: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

**Parameters**

• p: Takes an HPX launch policy. Allows the user to change the way the function is launched i.e. async, sync, etc.
• t: A container to restore.
• t/s: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

template<typename T, typename ...Ts>

```cpp
hpx::future<checkpoint> prepare_checkpoint (hpx::launch p, checkpoint &c, T const &t,
                               Ts const&... ts)
```

Prepare_checkpoint

Prepare_checkpoint takes the containers which have to be filled from the byte stream by a subsequent restore_checkpoint invocation. prepare_checkpoint will calculate the necessary buffer size and will return an appropriately sized checkpoint object.

**Return**

Prepare_checkpoint returns a properly resized checkpoint object that can be used for a subsequent restore_checkpoint operation.

**Template Parameters**

• T: A container to restore.
• T/s: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

**Parameters**

• p: Takes an HPX launch policy. Allows the user to change the way the function is launched i.e. async, sync, etc.
• c: Takes a pre-initialized checkpoint to prepare
• t: A container to restore.
• t/s: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

```cpp
void restore_checkpoint (checkpoint const &c, T &t, Ts&... ts)
```

Restore_checkpoint

Restore_checkpoint takes a checkpoint object as a first argument and the containers which will be filled from the byte stream (in the same order as they were placed in save_checkpoint). Restore_checkpoint can resurrect a stored component in two ways: by passing in an instance of a component’s shared_ptr or by passing in an instance of the component’s client.

**Return**

Restore_checkpoint returns void.

**Template Parameters**

• T: A container to restore.
• T/s: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

**Parameters**

• c: The checkpoint to restore.
• t: A container to restore.
• t/s: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

```cpp
class checkpoint
#include <checkpoint.hpp> Checkpoint Object
```

704 Chapter 2. What’s so special about HPX?
Checkpoint is the container object which is produced by save_checkpoint and is consumed by a re-
store_checkpoint. A checkpoint may be moved into the save_checkpoint object to write the byte
stream to the pre-created checkpoint object.

Checkpoints are able to store all containers which are able to be serialized including components.

**Public Types**

### Friends

```cpp
friend hpx::util::hpx::serialization::access
```

**std::ostream & operator<<(std::ostream &ost, checkpoint const &ckp)**

Operator<< Overload

This overload is the main way to write data from a checkpoint to an object such as a file. Inside the function, the size of the checkpoint will be written to the stream before the checkpoint’s data. The operator>> overload uses this to read the correct number of bytes. Be mindful of this additional write and read when you use different facilities to write out or read in data to a checkpoint!

**Parameters**
- `ost`: Output stream to write to.
- `ckp`: Checkpoint to copy from.

**Return** Operator<< returns the ostream object.

```cpp
std::istream & operator>>(std::istream &ist, checkpoint &ckp)
```

Operator>> Overload

This overload is the main way to read in data from an object such as a file to a checkpoint. It is important to note that inside the function, the first variable to be read is the size of the checkpoint. This size variable is written to the stream before the checkpoint’s data in the operator<< overload. Be mindful of this additional read and write when you use different facilities to read in or write out data from a checkpoint!

**Parameters**
- `ist`: Input stream to write from.
- `ckp`: Checkpoint to write to.

**Return** Operator>> returns the ostream object.

```cpp
template<typename T, typename ...Ts>
void restore_checkpoint (checkpoint const &c, T &t, Ts&... ts)
```

Restore_checkpoint

Restore_checkpoint takes a checkpoint object as a first argument and the containers which will be filled from the byte stream (in the same order as they were placed in save_checkpoint). Restore_checkpoint can resurrect a stored component in two ways: by passing in a instance of a component’s shared_ptr or by passing in an instance of the component’s client.

**Return** Restore_checkpoint returns void.

**Template Parameters**
- `T`: A container to restore.
- `Ts`: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

**Parameters**
- `c`: The checkpoint to restore.
- `t`: A container to restore.
- `ts`: Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

```cpp
bool operator==(checkpoint const &lhs, checkpoint const &rhs)
```

bool operator!= (checkpoint const &lhs, checkpoint const &rhs)

checkpoint_base

The contents of this module can be included with the header `hpx/modules/checkpoint_base.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/checkpoint_base.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

namespace hpx

namespace util

Functions

template<typename Container, typename ...Ts>
void save_checkpoint_data (Container &data, Ts&&... ts)
  save_checkpoint_data

Save_checkpoint_data takes any number of objects which a user may wish to store in the given container.

Template Parameters
- Container: Container used to store the check-pointed data.
- Ts: Types of variables to checkpoint

Parameters
- cont: Container instance used to store the checkpoint data
- ts: Variable instances to be inserted into the checkpoint.

template<typename ...Ts>
std::size_t prepare_checkpoint_data (Ts const&&... ts)
  prepare_checkpoint_data

prepare_checkpoint_data takes any number of objects which a user may wish to store in a subsequent save_checkpoint_data operation. The function will return the number of bytes necessary to store the data that will be produced.

Template Parameters
- Ts: Types of variables to checkpoint

Parameters
- ts: Variable instances to be inserted into the checkpoint.

template<typename Container, typename ...Ts>
void restore_checkpoint_data (Container const &cont, Ts&&... ts)
  restore_checkpoint_data

restore_checkpoint_data takes any number of objects which a user may wish to restore from the given container. The sequence of objects has to correspond to the sequence of objects for the corresponding call to save_checkpoint_data that had used the given container instance.

Template Parameters
- Container: Container used to restore the check-pointed data.
The contents of this module can be included with the header `hpx/modules/collectives.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we **strongly** suggest only including the module header `hpx/modules/collectives.hpp`, not the particular header in which the functionality you would like to use is defined. See **Public API** for a list of names that are part of the public **HPX** API.

**namespace hpx**

**namespace lcos**

**Functions**

```cpp
template<typename T>
hpx::future<std::vector<T>> all_gather(char const *basename, hpx::future<T> &&result,
    std::size_t num_sites = std::size_t(-1), std::size_t generation = std::size_t(-1), std::size_t this_site = std::size_t(-1), std::size_t root_site = 0)
```

AllToAll a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

**Note** Each `all_gather` operation has to be accompanied with a unique usage of the `HPX_REGISTER_ALLTOALL` macro to define the necessary internal facilities used by `all_gather`.

**Return** This function returns a future holding a vector with all values send by all participating sites. It will become ready once the `all_gather` operation has been completed.

**Parameters**

- `basename`: The base name identifying the `all_gather` operation
- `local_result`: A future referring to the value to transmit to all participating sites from this call site.
- `num_sites`: The number of participating sites (default: all localities).
- `generation`: The generational counter identifying the sequence number of the `all_gather` operation performed on the given base name. This is optional and needs to be supplied only if the `all_gather` operation on the given base name has to be performed more than once.
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns. **\params root_site The site that is responsible for creating the `all_gather` support object. This value is optional and defaults to ‘0’ (zero).**

```cpp
template<typename T>
AllToAll a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Note Each all_gather operation has to be accompanied with a unique usage of the `HPX_REGISTER_ALLTOALL` macro to define the necessary internal facilities used by all_gather.

Return This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all_gather operation has been completed.

Parameters
- `basename`: The base name identifying the all_gather operation
- `local_result`: The value to transmit to all participating sites from this call site.
- `num_sites`: The number of participating sites (default: all localities).
- `generation`: The generational counter identifying the sequence number of the all_gather operation performed on the given base name. This is optional and needs to be supplied only if the all_gather operation on the given base name has to be performed more than once.
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.
- `root_site`: The site that is responsible for creating the all_gather support object. This value is optional and defaults to ‘0’ (zero).

namespace hpx

namespace lcos

Functions

template<
typename T, typename F>
hpx::future<T> all_reduce (char const *basename, hpx::future<T> result, F &&op, std::size_t num_sites = std::size_t(-1), std::size_t generation = std::size_t(-1), std::size_t this_site = std::size_t(-1), std::size_t root_site = 0)

AllReduce a set of values from different call sites

This function receives a set of values that are the result of applying a given operator on values supplied from all call sites operating on the given base name.

Note Each all_reduce operation has to be accompanied with a unique usage of the `HPX_REGISTER_ALLREDUCE` macro to define the necessary internal facilities used by all_reduce.

Return This function returns a future holding a value calculated based on the values send by all participating sites. It will become ready once the all_reduce operation has been completed.

Parameters
- `basename`: The base name identifying the all_reduce operation
• local_result: A future referring to the value to transmit to all participating sites from this call site.
• op: Reduction operation to apply to all values supplied from all participating sites
• num_sites: The number of participating sites (default: all localities).
• generation: The generational counter identifying the sequence number of the all_reduce operation performed on the given base name. This is optional and needs to be supplied only if the all_reduce operation on the given base name has to be performed more than once.
• this_site: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns. 

\params root_site The site that is responsible for creating the all_reduce support object. This value is optional and defaults to ‘0’ (zero).

```cpp
template<typename T, typename F>
hpx::future<std::vector<T>> all_reduce(char const *basename, T &&result, F &&op, std::size_t num_sites = std::size_t(-1), std::size_t generation = std::size_t(-1), std::size_t this_site = std::size_t(-1), std::size_t root_site = 0)
```

AllReduce a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

\**Note** Each all_reduce operation has to be accompanied with a unique usage of the HPX_REGISTER_ALLREDUCE macro to define the necessary internal facilities used by all_reduce.

\**Return** This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all_reduce operation has been completed.

\**Parameters**

- basename: The base name identifying the all_reduce operation
- local_result: The value to transmit to all participating sites from this call site.
- op: Reduction operation to apply to all values supplied from all participating sites
- num_sites: The number of participating sites (default: all localities).
- generation: The generational counter identifying the sequence number of the all_reduce operation performed on the given base name. This is optional and needs to be supplied only if the all_reduce operation on the given base name has to be performed more than once.
- this_site: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns. 

\params root_site The site that is responsible for creating the all_reduce support object. This value is optional and defaults to ‘0’ (zero).

```cpp
namespace hpx

namespace lcos

Functions

```cpp
template<typename T>
hpx::future<std::vector<T>> all_to_all(char const *basename, hpx::future<std::vector<T>> &&result, std::size_t num_sites = std::size_t(-1), std::size_t generation = std::size_t(-1), std::size_t this_site = std::size_t(-1), std::size_t root_site = 0)
```

AllToAll a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.
Note Each all_to_all operation has to be accompanied with a unique usage of the HPX_REGISTER_ALLTOALL macro to define the necessary internal facilities used by all_to_all.

Return This function returns a future holding a vector with all values send by all participating sites.

It will become ready once the all_to_all operation has been completed.

Parameters
- basename: The base name identifying the all_to_all operation
- local_result: A future referring to the value to transmit to all participating sites from this call site.
- num_sites: The number of participating sites (default: all localities).
- generation: The generational counter identifying the sequence number of the all_to_all operation performed on the given base name. This is optional and needs to be supplied only if the all_to_all operation on the given base name has to be performed more than once.
- this_site: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns. 
- params root_site The site that is responsible for creating the all_to_all support object. This value is optional and defaults to ‘0’ (zero).

```cpp
template<typename T>
hp::future<
  std::vector<
    typename std::decay<T>::type>>
  all_to_all(char const *basename, T &&local_result,
  std::size_t num_sites = std::size_t(-1),
  std::size_t generation = std::size_t(-1),
  std::size_t this_site = std::size_t(-1),
  std::size_t root_site = 0)
```

AllToAll a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Note Each all_to_all operation has to be accompanied with a unique usage of the HPX_REGISTER_ALLTOALL macro to define the necessary internal facilities used by all_to_all.

Return This function returns a future holding a vector with all values send by all participating sites.

It will become ready once the all_to_all operation has been completed.

Parameters
- basename: The base name identifying the all_to_all operation
- local_result: The value to transmit to all participating sites from this call site.
- num_sites: The number of participating sites (default: all localities).
- generation: The generational counter identifying the sequence number of the all_to_all operation performed on the given base name. This is optional and needs to be supplied only if the all_to_all operation on the given base name has to be performed more than once.
- this_site: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns. 
- params root_site The site that is responsible for creating the all_to_all support object. This value is optional and defaults to ‘0’ (zero).

```cpp
namespace hpx

namespace lcos

class barrier
  #include <barrier.hpp> The barrier is an implementation performing a barrier over a number of par-
```
ticipating threads. The different threads don’t have to be on the same locality. This barrier can be invoked in a distributed application.

For a local only barrier
See hpx::lcos::local::barrier.

Public Functions

```cpp
barrier (std::string const &base_name)
   Creates a barrier, rank is locality id, size is number of localities
```

A barrier `base_name` is created. It expects that hpx::get_num_localities() participate and the local rank is hpx::get_locality_id().

**Parameters**
- `base_name`: The name of the barrier

```cpp
barrier (std::string const &base_name, std::size_t num)
   Creates a barrier with a given size, rank is locality id
```

A barrier `base_name` is created. It expects that `num` participate and the local rank is hpx::get_locality_id().

**Parameters**
- `base_name`: The name of the barrier
- `num`: The number of participating threads

```cpp
barrier (std::string const &base_name, std::size_t num, std::size_t rank)
   Creates a barrier with a given size and rank
```

A barrier `base_name` is created. It expects that `num` participate and the local rank is `rank`.

**Parameters**
- `base_name`: The name of the barrier
- `num`: The number of participating threads
- `rank`: The rank of the calling site for this invocation

```cpp
barrier (std::string const &base_name, std::vector<std::size_t> const &ranks, std::size_t rank)
   Creates a barrier with a vector of ranks
```

A barrier `base_name` is created. It expects that ranks.size() and the local rank is `rank` (must be contained in ranks).

**Parameters**
- `base_name`: The name of the barrier
- `ranks`: Gives a list of participating ranks (this could be derived from a list of locality ids
- `rank`: The rank of the calling site for this invocation

```cpp
void wait ()
   Wait until each participant entered the barrier. Must be called by all participants
```

**Return** This function returns once all participants have entered the barrier (have called `wait`).
```cpp
hpx::future<void> wait(hpx::launch::async_policy)
Wait until each participant entered the barrier. Must be called by all participants

**Return** a future that becomes ready once all participants have entered the barrier (have called `wait`).

**Public Static Functions**

```cpp
static void synchronize()
Perform a global synchronization using the default global barrier The barrier is created once at startup and can be reused throughout the lifetime of an HPX application.

**Note** This function currently does not support dynamic connection and disconnection of localities.
```

```cpp
namespace hpx

namespace lcos

**Functions**

```cpp
template<typename Action, typename ArgN, ...> hpx::future<std::vector<decltype(Action(hpx::id_type, ArgN, ...))> > hpx::lcos::broadcast(std::vector<hpx::id_type> const & ids, ArgN argN, ...)
Perform a distributed broadcast operation.

The function hpx::lcos::broadcast performs a distributed broadcast operation resulting in action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action.

The given action is invoked asynchronously on all given identifiers, and the arguments ArgN are passed along to those invocations.

**Return** This function returns a future representing the result of the overall reduction operation.

**Note** If decltype(Action(...)) is void, then the result of this function is future<void>.

**Parameters**

- **ids**: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- **argN**: [in] Any number of arbitrary arguments (passed by const reference) which will be forwarded to the action invocation.

```cpp
template<typename Action, typename ArgN, ...> void hpx::lcos::broadcast_apply(std::vector<hpx::id_type> const & ids, ArgN argN, ...)
Perform an asynchronous (fire&forget) distributed broadcast operation.

The function hpx::lcos::broadcast_apply performs an asynchronous (fire&forget) distributed broadcast operation resulting in action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action.

The given action is invoked asynchronously on all given identifiers, and the arguments ArgN are passed along to those invocations.

**Parameters**
• **ids**: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
• **argN**: [in] Any number of arbitrary arguments (passed by const reference) which will be forwarded to the action invocation.

**template<typename Action, typename ArgN, ...>hpx::future< std::vector<decltype(Action(hpx::id_type, ArgN, ..., std::size_t))> > hpx::lcos::broadcast_with_index(std::vector< hpx::id_type > const & ids, ArgN argN, ...)**

Perform a distributed broadcast operation.

The function hpx::lcos::broadcast_with_index performs a distributed broadcast operation resulting in action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).

The given action is invoked asynchronously on all given identifiers, and the arguments ArgN are passed along to those invocations.

The function passes the index of the global identifier in the given list of identifiers as the last argument to the action.

**Return**  This function returns a future representing the result of the overall reduction operation.

**Note**  If decltype(Action(...)) is void, then the result of this function is future<void>.

**Parameters**
• **ids**: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
• **argN**: [in] Any number of arbitrary arguments (passed by const reference) which will be forwarded to the action invocation.

**template<typename Action, typename ArgN, ...>void hpx::lcos::broadcast_apply_with_index(std::vector< hpx::id_type > const & ids, ArgN argN, ...)**

Perform an asynchronous (fire&forget) distributed broadcast operation.

The function hpx::lcos::broadcast_apply_with_index performs an asynchronous (fire&forget) distributed broadcast operation resulting in action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).

The given action is invoked asynchronously on all given identifiers, and the arguments ArgN are passed along to those invocations.

The function passes the index of the global identifier in the given list of identifiers as the last argument to the action.

**Parameters**
• **ids**: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
• **argN**: [in] Any number of arbitrary arguments (passed by const reference) which will be forwarded to the action invocation.
The function `create_communication_set` sets up a (distributed) tree-like communication structure that can be used with any of the collective APIs (such like `all_to_all` and similar).

Return  This function returns a future holding an `id_type` of the communicator object to be used on the current locality.

Parameters  
- **basename**: The base name identifying the `all_to_all` operation
- **num_sites**: The number of participating sites (default: all localities).
- **this_site**: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- **arity**: The number of children each of the communication nodes is connected to (default: picked based on `num_sites`)

### namespace hpx

### namespace lcos

#### Functions

```cpp
template<typename Action, typename FoldOp, typename Init, typename ArgN, ...> hpx::future<decltype(Action(hpx::id_type, ...))> hpx::lcos::fold_with_index(std::vector<hpx::id_type> const & ids, FoldOp && fold_op, Init && init, ArgN argN, ...)
```

Perform a distributed folding operation.

The function `hpx::lcos::fold_with_index` performs a distributed folding operation over results returned from action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).

Note  The type of the initial value must be convertible to the result type returned from the invoked action.

Return  This function returns a future representing the result of the overall folding operation.

Parameters  
- **ids**: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- **fold_op**: [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the folding operation performed on its arguments.
- **init**: [in] The initial value to be used for the folding operation
- **argN**: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the action invocation.

```cpp
template<typename Action, typename FoldOp, typename Init, typename ArgN, ...> hpx::future<decltype(Action(hpx::id_type, ...))> hpx::lcos::fold_with_index(std::vector<hpx::id_type> const & ids, FoldOp && fold_op, Init && init, ArgN argN, ...)
```

Perform a distributed folding operation.

The function `hpx::lcos::fold_with_index` performs a distributed folding operation over results returned from action invocations on a given set of global identifiers. The action can be either plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).
The function passes the index of the global identifier in the given list of identifiers as the last argument to the action.

**Note** The type of the initial value must be convertible to the result type returned from the invoked action.

**Return** This function returns a future representing the result of the overall folding operation.

**Parameters**
- `ids`: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- `fold_op`: [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the folding operation performed on its arguments.
- `init`: [in] The initial value to be used for the folding operation
- `argN`: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the action invocation.

```cpp
template<typename Action, typename FoldOp, typename Init, typename ArgN, ...> hpx::future<decltype(Action(hpx::id_type, ArgN, ...))> hpx::lcos::inverse_fold(std::vector<hpx::id_type> const & ids, FoldOp && fold_op, Init && init, ArgN argN, ...)
```

Perform a distributed inverse folding operation.

The function `hpx::lcos::inverse_fold` performs an inverse distributed folding operation over results returned from action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action.

**Note** The type of the initial value must be convertible to the result type returned from the invoked action.

**Return** This function returns a future representing the result of the overall folding operation.

**Parameters**
- `ids`: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- `fold_op`: [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the folding operation performed on its arguments.
- `init`: [in] The initial value to be used for the folding operation
- `argN`: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the action invocation.

```cpp
template<typename Action, typename FoldOp, typename Init, typename ArgN, ...> hpx::future<decltype(hpx::id_type, ArgN, ...))> hpx::lcos::inverse_fold_with_index(std::vector<hpx::id_type> const & ids, FoldOp && fold_op, Init && init, ArgN argN, ...)
```

Perform a distributed inverse folding operation.

The function `hpx::lcos::inverse_fold_with_index` performs an inverse distributed folding operation over results returned from action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action.

The function passes the index of the global identifier in the given list of identifiers as the last argument to the action.

**Note** The type of the initial value must be convertible to the result type returned from the invoked action.

**Return** This function returns a future representing the result of the overall folding operation.

**Parameters**
- `ids`: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.

```cpp
template<typename Action, typename FoldOp, typename Init, typename ArgN, ...> hpx::future<decltype(hpx::id_type, ArgN, ...))> hpx::lcos::inverse_fold_with_index(std::vector<hpx::id_type> const & ids, FoldOp && fold_op, Init && init, ArgN argN, ...)
```

Perform a distributed inverse folding operation.

The function passes the index of the global identifier in the given list of identifiers as the last argument to the action.
• fold_op: [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the folding operation performed on its arguments.
• init: [in] The initial value to be used for the folding operation
• argN: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the action invocation.

namespace hpx

namespace lcos

Functions

template<typename T>
hpx::future<std::vector<T>> gather_here(char const *basename, hpx::future<T> result,
std::size_t num_sites = std::size_t(-1), std::size_t
generation = std::size_t(-1), std::size_t this_site =
std::size_t(-1))

Gather a set of values from different call sites
This function receives a set of values from all call sites operating on the given base name.

Note Each gather operation has to be accompanied with a unique usage of the
HPX_REGISTER_GATHER macro to define the necessary internal facilities used by gather_here
and gather_there

Return This function returns a future holding a vector with all gathered values. It will become ready
once the gather operation has been completed.

Parameters
• basename: The base name identifying the gather operation
• result: A future referring to the value to transmit to the central gather point from this call
  site.
• num_sites: The number of participating sites (default: all localities).
• generation: The generational counter identifying the sequence number of the gather operation
  performed on the given base name. This is optional and needs to be supplied only if the
gather operation on the given base name has to be performed more than once.
• this_site: The sequence number of this invocation (usually the locality id). This value is
  optional and defaults to whatever hpx::get_locality_id() returns.

template<typename T>
hpx::future<std::vector<T>> gather_there(char const *basename, hpx::future<T> result,
std::size_t generation = std::size_t(-1), std::size_t
this_site = std::size_t(-1), std::size_t root_site = 0)

Gather a given value at the given call site
This function transmits the value given by result to a central gather site (where the corresponding
gather_here is executed)

Note Each gather operation has to be accompanied with a unique usage of the
HPX_REGISTER_GATHER macro to define the necessary internal facilities used by gather_here
and gather_there

Return This function returns a future holding a vector with all gathered values. It will become ready
once the gather operation has been completed.

Parameters
• basename: The base name identifying the gather operation
• result: A future referring to the value to transmit to the central gather point from this call site.
• generation: The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once.
• this_site: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.
• root_site: The sequence number of the central gather point (usually the locality id). This value is optional and defaults to 0.

```cpp
template<typename T>
hpx::future<std::vector<typename std::decay<T>::type>> gather_here(char const *basename, T &&result, std::size_t num_sites = std::size_t(-1), std::size_t generation = std::size_t(-1), std::size_t this_site = std::size_t(-1))
```

Gather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

**Note** Each gather operation has to be accompanied with a unique usage of the `HPX_REGISTER_GATHER` macro to define the necessary internal facilities used by `gather_here` and `gather_there`

**Return** This function returns a future holding a vector with all gathered values. It will become ready once the gather operation has been completed.

**Parameters**
• basename: The base name identifying the gather operation
• result: The value to transmit to the central gather point from this call site.
• num_sites: The number of participating sites (default: all localities).
• generation: The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once.
• this_site: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

```cpp
template<typename T>
hpx::future<std::vector<typename std::decay<T>::type>> gather_there(char const *basename, T &&result, std::size_t generation = std::size_t(-1), std::size_t this_site = std::size_t(-1), std::size_t root_site = 0)
```

Gather a given value at the given call site

This function transmits the value given by `result` to a central gather site (where the corresponding `gather_here` is executed)
Note Each gather operation has to be accompanied with a unique usage of the 
`HPX_REGISTER_GATHER` macro to define the necessary internal facilities used by `gather_here` 
and `gather_there`.

Return This function returns a future holding a vector with all gathered values. It will become ready 
once the gather operation has been completed.

Parameters

- `basename`: The base name identifying the gather operation.
- `result`: The value to transmit to the central gather point from this call site.
- `generation`: The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once.
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- `root_site`: The sequence number of the central gather point (usually the locality id). This value is optional and defaults to 0.

namespace hpx

namespace lcos

class latch : public components::client_base<latch, lcos::server::latch>

Public Functions

latch ()
latch (`std::ptrdiff_t count`) 
Initialize the latch

Requires: count >= 0. Synchronization: None Postconditions: counter_ == count.
latch (`naming::id_type const &id`) 
Extension: Create a client side representation for the existing server::latch instance with the given 
global id `id`.
latch (`hpx::future<naming::id_type> &&f`) 
Extension: Create a client side representation for the existing server::latch instance with the given 
global id `id`.
latch (`hpx::shared_future<naming::id_type> const &id`) 
Extension: Create a client side representation for the existing server::latch instance with the given 
global id `id`.
latch (`hpx::shared_future<naming::id_type> &&id`) 
void count_down_and_wait ()
Decrement counter_ by 1 . Blocks at the synchronization point until counter_ reaches 0.

Requires: counter_ > 0.

Synchronization: Synchronizes with all calls that block on this latch and with all `is_ready` calls 
on this latch that return true.

Exceptions

- Nothing.
void **count_down** (**std::ptrdiff_t** n)
Decrement counter by n. Does not block.

Requires: counter_ >= n and n >= 0.

Synchronization: Synchronizes with all calls that block on this latch and with all is_ready calls on this latch that return true.

**Exceptions**
- Nothing.

**bool is_ready() const**
Returns: counter_ == 0. Does not block.

**Exceptions**
- Nothing.

**void wait() const**
If counter_ is 0, returns immediately. Otherwise, blocks the calling thread at the synchronization point until counter_ reaches 0.

**Exceptions**
- Nothing.

**Private Types**

```
typedef components::client_base<latch, lcos::server::latch> base_type
```

**namespace hpx**

**namespace lcos**

**Functions**

```
template<
    typename Action,
    typename ReduceOp,
    typename ArgN,
    ...
> hpx::future<
    decltype(
        Action(hpx::id_type, ArgN, ...
    )

Perform a distributed reduction operation.
```

The function hpx::lcos::reduce performs a distributed reduction operation over results returned from action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action.

**Return** This function returns a future representing the result of the overall reduction operation.

**Parameters**
- **ids**: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- **reduce_op**: [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the reduction operation performed on its arguments.
- **argN**: [in] Any number of arbitrary arguments (passed by by const reference) which will be forwarded to the action invocation.
template<typename Action, typename ReduceOp, typename ArgN, ...>

hpx::future<decltype(Action(hpx::id_type, ArgN, ..., std::size_t))> hpx::lcos::reduce_with_index(std::vector< hpx::id_type > const & ids, ReduceOp && reduce_op, ArgN argN, ...)

Perform a distributed reduction operation.

The function hpx::lcos::reduce_with_index performs a distributed reduction operation over results returned from action invocations on a given set of global identifiers. The action can be either plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).

The function passes the index of the global identifier in the given list of identifiers as the last argument to the action.

Return

This function returns a future representing the result of the overall reduction operation.

Parameters

- ids: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- reduce_op: [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the reduction operation performed on its arguments.
- argN: [in] Any number of arbitrary arguments (passed by by const reference) which will be forwarded to the action invocation.

namespace lcos

Functions

template<typename T>

hpx::future<T> scatter_from(char const *basename, std::size_t generation = std::size_t(-1),
std::size_t this_site = std::size_t(-1), std::size_t root_site = 0)

Scatter (receive) a set of values to different call sites

This function receives an element of a set of values operating on the given base name.

Scatter (receive) a set of values to different call sites

Note Each scatter operation has to be accompanied with a unique usage of the HPX_REGISTER_SCATTER macro to define the necessary internal facilities used by scatter_from and scatter_to

Return This function returns a future holding a the scattered value. It will become ready once the scatter operation has been completed.

Parameters

- basename: The base name identifying the scatter operation
- result: A future referring to the value to transmit to the central scatter point from this call site.
- generation: The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once.
- this_site: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.
- root_site: The sequence number of the central scatter point (usually the locality id). This value is optional and defaults to 0.

This function receives an element of a set of values operating on the given base name.
Note Each scatter operation has to be accompanied with a unique usage of the 
`HPX_REGISTER_SCATTER` macro to define the necessary internal facilities used by `scatter_from` and `scatter_to`.

Return This function returns a future holding a the scattered value. It will become ready once the 
scatter operation has been completed.

Parameters
- `basename`: The base name identifying the scatter operation
- `result`: The value to transmit to the central scatter point from this call site.
- `generation`: The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once.
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
- `root_site`: The sequence number of the central scatter point (usually the locality id). This value is optional and defaults to 0.

```cpp
template<typename T>
hpX::future<T> scatter_to (char const *basename, hpx::future<std::vector<T>> result,
    std::size_t generation = std::size_t(-1), std::size_t this_site = std::size_t(-1))
```

Scatter (send) a part of the value set at the given call site.

This function transmits the value given by `result` to a central scatter site (where the corresponding 
`scatter_from` is executed).

Note Each scatter operation has to be accompanied with a unique usage of the 
`HPX_REGISTER_SCATTER` macro to define the necessary internal facilities used by `scatter_from` and `scatter_to`.

Return This function returns a future holding a the scattered value. It will become ready once the 
scatter operation has been completed.

Parameters
- `basename`: The base name identifying the scatter operation
- `result`: A future referring to the value to transmit to the central scatter point from this call site.
- `num_sites`: The number of participating sites (default: all localities).
- `generation`: The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once.
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

```cpp
template<typename T>
hpX::future<T> scatter_to (char const *basename, std::vector<T> const &result,
    std::size_t num_sites = std::size_t(-1), std::size_t generation = std::size_t(-1),
    std::size_t this_site = std::size_t(-1))
```

Scatter (send) a part of the value set at the given call site.

This function transmits the value given by `result` to a central scatter site (where the corresponding 
`scatter_from` is executed).

Note Each scatter operation has to be accompanied with a unique usage of the 
`HPX_REGISTER_SCATTER` macro to define the necessary internal facilities used by `scatter_from` and `scatter_to`.

Return This function returns a future holding a the scattered value. It will become ready once the 
scatter operation has been completed.
Parameters

- **basename**: The base name identifying the scatter operation
- **result**: The value to transmit to the central scatter point from this call site.
- **num_sites**: The number of participating sites (default: all localities).
- **generation**: The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once.
- **this_site**: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

```cpp
template<typename T>
hpx::future<T> scatter_to(char const *basename, std::vector<T> &&result, std::size_t num_sites = std::size_t(-1), std::size_t generation = std::size_t(-1), std::size_t this_site = std::size_t(-1))
```

namespace hpx

namespace lcos

Functions

```cpp
template<typename F, typename ...Args>
hpx::future<void> define_spmd_block(std::string &&name, std::size_t images_per_locality, F&&, Args&&... args)
```

**struct spmd_block**

#include <spmd_block.hpp> The class spmd_block defines an interface for launching multiple images while giving handles to each image to interact with the remaining images. The define_spmd_block function templates create multiple images of a user-defined action and launches them in a possibly separate thread. A temporary spmd block object is created and diffused to each image. The constraint for the action given to the define_spmd_block function is to accept a spmd_block as first parameter.

**Public Functions**

```cpp
spmd_block() const

spmd_block(std::string const &name, std::size_t images_per_locality, std::size_t num_images, std::size_t image_id)
```

```cpp
std::size_t get_images_per_locality() const

std::size_t get_num_images() const

std::size_t this_image() const
```

```cpp
void sync_all() const
```

```cpp

```cpp
namespace hpx

Functions

template<typename Client>
std::vector<Client> find_all_from_basename (std::string base_name, std::size_t num_ids)
Return all registered clients from all localities from the given base name.

This function locates all ids which were registered with the given base name. It returns a list of futures representing those ids.

Return all registered ids from all localities from the given base name.

Note The futures embedded in the returned client objects will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

Template Parameters
- **Client**: The client type to return

Parameters
- **base_name**: [in] The base name for which to retrieve the registered ids.
- **num_ids**: [in] The number of registered ids to expect.

This function locates all ids which were registered with the given base name. It returns a list of futures representing those ids.

Return A list of futures representing the ids which were registered using the given base name.

Note The futures will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

Parameters
- **base_name**: [in] The base name for which to retrieve the registered ids.
- **num_ids**: [in] The number of registered ids to expect.

```
Return registered ids from the given base name and sequence numbers.

**Return** A list of futures representing the ids which were registered using the given base name and sequence numbers.

**Note** The futures embedded in the returned client objects will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

**Template Parameters**
- **Client**: The client type to return

**Parameters**
- **base_name**: [in] The base name for which to retrieve the registered ids.
- **ids**: [in] The sequence numbers of the registered ids.

This function locates the ids which were registered with the given base name and the given sequence numbers. It returns a list of futures representing those ids.

**Return** A list of futures representing the ids which were registered using the given base name and sequence numbers.

**Note** The futures will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

**Parameters**
- **base_name**: [in] The base name for which to retrieve the registered ids.
- **ids**: [in] The sequence numbers of the registered ids.

```cpp
template<typename Client>
Client find_from_basename (std::string base_name, std::size_t sequence_nr)
```

This function locates the id which was registered with the given base name and sequence number. It returns a future representing those id.

This function locates the id which was registered with the given base name and the given sequence number. It returns a future representing those id.

**Return** A representing the id which was registered using the given base name and sequence numbers.

**Note** The future embedded in the returned client object will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

**Template Parameters**
- **Client**: The client type to return

**Parameters**
- **base_name**: [in] The base name for which to retrieve the registered ids.
- **sequence_nr**: [in] The sequence number of the registered id.
Return  A future representing the id which was registered using the given base name and sequence numbers.

Note  The future will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

Parameters

- `base_name`: [in] The base name for which to retrieve the registered ids.
- `sequence_nr`: [in] The sequence number of the registered id.

```cpp
template<typename Client, typename Stub>
hpx::future<bool> register_with_basename(
    std::string base_name,
    components::client_base<Client, Stub> &client,
    std::size_t sequence_nr)
```

Register the id wrapped in the given client using the given base name.

Return  A future representing the result of the registration operation itself.

Note  The operation will fail if the given sequence number is not unique.

Template Parameters

- `Client`: The client type to register

Parameters

- `base_name`: [in] The base name for which to retrieve the registered ids.
- `client`: [in] The client which should be registered using the given base name.
- `sequence_nr`: [in, optional] The sequential number to use for the registration of the id. This number has to be unique system wide for each registration using the same base name. The default is the current locality identifier. Also, the sequence numbers have to be consecutive starting from zero.

```cpp
template<typename Client>
Client unregister_with_basename(std::string base_name, std::size_t sequence_nr)
```

Unregister the given id using the given base name.

Return  A future representing the result of the un-registration operation itself.

Template Parameters

- `Client`: The client type to return

Parameters

- `base_name`: [in] The base name for which to retrieve the registered ids.
- `sequence_nr`: [in, optional] The sequential number to use for the un-registration. This number has to be the same as has been used with `register_with_basename` before.
Return A future representing the result of the un-registration operation itself.

Parameters

• base_name: [in] The base name for which to retrieve the registered ids.
• sequence_nr: [in, optional] The sequential number to use for the un-registration. This number has to be the same as has been used with register_with_basename before.

namespace hpx

Functions

**hpx::future<bool> register_with_basename**(std::string base_name, hpx::id_type id, std::size_t sequence_nr = std::numeric_limits<std::size_t>::max())

Register the given id using the given base name.

The function registers the given ids using the provided base name.

Return A future representing the result of the registration operation itself.

Note The operation will fail if the given sequence number is not unique.

Parameters

• base_name: [in] The base name for which to retrieve the registered ids.
• id: [in] The id to register using the given base name.
• sequence_nr: [in, optional] The sequential number to use for the registration of the id. This number has to be unique system wide for each registration using the same base name. The default is the current locality identifier. Also, the sequence numbers have to be consecutive starting from zero.

**hpx::future<bool> register_with_basename**(std::string base_name, hpx::future<hpx::id_type> f, std::size_t sequence_nr = std::numeric_limits<std::size_t>::max())

Register the id wrapped in the given future using the given base name.

The function registers the object the given future refers to using the provided base name.

Return A future representing the result of the registration operation itself.

Note The operation will fail if the given sequence number is not unique.

Parameters

• base_name: [in] The base name for which to retrieve the registered ids.
• f: [in] The future which should be registered using the given base name.
• sequence_nr: [in, optional] The sequential number to use for the registration of the id. This number has to be unique system wide for each registration using the same base name. The default is the current locality identifier. Also, the sequence numbers have to be consecutive starting from zero.

Functions

template<typename Component>
hp::future<std::shared_ptr<Component>> get_ptr (naming::id_type const &id)
Returns a future referring to the pointer to the underlying memory of a component.

The function hpx::get_ptr can be used to extract a future referring to the pointer to the underlying memory of a given component.

Return This function returns a future representing the pointer to the underlying memory for the component instance with the given id.

Note This function will successfully return the requested result only if the given component is currently located on the calling locality. Otherwise the function will raise an error.

Note The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned shared_ptr alive.

Parameters

• id: [in] The global id of the component for which the pointer to the underlying memory should be retrieved.

Template Parameters

• The: only template parameter has to be the type of the server side component.

template<typename Derived, typename Stub>
hp::future<std::shared_ptr<typename components::client_base<Derived, Stub>::server_component_type>> get_ptr (components::client_base<Derived, Stub>::const &c)

Returns a future referring to the pointer to the underlying memory of a component.

The function hpx::get_ptr can be used to extract a future referring to the pointer to the underlying memory of a given component.

Return This function returns a future representing the pointer to the underlying memory for the component instance with the given id.

Note This function will successfully return the requested result only if the given component is currently located on the calling locality. Otherwise the function will raise an error.

Note The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned shared_ptr alive.

Parameters
• c: [in] A client side representation of the component for which the pointer to the underlying memory should be retrieved.

```cpp
template<typename Component>
std::shared_ptr<Component> get_ptr (launch::sync_policy p, naming::id_type const &id, error_code &ec = throws)
```

Returns the pointer to the underlying memory of a component.

The function hpx::get_ptr_sync can be used to extract the pointer to the underlying memory of a given component.

**Return** This function returns the pointer to the underlying memory for the component instance with the given *id*.

**Note** This function will successfully return the requested result only if the given component is currently located on the requesting locality. Otherwise the function will raise and error.

**Note** The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned shared_ptr alive.

**Note** As long as *ec* is not pre-initialized to *hpx::throws* this function doesn’t throw but returns the result code using the parameter *ec*. Otherwise it throws an instance of *hpx::exception*.

**Parameters**

- *p*: [in] The parameter *p* represents a placeholder type to turn make the call synchronous.
- *id*: [in] The global id of the component for which the pointer to the underlying memory should be retrieved.
- *ec*: [in,out] this represents the error status on exit, if this is pre-initialized to *hpx::throws* the function will throw on error instead.

**Template Parameters**

- The: only template parameter has to be the type of the server side component.

```cpp
template<typename Derived, typename Stub>
std::shared_ptr<typename components::client_base<Derived, Stub>::server_component_type> get_ptr (launch::sync_policy p,
components::client_base<
Stub> const
&c,
error_code &ec
= throws)
```

Returns the pointer to the underlying memory of a component.

The function hpx::get_ptr_sync can be used to extract the pointer to the underlying memory of a given component.

**Return** This function returns the pointer to the underlying memory for the component instance with the given *id*. 

Note This function will successfully return the requested result only if the given component is currently located on the requesting locality. Otherwise the function will raise an error.

Note The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned shared_ptr alive.

Note As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

Parameters

- `p`: [in] The parameter `p` represents a placeholder type to turn make the call synchronous.
- `c`: [in] A client side representation of the component for which the pointer to the underlying memory should be retrieved.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

#include <component_startup_shutdown.hpp> The component_startup_shutdown class provides a
minimal implementation of a component’s startup/shutdown function provider.

Public Functions

bool get_startup_function(startup_function_type &startup, bool &pre_startup)
Return any startup function for this component.

Return Returns true if the parameter startup has been successfully initialized with the startup
function.

Parameters

• startup: [in, out] The module is expected to fill this function object with a reference to a
startup function. This function will be executed by the runtime system during system startup.

bool get_shutdown_function(shutdown_function_type &shutdown, bool &pre_shutdown)
Return any startup function for this component.

Return Returns true if the parameter shutdown has been successfully initialized with the shut-
down function.

Parameters

• shutdown: [in, out] The module is expected to fill this function object with a reference
to a startup function. This function will be executed by the runtime system during system
startup.

Chapter 2. What’s so special about HPX?
### Typedefs

```cpp
typedef void (*component_deleter_type)(hpx::naming::gid_type const&, hpx::naming::address const&);
```

### Enums

```cpp
enum component_enum_type {component_invalid = naming::address::component_invalid, component_runtime_support = 0, component_plain_function = 1, component_base_lco = 2, component_base_lco_with_value_unmanaged = 3, component_base_lco_with_value = 4, component_latch = ((5 << 10) | component_base_lco_with_value), component_barrier = ((6 << 10) | component_base_lco), component_promise = ((7 << 10) | component_base_lco_with_value), component_agas_locality_namespace = 8, component_agas_primary_namespace = 9, component_agas_component_namespace = 10, component_agas_symbol_namespace = 11, component_last, component_first_dynamic = component_last, component_upper_bound = 0xffffffffL
```

```cpp
enum factory_state_enum {factory_enabled = 0, factory_disabled = 1, factory_check = 2
```

### Functions

```cpp
bool &enabled(component_type type)
util::atomic_count &instance_count,(component_type type)
component_deleter_type &deleter(component_type type)
bool enumerate_instance_counts,(util::unique_function_nonser<bool) component_type
    > const &f
```
```
const std::string get_component_type_name (component_type type)
    Return the string representation for a given component type id.

constexpr component_type get_base_type (component_type t)
The lower short word of the component type is the type of the component exposing the actions.

constexpr component_type get Derived_type (component_type t)
The upper short word of the component is the actual component type.

constexpr component_type derived_component_type (component_type derived, component_type base)
    A component derived from a base component exposing the actions needs to have a specially formatted component type.

constexpr bool types_are_compatible (component_type lhs, component_type rhs)
    Verify the two given component types are matching (compatible)
```

```
template<typename Component, typename Enable = void>
    constexpr char *get_component_name ()

template<typename Component, typename Enable = void>
    constexpr const char *get_component_base_name ()

template<typename Component>
    component_type get_component_type ()

template<typename Component>
    void set_component_type (component_type type)
```

```namespace naming```

```
Functions

std::ostream &operator<<(std::ostream&, address const&)
```

```
namespace hpx
```

```
namespace components```

```
Typedefs

typedef component_base<Component> instead
```

```
template<typename Component>
using abstract_simple_component_base = abstract_component_base<Component>
```

```
template<typename Component, typename Derived>
class managed_component
    #include <managed_component_base.hpp> The managed_component template is used as a indirection layer for components allowing to gracefully handle the access to non-existing components.

    Additionally it provides memory management capabilities for the wrapping instances, and it integrates the memory management with the AGAS service. Every instance of a managed_component gets assigned a global id. The provided memory management allocates the managed_component instances from a special heap, ensuring fast allocation and avoids a full network round trip to the AGAS service for each of the allocated instances.
```
Template Parameters

- Component:
- Derived:

template<typename Component>

Public Static Functions

static Component * call (naming::address_type lva)

namespace hpx

template<typename Component, typename Enable = void>
struct get_lva
#include <get_lva.hpp> The get_lva template is a helper structure allowing to convert a local virtual address as stored in a local address (returned from the function resolver_client::resolve) to the address of the component implementing the action.

The default implementation uses the template argument Component to deduce the type wrapping the component implementing the action. This is used to get the needed address.

Template Parameters

- Component: This is the type of the component implementing the action to execute.
Public Static Functions

static Component *call (naming::address_type lva)

compute

The contents of this module can be included with the header `hpx/modules/compute.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/compute.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

```cpp
namespace hpx

namespace compute

Functions

```
typedef detail::iterator<T const, Allocator> const_iterator
typedef detail::reverse_iterator<T, Allocator> reverse_iterator
typedef detail::const_reverse_iterator<T, Allocator> const_reverse_iterator

Public Functions

vector (Allocator const &alloc = Allocator())
vector (size_type count, T const &value, Allocator const &alloc = Allocator())
vector (size_type count, Allocator const &alloc = Allocator())
template<typename InIter, typename Enable = typename std::enable_if<hpx::traits::is_input_iterator<InIter>::value>::type>
vector (InIter first, InIter last, Allocator const &alloc)
vector (vector const &other)
vector (vector const &other, Allocator const &alloc)
vector (vector &other)
vector (vector &other, Allocator const &alloc)
vector (std::initializer_list<T> init, Allocator const &alloc)
~vector ()
vector &operator=(vector const &other)
vector &operator=(vector &&other)

allocator_type get_allocator () const
Returns the allocator associated with the container.

reference operator[] (size_type pos)

const_reference operator[] (size_type pos) const

pointer data ()
Returns pointer to the underlying array serving as element storage. The pointer is such that range [data(); data() + size()) is always a valid range, even if the container is empty (data() is not dereferenceable in that case).

const_pointer data () const
Returns pointer to the underlying array serving as element storage. The pointer is such that range [data(); data() + size()) is always a valid range, even if the container is empty (data() is not dereferenceable in that case).

T *device_data () const
Returns a raw pointer corresponding to the address of the data allocated on the device.

std::size_t size () const

std::size_t capacity () const

bool empty () const
Returns: size() == 0.
void ** resize**(size_type)

Effects: If size <= size(), equivalent to calling pop_back() size() - size times. If size() < size, appends size - size() default-inserted elements to the sequence.

Requires: T shall be MoveInsertable and DefaultInsertable into *this.

Remarks: If an exception is thrown other than by the move constructor of a non-CopyInsertable T there are no effects.

void ** resize**(size_type, T const&)

Effects: If size <= size(), equivalent to calling pop_back() size() - size times. If size() < size, appends size - size() copies of val to the sequence.

Requires: T shall be CopyInsertable into *this.

Remarks: If an exception is thrown there are no effects.

**iterator** begin ()

**iterator** end ()

**const_iterator** cbegin () const

**const_iterator** cend () const

**const_iterator** begin() const

**const_iterator** end() const

void ** swap**(vector &other)

Effects: Exchanges the contents and capacity() of *this with that of x.

Complexity: Constant time.

void ** clear ()**

Effects: Erases all elements in the range [begin(),end()). Destroys all elements in a. Invalidates all references, pointers, and iterators referring to the elements of a and may invalidate the past-the-end iterator.

Post: a.empty() returns true.

Complexity: Linear.

**namespace hpx**

**namespace components**

**Variables**

```cpp
const binpacking_distribution_policy binpacked = {}
```

A predefined instance of the binpacking `distribution_policy`. It will represent the local locality and will place all items to create here.

```cpp
struct binpacking_distribution_policy
#include <binpacking_distribution_policy.hpp> This class specifies the parameters for a binpacking distribution policy to use for creating a given number of items on a given set of localities. The binpacking policy will distribute the new objects in a way such that each of the localities will equalize the number of overall objects of this type based on a given criteria (by default this criteria is the overall number of objects of this type).```
Public Functions

`binpacking_distribution_policy()`  
Default-construct a new instance of a binpacking_distribution_policy. This policy will represent one locality (the local locality).

`binpacking_distribution_policy operator() (std::vector<id_type> const &locs,  
char const *perf_counter_name = default_binpacking_counter_name) const  
Create a new default_distribution policy representing the given set of localities.

Parameters
• locs: [in] The list of localities the new instance should represent
• perf_counter_name: [in] The name of the performance counter which should be used as the distribution criteria (by default the overall number of existing instances of the given component type will be used).

`binpacking_distribution_policy operator() (std::vector<id_type> &&locs, char  
const *perf_counter_name = default_binpacking_counter_name) const  
Create a new default_distribution policy representing the given set of localities.

Parameters
• locs: [in] The list of localities the new instance should represent
• perf_counter_name: [in] The name of the performance counter which should be used as the distribution criteria (by default the overall number of existing instances of the given component type will be used).

`binpacking_distribution_policy operator() (id_type const &loc, char  
const *perf_counter_name = default_binpacking_counter_name) const  
Create a new default_distribution policy representing the given locality

Parameters
• loc: [in] The locality the new instance should represent
• perf_counter_name: [in] The name of the performance counter that should be used as the distribution criteria (by default the overall number of existing instances of the given component type will be used).

`template<typename Component, typename ... Ts>  
hpx::future<hpx::id_type> create(Ts&&... vs) const  
Create one object on one of the localities associated by this policy instance

Return  A future holding the global address which represents the newly created object
Parameters  
• vs: [in] The arguments which will be forwarded to the constructor of the new object.

`template<typename Component, typename ... Ts>  
hpx::future<std::vector<bulk_locality_result>> bulk_create (std::size_t count, Ts&&... vs)  
Create multiple objects on the localities associated by this policy instance

Return  A future holding the list of global addresses which represent the newly created objects
Parameters

• **count**: [in] The number of objects to create
• **vs**: [in] The arguments which will be forwarded to the constructors of the new objects.

```cpp
std::string const & get_counter_name() const
```

Returns the name of the performance counter associated with this policy instance.

```cpp
std::size_t get_num_localities() const
```

Returns the number of associated localities for this distribution policy.

**Note** This function is part of the creation policy implemented by this class

```
namespace hpx

namespace components

Variables

const colocating_distribution_policy colocated = {}
```

A predefined instance of the co-locating distribution_policy. It will represent the local locality and will place all items to create here.

```
struct colocating_distribution_policy
#include <colocating_distribution_policy.hpp>
```

This class specifies the parameters for a distribution policy to use for creating a given number of items on the locality where a given object is currently placed.

**Public Functions**

```
colocating_distribution_policy()       
```

Default-construct a new instance of a colocating_distribution_policy. This policy will represent the local locality.

```
colocating_distribution_policy operator()(id_type const & id) const
```

Create a new colocating_distribution_policy representing the locality where the given object is current located.

**Parameters**

• **id**: [in] The global address of the object with which the new instances should be colocated on

```
template<typename Client, typename Stub>
colocating_distribution_policy operator()(client_base<Client, Stub> const & client) const
```

Create a new colocating_distribution_policy representing the locality where the given object is current located

**Parameters**

• **client**: [in] The client side representation of the object with which the new instances should be colocated on

```
template<typename Component, typename ... Ts>
```

**HPX Documentation, master**

```cpp
hpx::future<hpx::id_type> create (Ts&&... vs) const
Create one object on the locality of the object this distribution policy instance is associated with

**Note**  This function is part of the placement policy implemented by this class
**Return**  A future holding the global address which represents the newly created object
**Parameters**
• vs: [in] The arguments which will be forwarded to the constructor of the new object.

```template<typename Component, typename ...Ts>
```hpx::future<std::vector<bulk_locality_result>> bulk_create (std::size_t count, Ts&&... vs) const
Create multiple objects colocated with the object represented by this policy instance

**Note**  This function is part of the placement policy implemented by this class
**Return**  A future holding the list of global addresses which represent the newly created objects
**Parameters**
• count: [in] The number of objects to create
• vs: [in] The arguments which will be forwarded to the constructors of the new objects.

```template<typename Action, typename ...Ts>
```async_result<Action>::type async (launch policy, Ts&&... vs) const
```async_result<Action>::type async_cb (launch policy, Callback&& cb, Ts&&... vs) const

Variables

```cpp
const target_distribution_policy target = {}
```

A predefined instance of the target_distribution_policy. It will represent the local locality and will place all items to create here.

```cpp
struct target_distribution_policy
#include <target_distribution_policy.hpp>
```

This class specifies the parameters for a simple distribution policy to use for creating (and evenly distributing) a given number of items on a given set of localities.

Public Functions

```cpp
target_distribution_policy()
```

Default-construct a new instance of a target_distribution_policy. This policy will represent one locality (the local locality).

```cpp
target_distribution_policy operator() (id_type const &id) const
```

Create a new target_distribution_policy representing the given locality

Parameters

- `loc`: [in] The locality the new instance should represent

```cpp
template<typename Component, typename ...Ts>
hpx::future<hpx::id_type> create (Ts&& ... vs) const
```

Create one object on one of the localities associated by this policy instance

Note This function is part of the placement policy implemented by this class

Return A future holding the global address which represents the newly created object

Chapter 2. What’s so special about HPX?
Parameters

- **vs**: [in] The arguments which will be forwarded to the constructor of the new object.

```cpp
template<typename Component, typename ...Ts>
hpx::future<std::vector<bulk_locality_result>> bulk_create (std::size_t count, Ts&&... vs) const
```

Create multiple objects on the localities associated by this policy instance

**Note** This function is part of the placement policy implemented by this class

**Return** A future holding the list of global addresses which represent the newly created objects

**Parameters**

- **count**: [in] The number of objects to create
- **vs**: [in] The arguments which will be forwarded to the constructors of the new objects.

```cpp
template<typename Action, typename ...Ts>
async_result<Action>::type async (launch policy, Ts&&... vs) const
```

```cpp
using task_cancelled_exception = hpx::parallel::task_canceled_exception
```

init_runtime

The contents of this module can be included with the header `hpx/modules/init_runtime.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/init_runtime.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

namespace hpx

Functions

```cpp
int finalize (double shutdown_timeout, double localwait = -1.0, error_code &ec = throws)
```

Main function to gracefully terminate the HPX runtime system.

The function `hpx::finalize` is the main way to (gracefully) exit any HPX application. It should be called from one locality only (usually the console) and it will notify all connected localities to finish execution. Only after all other localities have exited this function will return, allowing to exit the console locality as well.

During the execution of this function the runtime system will invoke all registered shutdown functions (see `hpx::init`) on all localities.
The default value (-1.0) will try to find a globally set timeout value (can be set as the configuration parameter `hpx.shutdown_timeout`), and if that is not set or -1.0 as well, it will disable any timeout, each connected locality will wait for all existing HPX-threads to terminate.

**Parameters**

- `shutdown_timeout`: This parameter allows to specify a timeout (in microseconds), specifying how long any of the connected localities should wait for pending tasks to be executed. After this timeout, all suspended HPX-threads will be aborted. Note, that this function will not abort any running HPX-threads. In any case the shutdown will not proceed as long as there is at least one pending/running HPX-thread.

The default value (-1.0) will try to find a globally set wait time value (can be set as the configuration parameter “hpx.finalize_wait_time”), and if this is not set or -1.0 as well, it will disable any addition local wait time before proceeding.

**Parameters**

- `localwait`: This parameter allows to specify a local wait time (in microseconds) before the connected localities will be notified and the overall shutdown process starts.

This function will block and wait for all connected localities to exit before returning to the caller. It should be the last HPX-function called by any application.

**Return** This function will always return zero.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Parameters**

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

Using this function is an alternative to `hpx::disconnect`, these functions do not need to be called both.

```cpp
int finalize (error_code &ec = throws)
```

Main function to gracefully terminate the HPX runtime system.

The function `hpx::finalize` is the main way to (gracefully) exit any HPX application. It should be called from one locality only (usually the console) and it will notify all connected localities to finish execution. Only after all other localities have exited this function will return, allowing to exit the console locality as well.

During the execution of this function the runtime system will invoke all registered shutdown functions (see `hpx::init`) on all localities.

This function will block and wait for all connected localities to exit before returning to the caller. It should be the last HPX-function called by any application.

**Return** This function will always return zero.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Parameters**

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.
Using this function is an alternative to `hpx::disconnect`, these functions do not need to be called both.

**HPX_NORETURN void hpx::terminate()**

Terminate any application non-gracefully.

The function `hpx::terminate` is the non-graceful way to exit any application immediately. It can be called from any locality and will terminate all localities currently used by the application.

**Note** This function will cause HPX to call `std::terminate()` on all localities associated with this application. If the function is called not from an HPX thread it will fail and return an error using the argument `ec`.

```cpp
int disconnect (double shutdown_timeout, double localwait = -1.0, error_code &ec = throws)
```

Disconnect this locality from the application.

The function `hpx::disconnect` can be used to disconnect a locality from a running HPX application.

During the execution of this function the runtime system will invoke all registered shutdown functions (see `hpx::init`) on this locality. The default value (`-1.0`) will try to find a globally set timeout value (can be set as the configuration parameter "hpx.shutdown_timeout"), and if that is not set or `-1.0` as well, it will disable any timeout, each connected locality will wait for all existing HPX-threads to terminate.

**Parameters**

- `shutdown_timeout`: This parameter allows to specify a timeout (in microseconds), specifying how long this locality should wait for pending tasks to be executed. After this timeout, all suspended HPX-threads will be aborted. Note, that this function will not abort any running HPX-threads. In any case the shutdown will not proceed as long as there is at least one pending/running HPX-thread.

The default value (`-1.0`) will try to find a globally set wait time value (can be set as the configuration parameter `hpx.finalize_wait_time`), and if this is not set or `-1.0` as well, it will disable any addition local wait time before proceeding.

**Parameters**

- `localwait`: This parameter allows to specify a local wait time (in microseconds) before the connected localities will be notified and the overall shutdown process starts.

This function will block and wait for this locality to finish executing before returning to the caller. It should be the last HPX-function called by any locality being disconnected.

**Return** This function will always return zero.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Parameters**

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
int disconnect (error_code &ec = throws)
```

Disconnect this locality from the application.

The function `hpx::disconnect` can be used to disconnect a locality from a running HPX application.
During the execution of this function the runtime system will invoke all registered shutdown functions (see \texttt{hpx::init}) on this locality.

This function will block and wait for this locality to finish executing before returning to the caller. It should be the last HPX-function called by any locality being disconnected.

\textbf{Return} This function will always return zero.

\textbf{Note} As long as \texttt{ec} is not pre-initialized to \texttt{hpx::throws} this function doesn’t throw but returns the result code using the parameter \texttt{ec}. Otherwise it throws an instance of \texttt{hpx::exception}.

\textbf{Parameters}

- \texttt{ec} \hfill [in,out] this represents the error status on exit, if this is pre-initialized to \texttt{hpx::throws} the function will throw on error instead.

\begin{verbatim}
int stop (error_code &ec = throws)
\end{verbatim}

Stop the runtime system.

This function will block and wait for this locality to finish executing before returning to the caller. It should be the last HPX-function called on every locality. This function should be used only if the runtime system was started using \texttt{hpx::start}.

\textbf{Return} The function returns the value, which has been returned from the user supplied main HPX function (usually \texttt{hpx\_main}).

\begin{verbatim}
namespace hpx

\textbf{Functions}

int init (util::function_nonser<int> hpx::program_options::variables_map&
    > const &f, int argc, char **argv, init_params const &params = init_params())Main entry point for launching the HPX runtime system.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users \texttt{main()} function. It will set up the HPX runtime environment and schedule the function given by \texttt{f} as a HPX thread. This overload will not call \texttt{hpx\_main}.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users \texttt{main()} function. It will set up the HPX runtime environment and schedule the function given by \texttt{f} as a HPX thread.

\textbf{Return} The function returns the value, which has been returned from the user supplied \texttt{f}.

\textbf{Note} If the parameter \texttt{mode} is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in \texttt{argc/argv}. Otherwise it will be executed as specified by the parameter \texttt{mode}.

\textbf{Parameters}

- \texttt{f} \hfill [in] The function to be scheduled as an HPX thread. Usually this function represents the main entry point of any HPX application. If \texttt{f} is \texttt{nullptr} the HPX runtime environment will be started without invoking \texttt{f}.

- \texttt{argc} \hfill [in] The number of command line arguments passed in \texttt{argv}. This is usually the unchanged value as passed by the operating system (to \texttt{main()}).
• **argv**: [in] The command line arguments for this application, usually that is the value as passed by the operating system (to `main()`).

• **params**: [in] The parameters to the `hpx::init` function (See documentation of `hpx::init_params`)

```cpp
int init (util::function_nonser<int> int, char**
> const &f, int argc, char **argv, init_params const &params = init_params())
```

This is the main entry point for launching the HPX runtime system. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. This overload will not call `hpx_main`.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread.

**Return** The function returns the value, which has been returned from the user supplied `f`.

**Note** If the parameter `mode` is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc/argv`. Otherwise it will be executed as specified by the parameter `mode`.

**Parameters**

• `f`: [in] The function to be scheduled as an HPX thread. Usually this function represents the main entry point of any HPX application. If `f` is `nullptr` the HPX runtime environment will be started without invoking `f`.

• `argc`: [in] The number of command line arguments passed in `argv`. This is usually the unchanged value as passed by the operating system (to `main()`).

• `argv`: [in] The command line arguments for this application, usually that is the value as passed by the operating system (to `main()`).

• `params`: [in] The parameters to the `hpx::init` function (See documentation of `hpx::init_params`)

```cpp
int init (int argc, char **argv, init_params const &params = init_params())
```

Main entry point for launching the HPX runtime system.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. This overload will not call `hpx_main`.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread.

• **params**: [in] The parameters to the `hpx::init` function (See documentation of `hpx::init_params`)

```cpp
int init (init_params const &params = init_params())
```

Main entry point for launching the HPX runtime system.

This is a simplified main entry point, which can be used to set up the runtime for an HPX application (the runtime system will be set up in console mode or worker mode depending on the command line settings).

This is a simplified main entry point, which can be used to set up the runtime for an HPX application (the runtime system will be set up in console mode or worker mode depending on the command line settings).

Return The function returns the value, which has been returned from `hpx_main` (or 0 when executed in worker mode).

Note The created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc/argv`. If not command line arguments are passed, console mode is assumed.

Note If no command line arguments are passed the HPX runtime system will not support any of the default command line options as described in the section 'HPX Command Line Options'.

Parameters

• **params**: [in] The parameters to the `hpx::init` function (See documentation of `hpx::init_params`)
namespace hpx

struct init_params
#include <hpx_init_params.hpp> Parameters used to initialize the HPX runtime through hpx::init and hpx::start.

Main non-blocking entry point for launching the HPX runtime system.

This is a simplified main, non-blocking entry point, which can be used to set up the runtime for an HPX application (the runtime system will be set up in console mode or worker mode depending on the command line settings). It will return immediately after that. Use `hpx::wait` and `hpx::stop` to synchronize with the runtime system’s execution.

This is the main, non-blocking entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and
schedule the function given by \( f \) as an HPX thread. It will return immediately after that. Use `hpx::wait` and `hpx::stop` to synchronize with the runtime system’s execution.

**Return** The function returns `true` if command line processing succeeded and the runtime system was started successfully. It will return `false` otherwise.

**Note** The created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc/argv`. If no command line arguments are passed, console mode is assumed.

**Note** If no command line arguments are passed the HPX runtime system will not support any of the default command line options as described in the section ‘HPX Command Line Options’.

**Parameters**
- `params`: [in] The parameters to the `hpx::start` function (See documentation of `hpx::init_params`)

```cpp
namespace hpx
{

Functions

int suspend (error_code &ec = throws)
Suspend the runtime system.

The function `hpx::suspend` is used to suspend the HPX runtime system. It can only be used when running HPX on a single locality. It will block waiting for all thread pools to be empty. This function only be called when the runtime is running, or already suspended in which case this function will do nothing.

**Return** This function will always return zero.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Parameters**
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

int resume (error_code &ec = throws)
Resume the HPX runtime system.

The function `hpx::resume` is used to resume the HPX runtime system. It can only be used when running HPX on a single locality. It will block waiting for all thread pools to be resumed. This function only be called when the runtime suspended, or already running in which case this function will do nothing.

**Return** This function will always return zero.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Parameters**
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```

```cpp
namespace hpx
```

```cpp
namespace naming
```
Functions

```cpp
id_type unmanaged(id_type const &id)
```

The helper function `hpx::unmanaged` can be used to generate a global identifier which does not participate in the automatic garbage collection.

**Return** This function returns a new global id referencing the same object as the parameter `id`. The only difference is that the returned global identifier does not participate in the automatic garbage collection.

**Note** This function allows to apply certain optimizations to the process of memory management in HPX. It however requires the user to take full responsibility for keeping the referenced objects alive long enough.

**Parameters**

- `id`: [in] The id to generated the unmanaged global id from. This parameter can be itself a managed or a unmanaged global id.

performance_counters

The contents of this module can be included with the header `hpx/modules/performance_counters.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/performance_counters.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

```cpp
namespace hpx

namespace performance_counters

Functions

```cpp
bool action_invocation_counter_discoverer(hpx::actions::detail::invocation_count_registry const &registry, counter_info const &info, counter_path_elements &p, discover_counter_func const &f, discover_counters_mode mode, error_code &ec)
```

```cpp
namespace hpx

namespace performance_counters
```
Functions

void register_agas_counter_types (agas::addressing_service &client)
Install performance counter types exposing properties from the local cache.

Functions

bool default_counter_discoverer(counter_info const&, discover_counter_func const&, discover_counters_mode, error_code&)

Default discovery function for performance counters; to be registered with the counter types. It will pass the counter_info and the error_code to the supplied function.

bool locality_counter_discoverer(counter_info const&, discover_counter_func const&, discover_counters_mode, error_code&)

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

/<objectname>(locality#<locality_id>/total)/<instancename>

bool locality_pool_counter_discoverer(counter_info const&, discover_counter_func const&, discover_counters_mode, error_code&)

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

/<objectname>(locality#<locality_id>/pool#<pool_name>/total)/<instancename>

bool locality0_counter_discoverer(counter_info const&, discover_counter_func const&, discover_counters_mode, error_code&)

Default discoverer function for AGAS performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

/<objectname>{locality#0/total}/<instancename>

bool locality_thread_counter_discoverer(counter_info const&, discover_counter_func const&, discover_counters_mode, error_code&)

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

/<objectname>(locality#<locality_id>/worker-thread#<threadnum>/)<instancename>
bool **locality_pool_thread_counter_discoverer**(counter_info const &info, discover_counter_func const &f, discover_counters_mode mode, error_code &ec)

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

/\objectname\{/locality#<locality_id>/pool#<poolname>/thread#<threadnum>\}/<instancename>

bool **locality_pool_thread_no_total_counter_discoverer**(counter_info const &info, discover_counter_func const &f, discover_counters_mode mode, error_code &ec)

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

/\objectname\{/locality#<locality_id>/pool#<poolname>/thread#<threadnum>\}/<instancename>

This is essentially the same as above just that locality*/total is not supported.

bool **locality_numa_counter_discoverer**(counter_info const &info, discover_counter_func const &f, discover_counters_mode, error_code &ec)

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

/\objectname\#/numa-node#<threadnum>\}/<instancename>

Typedefs

typedef hpx::util::function_nonser<naming::gid_type (counter_info const&, error_code&)>
create_counter_func
This declares the type of a function, which will be called by HPX whenever a new performance counter instance of a particular type needs to be created.

typedef hpx::util::function_nonser<bool (counter_info const&, error_code&)> discover_counter_func
This declares a type of a function, which will be passed to a discover_count_func in order to be called for each discovered performance counter instance.

typedef hpx::util::function_nonser<bool (counter_info const&, discover_counter_func const&, discover_counters_mode, error_code&)> discover_counters_func
This declares the type of a function, which will be called by HPX whenever it needs to discover all performance counter instances of a particular type.

Enums

class enum counter_type
Values:

counter_text
counter_text shows a variable-length text string. It does not deliver calculated values.
Formula: None Average: None Type: Text

counter_raw
counter_raw shows the last observed value only. It does not deliver an average.
Formula: None. Shows raw data as collected. Average: None Type: Instantaneous

counter_monotonically_increasing

counter_average_base
counter_average_base is used as the base data (denominator) in the computation of time or count averages for the counter_average_count and counter_average_timer counter types. This counter type collects the last observed value only.
Formula: None. This counter uses raw data in factional calculations without delivering an output. Average: SUM (N) / x Type: Instantaneous

counter_average_count
counter_average_count shows how many items are processed, on average, during an operation.
Counters of this type display a ratio of the items processed (such as bytes sent) to the number of operations completed. The ratio is calculated by comparing the number of items processed during the last interval to the number of operations completed during the last interval.

Formula: \( \frac{(N_1 - N_0)}{(D_1 - D_0)} \), where the numerator \( N \) represents the number of items processed during the last sample interval, and the denominator \( D \) represents the number of operations completed during the last sample interval. Average: \( \frac{(N_x - N_0)}{(D_x - D_0)} \) Type: Average

counter_aggregating

counter_aggregating applies a function to an embedded counter instance. The embedded counter is usually evaluated repeatedly after a fixed (but configurable) time interval.

Formula: \( F(N_x) \)

counter_average_timer

counter_average_timer measures the average time it takes to complete a process or operation. Counters of this type display a ratio of the total elapsed time of the sample interval to the number of processes or operations completed during that time. This counter type measures time in ticks of the system clock. The variable \( F \) represents the number of ticks per second. The value of \( F \) is factored into the equation so that the result is displayed in seconds.

Formula: \( \frac{((N_1 - N_0) / F)}{(D_1 - D_0)} \), where the numerator \( N \) represents the number of ticks counted during the last sample interval, the variable \( F \) represents the frequency of the ticks, and the denominator \( D \) represents the number of operations completed during the last sample interval. Average: \( \frac{((N_x - N_0) / F)}{(D_x - D_0)} \) Type: Average

counter_elapsed_time

counter_elapsed_time shows the total time between when the component or process started and the time when this value is calculated. The variable \( F \) represents the number of time units that elapse in one second. The value of \( F \) is factored into the equation so that the result is displayed in seconds.

Formula: \( \frac{(D_0 - N_0)}{F} \), where the nominator \( D \) represents the current time, the numerator \( N \) represents the time the object was started, and the variable \( F \) represents the number of time units that elapse in one second. Average: \( \frac{(D_x - N_0)}{F} \) Type: Difference

counter_histogram

counter_histogram exposes a histogram of the measured values instead of a single value as many of the other counter types. Counters of this type expose a counter_value_array instead of a counter_value. Those will also not implement the get_counter_value() functionality. The results are exposed through a separate get_counter_values_array() function.

The first three values in the returned array represent the lower and upper boundaries, and the size of the histogram buckets. All remaining values in the returned array represent the number of measurements for each of the buckets in the histogram.

counter_raw_values

counter_raw_values exposes an array of measured values instead of a single value as many of the other counter types. Counters of this type expose a counter_value_array instead of a counter_value. Those will also not implement the get_counter_value() functionality. The results are exposed through a separate get_counter_values_array() function.

counter_text

counter_text shows a variable-length text string. It does not deliver calculated values.

Formula: None Average: None Type: Text

counter_raw

counter_raw shows the last observed value only. It does not deliver an average.
counter_monotonically_increasing

**counter_average_base**

*counter_average_base* is used as the base data (denominator) in the computation of time or count averages for the *counter_average_count* and *counter_average_timer* counter types. This counter type collects the last observed value only.

Formula: None. This counter uses raw data in factional calculations without delivering an output. Average: SUM (N) / x Type: Instantaneous

counter_average_count

*counter_average_count* shows how many items are processed, on average, during an operation. Counters of this type display a ratio of the items processed (such as bytes sent) to the number of operations completed. The ratio is calculated by comparing the number of items processed during the last interval to the number of operations completed during the last interval.

Formula: \((N_1 - N_0) / (D_1 - D_0)\), where the numerator (N) represents the number of items processed during the last sample interval, and the denominator (D) represents the number of operations completed during the last two sample intervals. Average: \((N_x - N_0) / (D_x - D_0)\) Type: Average

counter_aggregating

*counter_aggregating* applies a function to an embedded counter instance. The embedded counter is usually evaluated repeatedly after a fixed (but configurable) time interval.

Formula: \(F(N_x)\)

counter_average_timer

*counter_average_timer* measures the average time it takes to complete a process or operation. Counters of this type display a ratio of the total elapsed time of the sample interval to the number of processes or operations completed during that time. This counter type measures time in ticks of the system clock. The variable F represents the number of ticks per second. The value of F is factored into the equation so that the result is displayed in seconds.

Formula: \(((N_1 - N_0) / F) / (D_1 - D_0)\), where the numerator (N) represents the number of ticks counted during the last sample interval, the variable F represents the frequency of the ticks, and the denominator (D) represents the number of operations completed during the last sample interval. Average: \(((N_x - N_0) / F) / (D_x - D_0)\) Type: Average

counter_elapsed_time

*counter_elapsed_time* shows the total time between when the component or process started and the time when this value is calculated. The variable F represents the number of time units that elapse in one second. The value of F is factored into the equation so that the result is displayed in seconds.

Formula: \((D_0 - N_0) / F\), where the nominator (D) represents the current time, the numerator (N) represents the time the object was started, and the variable F represents the number of time units that elapse in one second. Average: \((D_x - N_0) / F\) Type: Difference

counter_histogram

*counter_histogram* exposes a histogram of the measured values instead of a single value as many of the other counter types. Counters of this type expose a *counter_value_array* instead of a *counter_value*. Those will also not implement the *get_counter_value()* functionality. The results are exposed through a separate *get_counter_values_array()* function.

The first three values in the returned array represent the lower and upper boundaries, and the size of the histogram buckets. All remaining values in the returned array represent the number of measurements for each of the buckets in the histogram.
counter_raw_values

counter_raw_values exposes an array of measured values instead of a single value as many of the other counter types. Counters of this type expose a counter_value_array instead of a counter_value. Those will also not implement the get_counter_value() functionality. The results are exposed through a separate get_counter_values_array() function.

enum counter_status

Status and error codes used by the functions related to performance counters.

Values:

status_valid_data
No error occurred, data is valid.

status_new_data
Data is valid and different from last call.

status_invalid_data
Some error occurred, data is not value.

status_already_defined
The type or instance already has been defined.

status_counter_unknown
The counter instance is unknown.

status_counter_type_unknown
The counter type is unknown.

status_generic_error
A unknown error occurred.

status_valid_data
No error occurred, data is valid.

status_new_data
Data is valid and different from last call.

status_invalid_data
Some error occurred, data is not value.

status_already_defined
The type or instance already has been defined.

status_counter_unknown
The counter instance is unknown.

status_counter_type_unknown
The counter type is unknown.

status_generic_error
A unknown error occurred.
Functions

```cpp
std::string &ensure_counter_prefix (std::string &name)
std::string ensure_counter_prefix (std::string const &counter)
std::string &remove_counter_prefix (std::string &name)
std::string remove_counter_prefix (std::string const &counter)
```

```cpp
char const *get_counter_type_name (counter_type state)
  Return the readable name of a given counter type.
bool status_is_valid (counter_status s)
counter_status add_counter_type (counter_info const &info, error_code &ec)
```

```cpp
naming::id_type get_counter (std::string const &name, error_code &ec)
naming::id_type get_counter (counter_info const &info, error_code &ec)
```

Variables

```cpp
constexpr const char counter_prefix[] = "/counters"
constexpr std::size_t counter_prefix_len = (sizeof(counter_prefix) / sizeof(counter_prefix[0])) - 1
```

```cpp
struct counter_info
```

Public Functions

```cpp
counter_info (counter_type type = counter_raw)
counter_info (std::string const &name)
counter_info (counter_type type, std::string const &name, std::string const &helptext = "", std::uint32_t version = HPX_PERFORMANCE_COUNTER_V1, std::string const &uom = "")
```

Public Members

```cpp
counter_type type_
  The type of the described counter.
std::uint32_t version_
  The version of the described counter using the 0xMMmmSSSS scheme
counter_status status_
  The status of the counter object.
std::string fullname_
  The full name of this counter.
std::string helptext_
  The full descriptive text for this counter.
std::string unit_of_measure_
  The unit of measure for this counter.
```
**Private Functions**

```cpp
void serialize(serialization::output_archive &ar, const unsigned int)
void serialize(serialization::input_archive &ar, const unsigned int)
```

**Friends**

```

**Public Members**

```cpp
std::string parentinstancename_
the name of the parent instance
```

```cpp
std::string instancename_
the name of the object instance
```

```cpp
std::string subinstancename_
the name of the object sub-instance
```

```cpp
std::int64_t parentinstanceindex_
the parent instance index
```

2.8. API reference
std::int64_t instanceindex_
    the instance index

std::int64_t subinstanceindex_
    the sub-instance index

bool parentinstance_is_basename_
    the parentinstance name

**Private Functions**

Defines

HPX_PERFORMANCE_COUNTER_V1

namespace hpx

namespace performance_counters

Enums

enum counter_type

Values:

counter_text
counter_text shows a variable-length text string. It does not deliver calculated values.

Formula: None Average: None Type: Text

counter_raw
counter_raw shows the last observed value only. It does not deliver an average.

Formula: None. Shows raw data as collected. Average: None Type: Instantaneous

counter_monotonically_increasing

counter_average_base
counter_average_base is used as the base data (denominator) in the computation of time or count
averages for the counter_average_count and counter_average_timer counter types. This counter
type collects the last observed value only.

Formula: None. This counter uses raw data in factional calculations without delivering an output.
Average: SUM (N) / x Type: Instantaneous

counter_average_count
counter_average_count shows how many items are processed, on average, during an operation.
Counters of this type display a ratio of the items processed (such as bytes sent) to the number of
operations completed. The ratio is calculated by comparing the number of items processed during
the last interval to the number of operations completed during the last interval.

Formula: (N1 - N0) / (D1 - D0), where the numerator (N) represents the number of items pro-
cessed during the last sample interval, and the denominator (D) represents the number of oper-
ations completed during the last two sample intervals. Average: (Nx - N0) / (Dx - D0) Type: Average
**counter_aggregating**

`counter_aggregating` applies a function to an embedded counter instance. The embedded counter is usually evaluated repeatedly after a fixed (but configurable) time interval.

Formula: F(Nx)

**counter_average_timer**

`counter_average_timer` measures the average time it takes to complete a process or operation. Counters of this type display a ratio of the total elapsed time of the sample interval to the number of processes or operations completed during that time. This counter type measures time in ticks of the system clock. The variable F represents the number of ticks per second. The value of F is factored into the equation so that the result is displayed in seconds.

Formula: \( \frac{(N_1 - N_0)}{F} / \frac{(D_1 - D_0)}{F} \)

Average: \( \frac{(N_x - N_0)}{F} / \frac{(D_x - D_0)}{F} \)

Type: Average

**counter_elapsed_time**

`counter_elapsed_time` shows the total time between when the component or process started and the time when this value is calculated. The variable F represents the number of time units that elapse in one second. The value of F is factored into the equation so that the result is displayed in seconds.

Formula: \( \frac{(D_0 - N_0)}{F} \)

Average: \( \frac{(D_x - N_0)}{F} \)

Type: Difference

**counter_histogram**

`counter_histogram` exposes a histogram of the measured values instead of a single value as many of the other counter types. Counters of this type expose a `counter_value_array` instead of a `counter_value`. Those will also not implement the `get_counter_value()` functionality. The results are exposed through a separate `get_counter_values_array()` function.

The first three values in the returned array represent the lower and upper boundaries, and the size of the histogram buckets. All remaining values in the returned array represent the number of measurements for each of the buckets in the histogram.

**counter_raw_values**

`counter_raw_values` exposes an array of measured values instead of a single value as many of the other counter types. Counters of this type expose a `counter_value_array` instead of a `counter_value`. Those will also not implement the `get_counter_value()` functionality. The results are exposed through a separate `get_counter_values_array()` function.

**counter_text**

`counter_text` shows a variable-length text string. It does not deliver calculated values.

Formula: None

Average: None

Type: Text

**counter_raw**

`counter_raw` shows the last observed value only. It does not deliver an average.

Formula: None. Shows raw data as collected.

Average: None

Type: Instantaneous

**counter_monotonically_increasing**

`counter_average_base` is used as the base data (denominator) in the computation of time or count averages for the `counter_average_count` and `counter_average_timer` counter types. This counter type collects the last observed value only.
Formula: None. This counter uses raw data in factional calculations without delivering an output. 
Average: \( \text{SUM} (N) / x \) Type: Instantaneous

**counter_average_count**

counter_average_count shows how many items are processed, on average, during an operation. Counters of this type display a ratio of the items processed (such as bytes sent) to the number of operations completed. The ratio is calculated by comparing the number of items processed during the last interval to the number of operations completed during the last interval.

Formula: \((N1 - N0) / (D1 - D0)\), where the numerator \(N\) represents the number of items processed during the last sample interval, and the denominator \(D\) represents the number of operations completed during the last two sample intervals. Average: \((Nx - N0) / (Dx - D0)\) Type: Average

**counter_aggregating**

counter_aggregating applies a function to an embedded counter instance. The embedded counter is usually evaluated repeatedly after a fixed (but configurable) time interval.

Formula: \(F(Nx)\)

**counter_average_timer**

counter_average_timer measures the average time it takes to complete a process or operation. Counters of this type display a ratio of the total elapsed time of the sample interval to the number of processes or operations completed during that time. This counter type measures time in ticks of the system clock. The variable \(F\) represents the number of ticks per second. The value of \(F\) is factored into the equation so that the result is displayed in seconds.

Formula: \[((N1 - N0) / F) / (D1 - D0)\], where the numerator \(N\) represents the number of ticks counted during the last sample interval, the variable \(F\) represents the frequency of the ticks, and the denominator \(D\) represents the number of operations completed during the last sample interval. Average: \[((Nx - N0) / F) / (Dx - D0)\) Type: Average

**counter_elapsed_time**

counter_elapsed_time shows the total time between when the component or process started and the time when this value is calculated. The variable \(F\) represents the number of time units that elapse in one second. The value of \(F\) is factored into the equation so that the result is displayed in seconds.

Formula: \((D0 - N0) / F\), where the nominator \(D\) represents the current time, the numerator \(N\) represents the time the object was started, and the variable \(F\) represents the number of time units that elapse in one second. Average: \((Dx - N0) / F\) Type: Difference

**counter_histogram**

counter_histogram exposes a histogram of the measured values instead of a single value as many of the other counter types. Counters of this type expose a counter_value_array instead of a counter_value. Those will also not implement the get_counter_value() functionality. The results are exposed through a separate get_counter_values_array() function.

The first three values in the returned array represent the lower and upper boundaries, and the size of the histogram buckets. All remaining values in the returned array represent the number of measurements for each of the buckets in the histogram.

**counter_raw_values**

counter_raw_values exposes an array of measured values instead of a single value as many of the other counter types. Counters of this type expose a counter_value_array instead of a counter_value. Those will also not implement the get_counter_value() functionality. The results are exposed through a separate get_counter_values_array() function.

**enum counter_status**

Values:
status_valid_data
   No error occurred, data is valid.

status_new_data
   Data is valid and different from last call.

status_invalid_data
   Some error occurred, data is not value.

status_already_defined
   The type or instance already has been defined.

status_counter_unknown
   The counter instance is unknown.

status_counter_type_unknown
   The counter type is unknown.

status_generic_error
   A unknown error occurred.

status_valid_data
   No error occurred, data is valid.

status_new_data
   Data is valid and different from last call.

status_invalid_data
   Some error occurred, data is not value.

status_already_defined
   The type or instance already has been defined.

status_counter_unknown
   The counter instance is unknown.

status_counter_type_unknown
   The counter type is unknown.

status_generic_error
   A unknown error occurred.

enum discover_counters_mode
   Values:

   discover_counters_minimal

discover_counters_full

Functions

counter_status get_counter_type_name (counter_type_path_elements const &path,
   std::string &result, error_code &ec = throws)
   Create a full name of a counter type from the contents of the given counter_type_path_elements
   instance. The generated counter type name will not contain any parameters.

counter_status get_full_counter_type_name (counter_type_path_elements const &path,
   std::string &result, error_code &ec = throws)
   Create a full name of a counter type from the contents of the given counter_type_path_elements
   instance. The generated counter type name will contain all parameters.
counter_status get_counter_name(counter_path_elements const &path, std::string &result, error_code &ec = throws)
Create a full name of a counter from the contents of the given counter_path_elements instance.

counter_status get_counter_instance_name(counter_path_elements const &path, std::string &result, error_code &ec = throws)
Create a name of a counter instance from the contents of the given counter_path_elements instance.

counter_status get_counter_type_path_elements(std::string const &name, counter_type_path_elements &path, error_code &ec = throws)
Fill the given counter_type_path_elements instance from the given full name of a counter type.

counter_status get_counter_path_elements(std::string const &name, counter_path_elements &path, error_code &ec = throws)
Fill the given counter_path_elements instance from the given full name of a counter.

counter_status get_counter_name(std::string const &name, std::string &countername, error_code &ec = throws)
Return the canonical counter instance name from a given full instance name.

counter_status get_counter_type_name(std::string const &name, std::string &type_name, error_code &ec = throws)
Return the canonical counter type name from a given (full) instance name.

counter_status complement_counter_info(counter_info &info, counter_info const &type_info, error_code &ec = throws)
Complement the counter info if parent instance name is missing.

counter_status complement_counter_info(counter_info &info, error_code &ec = throws)

counter_status add_counter_type(counter_info const &info, create_counter_func const &create_counter, discover_counters_func const &discover_counters, error_code &ec = throws)
Call the supplied function for each registered counter type.

counter_status discover_counter_types(discover_counter_func const &discover_counter, discover_counters_mode mode = discover_counters_minimal, error_code &ec = throws)
Call the supplied function for each registered counter type.

counter_status discover_counter_types(std::vector<counter_info> &counters, discover_counters_mode mode = discover_counters_minimal, error_code &ec = throws)
Return a list of all available counter descriptions.

counter_status discover_counter_type(std::string const &name, discover_counter_func const &discover_counter, discover_counters_mode mode = discover_counters_minimal, error_code &ec = throws)
Call the supplied function for the given registered counter type.

counter_status discover_counter_type(counter_info const &info, discover_counter_func const &discover_counter, discover_counters_mode mode = discover_counters_minimal, error_code &ec = throws)
counter_status discover_counter_type (std::string const &name, 
    std::vector<counter_info> &counters, 
    discover_counters_mode mode = discover_counters_minimal, 
    error_code &ec = throws)

Return a list of matching counter descriptions for the given registered counter type.

counter_status discover_counter_type (counter_info const &info, 
    std::vector<counter_info> &counters, 
    discover_counters_mode mode = discover_counters_minimal, 
    error_code &ec = throws)

bool expand_counter_info (counter_info const&, 
    discover_counter_func const&, 
    error_code&)

call the supplied function will all expanded versions of the supplied counter info.

This function expands all locality#* and worker-thread#* wild cards only.

counter_status remove_counter_type (counter_info const &info, 
    error_code &ec = throws)

Remove an existing counter type from the (local) registry.

Note This doesn’t remove existing counters of this type, it just inhibits defining new counters using this type.

counter_status get_counter_type (std::string const &name, 
    counter_info &info, 
    error_code &ec = throws)

Retrieve the counter type for the given counter name from the (local) registry.

lcos::future<naming::id_type> get_counter_async (std::string name, 
    error_code &ec = throws)

Get the global id of an existing performance counter, if the counter does not exist yet, the function attempts to create the counter based on the given counter name.

lcos::future<naming::id_type> get_counter_async (counter_info const &info, 
    error_code &ec = throws)

Get the global id of an existing performance counter, if the counter does not exist yet, the function attempts to create the counter based on the given counter info.

void get_counter_infos (counter_info const &info, 
    counter_type &type, 
    std::string &help_text, 
    std::uint32_t &version, 
    error_code &ec = throws)

Retrieve the meta data specific for the given counter instance.

void get_counter_infos (std::string name, 
    counter_type &type, 
    std::string &help_text, 
    std::uint32_t &version, 
    error_code &ec = throws)

Retrieve the meta data specific for the given counter instance.

struct counter_value
Public Functions

`counter_value` \( (\text{std}::\text{int64}_t \text{ value} = 0, \text{std}::\text{int64}_t \text{ scaling} = 1, \text{bool} \text{ scale_inverse} = \text{false}) \)

template<typename T>
\( T \text{ get_value} (\text{error_code} & \text{ec} = \text{throws}) \) const

Retrieve the ‘real’ value of the `counter_value`, converted to the requested type \( T \).

Public Members

\( \text{std}::\text{uint64}_t \text{ time}_\)

The local time when data was collected.

\( \text{std}::\text{uint64}_t \text{ count}_\)

The invocation counter for the data.

\( \text{std}::\text{int64}_t \text{ value}_\)

The current counter value.

\( \text{std}::\text{int64}_t \text{ scaling}_\)

The scaling of the current counter value.

`counter_status` \( \text{status}_\)

The status of the counter value.

\text{bool} \text{ scale_inverse}_\)

If true, value needs to be divided by scaling, otherwise it has to be multiplied.

```
frend hpx::performance_counters::hpx::serialization::access
namespace hpx

namespace agas

Functions

void locality_namespace_register_counter_types (error_code & ec = throws)
```

**Functions**

```
void install_counter (naming::id_type const & id, counter_info const & info, error_code & ec = throws)
    Install a new performance counter in a way, which will uninstall it automatically during shutdown.
```
### Functions

```cpp
counter_status install_counter_type (std::string const &name,
                                  hpx::util::function_nonser <std::int64_t> bool
                                 >&counter_value,
                                  std::string const &helptext = "",
                                  std::string const &uom = "",
                                  counter_type type = counter_raw,
                                  error_code &ec = throws)
```

Install a new generic performance counter type in a way, which will uninstall it automatically during shutdown.

The function `install_counter_type` will register a new generic counter type based on the provided function. The counter type will be automatically unregistered during system shutdown. Any consumer querying any instance of this counter type will cause the provided function to be called and the returned value to be exposed as the counter value.

The counter type is registered such that there can be one counter instance per locality. The expected naming scheme for the counter instances is: `'/objectname{locality#<*>/total}/countername'` where `<*>` is a zero based integer identifying the locality the counter is created on.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Return** If successful, this function returns `status_valid_data`, otherwise it will either throw an exception or return an error_code from the enum `counter_status` (also, see note related to parameter `ec`).

**Note** The counter type registry is a locality based service. You will have to register each counter type on every locality where a corresponding performance counter will be created.

**Parameters**
- `name`: [in] The global virtual name of the counter type. This name is expected to have the format `objectname/countername`.
- `counter_value`: [in] The function to call whenever the counter value is requested by a consumer.
- `helptext`: [in, optional] A longer descriptive text shown to the user to explain the nature of the counters created from this type.
- `uom`: [in] The unit of measure for the new performance counter type.
- `type`: [in] Type for the new performance counter type.
- `ec`: [in,out] This represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
counter_status install_counter_type (std::string const &name,
                                  hpx::util::function_nonser <std::vector<std::int64_t>> bool
                                 >&counter_value,
                                  std::string const &helptext = "",
                                  std::string const &uom = "",
                                  error_code &ec = throws)
```

Install a new generic performance counter type returning an array of values in a way, that will uninstall it automatically during shutdown.

The function `install_counter_type` will register a new generic counter type that returns an array of values based on the provided function. The counter type will be automatically unregistered during system shutdown. Any consumer querying any instance of this counter type will cause the provided function to be called and the returned array value to be exposed as the counter value.

The counter type is registered such that there can be one counter instance per locality. The expected naming scheme for the counter instances is: `'/objectname{locality#<*>/total}/countername'` where `<*>` is a zero based integer identifying the locality the counter is created on.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.
Return If successful, this function returns \textit{status_valid_data}, otherwise it will either throw an exception or return an \textit{error_code} from the enum \textit{counter_status} (also, see note related to parameter \textit{ec}).

Note The counter type registry is a locality based service. You will have to register each counter type on every locality where a corresponding performance counter will be created.

Parameters

- \textbf{name}: [in] The global virtual name of the counter type. This name is expected to have the format /\texttt{objectname}/countername.
- \textbf{counter_value}: [in] The function to call whenever the counter value (array of values) is requested by a consumer.
- \textbf{helptext}: [in, optional] A longer descriptive text shown to the user to explain the nature of the counters created from this type.
- \textbf{uom}: [in] The unit of measure for the new performance counter type.
- \textbf{ec}: [in,out] this represents the error status on exit, if this is pre-initialized to \textit{hpx::throws} the function will throw on error instead.

\begin{verbatim}
void \textbf{install_counter_type}(std::string const &name, counter_type type, error_code &ec = throws)
\end{verbatim}

Install a new performance counter type in a way, which will uninstall it automatically during shutdown.

The function \textbf{install_counter_type} will register a new counter type based on the provided \textit{counter_type_info}. The counter type will be automatically unregistered during system shutdown.

Return If successful, this function returns \textit{status_valid_data}, otherwise it will either throw an exception or return an \textit{error_code} from the enum \textit{counter_status} (also, see note related to parameter \textit{ec}).

Note The counter type registry is a locality based service. You will have to register each counter type on every locality where a corresponding performance counter will be created.

Note As long as \textit{ec} is not pre-initialized to \textit{hpx::throws} this function doesn’t throw but returns the result code using the parameter \textit{ec}. Otherwise it throws an instance of \textit{hpx::exception}.

Parameters

- \textbf{name}: [in] The global virtual name of the counter type. This name is expected to have the format /\texttt{objectname}/countername.
- \textbf{type}: [in] The type of the counters of this \textit{counter_type}.
- \textbf{ec}: [in,out] this represents the error status on exit, if this is pre-initialized to \textit{hpx::throws} the function will throw on error instead.

\begin{verbatim}
counter_status \textbf{install_counter_type}(std::string const &name, counter_type const &type, std::string const &helptext, std::string const &uom = "", std::uint32_t version = HPX_PERFORMANCE_COUNTER_V1, error_code &ec = throws)
\end{verbatim}

Install a new performance counter type in a way, which will uninstall it automatically during shutdown.

The function \textbf{install_counter_type} will register a new counter type based on the provided \textit{counter_type_info}. The counter type will be automatically unregistered during system shutdown.

Return If successful, this function returns \textit{status_valid_data}, otherwise it will either throw an exception or return an \textit{error_code} from the enum \textit{counter_status} (also, see note related to parameter \textit{ec}).

Note The counter type registry is a locality based service. You will have to register each counter type on every locality where a corresponding performance counter will be created.
As long as \textit{ec} is not pre-initialized to \texttt{hpx::throws} this function doesn’t throw but returns the result code using the parameter \textit{ec}. Otherwise it throws an instance of hpx::exception.

**Parameters**

- **name**: [in] The global virtual name of the counter type. This name is expected to have the format /objectname/countername.
- **type**: [in] The type of the counters of this \texttt{counter_type}.
- **helptext**: [in] A longer descriptive text shown to the user to explain the nature of the counters created from this type.
- **uom**: [in] The unit of measure for the new performance counter type.
- **version**: [in] The version of the counter type. This is currently expected to be set to \texttt{HPX_PERFORMANCE COUNTER V1}.
- **ec**: [in, out] this represents the error status on exit, if this is pre-initialized to \texttt{hpx::throws} the function will throw on error instead.

\begin{verbatim}
namespace hpx
namespace performance_counters

counter_status install_counter_type (std::string const &name, counter_type type,
                                        std::string const &helptext, create_counter_func
                                        const &create_counter, discover_counters_func
                                        const &discover_counters, std::uint32_t version =
                                        HPX_PERFORMANCE COUNTER V1, std::string
                                        const &uom = "", error_code &ec = throws)

Install a new generic performance counter type in a way, which will uninstall it automatically during shutdown.

The function \texttt{install_counter_type} will register a new generic counter type based on the provided \texttt{counter_type_info}. The counter type will be automatically unregistered during system shutdown.

As long as \textit{ec} is not pre-initialized to \texttt{hpx::throws} this function doesn’t throw but returns the result code using the parameter \textit{ec}. Otherwise it throws an instance of hpx::exception.

**Return** If successful, this function returns \texttt{status_valid_data}, otherwise it will either throw an exception or return an error_code from the enum \texttt{counter_status} (also, see note related to parameter \textit{ec}).

The counter type registry is a locality based service. You will have to register each counter type on every locality where a corresponding performance counter will be created.

**Parameters**

- **name**: [in] The global virtual name of the counter type. This name is expected to have the format /objectname/countername.
- **type**: [in] The type of the counters of this \texttt{counter_type}.
- **helptext**: [in] A longer descriptive text shown to the user to explain the nature of the counters created from this type.
- **version**: [in] The version of the counter type. This is currently expected to be set to \texttt{HPX_PERFORMANCE COUNTER V1}.
- **create_counter**: [in] The function which will be called to create a new instance of this counter type.
- **discover_counters**: [in] The function will be called to discover counter instances which can be created.
- **uom**: [in] The unit of measure of the counter type (default: "")
- **ec**: [in, out] this represents the error status on exit, if this is pre-initialized to \texttt{hpx::throws} the function will throw on error instead.

\end{verbatim}

class performance_counter_set

Public Functions

performance_counter_set (bool print_counters_locally = false)
Create an empty set of performance counters.

performance_counter_set (std::string const &names, bool reset = false)
Create a set of performance counters from a name, possibly containing wild-card characters

performance_counter_set (std::vector<std::string> const &names, bool reset = false)

void add_counters (std::string const &names, bool reset = false, error_code &ec = throws)
Add more performance counters to the set based on the given name, possibly containing wild-card characters

void add_counters (std::vector<std::string> const &names, bool reset = false, error_code &ec = throws)

std::vector<counter_info> get_counter_infos () const
Retrieve the counter infos for all counters in this set.

std::vector<hpx::future<counter_value>> get_counter_values (bool reset = false) const
Retrieve the values for all counters in this set supporting this operation

std::vector<counter_value> get_counter_values (launch::sync_policy, bool reset = false, error_code &ec = throws) const

std::vector<hpx::future<counter_values_array>> get_counter_values_array (bool reset = false) const
Retrieve the array-values for all counters in this set supporting this operation

std::vector<counter_values_array> get_counter_values_array (launch::sync_policy, bool reset = false, error_code &ec = throws) const

std::vector<hpx::future<void>> reset ()
Reset all counters in this set.

void reset (launch::sync_policy, error_code &ec = throws)

std::vector<hpx::future<bool>> start ()
Start all counters in this set.

bool start (launch::sync_policy, error_code &ec = throws)

std::vector<hpx::future<bool>> stop ()
Stop all counters in this set.
bool stop (launch::sync_policy, error_code &ec = throws)

std::vector<hpx::future<void>> reinit (bool reset = true)
   Re-initialize all counters in this set.

void reinit (launch::sync_policy, bool reset = true, error_code &ec = throws)

void release ()
   Release all references to counters in the set.

std::size_t size() const
   Return the number of counters in this set.

class registry

Public Functions

registry()

void clear()

Reset registry by deleting all stored counter types.

counter_status add_counter_type (counter_info const &info, create_counter_func const &create_counter, discover_counters_func const &discover_counters, error_code &ec = throws)

Add a new performance counter type to the (local) registry.

counter_status discover_counter_types (discover_counter_func discover_counter, discover_counters_mode mode, error_code &ec = throws)

Call the supplied function for all registered counter types.

counter_status discover_counter_type (std::string const &fullname, discover_counter_func discover_counter, discover_counters_mode mode, error_code &ec = throws)

Call the supplied function for the given registered counter type.

counter_status discover_counter_type (counter_info const &info, discover_counter_func const &f, discover_counters_mode mode, error_code &ec = throws)

counter_status get_counter_create_function (counter_info const &info, create_counter_func &create_counter, error_code &ec = throws) const

Retrieve the counter creation function which is associated with a given counter type.

counter_status get_counter_discovery_function (counter_info const &info, discover_counters_func &func, error_code &ec) const

Retrieve the counter discovery function which is associated with a given counter type.

counter_status remove_counter_type (counter_info const &info, error_code &ec = throws)

Remove an existing counter type from the (local) registry.

Note This doesn’t remove existing counters of this type, it just inhibits defining new counters using this type.

counter_status create_raw_counter_value (counter_info const &info, std::int64_t *countervalue, naming::gid_type &id, error_code &ec = throws)

Create a new performance counter instance of type raw_counter based on given counter value.
counter_status create_raw_counter (counter_info const &info, hpx::util::function_nonser<std::int64_t> &f, naming::gid_type &id, error_code &ec = throws)
Create a new performance counter instance of type raw_counter based on given function returning the counter value.

counter_status create_raw_counter (counter_info const &info, hpx::util::function_nonser<std::int64_t> bool &f, naming::gid_type &id, error_code &ec = throws)
Create a new performance counter instance of type raw_counter based on given function returning the counter value.

counter_status create_raw_counter (counter_info const &info, hpx::util::function_nonser<std::vector<std::int64_t>> bool &f, naming::gid_type &id, error_code &ec = throws)
Create a new performance counter instance of type raw_counter based on given function returning the counter value.

counter_status create_counter (counter_info const &info, naming::gid_type &id, error_code &ec = throws)
Create a new performance counter instance based on given counter info.

counter_status create_statistics_counter (counter_info const &info, std::string const &base_counter_name, std::vector<std::size_t> const &parameters, naming::gid_type &id, error_code &ec = throws)
Create a new statistics performance counter instance based on given base counter name and given base time interval (milliseconds).

counter_status create_arithmetics_counter (counter_info const &info, std::vector<std::string> const &base_counter_names, naming::gid_type &id, error_code &ec = throws)
Create a new arithmetics performance counter instance based on given base counter names.

counter_status create_arithmetics_counter_extended (counter_info const &info, std::vector<std::string> const &base_counter_names, naming::gid_type &id, error_code &ec = throws)
Create a new extended arithmetics performance counter instance based on given base counter names.

counter_status add_counter (naming::id_type const &id, counter_info const &info, error_code &ec = throws)
Add an existing performance counter instance to the registry.

counter_status remove_counter (counter_info const &info, naming::id_type const &id, error_code &ec = throws)
remove the existing performance counter from the registry.

counter_status get_counter_type (std::string const &name, counter_info &info, error_code &ec = throws)
Retrieve counter type information for given counter name.

HPX_DEFINE_PLAIN_ACTION(symbol_namespace_statistics_counter, symbol_namespace_statistics_counter_action)
The contents of this module can be included with the header `hpx/modules/program_options.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/program_options.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

```cpp
namespace hpx

namespace program_options

namespace command_line_style

Enums

enum style_t

Various possible styles of options.

There are “long” options, which start with “–” and “short”, which start with either “-” or “/”. Both kinds can be allowed or disallowed, see allow_long and allow_short. The allowed character for short options is also configurable.

Option’s value can be specified in the same token as name (“–foo=bar”), or in the next token.

It’s possible to introduce long options by the same character as short options, see allow_long_disguise.

Finally, guessing (specifying only prefix of option) and case insensitive processing are supported.

Values:

allow_long = 1
  Allow “–long_name” style.

allow_short = allow_long << 1
  Allow “-<single character” style.

allow_dash_for_short = allow_short << 1
  Allow “-” in short options.

allow_slash_for_short = allow_dash_for_short << 1
  Allow “/” in short options.

long_allow_adjacent = allow_slash_for_short << 1
  Allow option parameter in the same token for long option, like in `--foo=10`

long_allow_next = long_allow_adjacent << 1
  Allow option parameter in the next token for long options.

short_allow_adjacent = long_allow_next << 1
  Allow option parameter in the same token for short options.

short_allow_next = short_allow_adjacent << 1
  Allow option parameter in the next token for short options.
allow_sticky = short_allow_next << 1
Allow to merge several short options together, so that “-s -k” become “-sk”. All of the options but last should accept no parameter. For example, if “-s” accept a parameter, then “k” will be taken as parameter, not another short option. Dos-style short options cannot be sticky.

allow_guessing = allow_sticky << 1
Allow abbreviated spellings for long options, if they unambiguously identify long option. No long option name should be prefix of other long option name if guessing is in effect.

long_case_insensitive = allow_guessing << 1
Ignore the difference in case for long options.

short_case_insensitive = long_case_insensitive << 1
Ignore the difference in case for short options.

case_insensitive = (long_case_insensitive | short_case_insensitive)
Ignore the difference in case for all options.

allow_long_disguise = short_case_insensitive << 1
Allow long options with single option starting character, e.g. -foo=10

unix_style = (allow_short | short_allow_adjacent | short_allow_next | allow_long | long_allow_adjacent | long_allow_next | allow_sticky | allow_guessing | allow_dash_for_short)
The more-or-less traditional unix style.

default_style = unix_style
The default style.

namespace hpx

namespace program_options

template<class Derived, class ValueType>
class eof_iterator : public util::iterator_facade<Derived, ValueType const, std::forward_iterator_tag>
#include <eof_iterator.hpp> The 'eof_iterator' class is useful for constructing forward iterators in
cases where iterator extract data from some source and it's easy to detect 'eof' – i.e. the situation
where there's no data. One apparent example is reading lines from a file.

Implementing such iterators using 'iterator_facade' directly would require to create class with three
core operation, a couple of constructors. When using 'eof_iterator', the derived class should define
only one method to get new value, plus a couple of constructors.

The basic idea is that iterator has 'eof' bit. Two iterators are equal only if both have their 'eof' bits
set. The 'get' method either obtains the new value or sets the 'eof' bit.

Specifically, derived class should define:

1. A default constructor, which creates iterator with 'eof' bit set. The constructor body should call
   'found_eof' method defined here.
2. Some other constructor. It should initialize some 'data pointer' used in iterator operation and then
call 'get'.
3. The 'get' method. It should operate this way:
   • look at some 'data pointer' to see if new element is available; if not, it should call 'found_eof'.
   • extract new element and store it at location returned by the 'value' method.
   • advance the data pointer.

Essentially, the 'get' method has the functionality of both 'increment' and 'dereference'. It's very
good for the cases where data extraction implicitly moves data pointer, like for stream operation.

Public Functions

eof_iterator ()

Protected Functions

ValueType &value ()
   Returns the reference which should be used by derived class to store the next value.

void found_eof ()
   Should be called by derived class to indicate that it can't produce next element.
Private Functions

void increment()
bool equal(const eof_iterator &other) const
const ValueType &dereference() const

```

class error : public logic_error

```
#include <errors.hpp>
```

Base class for all errors in the library.

Subclassed by `hpx::program_options::duplicate_option_error`, `hpx::program_options::error_with_option_name`, `hpx::program_options::invalid_command_line_style`, `hpx::program_options::reading_file`, `hpx::program_options::too_many_positional_options_error`

Public Functions

```
error (const std::string &xwhat)
```

class error_with_no_option_name : public hpx::program_options::error_with_option_name

```
#include <errors.hpp>
```

Base class of un-parsable options, when the desired option cannot be identified.

It makes no sense to have an option name, when we can’t match an option to the parameter

Having this a part of the `error_with_option_name` hierarchy makes error handling a lot easier, even if the name indicates some sort of conceptual dissonance!

Subclassed by `hpx::program_options::ambiguous_option`, `hpx::program_options::unknown_option`

Public Functions

```
error_with_no_option_name (const std::string &template_, const std::string &original_token = "")
```

void set_option_name (const std::string &)

Does NOT set option name, because no option name makes sense

~error_with_no_option_name ()

class error_with_option_name : public hpx::program_options::error

```
#include <errors.hpp>
```

Base class for most exceptions in the library.

Substitutes the values for the parameter name placeholders in the template to create the human readable error message

Placeholders are surrounded by % signs: example% Poor man’s version of boost::format

If a parameter name is absent, perform default substitutions instead so ugly placeholders are never left in-place.

Options are displayed in “canonical” form This is the most unambiguous form of the parsed option name and would correspond to `option_description::format_name()` i.e. what is shown by `print_usage()`

The “canonical” form depends on whether the option is specified in short or long form, using dashes or slashes or without a prefix (from a configuration file)

Subclassed by `hpx::program_options::invalid_syntax`, `hpx::program_options::multiple_occurrences`, `hpx::program_options::multiple_values`, `hpx::program_options::required_option`, `hpx::program_options::validation_error`

namespace hpx

namespace program_options

Typedefs

using option = basic_option<char>
using woption = basic_option<wchar_t>

template<class Char>
class basic_option
#include <option.hpp> Option found in input source. Contains a key and a value. The key, in turn, can be a string (name of an option), or an integer (position in input source) – in case no name is specified. The latter is only possible for command line. The template parameter specifies the type of char used for storing the option’s value.

Public Functions

basic_option()

basic_option(const std::string &xstring_key, const std::vector<std::string> &xvalue)

Public Members

std::string string_key
String key of this option. Intentionally independent of the template parameter.

int position_key
Position key of this option. All options without an explicit name are sequentially numbered starting from 0. If an option has explicit name, ‘position_key’ is equal to -1. It is possible that both position_key and string_key is specified, in case name is implicitly added.

std::vector<std::basic_string<Char>> value
Option’s value

std::vector<std::basic_string<Char>> original_tokens
The original unchanged tokens this option was created from.

bool unregistered
True if option was not recognized. In that case, ‘string_key’ and ‘value’ are results of purely syntactic parsing of source. The original tokens can be recovered from the “original_tokens” member.

bool case_insensitive
True if string_key has to be handled case insensitive.

namespace hpx

namespace program_options
class duplicate_option_error: public hpx::program_options::error
#include <options_description.hpp> Class thrown when duplicate option description is found.

Public Functions

duplicate_option_error(const std::string &xwhat)

class option_description
#include <options_description.hpp> Describes one possible command line/config file option. There
are two kinds of properties of an option. First describe it syntactically and are used only to validate
input. Second affect interpretation of the option, for example default value for it or function that
should be called when the value is finally known. Routines which perform parsing never use second
kind of properties – they are side effect free.
See options_description

Public Types

enum match_result
Values:
  no_match
  full_match
  approximate_match

Public Functions

option_description()

option_description(const char *name, const value_semantic *s)
    Initializes the object with the passed data.

    Note: it would be nice to make the second parameter auto_ptr, to explicitly pass owner-
ship. Unfortunately, it’s often needed to create objects of types derived from ‘value_semantic’:
options_description d; d.add_options()("a", parameter<int>("n")->default_value(1)); Here, the
static type returned by ‘parameter’ should be derived from value_semantic.

    Alas, derived->base conversion for auto_ptr does not really work, see http://www.open-std.org/
defects.html#84

    So, we have to use plain old pointers. Besides, users are not expected to use the constructor
directly.

    The ‘name’ parameter is interpreted by the following rules:
    • if there’s no ‘,” character in ‘name’, it specifies long name
    • otherwise, the part before ‘,” specifies long name and the part after – short name.

option_description(const char *name, const value_semantic *s, const char *de-
    scription)
    Initializes the class with the passed data.

virtual ~option_description()
match_result match (const std::string &option, bool approx, bool long_ignore_case, bool short_ignore_case) const

Given ‘option’, specified in the input source, returns ‘true’ if ‘option’ specifies ‘this.

const std::string &key (const std::string &option) const

Returns the key that should identify the option, in particular in the variables_map class. The ‘option’ parameter is the option spelling from the input source. If option name contains ‘*’, returns ‘option’. If long name was specified, it’s the long name, otherwise it’s a short name with pre-pended ‘-‘.

std::string canonical_display_name (int canonical_option_style = 0) const

Returns the canonical name for the option description to enable the user to recognized a matching option. 1) For short options (‘-‘, ‘!’), returns the short name prefixed. 2) For long options (‘‘ / ‘-‘) returns the first long name prefixed 3) All other cases, returns the first long name (if present) or the short name, un-prefixed.

const std::string &long_name () const

const std::pair<const std::string*, std::size_t> long_names () const

const std::string &description () const

Explanation of this option.

std::shared_ptr<const value_semantic> semantic () const

Semantic of option’s value.

std::string format_name () const

Returns the option name, formatted suitably for usage message.

std::string format_parameter () const

Returns the parameter name and properties, formatted suitably for usage message.

Private Functions

option_description &set_names (const char *name)

Private Members

std::string m_short_name

a one-character “switch” name - with its prefix, so that this is either empty or has length 2 (e.g. “C”)

std::vector<std::string> m_long_names

one or more names by which this option may be specified on a command-line or in a config file, which are not a single-letter switch. The names here are without any prefix.

std::string m_description

std::shared_ptr<const value_semantic> m_value_semantic

class options_description

#include <options_description.hpp> A set of option descriptions. This provides convenient interface for adding new option (the add_options) method, and facilities to search for options by name.

See here for option adding interface discussion.

See option_description
Public Functions

```
options_description(unsigned line_length = m_default_line_length, unsigned min_description_length = m_default_line_length / 2)
Creates the instance.

options_description(const std::string &caption, unsigned line_length = m_default_line_length, unsigned min_description_length = m_default_line_length / 2)
Creates the instance. The ‘caption’ parameter gives the name of this ‘options_description’ instance. Primarily useful for output. The ‘description_length’ specifies the number of columns that should be reserved for the description text; if the option text encroaches into this, then the description will start on the next line.

void add(std::shared_ptr<option_description> desc)
Adds new variable description. Throws duplicate_variable_error if either short or long name matches that of already present one.

options_description &add(const options_description &desc)
Adds a group of option description. This has the same effect as adding all option_descriptions in ‘desc’ individually, except that output operator will show a separate group. Returns *this.

std::size_t get_option_column_width() const
Find the maximum width of the option column, including options in groups.

options_description_easy_init add_options()
Returns an object of implementation-defined type suitable for adding options to options_description. The returned object will have overloaded operator() with parameter type matching ‘option_description’ constructors. Calling the operator will create new option_description instance and add it.

const option_description &find(const std::string &name, bool approx, bool long_ignore_case = false, bool short_ignore_case = false) const

const option_description *find_nothrow(const std::string &name, bool approx, bool long_ignore_case = false, bool short_ignore_case = false) const

const std::vector<std::shared_ptr<option_description>> &options() const
Outputs ‘desc’ to the specified stream, calling ‘f’ to output each option_description element.
```

Public Static Attributes

```
const unsigned m_default_line_length
```

2.8. API reference
**Private Types**

namespace program_options
```
Typedefs

```cpp
using parsed_options = basic_parsed_options<char>
using wparsed_options = basic_parsed_options<wchar_t>
using ext_parser = std::function<std::pair<std::string, std::string>(const std::string&)> // Augments basic_parsed_options<wchar_t> with conversion from 'parsed_options'
using command_line_parser = basic_command_line_parser<char>
using wcommand_line_parser = basic_command_line_parser<wchar_t>
```

Enums

```cpp
enum collect_unrecognized_mode

Controls if the ‘collect_unregistered’ function should include positional options, or not.

Values:
- include_positional
- exclude_positional
```

Functions

```cpp
template<class Char>
basic_parsed_options<Char> parse_command_line(int argc, const Char *const argv[],
const options_description&, int style = 0, std::function<std::pair<std::string, std::string>(const std::string&)> ext = ext_parser()) // Creates instance of ‘command_line_parser’, passes parameters to it, and returns the result of calling the ‘run’ method.

template<class Char>
basic_parsed_options<Char> parse_config_file(std::basic_istream<Char>&, const options_description&, bool allow_unregistered = false) // Parses a config file.

template<class Char = char>
basic_parsed_options<Char> parse_config_file(const char *filename, const options_description&, bool allow_unregistered = false) // Parses a config file.

std::vector<basic_string<Char>> collect_unrecognized(const std::vector<basic_option<Char>> &options, enum collect_unrecognized_mode mode) // Collects the original tokens for all named options with ‘unregistered’ flag set. If ‘mode’ is ‘include_positional’ also collects all positional options. Returns the vector of original tokens for all collected options.
```
parsed_options parse_environment (const options_description&, const std::function<std::string>& name_mapper)

Parse environment.

For each environment variable, the `name_mapper` function is called to obtain the option name. If it returns empty string, the variable is ignored.

This is done since naming of environment variables is typically different from the naming of command line options.

parsed_options parse_environment (const options_description&, const std::string& prefix)

Parse environment.

Takes all environment variables which start with `prefix`. The option name is obtained from variable name by removing the prefix and converting the remaining string into lower case.

parsed_options parse_environment (const options_description&, const char *prefix)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts. This function exists to resolve ambiguity between the two above functions when second argument is of `char*` type. There’s implicit conversion to both std::function and string.

std::vector<std::string> split_unix(const std::string &cmdline, const std::string &separator = " 	", const std::string &quote = "'", const std::string &escape = "\\")

Splits a given string to a collection of single strings which can be passed to command_line_parser. The second parameter is used to specify a collection of possible separator chars used for splitting. The separator is defaulted to space " ". Splitting is done in a unix style way, with respect to quotes ‘’ and escape characters ‘’.

std::vector<std::wstring> hpx::program_options::split_unix(const std::wstring &cmdline, const std::wstring &separator = L" 	", const std::wstring &quote = L"'", const std::wstring &escape = L"\\")

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

template<class Char>

class basic_command_line_parser : private cmdline

#include <parsers.hpp> Command line parser.

The class allows one to specify all the information needed for parsing and to parse the command line. It is primarily needed to emulate named function parameters – a regular function with 5 parameters will be hard to use and creating overloads with a smaller number of parameters will be confusing.

For the most common case, the function parse_command_line is a better alternative.

There are two typedefs – command_line_parser and wcommand_line_parser, for charT == char and charT == wchar_t cases.

Public Functions

basic_command_line_parser (const std::vector<std::basic_string<char>> &args)

Creates a command line parser for the specified arguments list. The ‘args’ parameter should not include program name.

basic_command_line_parser (int argc, const Char *const argv[])

Creates a command line parser for the specified arguments list. The parameters should be the same as passed to ‘main’.
basic_command_line_parser &options(const options_description &desc)
    Sets options descriptions to use.

basic_command_line_parser &positional(const positional_options_description &desc)
    Sets positional options description to use.

basic_command_line_parser &style(int)
    Sets the command line style.

basic_command_line_parser &extra_parser(ext_parser)
    Sets the extra parsers.

basic_parsed_options<Char> run()
    Parses the options and returns the result of parsing. Throws on error.

basic_command_line_parser &allow_unregistered()
    Specifies that unregistered options are allowed and should be passed through. For each command
    like token that looks like an option but does not contain a recognized name, an instance of ba-
    sic_option<Char> will be added to result, with 'unrecognized' field set to 'true'. It's possible to
    collect all unrecognized options with the 'collect_unrecognized' function.

basic_command_line_parser &extra_style_parser(style_parser s)

Private Members

const options_description *m_desc

template<class Char>
class basic_parsed_options
    #include <parsers.hpp> Results of parsing an input source. The primary use of this class is passing
    information from parsers component to value storage component. This class does not makes much
    sense itself.

Public Functions

basic_parsed_options(const options_description *xdescription, int options_prefix = 0)

Public Members

std::vector<basic_option<Char>> options
    Options found in the source.

const options_description *description
    Options description that was used for parsing. Parsers should return pointer to the instance of
    option_description passed to them, and issues of lifetime are up to the caller. Can be NULL.

int m_options_prefix
    Mainly used for the diagnostic messages in exceptions. The canonical option prefix for the parser
    which generated these results, depending on the settings for basic_command_line_parser::style()
    or cmdline::style(). In order of precedence of command_line_style enums: allow_long al-
    low_long_disguise allow_dash_for_short allow_slash_for_short

template<>
class basic_parsed_options<
#include <parsers.hpp> Specialization of basic_parsed_options which:
• provides convenient conversion from basic_parsed_options<char>
• stores the passed char-based options for later use.

Public Functions

basic_parsed_options(const basic_parsed_options<char> &po)
Constructs wrapped options from options in UTF8 encoding.

Public Members

std::vector<basic_option<wchar_t>> options
const options_description *description

basic_parsed_options<char> utf8_encoded_options
Stores UTF8 encoded options that were passed to constructor, to avoid reverse conversion in some cases.

int m_options_prefix
Mainly used for the diagnostic messages in exceptions. The canonical option prefix for the parser which generated these results, depending on the settings for basic_command_line_parser::style() or cmdline::style(). In order of precedence of command_line_style enums: allow_long allow_long_disguise allow_dash_for_short allow_slash_for_short

namespace hpex

namespace program_options

class positional_options_description
#include <positional_options.hpp> Describes positional options.
The class allows to guess option names for positional options, which are specified on the command line and are identified by the position. The class uses the information provided by the user to associate a name with every positional option, or tell that no name is known.
The primary assumption is that only the relative order of the positional options themselves matters, and that any interleaving ordinary options don’t affect interpretation of positional options.
The user initializes the class by specifying that first N positional options should be given the name X1, following M options should be given the name X2 and so on.

Public Functions

positional_options_description() positional_options_description &add(const char *name, int max_count)
Species that up to ‘max_count’ next positional options should be given the ‘name’. The value of ‘-1’ means ‘unlimited’. No calls to ‘add’ can be made after call with ‘max_value’ equal to ‘-1’.

unsigned max_total_count() const
Returns the maximum number of positional options that can be present. Can return (numeric_limits<unsigned>::max)() to indicate unlimited number.
const std::string &name_for_position(unsigned position) const

Returns the name that should be associated with positional options at ‘position’. Precondition: position < max_total_count()

Private Members

std::vector<std::string> m_names
std::string m_trailing

namespace hpx

namespace program_options

Functions

template<class T>
typed_value<T> *value()

Creates a typed_value<T> instance. This function is the primary method to create value_semantic instance for a specific type, which can later be passed to 'option_description' constructor. The second overload is used when it’s additionally desired to store the value of option into program variable.

template<class T>
typed_value<T> *value(T *v)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

template<class T>
typed_value<T, wchar_t> *wvalue()

Creates a typed_value<T> instance. This function is the primary method to create value_semantic instance for a specific type, which can later be passed to 'option_description' constructor.

template<class T>
typed_value<T, wchar_t> *wvalue(T *v)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

typed_value<bool> *bool_switch()

Works the same way as the ‘value<bool>’ function, but the created value_semantic won’t accept any explicit value. So, if the option is present on the command line, the value will be ‘true’.

typed_value<bool> *bool_switch(bool *v)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

template<class T, class Char = char>
class typed_value: public hpx::program_options::value_semantic_codecvt_helper<Char>, public hpx::program_options::value_semantic_codecvt_helper<Char>, public hpx::program_options::value_semantic_codecvt_helper<Char>, public hpx::program_options::value_semantic_codecvt_helper<Char>,
#include <value_semantic.hpp> Class which handles value of a specific type.
Public Functions

typed_value(T *store_to)
Ctor. The ‘store_to’ parameter tells where to store the value when it’s known. The parameter can be NULL.

typed_value *default_value(const T &v)
Specifies default value, which will be used if none is explicitly specified. The type ‘T’ should provide operator<< for ostream.

typed_value *default_value(const T &v, const std::string &textual)
Specifies default value, which will be used if none is explicitly specified. Unlike the above overload, the type ‘T’ need not provide operator<< for ostream, but textual representation of default value must be provided by the user.

typed_value *implicit_value(const T &v)
Specifies an implicit value, which will be used if the option is given, but without an adjacent value. Using this implies that an explicit value is optional,

typed_value *value_name(const std::string &name)
Specifies the name used to to the value in help message.

typed_value *implicit_value(const T &v, const std::string &textual)
Specifies an implicit value, which will be used if the option is given, but without an adjacent value. Using this implies that an implicit value is optional, but if given, must be strictly adjacent to the option, i.e.: ‘-o=value’ or ‘option=value’. Giving ‘-o’ or ‘option’ will cause the implicit value to be applied. Unlike the above overload, the type ‘T’ need not provide operator<< for ostream, but textual representation of default value must be provided by the user.

typed_value *notifier (std::function<void(const T&)> f)
Specifies a function to be called when the final value is determined.

typed_value *composing()
Specifies that the value is composing. See the ‘is_composing’ method for explanation.

typed_value *multitoken()
Specifies that the value can span multiple tokens.

typed_value *zero_tokens()
Specifies that no tokens may be provided as the value of this option, which means that only presence of the option is significant. For such option to be useful, either the ‘validate’ function should be specialized, or the ‘implicit_value’ method should be also used. In most cases, you can use the ‘bool_switch’ function instead of using this method.

typed_value *required()
Specifies that the value must occur.

std::string name() const
Returns the name of the option. The name is only meaningful for automatic help message.

bool is_composing() const
Returns true if values from different sources should be composed. Otherwise, value from the first source is used and values from other sources are discarded.

unsigned min_tokens() const
The minimum number of tokens for this option that should be present on the command line.
unsigned \texttt{max\_tokens()} \textbf{const}  

The maximum number of tokens for this option that should be present on the command line.

bool \textbf{is\_required()} \textbf{const}  

Returns true if value must be given. Non-optional value

void \texttt{xparse(hpx::any\_nonser &value\_store, const std::vector<std::basic\_string<Char>> &new\_tokens) const}  

Creates an instance of the ‘validator’ class and calls its operator() to perform the actual conversion.

\texttt{virtual bool apply\_default(hpx::any\_nonser &value\_store) const}  

If default value was specified via previous call to ‘default\_value’, stores that value into ‘value\_store’. Returns true if default value was stored.

void \texttt{notify(const hpx::any\_nonser &value\_store) const}  

If an address of variable to store value was specified when creating *this, stores the value there. Otherwise, does nothing.

\texttt{const std::type\_info \&value\_type() const}  

**Private Members**

bool \texttt{m\_zero\_tokens}  

bool \texttt{m\_required}  

\texttt{std::function<void(const T&)> m\_notifier}  

class \texttt{typed\_value\_base}  

\#include \texttt{<value\_semantic.hpp>} Base class for all option that have a fixed type, and are willing to announce this type to the outside world. Any ‘value\_semantics’ for which you want to find out the type can be dynamic\_cast-ed to \texttt{typed\_value\_base}. If conversion succeeds, the ‘type’ method can be called.  

Subclassed by \texttt{hpx::program\_options::typed\_value< T, Char >}
Public Functions

```cpp
virtual const std::type_info & value_type() const = 0
virtual ~typed_value_base()
```

class untyped_value : public hpx::program_options::value_semantic_codecvt_helper<char>
#include <value_semantic.hpp> Class which specifies a simple handling of a value: the value will have string type and only one token is allowed.

Public Functions

```cpp
untyped_value (bool zero_tokens = false)

std::string name() const
    Returns the name of the option. The name is only meaningful for automatic help message.

unsigned min_tokens() const
    The minimum number of tokens for this option that should be present on the command line.

unsigned max_tokens() const
    The maximum number of tokens for this option that should be present on the command line.

bool is_composing() const
    Returns true if values from different sources should be composed. Otherwise, value from the first source is used and values from other sources are discarded.

bool is_required() const
    Returns true if value must be given. Non-optional value

void xparse (hpx::any_nonser &value_store, const std::vector<std::string> &new_tokens)
    If ‘value_store’ is already initialized, or new_tokens has more than one elements, throws. Otherwise, assigns the first string from ‘new_tokens’ to ‘value_store’, without any modifications.

bool apply_default (hpx::any_nonser&) const
    Does nothing.

void notify (const hpx::any_nonser&) const
    Does nothing.
```

Private Members

```cpp
bool m_zero_tokens
```

class value_semantic
#include <value_semantic.hpp> Class which specifies how the option’s value is to be parsed and converted into C++ types.

Subclassed by hpx::program_options::value_semantic_codecvt_helper<char>, hpx::program_options::value_semantic_codecvt_helper<wchar_t>
Public Functions

virtual std::string name() const = 0
    Returns the name of the option. The name is only meaningful for automatic help message.

virtual unsigned min_tokens() const = 0
    The minimum number of tokens for this option that should be present on the command line.

virtual unsigned max_tokens() const = 0
    The maximum number of tokens for this option that should be present on the command line.

virtual bool is_composing() const = 0
    Returns true if values from different sources should be composed. Otherwise, value from the first
    source is used and values from other sources are discarded.

virtual bool is_required() const = 0
    Returns true if value must be given. Non-optional value

virtual void parse(hpx::any_nonser &value_store, const std::vector<std::string>& new_tokens, bool utf8) const = 0
    Parses a group of tokens that specify a value of option. Stores the result in ‘value_store’, using
    whatever representation is desired. May be be called several times if value of the same option is
    specified more than once.

virtual bool apply_default(hpx::any_nonser &value_store) const = 0
    Called to assign default value to ‘value_store’. Returns true if default value is assigned, and false
    if no default value exists.

virtual void notify(const hpx::any_nonser &value_store) const = 0
    Called when final value of an option is determined.

virtual ~value_semantic() 

template<class Char>
class value_semantic_codecvt_helper
    #include <value_semantic.hpp> Helper class which perform necessary character conversions in the
    ‘parse’ method and forwards the data further.

template<>
class value_semantic_codecvt_helper<Char> : public hpx::program_options::value_semantic
    #include <value_semantic.hpp> Helper conversion class for values that accept ascii strings as in-
    put. Overrides the ‘parse’ method and defines new ‘xparse’ method taking std::string. Depending
    on whether input to parse is ascii or UTF8, will pass it to xparse unmodified, or with UTF8->ascii
    conversion.
    Subclassed by hpx::program_options::typed_value< T, Char >,
    hpx::program_options::untyped_value
Protected Functions

```cpp
virtual void xparse(hpx::any_nonser &value_store, const std::vector<std::string> &new_tokens) const = 0
```

Private Functions

```cpp
void parse(hpx::any_nonser &value_store, const std::vector<std::string> &new_tokens, bool utf8) const

Parses a group of tokens that specify a value of option. Stores the result in ‘value_store’, using whatever representation is desired. May be be called several times if value of the same option is specified more than once.
```

```cpp
template<>
class value_semantic_codecvt_helper<wchar_t> : public hpx::program_options::value_semantic
#include <value_semantic.hpp>

Helper conversion class for values that accept ascii strings as input. Overrides the ‘parse’ method and defines new ‘xparse’ method taking std::wstring. Depending on whether input to parse is ascii or UTF8, will recode input to Unicode, or pass it unmodified.
```

Protected Functions

```cpp
virtual void xparse(hpx::any_nonser &value_store, const std::vector<std::wstring> &new_tokens) const = 0
```

Private Functions

```cpp
void parse(hpx::any_nonser &value_store, const std::vector<std::string> &new_tokens, bool utf8) const

Parses a group of tokens that specify a value of option. Stores the result in ‘value_store’, using whatever representation is desired. May be be called several times if value of the same option is specified more than once.
```

```cpp
namespace hpx
```

```cpp
namespace program_options
```

Functions

```cpp
void store(const basic_parsed_options<char> &options, variables_map &m, bool utf8 = false)

Stores in ‘m’ all options that are defined in ‘options’. If ‘m’ already has a non-defaulted value of an option, that value is not changed, even if ‘options’ specify some value.
```

```cpp
void store(const basic_parsed_options<wchar_t> &options, variables_map &m)

Stores in ‘m’ all options that are defined in ‘options’. If ‘m’ already has a non-defaulted value of an option, that value is not changed, even if ‘options’ specify some value. This is wide character variant.
```

```cpp
void notify(variables_map &m)

Runs all ‘notify’ function for options in ‘m’.
```

884 Chapter 2. What’s so special about HPX?
class abstract_variables_map
#include <variables_map.hpp> Implements string->string mapping with convenient value casting
facilities.

Subclassed by hpx::program_options::variables_map

Public Functions

abstract_variables_map()
abstract_variables_map(const abstract_variables_map *next)
virtual ~abstract_variables_map()

const variable_value &operator[] (const std::string &name) const
Obtains the value of variable ‘name’, from *this and possibly from the chain of variable maps.

• if there’s no value in *this.
  – if there’s next variable map, returns value from it
  – otherwise, returns empty value
• if there’s defaulted value
  – if there’s next variable map, which has a non-defaulted value, return that
  – otherwise, return value from *this
• if there’s a non-defaulted value, returns it.

void next (abstract_variables_map *next)
Sets next variable map, which will be used to find variables not found in *this.

Private Functions

virtual const variable_value &get (const std::string &name) const = 0
Returns value of variable ‘name’ stored in *this, or empty value otherwise.

Private Members

const abstract_variables_map *m_next

class variable_value
#include <variables_map.hpp> Class holding value of option. Contains details about how the value
is set and allows to conveniently obtain the value.

Public Functions

variable_value()

variable_value(const hpx::any_nonser &xv, bool xdefaulted)

template<class T>
const T &as () const
If stored value if of type T, returns that value. Otherwise, throws boost::bad_any_cast exception.

template<class T>
\( T \& as() \)

This is an overloaded member function, provided for convenience. It differs from the above
function only in what argument(s) it accepts.

bool \textbf{empty()} \textbf{const}

Returns true if no value is stored.

bool \textbf{defaulted()} \textbf{const}

Returns true if the value was not explicitly given, but has default value.

\textit{hpx:}:\textit{any\_nonser} \&\textbf{value()} \textbf{const}

Returns the contained value.

\textit{hpx:}:\textit{any\_nonser} \&\textbf{value()}

Returns the contained value.

\textbf{Private Members}

\textit{hpx:}:\textit{any\_nonser} \textbf{v}

bool \textbf{m\_defaulted}

\textit{std::shared\_ptr<\textbf{const value\_semantic}> m\_value\_semantic}

\textbf{Friends}

\textbf{friend hpx:}:\textbf{program\_options::variables\_map}

\textbf{void store(const basic\_parsed\_options<char> &options, variables\_map &m, bool utf8)}

Stores in ‘m’ all options that are defined in ‘options’. If ‘m’ already has a non-defaulted value of
an option, that value is not changed, even if ‘options’ specify some value.

\textbf{class variables\_map: public hpx:}:\textbf{program\_options:}:\textbf{abstract\_variables\_map}. \textbf{public std::map<std::string, variable\_value}}

\#include <variables\_map.hpp> Concrete variables map which store variables in real map.

This class is derived from std::map<std::string, variable_value>, so you can use all map operators to
examine its content.

\textbf{Public Functions}

\textbf{variables\_map()}

\textbf{variables\_map(const abstract\_variables\_map *next)}

\textbf{const variable\_value &operator[](const std::string &name) const}

\textbf{void clear()}

\textbf{void notify()}

886 Chapter 2. What’s so special about \textit{HPX}?
Private Functions

```cpp
const variable_value & get (const std::string & name) const
```
Implementation of abstract_variables_map::get which does ‘find’ in *this.

Private Members

```cpp
std::set<std::string> m_final
```
Names of option with ‘final’ values – which should not be changed by subsequence assignments.

```cpp
std::map<std::string, std::string> m_required
```
Names of required options, filled by parser which has access to options_description. The map values are the “canonical” names for each corresponding option. This is useful in creating diagnostic messages when the option is absent.

Friends

```cpp
void store (const basic_parsed_options<char> & options, variables_map & xm, bool utf8)
```
Stores in ‘m’ all options that are defined in ‘options’. If ‘m’ already has a non-defaulted value of an option, that value is not changed, even if ‘options’ specify some value.

Defines

```cpp
HPX_PROGRAM_OPTIONS_VERSION
```
The version of the source interface. The value will be incremented whenever a change is made which might cause compilation errors for existing code.

```cpp
HPX_PROGRAM_OPTIONS_IMPLICIT_VALUE_NEXT_TOKEN
```

  hpx::threads::thread_pool_init_parameters,
  hpx::threads::policies::thread_queue_init_parameters>
```

Enums

```cpp
enum partitioner_mode
```
This enumeration describes the modes available when creating a resource partitioner.

Values:

- `mode_default = 0`
  Default mode.

- `mode_allow_oversubscription = 1`
  Allow processing units to be oversubscribed, i.e. multiple worker threads to share a single processing unit.

- `mode_allow_dynamic_pools = 2`
  Allow worker threads to be added and removed from thread pools.

```cpp
enum scheduling_policy
```
This enumeration lists the available scheduling policies (or schedulers) when creating thread pools.

Values:

- `user_defined = -2`
- `unspecified = -1`
- `local = 0`
- `local_priority_fifo = 1`
- `local_priority_lifo = 2`
- `static_ = 3`
- `static_priority = 4`
- `abp_priority_fifo = 5`
- `abp_priority_lifo = 6`
- `shared_priority = 7`

Functions

```cpp
detail::partitioner &get_partitioner()```
May be used anywhere in code and returns a reference to the single, global resource partitioner.

```cpp
bool is_partitioner_valid()```
Returns true if the resource partitioner has been initialized. Returns false otherwise.

namespace hpx

namespace components

Variables

const default_distribution_policy default_layout = {};

A predefined instance of the default distribution_policy. It will represent the local locality and will place all items to create here.

struct default_distribution_policy

#include <default_distribution_policy.hpp>

This class specifies the parameters for a simple distribution policy to use for creating (and evenly distributing) a given number of items on a given set of localities.

Public Functions

constexpr default_distribution_policy ()

Default-construct a new instance of a default_distribution_policy. This policy will represent one locality (the local locality).

default_distribution_policy operator() (std::vector<id_type> const &locs) const

Create a new default_distribution policy representing the given set of localities.

Parameters

• locs: [in] The list of localities the new instance should represent

default_distribution_policy operator() (std::vector<id_type> &&locs) const

Create a new default_distribution policy representing the given set of localities.

Parameters

• locs: [in] The list of localities the new instance should represent

default_distribution_policy operator() (id_type const &loc) const

Create a new default_distribution policy representing the given locality

Parameters

• loc: [in] The locality the new instance should represent

template<typename Component, typename ...Ts>

hpx::future<hpx::id_type> create (Ts&& ... vs) const

Create one object on one of the localities associated by this policy instance

Note  This function is part of the placement policy implemented by this class

Return  A future holding the global address which represents the newly created object

Parameters

• vs: [in] The arguments which will be forwarded to the constructor of the new object.
template<typename Component, typename ...Ts>

hp::future<std::vector<bulk_locality_result>> bulk_create (std::size_t count, Ts&&... vs) const

Create multiple objects on the localities associated by this policy instance

**Note**  This function is part of the placement policy implemented by this class

**Return**  A future holding the list of global addresses which represent the newly created objects

**Parameters**

- **count**: [in] The number of objects to create
- **vs**: [in] The arguments which will be forwarded to the constructors of the new objects.

template<typename Action, typename ...Ts>

async_result<Action>::type async (launch policy, Ts&&... vs) const

Note  This function is part of the invocation policy implemented by this class

template<typename Action, typename Callback, typename ...Ts>

async_result<Action>::type async_cb (launch policy, Callback &cb, Ts&&... vs) const

**Note**  This function is part of the invocation policy implemented by this class

template<typename Action, typename Continuation, typename ...Ts>

bool apply (Continuation &c, threads::thread_priority priority, Ts&&... vs) const

**Note**  This function is part of the invocation policy implemented by this class

template<typename Action, typename ...Ts>

bool apply (threads::thread_priority priority, Ts&&... vs) const

**Note**  This function is part of the invocation policy implemented by this class

template<typename Action, typename Continuation, typename Callback, typename ...Ts>

bool apply_cb (Continuation &c, threads::thread_priority priority, Callback &cb, Ts&&... vs) const

**Note**  This function is part of the invocation policy implemented by this class

template<typename Action, typename Callback, typename ...Ts>

bool apply_cb (threads::thread_priority priority, Callback &cb, Ts&&... vs) const

std::size_t get_num_localities () const

Returns the number of associated localities for this distribution policy

**Note**  This function is part of the creation policy implemented by this class

hp::id_type get_next_target () const

Returns the locality which is anticipated to be used for the next async operation

**Note**  This function is part of the creation policy implemented by this class

template<typename Action>

struct async_result

#include <default_distribution_policy.hpp>

**Note**  This function is part of the invocation policy implemented by this class

Public Types

template<>
using type = hpx::future<typename traits::promise_local_result<typename traits::extract_action<Action>::remote_result_type>::type>

namespace hpx

Functions

template<typename Component, typename... Ts><unspecified> hpx::new_(id_type const & locality, Ts &&... vs)
Create one or more new instances of the given Component type on the specified locality.
This function creates one or more new instances of the given Component type on the specified locality and returns a future object for the global address which can be used to reference the new component instance.

Note This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```cpp
hpx::future<hpx::id_type> f =
  hpx::new_<some_component>(hpx::find_here(), ...);
hpx::id_type id = f.get();
```

Return The function returns different types depending on its use:

- If the explicit template argument Component represents a component type (traits::is_component<Component>::value evaluates to true), the function will return an hpx::future object instance which can be used to retrieve the global address of the newly created component.
- If the explicit template argument Component represents a client side object (traits::is_client<Component>::value evaluates to true), the function will return a new instance of that type which can be used to refer to the newly created component instance.

Parameters

- locality: [in] The global address of the locality where the new instance should be created on.
- vs: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

template<typename Component, typename... Ts><unspecified> hpx::local_new(Ts &&... vs)
Create one new instance of the given Component type on the current locality.
This function creates one new instance of the given Component type on the current locality and returns a future object for the global address which can be used to reference the new component instance.

Note This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```cpp
hpx::future<hpx::id_type> f =
  hpx::local_new<some_component>(...);
hpx::id_type id = f.get();
```

Return The function returns different types depending on its use:
• If the explicit template argument `Component` represents a component type (traits::is_component<Component>::value evaluates to true), the function will return an `hpx::future` object instance which can be used to retrieve the global address of the newly created component. If the first argument is `hpx::launch::sync` the function will directly return an `hpx::id_type`.

• If the explicit template argument `Component` represents a client side object (traits::is_client<Component>::value evaluates to true), the function will return a new instance of that type which can be used to refer to the newly created component instance.

**Note** The difference of this function to `hpx::new_` is that it can be used in cases where the supplied arguments are non-copyable and non-movable. All operations are guaranteed to be local only.

**Parameters**

- `vs`: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

```cpp
template<typename Component, typename... Ts><unspecified> hpx::new_(id_type const & locality, std::size_t count, Ts &&... vs)
Create multiple new instances of the given Component type on the specified locality.
```

This function creates multiple new instances of the given Component type on the specified locality and returns a future object for the global address which can be used to reference the new component instance.

**Note** This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```cpp
hpx::future<std::vector<hpx::id_type> > f =
  hpx::new_<some_component[]>(hpx::find_here(), 10, ...);
```

**Return** The function returns different types depending on its use:

- If the explicit template argument `Component` represents an array of a component type (i.e. Component[], where traits::is_component<Component>::value evaluates to true), the function will return an `hpx::future` object instance which holds a std::vector<hpx::id_type>, where each of the items in this vector is a global address of one of the newly created components.

- If the explicit template argument `Component` represents an array of a client side object type (i.e. Component[], where traits::is_client<Component>::value evaluates to true), the function will return an `hpx::future` object instance which holds a std::vector<hpx::id_type>, where each of the items in this vector is a client side instance of the given type, each representing one of the newly created components.

**Parameters**

- `locality`: [in] The global address of the locality where the new instance should be created on.
- `count`: [in] The number of component instances to create
- `vs`: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

```cpp
template<typename Component, typename DistPolicy, typename... Ts><unspecified> hpx::new_(DistPolicy const & policy, Ts &&... vs)
Create one or more new instances of the given Component type based on the given distribution policy.
```

This function creates one or more new instances of the given Component type on the localities defined by the given distribution policy and returns a future object for global address which can be used to reference the new component instance(s).
Note This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```cpp
hpx::future<hpx::id_type> f = 
    hpx::new_<some_component>(hpx::default_layout, ...);
hpx::id_type id = f.get();
```

**Return** The function returns different types depending on its use:

- If the explicit template argument `Component` represents a component type (traits::is_component<Component>::value evaluates to true), the function will return an `hpx::future` object instance which can be used to retrieve the global address of the newly created component.
- If the explicit template argument `Component` represents a client side object (traits::is_client<Component>::value evaluates to true), the function will return a new instance of that type which can be used to refer to the newly created component instance.

**Parameters**

- `policy`: [in] The distribution policy used to decide where to place the newly created.
- `vs`: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

```
template<typename Component, typename DistPolicy, typename... Ts><unspecified> hpx::new_(DistPolicy const & policy, std::size_t count, Ts &&... vs)
```

Create multiple new instances of the given Component type on the localities as defined by the given distribution policy.

This function creates multiple new instances of the given Component type on the localities defined by the given distribution policy and returns a future object for the global address which can be used to reference the new component instance.

Note This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```cpp
hpx::future<std::vector<hpx::id_type> > f = 
    hpx::new_<some_component[]>(hpx::default_layout, 10, ...);
hpx::id_type id = f.get();
```

**Return** The function returns different types depending on its use:

- If the explicit template argument `Component` represents an array of a component type (i.e. `Component[]`, where traits::is_component<Component>::value evaluates to true), the function will return an `hpx::future` object instance which holds a std::vector<hpx::id_type>, where each of the items in this vector is a global address of one of the newly created components.
- If the explicit template argument `Component` represents an array of a client side object type (i.e. `Component[]`, where traits::is_client<Component>::value evaluates to true), the function will return an `hpx::future` object instance which holds a std::vector<hpx::id_type>, where each of the items in this vector is a client side instance of the given type, each representing one of the newly created components.

**Parameters**

- `policy`: [in] The distribution policy used to decide where to place the newly created.
• count: [in] The number of component instances to create
• vs: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

runtime_components_base

The contents of this module can be included with the header hpx/modules/runtime_components_base.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/runtime_components_base.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

Defines

HPX_REGISTER_COMPONENT (type, name, mode)

Define a component factory for a component type.

This macro is used create and to register a minimal component factory for a component type which allows it to be remotely created using the hpx::new<> function.

This macro can be invoked with one, two or three arguments

Parameters

- type: The type parameter is a (fully decorated) type of the component type for which a factory should be defined.
- name: The name parameter specifies the name to use to register the factory. This should uniquely (system-wide) identify the component type. The name parameter must conform to the C++ identifier rules (without any namespace). If this parameter is not given, the first parameter is used.
- mode: The mode parameter has to be one of the defined enumeration values of the enumeration hpx::components::factory_state_enum. The default for this parameter is hpx::components::factory_enabled.

Defines

HPX_REGISTER_MINIMAL_COMPONENT_REGISTRY (...)

This macro is used create and to register a minimal component registry with Hpx.Plugin.

HPX_REGISTER_MINIMAL_COMPONENT_REGISTRY_ (...)

namespace hpx

namespace components

template<typename Component, factory_state_enum state>
struct component_registry : public component_registry_base
#include <component_registry.hpp>
The component_registry provides a minimal implementation of a component’s registry. If no additional functionality is required this type can be used to implement the full set of minimally required functions to be exposed by a component’s registry instance.

Template Parameters
• Component: The component type this registry should be responsible for.

Public Functions

bool get_component_info (std::vector<std::string> &fillini, std::string const &filepath, bool is_static = false)
Return the ini-information for all contained components.

Return Returns true if the parameter fillini has been successfully initialized with the registry data of all implemented in this module.

Parameters
• fillini: [in] The module is expected to fill this vector with the ini-information (one line per vector element) for all components implemented in this module.

void register_component_type ()
Return the unique identifier of the component type this factory is responsible for.

Return Returns the unique identifier of the component type this factory instance is responsible for. This function throws on any error.

Parameters
• locality: [in] The id of the locality this factory is responsible for.
• agas_client: [in] The AGAS client to use for component id registration (if needed).

Defines

HPX_REGISTER_DERIVED_COMPONENT_FACTORY (...)
This macro is used create and to register a minimal component factory with Hpx.Plugin. This macro may be used if the registered component factory is the only factory to be exposed from a particular module. If more than one factory needs to be exposed the HPX_REGISTER_COMPONENT_FACTORY and HPX_REGISTER_COMPONENT_MODULE macros should be used instead.

HPX_REGISTER_DERIVED_COMPONENT_FACTORY_ (...)

HPX_REGISTER_DERIVED_COMPONENT_FACTORY_3 (ComponentType, componentname, basecomponentname)

    namespace agas

        Enums

            enum service_mode
                Values:
                    service_mode_invalid = -1
                    service_mode_bootstrap = 0
                    service_mode_hosted = 1

        Defines

            HPX_REGISTER_COMMANDLINE_REGISTRY (RegistryType, componentname)
                The macro HPX_REGISTER_COMMANDLINE_REGISTRY is used to register the given component factory with Hpx.Plugin. This macro has to be used for each of the components.

            HPX_REGISTER_COMMANDLINE_REGISTRY_DYNAMIC (RegistryType, componentname)

            HPX_REGISTER_COMMANDLINE_OPTIONS ()
                The macro HPX_REGISTER_COMMANDLINE_OPTIONS is used to define the required Hpx.Plugin entry point for the command line option registry. This macro has to be used in not more than one compilation unit of a component module.

            HPX_REGISTER_COMMANDLINE_OPTIONS_DYNAMIC ()

        namespace hpx

            namespace components

                struct component_commandline_base
                    #include <component_commandline_base.hpp> The component_commandline_base has to be used as a base class for all component command-line line handling registries.
Public Functions

virtual ~component_commandline_base()

virtual hpx::program_options::options_description add_commandline_options() = 0
Return any additional command line options valid for this component.

Note This function will be executed by the runtime system during system startup.

Defines

HPX_REGISTER_COMPONENT_FACTORY (componentname)
This macro is used to register the given component factory with Hpx.Plugin. This macro has to be used for each of the component factories.

HPX_REGISTER_COMPONENT_MODULE ()
This macro is used to define the required Hpx.Plugin entry points. This macro has to be used in exactly one compilation unit of a component module.

HPX_REGISTER_COMPONENT_MODULE_DYNAMIC ()

Defines

HPX_REGISTER_COMPONENT_REGISTRY (RegistryType, componentname)
This macro is used to register the given component factory with Hpx.Plugin. This macro has to be used for each of the components.

HPX_REGISTER_COMPONENT_REGISTRY_DYNAMIC (RegistryType, componentname)

HPX_REGISTER_REGISTRY_MODULE ()
This macro is used to define the required Hpx.Plugin entry points. This macro has to be used in exactly one compilation unit of a component module.

HPX_REGISTER_REGISTRY_MODULE_DYNAMIC ()

namespace hpx

namespace components

struct component_registry_base
#include <component_registry_base.hpp> The component_registry_base has to be used as a base class for all component registries.
Public Functions

```cpp
virtual ~component_registry_base() = default;

virtual bool get_component_info(std::vector<std::string> &fillini, std::string const &filepath, bool is_static = false) = 0
Return the ini-information for all contained components.
```

**Return** Returns true if the parameter `fillini` has been successfully initialized with the registry data of all implemented in this module.

**Parameters**
- `fillini`: [in, out] The module is expected to fill this vector with the ini-information (one line per vector element) for all components implemented in this module.

```cpp
virtual void register_component_type() = 0
Return the unique identifier of the component type this factory is responsible for.
```

**Return** Returns the unique identifier of the component type this factory instance is responsible for. This function throws on any error.

**Parameters**
- `locality`: [in] The id of the locality this factory is responsible for.
- `agas_client`: [in] The AGAS client to use for component id registration (if needed).

Defines

HPX_REGISTER_PLUGIN_BASE_REGISTRY (PluginType, name)

This macro is used to register the given component factory with Hpx.Plugin. This macro has to be used for each of the components.

HPX_REGISTER_PLUGIN_REGISTRY_MODULE ()

This macro is used to define the required Hpx.Plugin entry points. This macro has to be used in exactly one compilation unit of a component module.

HPX_REGISTER_PLUGIN_REGISTRY_MODULE_DYNAMIC ()
namespace hpx

namespace plugins

struct plugin_registry_base
#include <plugin_registry_base.hpp> The plugin_registry_base has to be used as a base class for all plugin registries.

Public Functions

virtual ~plugin_registry_base()

virtual bool get_plugin_info(std::vector<std::string> &fillini) = 0
    Return the configuration information for any plugin implemented by this module

    Return  Returns true if the parameter fillini has been successfully initialized with the registry data
    all implemented in this module.

    Parameters
    • fillini: [in, out] The module is expected to fill this vector with the ini-information (one
    line per vector element) for all plugins implemented in this module.

namespace hpx
Enums

enum runtime_mode
A HPX runtime can be executed in two different modes: console mode and worker mode.

Values:

invalid = -1
console = 0
The runtime is the console locality.
worker = 1
The runtime is a worker locality.
connect = 2
The runtime is a worker locality connecting late
local = 3
The runtime is fully local.
default_ = 4
The runtime mode will be determined based on the command line arguments
last

Functions

char const *get_runtime_mode_name (runtime_mode state)
Get the readable string representing the name of the given runtime_mode constant.

runtime_mode get_runtime_mode_from_name (std::string const &mode)
Returns the internal representation (runtime_mode constant) from the readable string representing the name.

This represents the internal representation from the readable string representing the name.

Parameters

• mode: this represents the runtime mode

runtime_distributed

The contents of this module can be included with the header hpx/modules/runtime_distributed.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/runtime_distributed.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

namespace hpx

Functions

bool tolerate_node_faults()

class runtime_distributed : public runtime
#include <runtime_distributed.hpp> The runtime class encapsulates the HPX runtime system in a simple to use way. It makes sure all required parts of the HPX runtime system are properly initialized.

Public Functions

runtime_distributed (util::runtime_configuration &rtcfg)

Construct a new HPX runtime instance

Parameters

• locality_mode: [in] This is the mode the given runtime instance should be executed in.

~runtime_distributed()

The destructor makes sure all HPX runtime services are properly shut down before exiting.

int start (util::function_nonser<hpx_main_function_type> const &func, bool blocking = false)

Start the runtime system.
Return If a blocking is a true, this function will return the value as returned as the result of the invocation of the function object given by the parameter func. Otherwise it will return zero.

Parameters

• func: [in] This is the main function of an HPX application. It will be scheduled for execution by the thread manager as soon as the runtime has been initialized. This function is expected to expose an interface as defined by the typedef hpx_main_function_type.

• blocking: [in] This allows to control whether this call blocks until the runtime system has been stopped. If this parameter is true the function runtime::start will call runtime::wait internally.

```c
int start (bool blocking = false)
Start the runtime system.
```

Return If a blocking is a true, this function will return the value as returned as the result of the invocation of the function object given by the parameter func. Otherwise it will return zero.

Parameters

• blocking: [in] This allows to control whether this call blocks until the runtime system has been stopped. If this parameter is true the function runtime::start will call runtime::wait internally.

```c
int wait ()
Wait for the shutdown action to be executed.
```

Return This function will return the value as returned as the result of the invocation of the function object given by the parameter func.

```c
void stop (bool blocking = true)
Initiate termination of the runtime system.
```

Parameters

• blocking: [in] This allows to control whether this call blocks until the runtime system has been fully stopped. If this parameter is false then this call will initiate the stop action but will return immediately. Use a second call to stop with this parameter set to true to wait for all internal work to be completed.

```c
int finalize (double shutdown_timeout)
```

```c
void stop_helper (bool blocking, std::condition_variable &cond, std::mutex &mtx)
Stop the runtime system, wait for termination.
```

Parameters

• blocking: [in] This allows to control whether this call blocks until the runtime system has been fully stopped. If this parameter is false then this call will initiate the stop action but will return immediately. Use a second call to stop with this parameter set to true to wait for all internal work to be completed.

```c
int suspend ()
Suspend the runtime system.
```

```c
int resume ()
Resume the runtime system.
```

```c
bool report_error (std::size_t num_thread, std::exception_ptr const &e, bool terminate_all = true)
Report a non-recoverable error to the runtime system.
```
Parameters

- **num_thread**: [in] The number of the operating system thread the error has been detected in.
- **e**: [in] This is an instance encapsulating an exception which lead to this function call.
- **terminate_all**: [in] Kill all localities attached to the currently running application (default: true)

```cpp
bool report_error (std::exception_ptr const & e, bool terminate_all = true)
```

Report a non-recoverable error to the runtime system.

**Note** This function will retrieve the number of the current shepherd thread and forward to the report_error function above.

Parameters

- **e**: [in] This is an instance encapsulating an exception which lead to this function call.
- **terminate_all**: [in] Kill all localities attached to the currently running application (default: true)

```cpp
int run (util::function_nonser<hpx_main_function_type> const & func)
```

Run the HPX runtime system, use the given function for the main thread and block waiting for all threads to finish.

**Note** The parameter `func` is optional. If no function is supplied, the runtime system will simply wait for the shutdown action without explicitly executing any main thread.

**Return** This function will return the value as returned as the result of the invocation of the function object given by the parameter `func`.

Parameters

- **func**: [in] This is the main function of an HPX application. It will be scheduled for execution by the thread manager as soon as the runtime has been initialized. This function is expected to expose an interface as defined by the typedef `hpx_main_function_type`. This parameter is optional and defaults to none main thread function, in which case all threads have to be scheduled explicitly.

```cpp
int run ()
```

Run the HPX runtime system, initially use the given number of (OS) threads in the thread-manager and block waiting for all threads to finish.

**Return** This function will always return 0 (zero).

```cpp
bool is_networking_enabled ()
```

**template<typename F>**

```cpp
components::server::console_error_dispatcher::sink_type set_error_sink (F & & sink)
```

**performance_counters::registry & get_counter_registry ()**

Allow access to the registry counter registry instance used by the HPX runtime.

```cpp
performance_counters::registry const & get_counter_registry () const
```

Allow access to the registry counter registry instance used by the HPX runtime.

```cpp
void register_counter_types ()
```

Install all performance counters related to this runtime instance.

```cpp
void register_query_counters (std::shared_ptr<util::query_counters> const & active_counters)
```
void `start_active_counters` (error_code &ec = throws)

void `stop_active_counters` (error_code &ec = throws)

void `reset_active_counters` (error_code &ec = throws)

void `reinit_active_counters` (bool reset = true, error_code &ec = throws)

void `evaluate_active_counters` (bool reset = false, char const *description = nullptr, error_code &ec = throws)

void `stop_evaluating_counters` (bool terminate = false)

```
naming::resolver_client &get_agas_client ()
   Allow access to the AGAS client instance used by the HPX runtime.

hpx::threads::threadmanager &get_thread_manager ()
   Allow access to the thread manager instance used by the HPX runtime.

applier::applier &get_applier ()
   Allow access to the applier instance used by the HPX runtime.

std::string here () const
   Returns a string of the locality endpoints (usable in debug output)

std::uint64_t get_runtime_support_lva () const
```

```
naming::gid_type get_next_id (std::size_t count = 1)
```

void `initialize_agas` ()
   Initialize AGAS operation.

void `add_pre_startup_function` (startup_function_type f)
   Add a function to be executed inside a HPX thread before hpx_main but guaranteed to be executed before any startup function registered with `add_startup_function`.

   **Note** The difference to a startup function is that all pre-startup functions will be (system-wide) executed before any startup function.

   **Parameters**
   - `f`: The function ‘f’ will be called from inside a HPX thread before hpx_main is executed. This is very useful to setup the runtime environment of the application (install performance counters, etc.)

void `add_startup_function` (startup_function_type f)
   Add a function to be executed inside a HPX thread before hpx_main

   **Parameters**
   - `f`: The function ‘f’ will be called from inside a HPX thread before hpx_main is executed. This is very useful to setup the runtime environment of the application (install performance counters, etc.)
void **add_pre_shutdown_function** (*shutdown_function_type f*)
Add a function to be executed inside a HPX thread during *hpx::finalize*, but guaranteed before any of the shutdown functions is executed.

**Note**  The difference to a shutdown function is that all pre-shutdown functions will be (system-wide) executed before any shutdown function.

**Parameters**
• *f*: The function ‘f’ will be called from inside a HPX thread while *hpx::finalize* is executed. This is very useful to tear down the runtime environment of the application (uninstall performance counters, etc.)

void **add_shutdown_function** (*shutdown_function_type f*)
Add a function to be executed inside a HPX thread during *hpx::finalize*

**Parameters**
• *f*: The function ‘f’ will be called from inside a HPX thread while *hpx::finalize* is executed. This is very useful to tear down the runtime environment of the application (uninstall performance counters, etc.)

*hpx::util::io_service_pool *get_thread_pool* (char const *name)*
Access one of the internal thread pools (io_service instances) HPX is using to perform specific tasks. The three possible values for the argument *name* are “main_pool”, “io_pool”, “parcel_pool”, and “timer_pool”. For any other argument value the function will return zero.

bool **register_thread** (char const *name, std::size_t *num = 0, bool *service_thread = true, error_code &*ec = throws)*
Register an external OS-thread with HPX.

notification_policy_type **get_notification_policy** (char const *prefix, run-time_local::os_thread_type *type)*
Generate a new notification policy instance for the given thread name prefix

std::uint32_t **get_locality_id** (error_code &*ec) const
std::size_t **get_num_worker_threads** () const

static void default_errorsink (std::string const &)

namespace hpx

namespace components
Functions

template<typename Component>
future<naming::id_type> copy (naming::id_type const &to_copy)
    Copy given component to the specified target locality.

    The function copy<Component> will create a copy of the component referenced by to_copy on the
    locality specified with target_locality. It returns a future referring to the newly created component
    instance.

Return  A future representing the global id of the newly (copied) component instance.
Note  The new component instance is created on the locality of the component instance which is to
be copied.
Parameters
    • to_copy: [in] The global id of the component to copy

Template Parameters
    • The: only template argument specifies the component type to create.

template<typename Component>
future<naming::id_type> copy (naming::id_type const &to_copy, naming::id_type const &target_locality)
    Copy given component to the specified target locality.

    The function copy<Component> will create a copy of the component referenced by to_copy on the
    locality specified with target_locality. It returns a future referring to the newly created component
    instance.

Return  A future representing the global id of the newly (copied) component instance.
Parameters
    • to_copy: [in] The global id of the component to copy
    • target_locality: [in ] The locality where the copy should be created.

Template Parameters
    • The: only template argument specifies the component type to create.

template<typename Derived, typename Stub>
Derived copy (client_base<Derived, Stub> const &to_copy, naming::id_type const &target_locality = naming::invalid_id)
    Copy given component to the specified target locality.

    The function copy will create a copy of the component referenced by the client side object to_copy
    on the locality specified with target_locality. It returns a new client side object future referring to the
    newly created component instance.

Return  A future representing the global id of the newly (copied) component instance.
Note  If the second argument is omitted (or is invalid_id) the new component instance is created on
the locality of the component instance which is to be copied.
Parameters
    • to_copy: [in] The client side object representing the component to copy
    • target_locality: [in, optional] The locality where the copy should be created (default is
      same locality as source).

Template Parameters
    • The: only template argument specifies the component type to create.

namespace hpx
Functions

\[ \text{std::vector<naming::id_type> find_all_localities (components::component_type type, error_code &ec = throws) } \]

Return the list of global ids representing all localities available to this application which support the given component type.

The function find_all_localities() can be used to retrieve the global ids of all localities currently available to this application which support the creation of instances of the given component type.

**Note** Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

**Return** The global ids representing the localities currently available to this application which support the creation of instances of the given component type. If no localities supporting the given component type are currently available, this function will return an empty vector.

**Note** As long as \( ec \) is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter \( ec \). Otherwise it throws an instance of hpx::exception.

**Note** This function will return meaningful results only if called from an HPX-thread. It will return an empty vector otherwise.

**See** hpx::find_here(), hpx::find_locality()

**Parameters**

- type: [in] The type of the components for which the function should return the available localities.
- ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

\[ \text{std::vector<naming::id_type> find_remote_localities (components::component_type type, error_code &ec = throws) } \]

Return the list of locality ids of remote localities supporting the given component type. By default this function will return the list of all remote localities (all but the current locality).

The function find_remote_localities() can be used to retrieve the global ids of all remote localities currently available to this application (i.e. all localities except the current one) which support the creation of instances of the given component type.

**Note** Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

**Return** The global ids representing the remote localities currently available to this application.

**Note** As long as \( ec \) is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter \( ec \). Otherwise it throws an instance of hpx::exception.

**Note** This function will return meaningful results only if called from an HPX-thread. It will return an empty vector otherwise.

**See** hpx::find_here(), hpx::find_locality()

**Parameters**

- type: [in] The type of the components for which the function should return the available remote localities.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
naming::id_type find_locality (components::component_type type, error_code &ec = throws)
```

Return the global id representing an arbitrary locality which supports the given component type.

The function `find_locality()` can be used to retrieve the global id of an arbitrary locality currently available to this application which supports the creation of instances of the given component type.

**Note** Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

**Return** The global id representing an arbitrary locality currently available to this application which supports the creation of instances of the given component type. If no locality supporting the given component type is currently available, this function will return `hpx::naming::invalid_id`.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Note** This function will return meaningful results only if called from an HPX-thread. It will return `hpx::naming::invalid_id` otherwise.

**See** `hpx::find_here()`, `hpx::find_all_localities()`

**Parameters**

- `type`: [in] The type of the components for which the function should return any available locality.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
namespace hpx
```

## Functions

```cpp
lcos::future<std::uint32_t> get_num_localities (components::component_type t)
```

Asynchronously return the number of localities which are currently registered for the running application.

The function `get_num_localities` asynchronously returns the number of localities currently connected to the console which support the creation of the given component type. The returned future represents the actual result.

**Note** This function will return meaningful results only if called from an HPX-thread. It will return 0 otherwise.

**See** `hpx::find_all_localities`, `hpx::get_num_localities`

**Parameters**

- `t`: The component type for which the number of connected localities should be retrieved.

```cpp
std::uint32_t get_num_localities (launch::sync_policy, components::component_type t, error_code &ec = throws)
```

Synchronously return the number of localities which are currently registered for the running application.

The function `get_num_localities` returns the number of localities currently connected to the console which support the creation of the given component type. The returned future represents the actual result.
Note This function will return meaningful results only if called from an HPX-thread. It will return 0 otherwise.

See `hpx::find_all_localities`, `hpx::get_num_localities`

Parameters

- `t`: The component type for which the number of connected localities should be retrieved.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
namespace hpx

namespace components

Functions

template<typename Component, typename DistPolicy>
future<naming::id_type> migrate (naming::id_type const &to_migrate, DistPolicy const &policy)

Migrate the given component to the specified target locality

The function `migrate<Component>` will migrate the component referenced by `to_migrate` to the locality specified with `target_locality`. It returns a future referring to the migrated component instance.

Return A future representing the global id of the migrated component instance. This should be the same as `migrate_to`.

Parameters

- `to_migrate`: [in] The client side representation of the component to migrate.
- `policy`: [in] A distribution policy which will be used to determine the locality to migrate this object to.

Template Parameters

- `Component`: Specifies the component type of the component to migrate.
- `DistPolicy`: Specifies the distribution policy to use to determine the destination locality.

template<typename Derived, typename Stub, typename DistPolicy>
Derived migrate (client_base<Derived, Stub> const &to_migrate, DistPolicy const &policy)

Migrate the given component to the specified target locality

The function `migrate<Component>` will migrate the component referenced by `to_migrate` to the locality specified with `target_locality`. It returns a future referring to the migrated component instance.

Return A future representing the global id of the migrated component instance. This should be the same as `migrate_to`.

Parameters

- `to_migrate`: [in] The client side representation of the component to migrate.
- `policy`: [in] A distribution policy which will be used to determine the locality to migrate this object to.

Template Parameters

- `Derived`: Specifies the component type of the component to migrate.
- `DistPolicy`: Specifies the distribution policy to use to determine the destination locality.

```
future<naming::id_type> migrate (naming::id_type const &to_migrate, naming::id_type const &target_locality)
Migrate the component with the given id to the specified target locality

The function migrate<Component> will migrate the component referenced by to_migrate to the locality specified with target_locality. It returns a future referring to the migrated component instance.

Return A future representing the global id of the migrated component instance. This should be the same as migrate_to.

Parameters
• to_migrate: [in] The global id of the component to migrate.
• target_locality: [in] The locality where the component should be migrated to.

Template Parameters
• Component: Specifies the component type of the component to migrate.

template<typename Derived, typename Stub>
Derived migrate (client_base<Derived, Stub> const &to_migrate, naming::id_type const &target_locality)
Migrate the given component to the specified target locality

The function migrate<Component> will migrate the component referenced by to_migrate to the locality specified with target_locality. It returns a future referring to the migrated component instance.

Return A client side representation of representing of the migrated component instance. This should be the same as migrate_to.

Parameters
• to_migrate: [in] The client side representation of the component to migrate.
• target_locality: [in] The id of the locality to migrate this object to.

Template Parameters
• Derived: Specifies the component type of the component to migrate.

namespace hpx

namespace components

class runtime_support : public hpx::components::stubs::runtime_support
#include <runtime_support.hpp> The runtime_support class is the client side representation of a server::runtime_support component

Public Functions

runtime_support (naming::id_type const &gid = naming::invalid_id)
Create a client side representation for the existing server::runtime_support instance with the given global id gid.

template<typename Component, typename ...Ts>
naming::id_type create_component (Ts&&... vs)
Create a new component type using the runtime_support.

template<typename Component, typename ...Ts>
lcos::future<naming::id_type> create_component_async (Ts&&... vs)
Asynchronously create a new component using the runtime_support.

template<typename Component, typename ...Ts>
std::vector<naming::id_type> bulk_create_component (std::size_t, Ts&&... vs)
   Asynchronously create N new default constructed components using the runtime_support

template<typename Component, typename ...Ts>
lcos::future<std::vector<naming::id_type>> bulk_create_components_async (std::size_t, Ts&&... vs)
   Asynchronously create a new component using the runtime_support.

lcos::future<int> load_components_async ()
int load_components ()

lcos::future<void> call_startup_functions_async (bool pre_startup)
void call_startup_functions (bool pre_startup)

lcos::future<void> shutdown_async (double timeout = -1)
   Shutdown the given runtime system.

void shutdown (double timeout = -1)
void shutdown_all (double timeout = -1)
   Shutdown the runtime systems of all localities.

lcos::future<void> terminate_async ()
void terminate ()
void terminate_all ()
   Terminate the runtime systems of all localities.

void get_config (util::section &ini)
   Retrieve configuration information.

naming::id_type const &get_id () const
naming::gid_type const &get_raw_gid () const

```
### runtime_local

The contents of this module can be included with the header `hpx/modules/runtime_local.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/runtime_local.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

### Defines

- **HPX_REGISTER_STARTUP_SHUTDOWN_REGISTRY**(`RegistryType, componentname`)  
  This macro is used to register the given component factory with Hpx.Plugin. This macro has to be used for each of the components.

- **HPX_REGISTER_STARTUP_SHUTDOWN_REGISTRY_DYNAMIC**(`RegistryType, componentname`)  
  **HPX_REGISTER_STARTUP_SHUTDOWN_FUNCTIONS**()  
  This macro is used to define the required Hpx.Plugin entry point for the startup/shutdown registry. This macro has to be used in not more than one compilation unit of a component module.

- **HPX_REGISTER_STARTUP_SHUTDOWN_FUNCTIONS_DYNAMIC**()

```cpp
namespace hpx

namespace components

struct component_startup_shutdown_base
#include <component_startup_shutdown_base.hpp> The component_startup_shutdown_base has to be used as a base class for all component startup/shutdown registries.

### Public Functions

- **virtual ~component_startup_shutdown_base**()

- **virtual bool get_startup_function**(startup_function_type &startup, bool &pre_startup) = 0
  
  Return any startup function for this component.

- **Parameters**

  - **Return** Returns `true` if the parameter `startup` has been successfully initialized with the startup function.

  - **Parameters**

    - **startup**: [in, out] The module is expected to fill this function object with a reference to a startup function. This function will be executed by the runtime system during system startup.

- **virtual bool get_shutdown_function**(shutdown_function_type &shutdown, bool &pre_shutdown) = 0
  
  Return any startup function for this component.

- **Return** Returns `true` if the parameter `shutdown` has been successfully initialized with the shutdown function.

- **Parameters**
• **shutdown**: [in, out] The module is expected to fill this function object with a reference to a startup function. This function will be executed by the runtime system during system startup.

```cpp
namespace hpx

Functions

std::string get_config_entry (std::string const &key, std::string const &dflt)
Retrieves the string value of a configuration entry given by `key`.

std::string get_config_entry (std::string const &key, std::size_t dflt)
Retrieves the integer value of a configuration entry given by `key`.

void set_config_entry (std::string const &key, std::string const &value)
Set the string value of a configuration entry given by `key`.

void set_config_entry (std::string const &key, std::size_t value)
Set the integer value of a configuration entry given by `key`.

void set_config_entry_callback (std::string const &key, util::function_nonser<void> const & callback)
Set the string value of a configuration entry given by `key`.
```

```cpp
namespace hpx

Functions

std::string diagnostic_information (exception_info const &xi)
Extracts the diagnostic information embedded in the given exception and returns a string holding a formatted message.

The function `hpx::diagnostic_information` can be used to extract all diagnostic information stored in the given exception instance as a formatted string. This simplifies debug output as it composes the diagnostics into one, easy to use function call. This includes the name of the source file and line number, the sequence number of the OS-thread and the HPX-thread id, the locality id and the stack backtrace of the point where the original exception was thrown.

**Return** The formatted string holding all of the available diagnostic information stored in the given exception instance.

**See** `hpx::get_error_locality_id()`, `hpx::get_error_host_name()`, `hpx::get_error_process_id()`, `hpx::get_error_function_name()`, `hpx::get_error_file_name()`, `hpx::get_error_line_number()`, `hpx::get_error_os_thread()`, `hpx::get_error_thread_id()`, `hpx::get_error_thread_description()`, `hpx::get_error()`, `hpx::get_error_backtrace()`, `hpx::get_error_env()`, `hpx::get_error_what()`, `hpx::get_error_config()`, `hpx::get_error_state()`

**Parameters**

- `xi`: The parameter will be inspected for all diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Exceptions**

- `std::bad_alloc`: (if any of the required allocation operations fail)
std::uint32_t get_error_locality_id (hpx::exception_info const &xi)

Return the locality id where the exception was thrown.

The function hpx::get_error_locality_id can be used to extract the diagnostic information element representing the locality id as stored in the given exception instance.

Return The locality id of the locality where the exception was thrown. If the exception instance does not hold this information, the function will return hpx::naming::invalid_locality_id.

See hpx::diagnostic_information(), hpx::get_error_host_name(), hpx::get_error_process_id(), hpx::get_error_function_name(), hpx::get_error_file_name(), hpx::get_error_line_number(), hpx::get_error_os_thread(), hpx::get_error_thread_id(), hpx::get_error_thread_description(), hpx::get_error(), hpx::get_error_backtrace(), hpx::get_error_env(), hpx::get_error_what(), hpx::get_error_config(), hpx::get_error_state()

Parameters
    • xi: The parameter e will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: hpx::exception_info, hpx::error_code, std::exception, or std::exception_ptr.

Exceptions
    • nothing:

std::string get_error_host_name (hpx::exception_info const &xi)

Return the hostname of the locality where the exception was thrown.

The function hpx::get_error_host_name can be used to extract the diagnostic information element representing the host name as stored in the given exception instance.

Return The hostname of the locality where the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

See hpx::diagnostic_information(), hpx::get_error_process_id(), hpx::get_error_function_name(), hpx::get_error_file_name(), hpx::get_error_line_number(), hpx::get_error_os_thread(), hpx::get_error_thread_id(), hpx::get_error_thread_description(), hpx::get_error(), hpx::get_error_backtrace(), hpx::get_error_env(), hpx::get_error_what(), hpx::get_error_config(), hpx::get_error_state()

Parameters
    • xi: The parameter e will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: hpx::exception_info, hpx::error_code, std::exception, or std::exception_ptr.

Exceptions
    • std::bad_alloc: (if one of the required allocations fails)

std::int64_t get_error_process_id (hpx::exception_info const &xi)

Return the (operating system) process id of the locality where the exception was thrown.

The function hpx::get_error_process_id can be used to extract the diagnostic information element representing the process id as stored in the given exception instance.

Return The process id of the OS-process which threw the exception. If the exception instance does not hold this information, the function will return 0.
See `hpx::diagnostic_information()`, `hpx::get_error_host_name()`, `hpx::get_error_function_name()`, `hpx::get_error_file_name()`, `hpx::get_error_line_number()`, `hpx::get_error_os_thread()`, `hpx::get_error_thread_id()`, `hpx::get_error_thread_description()`, `hpx::get_error()`, `hpx::get_error_backtrace()`, `hpx::get_error_env()`, `hpx::get_error_what()`, `hpx::get_error_config()`, `hpx::get_error_state()`

Parameters

- `xi`: The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

Exceptions

- `nothing`

`std::string get_error_env (hpx::exception_info const &xi)`

Return the environment of the OS-process at the point the exception was thrown.

The function `hpx::get_error_env` can be used to extract the diagnostic information element representing the environment of the OS-process collected at the point the exception was thrown.

Return The environment from the point the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

See `hpx::diagnostic_information()`, `hpx::get_error_host_name()`, `hpx::get_error_process_id()`, `hpx::get_error_function_name()`, `hpx::get_error_file_name()`, `hpx::get_error_line_number()`, `hpx::get_error_os_thread()`, `hpx::get_error_thread_id()`, `hpx::get_error_thread_description()`, `hpx::get_error()`, `hpx::get_error_backtrace()`, `hpx::get_error_env()`, `hpx::get_error_what()`, `hpx::get_error_config()`, `hpx::get_error_state()`

Parameters

- `xi`: The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

Exceptions

- `std::bad_alloc`: (if one of the required allocations fails)

`std::string get_error_backtrace (hpx::exception_info const &xi)`

Return the stack backtrace from the point the exception was thrown.

The function `hpx::get_error_backtrace` can be used to extract the diagnostic information element representing the stack backtrace collected at the point the exception was thrown.

Return The stack back trace from the point the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

See `hpx::diagnostic_information()`, `hpx::get_error_host_name()`, `hpx::get_error_process_id()`, `hpx::get_error_function_name()`, `hpx::get_error_file_name()`, `hpx::get_error_line_number()`, `hpx::get_error_os_thread()`, `hpx::get_error_thread_id()`, `hpx::get_error_thread_description()`, `hpx::get_error()`, `hpx::get_error_backtrace()`, `hpx::get_error_env()`, `hpx::get_error_what()`, `hpx::get_error_config()`, `hpx::get_error_state()`

Parameters
• xi: The parameter e will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: hpx::exception_info, hpx::error_code, std::exception, or std::exception_ptr.

Exceptions

• std::bad_alloc: (if one of the required allocations fails)

```cpp
std::size_t get_error_os_thread(hpx::exception_info const &xi)
```

Return the sequence number of the OS-thread used to execute HPX-threads from which the exception was thrown.

The function hpx::get_error_os_thread can be used to extract the diagnostic information element representing the sequence number of the OS-thread as stored in the given exception instance.

Return The sequence number of the OS-thread used to execute the HPX-thread from which the exception was thrown. If the exception instance does not hold this information, the function will return std::size_t(-1).

See hpx::diagnostic_information(), hpx::get_error_host_name(), hpx::get_error_process_id(), hpx::get_error_function_name(), hpx::get_error_file_name(), hpx::get_error_line_number(), hpx::get_error_thread_id(), hpx::get_error_thread_description(), hpx::get_error(), hpx::get_error_backtrace(), hpx::get_error_env(), hpx::get_error_what(), hpx::get_error_config(), hpx::get_error_state()

Parameters

• xi: The parameter e will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: hpx::exception_info, hpx::error_code, std::exception, or std::exception_ptr.

Exceptions

• nothing:

```cpp
std::size_t get_error_thread_id(hpx::exception_info const &xi)
```

Return the unique thread id of the HPX-thread from which the exception was thrown.

The function hpx::get_error_thread_id can be used to extract the diagnostic information element representing the HPX-thread id as stored in the given exception instance.

Return The unique thread id of the HPX-thread from which the exception was thrown. If the exception instance does not hold this information, the function will return std::size_t(0).

See hpx::diagnostic_information(), hpx::get_error_host_name(), hpx::get_error_process_id(), hpx::get_error_function_name(), hpx::get_error_file_name(), hpx::get_error_line_number(), hpx::get_error_os_thread() hpx::get_error_thread_description(), hpx::get_error(), hpx::get_error_backtrace(), hpx::get_error_env(), hpx::get_error_what(), hpx::get_error_config(), hpx::get_error_state()

Parameters

• xi: The parameter e will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: hpx::exception_info, hpx::error_code, std::exception, or std::exception_ptr.

Exceptions

• nothing:
\texttt{std::string get_error_thread_description (hpx::exception_info const &xi)}

Return any additionally available thread description of the HPX-thread from which the exception was thrown.

The function \texttt{hpx::get_error_thread_description} can be used to extract the diagnostic information element representing the additional thread description as stored in the given exception instance.

Return Any additionally available thread description of the HPX-thread from which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

See \texttt{hpx::diagnostic_information()}, \texttt{hpx::get_error_host_name()}, \texttt{hpx::get_error_process_id()}, \texttt{hpx::get_error_function_name()}, \texttt{hpx::get_error_file_name()}, \texttt{hpx::get_error_line_number()}, \texttt{hpx::get_error_os_thread()}, \texttt{hpx::get_error_thread_id()}, \texttt{hpx::get_error_backtrace()}, \texttt{hpx::get_error_env()}, \texttt{hpx::get_error()}, \texttt{hpx::get_error_state()}, \texttt{hpx::get_error_what()}, \texttt{hpx::get_error_config()}

Parameters

• \texttt{xi}: The parameter \texttt{e} will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: \texttt{hpix::exception_info, hpx::error_code, std::exception, or std::exception_ptr.}

Exceptions

• \texttt{std::bad_alloc}: (if one of the required allocations fails)

\texttt{std::string get_error_config (hpx::exception_info const &xi)}

Return the HPX configuration information point from which the exception was thrown.

The function \texttt{hpx::get_error_config} can be used to extract the HPX configuration information element representing the full HPX configuration information as stored in the given exception instance.

Return Any additionally available HPX configuration information the point from which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

See \texttt{hpx::diagnostic_information()}, \texttt{hpx::get_error_host_name()}, \texttt{hpx::get_error_process_id()}, \texttt{hpx::get_error_function_name()}, \texttt{hpx::get_error_file_name()}, \texttt{hpx::get_error_line_number()}, \texttt{hpx::get_error_os_thread()}, \texttt{hpx::get_error_thread_id()}, \texttt{hpx::get_error_backtrace()}, \texttt{hpx::get_error_env()}, \texttt{hpx::get_error()}, \texttt{hpx::get_error_state()}, \texttt{hpx::get_error_what()}, \texttt{hpx::get_error_thread_description()}

Parameters

• \texttt{xi}: The parameter \texttt{e} will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: \texttt{hpix::exception_info, hpx::error_code, std::exception, or std::exception_ptr.}

Exceptions

• \texttt{std::bad_alloc}: (if one of the required allocations fails)

\texttt{std::string get_error_state (hpx::exception_info const &xi)}

Return the HPX runtime state information at which the exception was thrown.

The function \texttt{hpx::get_error_state} can be used to extract the HPX runtime state information element representing the state the runtime system is currently in as stored in the given exception instance.
**Return**  The point runtime state at the point at which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

**See**  `hpx::diagnostic_information()`, `hpx::get_error_host_name()`, `hpx::get_error_process_id()`, `hpx::get_error_function_name()`, `hpx::get_error_file_name()`, `hpx::get_error_line_number()`, `hpx::get_error_os_thread()`, `hpx::get_error_thread_id()`, `hpx::get_error_backtrace()`, `hpx::get_error_env()`, `hpx::get_error()`, `hpx::get_error_what()`, `hpx::get_error_thread_description()`

**Parameters**

- `xi`: The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Exceptions**

- `std::bad_alloc`: (if one of the required allocations fails)

namespace hpx

namespace util

**Functions**

```cpp
void may_attach_debugger (std::string const &category)
```

Attaches a debugger if `category` is equal to the configuration entry `hpx::attach-debugger`.

namespace hpx

**Functions**

```cpp
std::uint32_t get_locality_id (error_code &ec = hpx::throws)
```

Return the number of the locality this function is being called from. This function returns the id of the current locality.

**Note**  The returned value is zero based and its maximum value is smaller than the overall number of localities the current application is running on (as returned by `get_num_localities()`).

**Note**  As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Note**  This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

**Parameters**

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

namespace hpx
Functions

```cpp
std::uint32_t get_initial_num_localities()
```

Return the number of localities which were registered at startup for the running application.

The function `get_initial_num_localities` returns the number of localities which were connected to the console at application startup.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**See** `hpx::find_all_localities`, `hpx::get_num_localities`

```cpp
lcos::future<std::uint32_t> get_num_localities()
```

Asynchronously return the number of localities which are currently registered for the running application.

The function `get_num_localities` asynchronously returns the number of localities currently connected to the console. The returned future represents the actual result.

**Note** This function will return meaningful results only if called from an HPX-thread. It will return 0 otherwise.

**See** `hpx::find_all_localities`, `hpx::get_num_localities`

```cpp
std::uint32_t get_num_localities(launch::sync_policy, error_code &ec = throws)
```

Return the number of localities which are currently registered for the running application.

The function `get_num_localities` returns the number of localities currently connected to the console.

**Note** This function will return meaningful results only if called from an HPX-thread. It will return 0 otherwise.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**See** `hpx::find_all_localities`, `hpx::get_num_localities`

**Parameters**

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

namespace hpx

Functions

```cpp
std::size_t get_os_thread_count()
```

Return the number of OS-threads running in the runtime instance the current HPX-thread is associated with.

```cpp
std::size_t get_os_thread_count(threads::executor const &exec)
```

Return the number of worker OS-threads used by the given executor to execute HPX threads.

This function returns the number of cores used to execute HPX threads for the given executor. If the function is called while no HPX runtime system is active, it will return zero. If the executor is not valid, this function will fall back to retrieving the number of OS threads used by HPX.
Parameters

- **exec**: [in] The executor to be used.

### namespace hpx

### Functions

**std::string get_thread_name()**

Return the name of the calling thread.

This function returns the name of the calling thread. This name uniquely identifies the thread in the context of HPX. If the function is called while no HPX runtime system is active, the result will be "<unknown>".

### namespace hpx

### namespace util

#### class interval_timer

**Public Functions**

namespace hpx

namespace runtime_local

** Enums**

`enum os_thread_type`

Types of kernel threads registered with the runtime.

*Values:*

- `unknown = -1`
- `main_thread = 0`
  kernel thread represents main thread
- `worker_thread`
  kernel thread is used to schedule HPX threads
- `io_thread`
  kernel thread can be used for IO operations
- `timer_thread`
  kernel is used by timer operations
- `parcel_thread`
  kernel is used by networking operations
- `custom_thread`
  kernel is registered by the application

**Functions**

`std::string get_os_thread_type_name(os_thread_type)`

Return a human-readable name representing one of the kernel thread types.

`struct os_thread_data`

#include <os_thread_type.hpp> Registration data for kernel threads that is maintained by the runtime internally
Public Members

`std::string label_`
name used for thread registration

`std::thread::id id_`
thread id of corresponding kernel thread

`std::uint64_t native_handle_`
the threads native handle

`os_thread_type type_`
HPX thread type.

namespace hpx

Functions

```cpp
void report_error (std::size_t num_thread, std::exception_ptr const &e)
```
The function report_error reports the given exception to the console.

```cpp
void report_error (std::exception_ptr const &e)
```
The function report_error reports the given exception to the console.

namespace hpx

namespace threads

T&&... vs)
```

namespace hpx

class runtime
Public Types

using notification_policy_type = threads::policies::callback_notifier
    Generate a new notification policy instance for the given thread name prefix.

using hpx_main_function_type = int()
    The hpx_main_function_type is the default function type usable as the main HPX thread function.

using hpx_errorsink_function_type = void (std::uint32_t, std::string const &)

Public Functions

virtual notification_policy_type get_notification_policy (char const *prefix, runtime_local::os_thread_type type)

state get_state() const

void set_state (state s)

runtime (util::runtime_configuration &rtcfg, bool initialize = true)
    Construct a new HPX runtime instance.

virtual ~runtime ()
    The destructor makes sure all HPX runtime services are properly shut down before exiting.

void on_exit (util::function_nonser< void > const &f)
    Manage list of functions to call on exit.

void starting ()
    Manage runtime ‘stopped’ state.

void stopping ()
    Call all registered on_exit functions.

bool stopped () const
    This accessor returns whether the runtime instance has been stopped.

util::runtime_configuration &get_config ()
    Access configuration information.

util::runtime_configuration const &get_config () const

std::size_t get_instance_number () const

util::thread_mapper &get_thread_mapper ()
    Return a reference to the internal PAPI thread manager.

threads::topology const &get_topology () const

virtual int run (util::function_nonser<hpx_main_function_type> const &func)
    Run the HPX runtime system, use the given function for the main thread and block waiting for all threads to finish.

Note  The parameter func is optional. If no function is supplied, the runtime system will simply wait for the shutdown action without explicitly executing any main thread.

Return  This function will return the value as returned as the result of the invocation of the function object given by the parameter func.
Parameters

• **func**: [in] This is the main function of an HPX application. It will be scheduled for execution by the thread manager as soon as the runtime has been initialized. This function is expected to expose an interface as defined by the typedef `hpx_main_function_type`. This parameter is optional and defaults to none main thread function, in which case all threads have to be scheduled explicitly.

**virtual int run()**

Run the HPX runtime system, initially use the given number of (OS) threads in the thread-manager and block waiting for all threads to finish.

**Return** This function will always return 0 (zero).

**virtual void rethrow_exception()**

Rethrow any stored exception (to be called after `stop()`)

**virtual int start (util::function_nonser<hpx_main_function_type> const &func, bool blocking = false)**

Start the runtime system.

**Return** If a blocking is a true, this function will return the value as returned as the result of the invocation of the function object given by the parameter `func`. Otherwise it will return zero.

**Parameters**

• **func**: [in] This is the main function of an HPX application. It will be scheduled for execution by the thread manager as soon as the runtime has been initialized. This function is expected to expose an interface as defined by the typedef `hpx_main_function_type`.

• **blocking**: [in] This allows to control whether this call blocks until the runtime system has been stopped. If this parameter is `true` the function runtime::start will call runtime::wait internally.

**virtual int start (bool blocking = false)**

Start the runtime system.

**Return** If a blocking is a true, this function will return the value as returned as the result of the invocation of the function object given by the parameter `func`. Otherwise it will return zero.

**Parameters**

• **blocking**: [in] This allows to control whether this call blocks until the runtime system has been stopped. If this parameter is `true` the function runtime::start will call runtime::wait internally.

**virtual int wait()**

Wait for the shutdown action to be executed.

**Return** This function will return the value as returned as the result of the invocation of the function object given by the parameter `func`.

**virtual void stop (bool blocking = true)**

Initiate termination of the runtime system.

**Parameters**

• **blocking**: [in] This allows to control whether this call blocks until the runtime system has been fully stopped. If this parameter is `false` then this call will initiate the stop action but will return immediately. Use a second call to stop with this parameter set to `true` to wait for all internal work to be completed.
virtual int suspend()
    
Suspend the runtime system.

virtual int resume()
    
Resume the runtime system.

virtual int finalize(double)

virtual bool is_networking_enabled()
    
Return true if networking is enabled.

virtual hpx::threads::threadmanager &get_thread_manager()
    
Allow access to the thread manager instance used by the HPX runtime.

virtual std::string here() const
    
Returns a string of the locality endpoints (usable in debug output)

virtual bool report_error(std::size_t num_thread, std::exception_ptr const &e, bool terminate_all = true)
    
Report a non-recoverable error to the runtime system.

Parameters
• num_thread: [in] The number of the operating system thread the error has been detected in.
• e: [in] This is an instance encapsulating an exception which lead to this function call.

virtual bool report_error(std::exception_ptr const &e, bool terminate_all = true)
    
Report a non-recoverable error to the runtime system.

Note  This function will retrieve the number of the current shepherd thread and forward to the report_error function above.

Parameters
• e: [in] This is an instance encapsulating an exception which lead to this function call.

virtual void add_pre_startup_function(startup_function_type f)
    
Add a function to be executed inside a HPX thread before hpx_main but guaranteed to be executed before any startup function registered with add_startup_function.

Note  The difference to a startup function is that all pre-startup functions will be (system-wide) executed before any startup function.

Parameters
• f: The function ‘f’ will be called from inside a HPX thread before hpx_main is executed. This is very useful to setup the runtime environment of the application (install performance counters, etc.)

virtual void add_startup_function(startup_function_type f)
    
Add a function to be executed inside a HPX thread before hpx_main

Parameters
• f: The function ‘f’ will be called from inside a HPX thread before hpx_main is executed. This is very useful to setup the runtime environment of the application (install performance counters, etc.)

virtual void add_pre_shutdown_function(shutdown_function_type f)
    
Add a function to be executed inside a HPX thread during hpx::finalize, but guaranteed before any of the shutdown functions is executed.
The difference to a shutdown function is that all pre-shutdown functions will be (system-wide) executed before any shutdown function.

Parameters
- \( f \): The function ‘\( f \)’ will be called from inside a HPX thread while \( \text{hpx}::\text{finalize} \) is executed. This is very useful to tear down the runtime environment of the application (uninstall performance counters, etc.)

```cpp
virtual void \textit{add\_shutdown\_function}(\textit{shutdown\_function\_type} \( f \))
```
Add a function to be executed inside a HPX thread during \( \text{hpx}::\text{finalize} \)

Parameters
- \( f \): The function ‘\( f \)’ will be called from inside a HPX thread while \( \text{hpx}::\text{finalize} \) is executed. This is very useful to tear down the runtime environment of the application (uninstall performance counters, etc.)

```cpp
virtual \textit{hpx}::\textit{util}::\textit{io\_service\_pool} \* \textit{get\_thread\_pool}(\textit{char const} \* \textit{name})
```
Access one of the internal thread pools (io\_service instances) HPX is using to perform specific tasks. The three possible values for the argument \textit{name} are “main\_pool”, “io\_pool”, “ parcel\_pool”, and “timer\_pool”. For any other argument value the function will return zero.

```cpp
virtual bool \textit{register\_thread}(\textit{char const} \* \textit{name}, \textit{std}::\textit{size\_t} \textit{num} = 0, bool \textit{service\_thread} = true, \textit{error\_code} \& \textit{ec} = \textit{throws})
```
Register an external OS-thread with HPX.

This function should be called from any OS-thread which is external to HPX (not created by HPX), but which needs to access HPX functionality, such as setting a value on a promise or similar.

Note: The function will compose a thread name of the form ‘<name>-thread#<num>’ which is used to register the thread. It is the user’s responsibility to ensure that each (composed) thread name is unique. HPX internally uses the following names for the threads it creates, do not reuse those:

Parameters
- \textit{name}: [in] The name to use for thread registration.
- \textit{num}: [in] The sequence number to use for thread registration. The default for this parameter is zero.
- \textit{service\_thread}: [in] The thread should be registered as a service thread. The default for this parameter is ‘true’. Any service threads will be pinned to cores not currently used by any of the HPX worker threads.

Note: This function should be called for each thread exactly once. It will fail if it is called more than once.

Return: This function will return whether the requested operation succeeded or not.

```cpp
virtual bool \textit{unregister\_thread}()
```
Unregister an external OS-thread with HPX.

This function will unregister any external OS-thread from HPX.

Note: This function should be called for each thread exactly once. It will fail if it is called more than once. It will fail as well if the thread has not been registered before (see \textit{register\_thread}).

Return: This function will return whether the requested operation succeeded or not.
virtual runtime_local::os_thread_data get_os_thread_data (std::string const &label) const

Access data for a given OS thread that was previously registered by register_thread.

virtual bool enumerate_os_threads (util::function_nonser<bool> runtime_local::os_thread_data const&)

> const &f const& Enumerate all OS threads that have registered with the runtime.

notification_policy_type::on_startstop_type on_start_func () const
notification_policy_type::on_startstop_type on_stop_func () const
notification_policy_type::on_error_type on_error_func () const
notification_policy_type::on_startstop_type on_start_func (notification_policy_type::on_startstop_type&&) notification_policy_type::on_startstop_type on_stop_func (notification_policy_type::on_startstop_type&&) notification_policy_type::on_error_type on_error_func (notification_policy_type::on_error_type&&)

virtual std::uint32_t get_locality_id (error_code &ec) const

virtual std::size_t get_num_worker_threads () const

virtual std::uint32_t get_num_localities (hpx::launch::sync_policy, error_code &ec) const

virtual std::uint32_t get_initial_num_localities () const

virtual lcos::future<std::uint32_t> get_num_localities () const

virtual std::uint32_t assign_cores (std::string const&, std::uint32_t)

virtual std::uint32_t assign_cores ()

Public Static Functions

Private Functions

void stop_helper (bool blocking, std::condition_variable &cond, std::mutex &mtx)
  Helper function to stop the runtime.

  Parameters
  • blocking: [in] This allows to control whether this call blocks until the runtime system has
    been fully stopped. If this parameter is false then this call will initiate the stop action but will
    return immediately. Use a second call to stop with this parameter set to true to wait for all
    internal work to be completed.

namespace threads

Functions

char const *get_stack_size_name (std::ptrdiff_t size)
Returns the stack size name.
Get the readable string representing the given stack size constant.

Parameters
• size: this represents the stack size

std::ptrdiff_t get_default_stack_size ()
Returns the default stack size.
Get the default stack size in bytes.

std::ptrdiff_t get_stack_size (thread_stacksize)
Returns the stack size corresponding to the given stack size enumeration.
Get the stack size corresponding to the given stack size enumeration.

Parameters
• size: this represents the stack size

namespace util
# Functions

```cpp
bool retrieve_commandline_arguments (hpx::program_options::options_description const &app_options,
                                    hpx::program_options::variables_map &vm)
```

```cpp
bool retrieve_commandline_arguments (std::string const &appname,
                                    hpx::program_options::variables_map &vm)
```

```cpp
namespace hpx {

    # Functions

    bool register_thread (runtime *rt, char const *name, error_code &ec = throws)
    
    Register the current kernel thread with HPX, this should be done once for each external OS-thread intended
to invoke HPX functionality. Calling this function more than once will return false.

    void unregister_thread (runtime *rt)
    
    Unregister the thread from HPX, this should be done once in the end before the external thread exists.

    runtime_local::os_thread_data get_os_thread_data (std::string const &label)
    
    Access data for a given OS thread that was previously registered by register_thread. This function must
be called from a thread that was previously registered with the runtime.

    bool enumerate_os_threads (util::function_nonser<bool>
                           os_thread_data const&
                           > const &f)
    
    Enumerate all OS threads that have registered with the runtime.

    std::size_t get_runtime_instance_number ()
    
    Return the runtime instance number associated with the runtime instance the current thread is running in.

    bool register_on_exit (util::function_nonser<void>)
    
    &fRegister a function to be called during system shutdown.

    bool is_starting ()
    
    Test whether the runtime system is currently being started.
    
    This function returns whether the runtime system is currently being started or not, e.g. whether the current
state of the runtime system is hpx::state_startup

    # Note This function needs to be executed on a HPX-thread. It will return false otherwise.

    bool tolerate_node_faults ()
    
    Test if HPX runs in fault-tolerant mode.
    
    This function returns whether the runtime system is running in fault-tolerant mode

    bool is_running ()
    
    Test whether the runtime system is currently running.
    
    This function returns whether the runtime system is currently running or not, e.g. whether the current state
of the runtime system is hpx::state_running

    # Note This function needs to be executed on a HPX-thread. It will return false otherwise.
```
bool is_stopped()
  Test whether the runtime system is currently stopped.
  This function returns whether the runtime system is currently stopped or not, e.g. whether the current state of the runtime system is `hpx::state_stopped`.

**Note** This function needs to be executed on a HPX-thread. It will return false otherwise.

bool is_stopped_or_shutting_down()
  Test whether the runtime system is currently being shut down.
  This function returns whether the runtime system is currently being shut down or not, e.g. whether the current state of the runtime system is `hpx::state_stopped` or `hpx::state_shutdown`.

**Note** This function needs to be executed on a HPX-thread. It will return false otherwise.

`std::size_t` get_num_worker_threads()
  Return the number of worker OS-threads used to execute HPX threads.
  This function returns the number of OS-threads used to execute HPX threads. If the function is called while no HPX runtime system is active, it will return zero.

`std::uint64_t` get_system_uptime()
  Return the system uptime measure on the thread executing this call.
  This function returns the system uptime measured in nanoseconds for the thread executing this call. If the function is called while no HPX runtime system is active, it will return zero.

namespace hpx

Typedefs

typedef util::unique_function_nonser< void () > shutdown_function_type

The type of a function which is registered to be executed as a shutdown or pre-shutdown function.

Functions

void register_pre_shutdown_function(shutdown_function_type f)

Add a function to be executed by a HPX thread during hpx::finalize() but guaranteed before any shutdown function is executed (system-wide)

Any of the functions registered with register_pre_shutdown_function are guaranteed to be executed by an HPX thread during the execution of hpx::finalize() before any of the registered shutdown functions are executed (see: hpx::register_shutdown_function()).

Note If this function is called while the pre-shutdown functions are being executed, or after that point, it will raise a invalid_status exception.

See hpx::register_shutdown_function()
Parameters

- \( f \): [in] The function to be registered to run by an HPX thread as a pre-shutdown function.

```cpp
void register_shutdown_function (shutdown_function_type f)
```

Add a function to be executed by a HPX thread during `hpx::finalize()` but guaranteed after any pre-shutdown function is executed (system-wide).

Any of the functions registered with `register_shutdown_function` are guaranteed to be executed by an HPX thread during the execution of `hpx::finalize()` after any of the registered pre-shutdown functions are executed (see: `hpx::register_pre_shutdown_function()`).

**Note** If this function is called while the shutdown functions are being executed, or after that point, it will raise a `invalid_status` exception.

**See** `hpx::register_pre_shutdown_function()`

**Parameters**

- \( f \): [in] The function to be registered to run by an HPX thread as a shutdown function.

```cpp
namespace hpx
```

**Typedefs**

```cpp
typedef util::unique_function_nonser<void () > startup_function_type
```

The type of a function which is registered to be executed as a startup or pre-startup function.

**Functions**

```cpp
void register_pre_startup_function (startup_function_type f)
```

Add a function to be executed by a HPX thread before `hpx_main` but guaranteed before any startup function is executed (system-wide).

Any of the functions registered with `register_pre_startup_function` are guaranteed to be executed by an HPX thread before any of the registered startup functions are executed (see `hpx::register_startup_function()`).

This function is one of the few API functions which can be called before the runtime system has been fully initialized. It will automatically stage the provided startup function to the runtime system during its initialization (if necessary).

**Note** If this function is called while the pre-startup functions are being executed or after that point, it will raise a `invalid_status` exception.

**Parameters**

- \( f \): [in] The function to be registered to run by an HPX thread as a pre-startup function.

```cpp
See hpx::register_startup_function()
```

```cpp
void register_startup_function (startup_function_type f)
```

Add a function to be executed by a HPX thread before `hpx_main` but guaranteed after any pre-startup function is executed (system-wide).
Any of the functions registered with \texttt{register\_startup\_function} are guaranteed to be executed by an HPX thread after any of the registered pre-startup functions are executed (see: hpx::register\_pre\_startup\_function()), but before hpx\_main is being called.

This function is one of the few API functions which can be called before the runtime system has been fully initialized. It will automatically stage the provided startup function to the runtime system during its initialization (if necessary).

\textbf{Note} If this function is called while the startup functions are being executed or after that point, it will raise a invalid\_status exception.

\textbf{Parameters}

\begin{itemize}
\item \texttt{f}: [in] The function to be registered to run by an HPX thread as a startup function.
\end{itemize}

\textbf{See} hpx::register\_pre\_startup\_function()

```
namespace hpx
    namespace threads

    Functions

    bool threadmanager\_is (state st)
    bool threadmanager\_is\_at\_least (state st)
```

```
namespace hpx

    Functions

    threads::policies::callback\_notifier::on\_startstop\_type
    get\_thread\_on\_start\_func ()
    Retrieve the currently installed start handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered start function chains into the previous one (see register\_thread\_on\_start\_func).

    \textbf{Return} The currently installed error handler function.

    \textbf{Note} This function can be called before the HPX runtime is initialized.

    threads::policies::callback\_notifier::on\_startstop\_type
    get\_thread\_on\_stop\_func ()
    Retrieve the currently installed stop handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered stop function chains into the previous one (see register\_thread\_on\_stop\_func).

    \textbf{Return} The currently installed error handler function.

    \textbf{Note} This function can be called before the HPX runtime is initialized.
threads::policies::callback_notifier::on_error_type get_thread_on_error_func()

Retrieve the currently installed error handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered error function chains into the previous one (see register_thread_on_error_func).

Return The currently installed error handler function.

Note This function can be called before the HPX runtime is initialized.

threads::policies::callback_notifier::on_startstop_type register_thread_on_start_func(threads::policies::callback_notifier::on_startstop_type &&f)

Set the currently installed start handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered start function chains into the previous one (see get_thread_on_start_func).

Return The previously registered function of this category. It is the user’s responsibility to call that function if the callback is invoked by HPX.

Note This function can be called before the HPX runtime is initialized.

Parameters

• f: The function to install as the new start handler.

threads::policies::callback_notifier::on_startstop_type register_thread_on_stop_func(threads::policies::callback_notifier::on_startstop_type &&f)

Set the currently installed stop handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered stop function chains into the previous one (see get_thread_on_stop_func).

Return The previously registered function of this category. It is the user’s responsibility to call that function if the callback is invoked by HPX.

Note This function can be called before the HPX runtime is initialized.

Parameters

• f: The function to install as the new stop handler.

threads::policies::callback_notifier::on_error_type register_thread_on_error_func(threads::policies::callback_notifier::on_error_type &&f)

Set the currently installed error handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered error function chains into the previous one (see get_thread_on_error_func).

Return The previously registered function of this category. It is the user’s responsibility to call that function if the callback is invoked by HPX.

Note This function can be called before the HPX runtime is initialized.

Parameters
• \( f \): The function to install as the new error handler.

namespace hpx

namespace resource

Functions

std::size_t get_num_thread_pools ()
   Return the number of thread pools currently managed by the resource_partitioner

std::size_t get_num_threads ()
   Return the number of threads in all thread pools currently managed by the resource_partitioner

std::size_t get_num_threads (std::string const &pool_name)
   Return the number of threads in the given thread pool currently managed by the resource_partitioner

std::size_t get_num_threads (std::size_t pool_index)
   Return the number of threads in the given thread pool currently managed by the resource_partitioner

std::size_t get_pool_index (std::string const &pool_name)
   Return the internal index of the pool given its name.

std::string const &get_pool_name (std::size_t pool_index)
   Return the name of the pool given its internal index.

threads::thread_pool_base &get_thread_pool (std::string const &pool_name)
   Return the name of the pool given its name.

threads::thread_pool_base &get_thread_pool (std::size_t pool_index)
   Return the thread pool given its internal index.

bool pool_exists (std::string const &pool_name)
   Return true if the pool with the given name exists.

bool pool_exists (std::size_t pool_index)
   Return true if the pool with the given index exists.

namespace threads
Functions

```cpp
std::int64_t get_thread_count(thread_schedule_state state = thread_schedule_state::unknown)
```

The function `get_thread_count` returns the number of currently known threads.

**Note** If `state == unknown` this function will not only return the number of currently existing threads, but will add the number of registered task descriptions (which have not been converted into threads yet).

**Parameters**
- `state`: [in] This specifies the thread-state for which the number of threads should be retrieved.

```cpp
std::int64_t get_thread_count(thread_priority priority, thread_schedule_state state = thread_schedule_state::unknown)
```

The function `get_thread_count` returns the number of currently known threads.

**Note** If `state == unknown` this function will not only return the number of currently existing threads, but will add the number of registered task descriptions (which have not been converted into threads yet).

**Parameters**
- `priority`: [in] This specifies the thread-priority for which the number of threads should be retrieved.
- `state`: [in] This specifies the thread-state for which the number of threads should be retrieved.

```cpp
std::int64_t get_idle_core_count()
```

The function `get_idle_core_count` returns the number of currently idling threads (cores).

```cpp
mask_type get_idle_core_mask()
```

The function `get_idle_core_mask` returns a bit-mask representing the currently idling threads (cores).

```cpp
bool enumerate_threads(util::function_nonser<bool> thread_id_type
> const &f, thread_schedule_state state = thread_schedule_state::unknown)
```

The function `enumerate_threads` will invoke the given function `f` for each thread with a matching thread state.

**Parameters**
- `f`: [in] The function which should be called for each matching thread. Returning ‘false’ from this function will stop the enumeration process.
- `state`: [in] This specifies the thread-state for which the threads should be enumerated.

namespace hpx

namespace threads

class threadmanager

#include <threadmanager.hpp> The thread-manager class is the central instance of management for all (non-depleted) threads

Public Types

typedef threads::policies::callback_notifier notification_policy_type

typedef std::unique_ptr<thread_pool_base> pool_type

typedef threads::policies::scheduler_base scheduler_type

typedef std::vector<pool_type> pool_vector

Public Functions

threadmanager (util::runtime_configuration &rtcfg_, notification_policy_type &notifier, detail::network_background_callback_type network_background_callback = detail::network_background_callback_type())

~threadmanager ()

void init ()

void create_pools ()

void print_pools (std::ostream&)

    FIXME move to private and add hpx:printpools cmd line option.

thread_pool_base &default_pool () const

scheduler_type &default_scheduler () const

thread_pool_base &get_pool (std::string const &pool_name) const

thread_pool_base &get_pool (pool_id_type const &pool_id) const

thread_pool_base &get_pool (std::size_t thread_index) const
bool pool_exists(const std::string &pool_name) const

bool pool_exists(size_t pool_index) const

void register_work(thread_init_data &data, error_code &ec = throws)

    The function register_work adds a new work item to the thread manager. It doesn’t immediately create a new thread, it just adds the task parameters (function, initial state and description) to the internal management data structures. The thread itself will be created when the number of existing threads drops below the number of threads specified by the constructors max_count parameter.

Parameters

- func: [in] The function or function object to execute as the thread’s function. This must have a signature as defined by thread_function_type.
- description: [in] The value of this parameter allows to specify a description of the thread to create. This information is used for logging purposes mainly, but might be useful for debugging as well. This parameter is optional and defaults to an empty string.

void register_thread(thread_init_data &data, thread_id_type &id, error_code &ec = throws)

    The function register_thread adds a new work item to the thread manager. It creates a new thread, adds it to the internal management data structures, and schedules the new thread, if appropriate.

Parameters

- func: [in] The function or function object to execute as the thread’s function. This must have a signature as defined by thread_function_type.
- id: [out] This parameter will hold the id of the created thread. This id is guaranteed to be validly initialized before the thread function is executed.
- description: [in] The value of this parameter allows to specify a description of the thread to create. This information is used for logging purposes mainly, but might be useful for debugging as well. This parameter is optional and defaults to an empty string.

bool run()

    Run the thread manager’s work queue. This function instantiates the specified number of OS threads in each pool. All OS threads are started to execute the function tfunc.

    Return The function returns true if the thread manager has been started successfully, otherwise it returns false.

void stop(bool blocking = true)

    Forcefully stop the thread-manager.

Parameters

- blocking:

void suspend()

void resume()

state status() const

    Return whether the thread manager is still running. This returns the “minimal state”, i.e. the state of the least advanced thread pool.
\texttt{std::int64_t \textbf{get_thread_count} (thread_schedule_state \texttt{state} =
thread_schedule_state::unknown, \texttt{thread_priority \texttt{priority} = thread_priority::default_, \texttt{std::size_t num_thread} =
\texttt{std::size_t(-1), bool reset = false})}

return the number of HPX-threads with the given state

\textbf{Note} This function lock the internal OS lock in the thread manager

\texttt{std::int64_t \textbf{get_idle_core_count} ()}

\texttt{mask_type \textbf{get_idle_core_mask} ()}

\texttt{std::int64_t \textbf{get_background_thread_count} ()}

\texttt{bool \textbf{enumerate_threads} (util::function_nonser<\texttt{bool}) thread_id_type
\texttt{> const \&f, thread_schedule_state \texttt{state} = thread_schedule_state::unknown \texttt{const}}

\texttt{void \textbf{abort_all_suspended_threads} ()}

\texttt{bool \textbf{cleanup_terminated} (bool \texttt{delete_all})}

\texttt{std::size_t \textbf{get_os_thread_count} () \texttt{const}}

Return the number of OS threads running in this thread-manager.

This function will return correct results only if the thread-manager is running.

\texttt{std::thread \&\textbf{get_os_thread_handle} (\texttt{std::size_t num_thread}) \texttt{const}}

\texttt{void \textbf{report_error} (\texttt{std::size_t num_thread, \texttt{std::exception_ptr const \&e})}

API functions forwarding to notification policy.

This notifies the thread manager that the passed exception has been raised. The exception will be routed through the notifier and the scheduler (which will result in it being passed to the runtime object, which in turn will report it to the console, etc.).

\texttt{mask_type \textbf{get_used_processing_units} () \texttt{const}}

Returns the mask identifying all processing units used by this thread manager.

\texttt{hwloc_bitmap_ptr \textbf{get_pool_numa_bitmap} (const \texttt{std::string \&pool_name}) \texttt{const}}

\texttt{void \textbf{set_scheduler_mode} (\texttt{threads::policies::scheduler_mode mode})}

\texttt{void \textbf{add_scheduler_mode} (\texttt{threads::policies::scheduler_mode mode})}

\texttt{void \textbf{add_remove_scheduler_mode} (\texttt{threads::policies::scheduler_mode to_add_mode}, \texttt{threads::policies::scheduler_mode to_remove_mode})}

Typedefs

using spmd_block = hpx::lcos::local::spmd_block
The class spmd_block defines an interface for launching multiple images while giving handles to each image to interact with the remaining images. The define_spmd_block function templates create multiple images of a user-defined function (or lambda) and launches them in a possibly separate thread. A temporary spmd block object is created and diffused to each image. The constraint for the function (or lambda) given to the define_spmd_block function is to accept a spmd_block as first parameter.

Functions

namespace hpx

namespace parallel
Functions

template<typename ExPolicy, typename F>
util::detail::algorithm_result<ExPolicy>::type define_task_block (ExPolicy &&policy, F &&f)

Constructs a task_block, tr, using the given execution policy policy, and invokes the expression f(tr) on the user-provided object, f.

Postcondition: All tasks spawned from f have finished execution. A call to define_task_block may return on a different thread than that on which it was called.

Template Parameters
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the task block may be parallelized.
- F: The type of the user defined function to invoke inside the define_task_block (deduced). F shall be MoveConstructible.

Parameters
- policy: The execution policy to use for the scheduling of the iterations.
- f: The user defined function to invoke inside the task block. Given an lvalue tr of type task_block, the expression, (void)f(tr), shall be well-formed.

Note It is expected (but not mandated) that f will (directly or indirectly) call tr.run(callable_object).

Exceptions
- An exception_list, as specified in Exception Handling.

template<typename F>
void define_task_block (F &&f)

Constructs a task_block, tr, and invokes the expression f(tr) on the user-provided object, f. This version uses parallel_policy for task scheduling.

Postcondition: All tasks spawned from f have finished execution. A call to define_task_block may return on a different thread than that on which it was called.

Template Parameters
- F: The type of the user defined function to invoke inside the define_task_block (deduced). F shall be MoveConstructible.

Parameters
- f: The user defined function to invoke inside the task block. Given an lvalue tr of type task_block, the expression, (void)f(tr), shall be well-formed.

Note It is expected (but not mandated) that f will (directly or indirectly) call tr.run(callable_object).

Exceptions
- An exception_list, as specified in Exception Handling.

template<typename ExPolicy, typename F>
util::detail::algorithm_result<ExPolicy>::type define_task_block_restore_thread (ExPolicy &&policy, F &&f)

Constructs a task_block, tr, and invokes the expression f(tr) on the user-provided object, f.

Postcondition: All tasks spawned from f have finished execution. A call to define_task_block_restore_thread always returns on the same thread as that on which it was called.
Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the task block may be parallelized.
- **F**: The type of the user defined function to invoke inside the define_task_block (deduced). \( F \) shall be MoveConstructible.

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **f**: The user defined function to invoke inside the define_task_block. Given an lvalue \( tr \) of type task_block, the expression, \((\text{void})f(tr)\), shall be well-formed.

Exceptions

- An: exception_list, as specified in Exception Handling.

**Note**

It is expected (but not mandated) that \( f \) will (directly or indirectly) call \( tr.\text{run}() \).

```cpp
template<
  typename F = hpx::execution::parallel_policy
>

void define_task_block_restore_thread(F &&f)

Constructs a task_block, \( tr \), and invokes the expression \( f(tr) \) on the user-provided object, \( f \). This version uses \textit{parallel\_policy} for task scheduling.

Postcondition: All tasks spawned from \( f \) have finished execution. A call to \textit{define\_task\_block\_restore\_thread} always returns on the same thread as that on which it was called.

namespace v2

template<
  typename ExPolicy = hpx::execution::parallel_policy
>

class task_block

#include <task_block.hpp> The class task_block defines an interface for forking and joining parallel tasks. The \textit{define\_task\_block} and \textit{define\_task\_block\_restore\_thread} function templates create an object of type task_block and pass a reference to that object to a user-provided callable object.

An object of class task_block cannot be constructed, destroyed, copied, or moved except by the implementation of the task region library. Taking the address of a task_block object via \texttt{operator&} or \texttt{addressof} is ill formed. The result of obtaining its address by any other means is unspecified.

A task_block is active if it was created by the nearest enclosing task block, where “task block” refers to an invocation of \textit{define\_task\_block} or \textit{define\_task\_block\_restore\_thread} and “nearest enclosing” means the most recent invocation that has not yet completed. Code designated for execution in another thread by means other than the facilities in this section (e.g., using thread or async) are not enclosed in the task region and a task_block passed to (or captured by) such code is not active within that code. Performing any operation on a task_block that is not active results in undefined behavior.
The task_block that is active before a specific call to the run member function is not active within the asynchronous function that invoked run. (The invoked function should not, therefore, capture the task_block from the surrounding block.)

Example:
```cpp
define_task_block([&] (auto & tr) {
    tr.run([&] {
        tr.run([] { f(); });
    });
    // Error: tr is not active
}
```
```cpp
define_task_block([&] (auto & tr) {
    tr.run(f);
    // OK: inner tr is active
```
until compute resources are available. `run` might or might not return before invocation of `f` completes.

**Exceptions**
- This function may throw `task_canceled_exception`, as described in Exception Handling.

```cpp
template<typename Executor, typename F, typename ... Ts>
void run(Executor & exec, F && f, Ts&&... ts)
```

Causes the expression `f()` to be invoked asynchronously using the given executor. The invocation of `f` is permitted to run on an unspecified thread associated with the given executor and in an unordered fashion relative to the sequence of operations following the call to `run(exec, f)` (the continuation), or indeterminately sequenced within the same thread as the continuation.

The call to `run` synchronizes with the invocation of `f`. The completion of `f()` synchronizes with the next invocation of `wait` on the same `task_block` or completion of the nearest enclosing task block (i.e., the `define_task_block` or `define_task_block_restore_thread` that created this task block).

Requires: `Executor` shall be a type modeling the `Executor` concept. `F` shall be `MoveConstructible`. The expression, `(void)f()`, shall be well-formed.

Precondition: this shall be the active `task_block`.

Postconditions: A call to `run` may return on a different thread than that on which it was called.

**Note** The call to `run` is sequenced before the continuation as if `run` returns on the same thread. The invocation of the user-supplied callable object `f` may be immediate or may be delayed until compute resources are available. `run` might or might not return before invocation of `f` completes.

**Exceptions**
- This function may throw `task_canceled_exception`, as described in Exception Handling.

```cpp
void wait()
```

Blocks until the tasks spawned using this `task_block` have finished.

Precondition: this shall be the active `task_block`.

Postcondition: All tasks spawned by the nearest enclosing task region have finished. A call to `wait` may return on a different thread than that on which it was called.

**Example:**
```cpp
define_task_block([s](auto& tr) {
  tr.run([s][ process(a, w, x); }); // Process a[w] through _
  if (y < x) tr.wait(); // Wait if overlap between [w, x)
  and [y, z)
  process(a, y, z); // Process a[y] through a[z]
});
```

**Note** The call to `wait` is sequenced before the continuation as if `wait` returns on the same thread.

**Exceptions**
- This function may throw `task_canceled_exception`, as described in Exception Handling.

```cpp
ExPolicy & policy()
```

Returns a reference to the execution policy used to construct this object.

Precondition: this shall be the active `task_block`.

---

2.8. API reference 975
ExPolicy const &policy() const

Returns a reference to the execution policy used to construct this object.

Precondition: this shall be the active task_block.

task_canceled_exception()

namespace hpx

namespace parallel

**Functions**

template<typename ExPolicy, typename FwdIter1, typename FwdIter2>

std::enable_if<hpx::isExecutionPolicy<ExPolicy>::value, typename util::detail::algorithm_result<ExPolicy, FwdIter2>::type>

Assigns each value in the range given by result its corresponding element in the range [first, last] and the one preceding it except *result, which is assigned *first

The difference operations in the parallel adjacent_difference invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Exactly (last - first) - 1 application of the binary operator and (last - first) assignments.

**Template Parameters**

- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• **FwdIter1**: The type of the source iterators used for the input range (deduced). This iterator type must meet the requirements of an forward iterator.

• **FwdIter2**: The type of the source iterators used for the output range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

• **policy**: The execution policy to use for the scheduling of the iterations.

• **first**: Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.

• **last**: Refers to the end of the sequence of elements of the range the algorithm will be applied to.

• **dest**: Refers to the beginning of the sequence of elements the results will be assigned to.

The difference operations in the parallel `adjacent_difference` invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of `adjacent_find` is available if the user decides to provide their algorithm their own binary predicate `op`.

**Return** The `adjacent_difference` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `adjacent_find` algorithm returns an iterator to the last element in the output range.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Op>
std::enable_if<hpx::is_execution_policy<ExPolicy>::value, typename util::detail::algorithm_result<ExPolicy, FwdIter2>::type>::type
adjacent_difference(ExPolicy&& policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest, Op&& op)
```

Assigns each value in the range given by result its corresponding element in the range [first, last] and the one preceding it except *result, which is assigned *first.

The difference operations in the parallel `adjacent_difference` invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Exactly (last - first) - 1 application of the binary operator and (last - first) assignments.

**Template Parameters**

• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **FwdIter1**: The type of the source iterators used for the input range (deduced). This iterator type must meet the requirements of an forward iterator.

• **FwdIter2**: The type of the source iterators used for the output range (deduced). This iterator type must meet the requirements of an forward iterator.

• **Op**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `adjacent_difference` requires `Op` to meet the requirements of CopyConstructible.

**Parameters**
• **policy**: The execution policy to use for the scheduling of the iterations.
• **first**: Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
• **last**: Refers to the end of the sequence of elements of the range the algorithm will be applied to.
• **dest**: Refers to the beginning of the sequence of elements the results will be assigned to.
• **op**: The binary operator which returns the difference of elements. The signature should be equivalent to the following:

```cpp
bool op(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types `Type1` must be such that objects of type `FwdIter1` can be dereferenced and then implicitly converted to the dereferenced type of `dest`.

The difference operations in the parallel `adjacent_difference` invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return: The `adjacent_difference` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `adjacent_find` algorithm returns an iterator to the last element in the output range.

```cpp
namespace hpx
```

**Functions**

```cpp
template<typename FwdIter, typename Pred = detail::equal_to>
FwdIter adjacent_find(FwdIter first, FwdIter last, Pred &&pred = Pred())
```

Searches the range `[first, last)` for two consecutive identical elements.

**Note** Complexity: Exactly the smaller of `(result - first) + 1` and `(last - first) - 1` application of the predicate where `result` is the value returned.

Return: The `adjacent_find` algorithm returns an iterator to the first of the identical elements. If no such elements are found, `last` is returned.

**Template Parameters**

- **FwdIter**: The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred**: The type of an optional function/function object to use.

**Parameters**

- **first**: Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **pred**: The binary predicate which returns `true` if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```
The signature does not need to have const &, but the function must not modify the objects passed to it. The types \( \text{Type1} \) must be such that objects of type \( \text{FwdIter} \) can be dereferenced and then implicitly converted to \( \text{Type1} \).

\[
\text{template<typename \text{ExPolicy}, typename \text{FwdIter}, typename \text{Pred} = \text{detail::equal_to}}
\\text{std::enable_if<\text{hpx::is_execution_policy}\langle\text{ExPolicy}\rangle::\text{value}, typename \text{util::detail::algorithm_result}\langle\text{ExPolicy}, \text{FwdIter}\rangle::\text{type}>::\text{type}
\\text{adjacent_find}\]
\[
(\text{ExPolicy} && \text{policy}, \text{FwdIter} \text{first}, \text{FwdIter} \text{last}, \text{Pred} && \text{pred} = \text{Pred}())
\]

Searches the range [first, last) for two consecutive identical elements. This version uses the given binary predicate \( \text{pred} \).

The comparison operations in the parallel \( \text{adjacent_find} \) invoked with an execution policy object of type \( \text{sequenced_policy} \) execute in sequential order in the calling thread.

**Note** Complexity: Exactly the smaller of (result - first) + 1 and (last - first) - 1 application of the predicate where \( \text{result} \) is the value returned

**Template Parameters**

- \( \text{ExPolicy} \): The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- \( \text{FwdIter} \): The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- \( \text{Pred} \): The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of \( \text{adjacent_find} \) requires \( \text{Pred} \) to meet the requirements of \( \text{CopyConstructible} \). This defaults to \( \text{std::equal_to}<> \)

**Parameters**

- \( \text{policy} \): The execution policy to use for the scheduling of the iterations.
- \( \text{first} \): Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- \( \text{last} \): Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- \( \text{pred} \): The binary predicate which returns \( \text{true} \) if the elements should be treated as equal. The signature should be equivalent to the following:

\[
\text{bool pred(const \text{Type1} \&a, const \text{Type1} \&b);}
\]

The signature does not need to have const &, but the function must not modify the objects passed to it. The types \( \text{Type1} \) must be such that objects of type \( \text{FwdIter} \) can be dereferenced and then implicitly converted to \( \text{Type1} \).
The comparison operations in the parallel `adjacent_find` invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of `adjacent_find` is available if the user decides to provide their algorithm their own binary predicate `pred`.

**Return** The `adjacent_find` algorithm returns a `hpx::future<InIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `InIter` otherwise. The `adjacent_find` algorithm returns an iterator to the first of the identical elements. If no such elements are found, `last` is returned.

```cpp
namespace hpx
{

Functions

template<typename ExPolicy, typename FwdIter, typename F, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, bool>::type none_of(ExPolicy &&policy, FwdIter first, FwdIter last, F &&f, Proj &&proj = Proj())
Checks if unary predicate `f` returns true for no elements in the range `[first, last)`.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: At most `last - first` applications of the predicate `f`

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- `FwdIter`: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- `F`: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `none_of` requires `F` to meet the requirements of `CopyConstructible`.
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- `policy`: The execution policy to use for the scheduling of the iterations.
- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last`: Refers to the end of the sequence of elements the algorithm will be applied to.
- `f`: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`. 

---

980 Chapter 2. What’s so special about HPX?
• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The none_of algorithm returns a hpx::future<bool> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns bool otherwise. The none_of algorithm returns true if the unary predicate \( f \) returns true for no elements in the range, false otherwise. It returns true if the range is empty.

```cpp
template<
    typename ExPolicy,
    typename FwdIter,
    typename F,
    typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, bool>::type none_of(
    ExPolicy &&policy,
    FwdIter first,
    FwdIter last,
    F &&f,
    Proj &&proj = Proj())
```

Checks if unary predicate \( f \) returns true for at least one element in the range \([first, last)\).

The application of function objects in parallel algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: At most \( last - first \) applications of the predicate \( f \)

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of any_of requires \( F \) to meet the requirements of CopyConstructible.
- **Proj**: The type of an optional projection function. This defaults to util::projection_identity

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([first, last)\). The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type FwdIter can be dereferenced and then implicitly converted to Type.

- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
Return The *any_of* algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The *any_of* algorithm returns true if the unary predicate `f` returns true for at least one element in the range, false otherwise. It returns false if the range is empty.

```cpp
template<typename ExPolicy, typename FwdIter, typename F, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, bool>::type all_of(
    ExPolicy &&policy,
    FwdIter first,
    FwdIter last,
    F &&f, Proj &&proj = Proj())
```

Checks if unary predicate `f` returns true for all elements in the range `[first, last)`. The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

Note Complexity: At most `last - first` applications of the predicate `f`

Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `all_of` requires `F` to meet the requirements of `CopyConstructible`.
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The *all_of* algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The *all_of* algorithm returns true if the unary predicate `f` returns true for all elements in the range, false otherwise. It returns true if the range is empty.
namespace hpx

Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2>

hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type copy(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest)

Copies the elements in the range, defined by [first, last), to another range beginning at dest.

The assignments in the parallel copy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Performs exactly last - first assignments.

Template Parameters

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• FwdIter1: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

• FwdIter2: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

• policy: The execution policy to use for the scheduling of the iterations.

• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.

• last: Refers to the end of the sequence of elements the algorithm will be applied to.

• dest: Refers to the beginning of the destination range.

The assignments in the parallel copy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The copy algorithm returns a hpx::future<FwdIter2> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter2> otherwise. The copy algorithm returns the pair of the input iterator last and the output iterator to the element in the destination range, one past the last element copied.

template<typename ExPolicy, typename FwdIter1, typename Size, typename FwdIter2>

hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type copy_n(ExPolicy &&policy, FwdIter1 first, Size count, FwdIter2 dest)

Copies the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest.

The assignments in the parallel copy_n algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Performs exactly count assignments, if count > 0, no assignments otherwise.
Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size**: The type of the argument specifying the number of elements to apply \( f \) to.
- **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count**: Refers to the number of elements starting at \( \text{first} \) the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.

The assignments in the parallel \( \text{copy}_n \) algorithm invoked with an execution policy object of type \( \text{parallel}_\text{policy} \) or \( \text{parallel}_\text{task}_\text{policy} \) are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return**
The \( \text{copy}_n \) algorithm returns a \( \text{hpx::future<}F\text{wdIter2>} \) if the execution policy is of type \( \text{sequenced}_\text{task}_\text{policy} \) or \( \text{parallel}_\text{task}_\text{policy} \) and returns \( F\text{wdIter2} \) otherwise. The \( \text{copy} \) algorithm returns the pair of the input iterator forwarded to the first element after the last in the input sequence and the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename F>

hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type

\text{copy}_\text{if}(ExPolicy &&\text{policy}, FwdIter1 first, FwdIter1 last, FwdIter2 dest, Pred &&\text{pred})
```

Copies the elements in the range, defined by \([\text{first}, \text{last})\), to another range beginning at \( \text{dest} \). Copies only the elements for which the predicate \( f \) returns true. The order of the elements that are not removed is preserved.

The assignments in the parallel \( \text{copy}_\text{if} \) algorithm invoked with an execution policy object of type \( \text{sequenced}_\text{policy} \) execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than \( \text{last} - \text{first} \) assignments, exactly \( \text{last} - \text{first} \) applications of the predicate \( f \).

Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
• **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `copy_if` requires `F` to meet the requirements of `CopyConstructible`.

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

  ```cpp
  bool pred(const Type &a);
  ```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`.

The assignments in the parallel `copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

### Return

The `copy_if` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `copy` algorithm returns the pair of the input iterator forwarded to the first element after the last in the input sequence and the output iterator to the element in the destination range, one past the last element copied.

### Functions

```cpp
namespace hpx
{

template<
typename ExPolicy,
typename FwdIterB,
typename FwdIterE,
typename T,
typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy,
typename std::iterator_traits<FwdIterB>::difference_type>::type
count(ExPolicy &&policy,
FwdIterB first,
FwdIterE last,
T const &value,
Proj &&proj = Proj())
```

Returns the number of elements in the range `[first, last)` satisfying a specific criteria. This version counts the elements that are equal to the given `value`.

The comparisons in the parallel `count` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.
Note Complexity: Performs exactly last - first comparisons.

Template Parameters
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the comparisons.
- `FwdIterB`: The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- `FwdIterE`: The type of the source end iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- `T`: The type of the value to search for (deduced).
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`

Parameters
- `policy`: The execution policy to use for the scheduling of the iterations.
- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last`: Refers to the end of the sequence of elements the algorithm will be applied to.
- `value`: The value to search for.
- `proj`: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Note The comparisons in the parallel `count` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The `count` algorithm returns a `hpx::future<difference_type>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `difference_type` otherwise (where `difference_type` is defined by `std::iterator_traits<Iter>::difference_type`). The `count` algorithm returns the number of elements satisfying the given criteria.

```
template<
  typename ExPolicy, 
  typename Iter, 
  typename Sent, 
  typename F, 
  typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, std::iterator_traits<Iter>::difference_type>::type count_if(
    ExPolicy &&policy,
    Iter &&first,
    Sent &&last,
    F &&f,
    Proj &&&proj = Proj())
```

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts elements for which predicate f returns true.

Note Complexity: Performs exactly last - first applications of the predicate.
Note The assignments in the parallel count_if algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note The assignments in the parallel count_if algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The count_if algorithm returns hpx::future<difference_type> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns difference_type otherwise (where difference_type is defined by std::iterator_traits<FwdIterB>::difference_type. The count algorithm returns the number of elements satisfying the given criteria.

Template Parameters

- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the comparisons.
- Iter: The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- Sent: The type of the source end iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- F: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of count_if requires F to meet the requirements of CopyConstructible.
- Proj: The type of an optional projection function. This defaults to util::projection_identity

Parameters

- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last: Refers to the end of the sequence of elements the algorithm will be applied to.
- f: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns true for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type FwdIterB can be dereferenced and then implicitly converted to Type.

- proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

namespace hpx

2.8. API reference 987
Functions

template<typename ExPolicy, typename FwdIter>
util::detail::algorithm_result<ExPolicy>::type destroy(ExPolicy &&policy, FwdIter first, FwdIter last)
Destroys objects of type typename iterator_traits<ForwardIt>::value_type in the range [first, last).

The operations in the parallel destroy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Performs exactly last - first operations.

Template Parameters

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• FwdIter: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

• policy: The execution policy to use for the scheduling of the iterations.

• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.

• last: Refers to the end of the sequence of elements the algorithm will be applied to.

The operations in the parallel destroy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The destroy algorithm returns a hpx::future<void>, if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns void otherwise.

template<typename ExPolicy, typename FwdIter, typename Size>
util::detail::algorithm_result<ExPolicy, FwdIter>::type destroy_n(ExPolicy &&policy, FwdIter first, Size count)
Destroys objects of type typename iterator_traits<ForwardIt>::value_type in the range [first, first + count).

The operations in the parallel destroy_n algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Performs exactly count operations, if count > 0, no assignments otherwise.

Template Parameters

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• FwdIter: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

• Size: The type of the argument specifying the number of elements to apply this algorithm to.

Parameters
• policy: The execution policy to use for the scheduling of the iterations.
• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• count: Refers to the number of elements starting at first the algorithm will be applied to.

The operations in the parallel destroy_n algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The destroy_n algorithm returns a hpx::future<FwdIter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter otherwise. The destroy_n algorithm returns the iterator to the element in the source range, one past the last element constructed.

namespace hpx

Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result<ExPolicy, bool>::type equal(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, Pred &&op = Pred())

Returns true if the range [first1, last1) is equal to the range [first2, last2), and false otherwise.

The comparison operations in the parallel equal algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: At most min(last1 - first1, last2 - first2) applications of the predicate f.

Template Parameters

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• FwdIter1: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
• FwdIter2: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
• Pred: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of equal requires Pred to meet the requirements of CopyConstructible. This defaults to std::equal_to<>.

Parameters

• policy: The execution policy to use for the scheduling of the iterations.
• first1: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
• last1: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
• first2: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
• **last2**: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

• **op**: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note**  The two ranges are considered equal if, for every iterator i in the range [first1,last1), *i equals *(first2 + (i - first1)). This overload of *equal* uses operator== to determine if two elements are equal.

**Return** The *equal* algorithm returns a `hpx::future<bool>` if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns `bool` otherwise. The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range [first1, last1) does not equal the length of the range [first2, last2), it returns false.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result<ExPolicy, bool>::type equal(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, Pred &&op = Pred())
```

Returns true if the range [first1, last1) is equal to the range starting at first2, and false otherwise.

The comparison operations in the parallel *equal* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

**Note**  Complexity: At most last1 - first1 applications of the predicate *f*.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
  
- **FwdIter1**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
  
- **FwdIter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
  
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
  
- **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
• last1: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
• first2: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
• op: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively.

The comparison operations in the parallel equal algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note** The two ranges are considered equal if, for every iterator i in the range [first1,last1), *i equals *(first2 + (i - first1)). This overload of equal uses operator== to determine if two elements are equal.

**Return** The equal algorithm returns a hpx::future<bool> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns bool otherwise. The equal algorithm returns true if the elements in the two ranges are equal, otherwise it returns false.

```cpp
namespace hpx

namespace parallel

Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename T, typename Op>
std::enable_if<hpx::is_execution_policy<ExPolicy>::value, typename util::detail::algorithm_result<ExPolicy, FwdIter2>::type>::type
exclusive_scan(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest, T init, Op &&op)
```

Assigns through each iterator i in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(binary_op, init, *first, . . . , *(first + (i - result) - 1)).

The reduce operations in the parallel exclusive_scan algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: O(last - first) applications of the predicate op.

**Template Parameters**
• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **FwdIter1**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

• **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

• **T**: The type of the value to be used as initial (and intermediate) values (deduced).

• **Op**: The type of the binary function object used for the reduction operation.

**Parameters**

• **policy**: The execution policy to use for the scheduling of the iterations.

• **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **last**: Refers to the end of the sequence of elements the algorithm will be applied to.

• **dest**: Refers to the beginning of the destination range.

• **init**: The initial value for the generalized sum.

• **op**: Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```cpp
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types Type1 and Ret must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

The reduce operations in the parallel `exclusive_scan` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `exclusive_scan` and `inclusive_scan` is that `inclusive_scan` includes the ith input element in the ith sum. If `op` is not mathematically associative, the behavior of `inclusive_scan` may be non-deterministic.

**Return** The `exclusive_scan` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `exclusive_scan` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

**Note** `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aN)` is defined as:

- a1 when N is 1
- op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, …, aN)) where 1 < K+1 = M <= N.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename T>
std::enable_if<hpx::is_execution_policy<ExPolicy>::value, typename util::detail::algorithm_result<ExPolicy, FwdIter2>::type>::type
```

Assigns through each iterator i in [result, result + (last - first)) the value of `GENERALIZED_NONCOMMUTATIVE_SUM(+, init, *first, …, *(first + (i - result) - 1))`
The reduce operations in the parallel exclusive_scan algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: $O(last - first)$ applications of the predicate `std::plus<T>`.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T**: The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **init**: The initial value for the generalized sum.

The reduce operations in the parallel exclusive_scan algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between exclusive_scan and inclusive_scan is that inclusive_scan includes the ith input element in the ith sum.

**Return** The exclusive_scan algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns `FwdIter2` otherwise. The exclusive_scan algorithm returns the output iterator to the element in the destination range, one past the last element copied.

**Note** GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ..., aN) is defined as:

- a1 when N is 1
- GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ..., aK) – GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, ..., aN) where 1 < K+1 = M <= N.

```cpp
namespace hpx
{

Functions

template<typename ExPolicy, typename FwdIter, typename T>
util::detail::algorithm_result<ExPolicy>::type fill (ExPolicy &policy, FwdIter first, FwdIter last, T value)
Assigns the given value to the elements in the range [first, last).

The comparisons in the parallel fill algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly last - first assignments.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an output iterator.

• **T**: The type of the value to be assigned (deduced).

**Parameters**

• **policy**: The execution policy to use for the scheduling of the iterations.

• **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **last**: Refers to the end of the sequence of elements the algorithm will be applied to.

• **value**: The value to be assigned.

The comparisons in the parallel fill algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return**

The fill algorithm returns a `hpx::future<void>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `difference_type` otherwise (where `difference_type` is defined by `void`).

```cpp
template<typename ExPolicy, typename FwdIter, typename Size, typename T>
util::detail::algorithm_result<ExPolicy, FwdIter>::type fill_n(
    ExPolicy && policy,
    FwdIter first,
    Size count,
    T value)
```

Assigns the given value value to the first count elements in the range beginning at first if count > 0. Does nothing otherwise.

The comparisons in the parallel fill_n algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly count assignments, for count > 0.

**Template Parameters**

• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an output iterator.

• **Size**: The type of the argument specifying the number of elements to apply f to.

• **T**: The type of the value to be assigned (deduced).

**Parameters**

• **policy**: The execution policy to use for the scheduling of the iterations.

• **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **count**: Refers to the number of elements starting at first the algorithm will be applied to.

• **value**: The value to be assigned.

The comparisons in the parallel fill_n algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
Return The fill_n algorithm returns a hpx::future<void> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns difference_type otherwise (where difference_type is defined by void).

namespace hpx

Functions

template<
typename ExPolicy, typename FwdIter, typename T>
util::detail::algorithm_result<ExPolicy, FwdIter>::type find(ExPolicy &policy, FwdIter first, FwdIter last, T const &val)

Returns the first element in the range [first, last) that is equal to value

The comparison operations in the parallel find algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: At most last - first applications of the operator==().

Template Parameters

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• FwdIter: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

• T: The type of the value to find (deduced).

Parameters

• policy: The execution policy to use for the scheduling of the iterations.

• first: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

• last: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

• val: the value to compare the elements to

The comparison operations in the parallel find algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The find algorithm returns a hpx::future<FwdIter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter otherwise. The find algorithm returns the first element in the range [first,last) that is equal to val. If no such element in the range of [first,last) is equal to val, then the algorithm returns last.

template<
typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result<ExPolicy, FwdIter>::type find_if(ExPolicy &policy, FwdIter first, FwdIter last, F &&f)

Returns the first element in the range [first, last) for which predicate f returns true

The comparison operations in the parallel find_if algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.
Note Complexity: At most last - first applications of the predicate.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `F` to meet the requirements of `CopyConstructible`.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **f**: The unary predicate which returns true for the required element. The signature of the predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

The comparison operations in the parallel `find_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `find_if` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `find_if` algorithm returns the first element in the range `[first, last)` that satisfies the predicate `f`. If no such element exists that satisfies the predicate `f`, the algorithm returns `last`.

```cpp
template<typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result<ExPolicy, FwdIter>::type find_if_not (ExPolicy &&policy, FwdIter first, FwdIter last, F &&f)
```

Returns the first element in the range `[first, last)` for which predicate `f` returns false.

The comparison operations in the parallel `find_if_not` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

Note Complexity: At most last - first applications of the predicate.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
• **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `F` to meet the requirements of `CopyConstructible`.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **f**: The unary predicate which returns false for the required element. The signature of the predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

The comparison operations in the parallel `find_if_not` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `find_if_not` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `find_if_not` algorithm returns the first element in the range `[first, last)` that does not satisfy the predicate `f`. If no such element exists that does not satisfy the predicate `f`, the algorithm returns `last`.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to> util::detail::algorithm_result<ExPolicy, FwdIter1>::type find_end(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, Pred &&op = Pred())
```

Returns the last subsequence of elements `[first2, last2)` found in the range `[first, last)` using the given predicate `f` to compare elements.

The comparison operations in the parallel `find_end` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: at most S*(N-S+1) comparisons where S = `distance(first2, last2)` and N = `distance(first1, last1)`.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
• **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `replace` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`.

• **Proj**: The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements of type dereferenced `FwdIter1` and dereferenced `FwdIter2`.

### Parameters

• **policy**: The execution policy to use for the scheduling of the iterations.

• **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

• **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

• **first2**: Refers to the beginning of the sequence of elements the algorithm will be searching for.

• **last2**: Refers to the end of the sequence of elements of the algorithm will be searching for.

• **op**: The binary predicate which returns `true` if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

• **proj**: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `FwdIter1` and dereferenced `FwdIter2` as a projection operation before the function `f` is invoked.

The comparison operations in the parallel `find_end` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of `find_end` is available if the user decides to provide the algorithm their own predicate `f`.

### Return

The `find_end` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `find_end` algorithm returns an iterator to the beginning of the last subsequence `[first2, last2)` in range `[first1, last1)`. If the length of the subsequence `[first2, last2)` is greater than the length of the range `[first1, last1)`, `last1` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `last1` is also returned.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result<ExPolicy, FwdIter1>::type find_first_of(ExPolicy &&policy,
    FwdIter1 first, FwdIter1 last, FwdIter2 s_first, FwdIter2 s_last, Pred &&op = Pred())
```

Searches the range `[first, last)` for any elements in the range `[s_first, s_last)`. Uses binary predicate `p` to compare elements.
The comparison operations in the parallel `find_first_of` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: at most \((S\times N)\) comparisons where \(S = \text{distance}(s\_first, s\_last)\) and \(N = \text{distance}(\text{first, last})\).

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- `FwdIter1`: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

- `FwdIter2`: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

- `Pred`: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>

- `Proj1`: The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements of type dereferenced `FwdIter1`.

- `Proj2`: The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements of type dereferenced `FwdIter2`.

**Parameters**

- `policy`: The execution policy to use for the scheduling of the iterations.

- `first`: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

- `last`: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

- `s_first`: Refers to the beginning of the sequence of elements the algorithm will be searching for.

- `s_last`: Refers to the end of the sequence of elements of the algorithm will be searching for.

- `op`: The binary predicate which returns `true` if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not have to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

- `proj1`: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `FwdIter1` as a projection operation before the function `op` is invoked.

- `proj2`: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `FwdIter2` as a projection operation before the function `op` is invoked.

The comparison operations in the parallel `find_first_of` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
Return The `find_first_of` algorithm returns a `hpx::future<FwdIter1>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter1` otherwise. The `find_first_of` algorithm returns an iterator to the first element in the range `[first, last)` that is equal to an element from the range `[s_first, s_last)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, last)`, `last` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `last` is also returned. This overload of `find_end` is available if the user decides to provide the algorithm their own predicate `f`.

namespace hpx

Functions

template<typename InIter, typename F>
F for_each(InIter first, InIter last, F &&f)
Applies `f` to the result of dereferencing every iterator in the range `[first, last)`.

If `f` returns a result, the result is ignored.

Note Complexity: Applies `f` exactly `last - first` times.

If the type of `first` satisfies the requirements of a mutable iterator, `f` may apply non-constant functions through the dereferenced iterator.

Return `f`.

Template Parameters

- `InIter`: The type of the source begin and end iterator used (deduced). This iterator type must meet the requirements of an input iterator.
- `F`: The type of the function/function object to use (deduced). `F` must meet requirements of `Move-Constructible`.

Parameters

- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last`: Refers to the end of the sequence of elements the algorithm will be applied to.
- `f`: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. The signature of this predicate should be equivalent to:

  ```c++
  <ignored> pred(const Type &a);
  ```

  The signature does not need to have `const&`. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

-tuple template<typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result<ExPolicy, void>::type for_each(ExPolicy &&policy, FwdIter first, FwdIter last, F &&f)
Applies `f` to the result of dereferencing every iterator in the range `[first, last)`.

If `f` returns a result, the result is ignored.

Note Complexity: Applies `f` exactly `last - first` times.
If the type of \textit{first} satisfies the requirements of a mutable iterator, \textit{f} may apply non-constant functions through the dereferenced iterator.

Unlike its sequential form, the parallel overload of \textit{for\_each} does not return a copy of its \textit{Function} parameter, since parallelization may not permit efficient state accumulation.

The application of function objects in parallel algorithm invoked with an execution policy object of type \textit{sequenced\_policy} execute in sequential order in the calling thread.

**Template Parameters**

- \textit{ExPolicy}: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- \textit{FwdIte}: The type of the source begin and end iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- \textit{F}: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \textit{for\_each} requires \textit{F} to meet the requirements of \textit{CopyConstructible}.

**Parameters**

- \textit{policy}: The execution policy to use for the scheduling of the iterations.
- \textit{first}: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- \textit{last}: Refers to the end of the sequence of elements the algorithm will be applied to.
- \textit{f}: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \texttt{[first, last)}. The signature of this predicate should be equivalent to:

\begin{verbatim}
<ignored> pred(const Type &a);
\end{verbatim}

The signature does not need to have const\&. The type \textit{Type} must be such that an object of type \textit{FwdIter} can be dereferenced and then implicitly converted to \textit{Type}.

The application of function objects in parallel algorithm invoked with an execution policy object of type \textit{parallel\_policy} or \textit{parallel\_task\_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The \textit{for\_each} algorithm returns a \texttt{hpx::future<void>} if the execution policy is of type \textit{sequenced\_task\_policy} or \textit{parallel\_task\_policy} and returns void otherwise.

\texttt{template<typename \texttt{InIter}, typename \texttt{Size}, typename \texttt{F}>}
\texttt{InIter \textbf{for\_each\_n}(InIter first, Size count, F &\&f)}

Applies \textit{f} to the result of dereferencing every iterator in the range \texttt{[first, first + count)}, starting from \texttt{first} and proceeding to \texttt{first + count - 1}.

If \textit{f} returns a result, the result is ignored.

**Note** Complexity: Applies \textit{f} exactly \textit{count} times.

If the type of \textit{first} satisfies the requirements of a mutable iterator, \textit{f} may apply non-constant functions through the dereferenced iterator.

**Return** \texttt{first + count} for non-negative values of \texttt{count} and \texttt{first} for negative values.
Template Parameters

- **InIter**: The type of the source begin and end iterator used (deduced). This iterator type must meet the requirements of an input iterator.
- **Size**: The type of the argument specifying the number of elements to apply \( f \) to.
- **F**: The type of the function/function object to use (deduced). \( F \) must meet requirements of *Move-Constructible*.

Parameters

- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count**: Refers to the number of elements starting at \( \text{first} \) the algorithm will be applied to.
- **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\). The signature of this predicate should be equivalent to:

  \[
  \text{<ignored> pred(const Type &a);} 
  \]

  The signature does not need to have const&. The type \( \text{Type} \) must be such that an object of type \( \text{FwdIter} \) can be dereferenced and then implicitly converted to \( \text{Type} \).

  \[
  \text{template<
  typename \text{ExPolicy}, typename \text{FwdIter},
  typename \text{Size},
  typename \text{F}>
  \text{util::detail::algorithm_result<ExPolicy, FwdIter>::type for_each_n(}
  \text{ExPolicy &&policy, FwdIter first, Size count, F &&f)}
  \]

  Applies \( f \) to the result of dereferencing every iterator in the range \([\text{first}, \text{first + count})\), starting from first and proceeding to \( \text{first + count - 1} \).

  If \( f \) returns a result, the result is ignored.

  **Note** Complexity: Applies \( f \) exactly \( \text{count} \) times.

  If the type of \( \text{first} \) satisfies the requirements of a mutable iterator, \( f \) may apply non-constant functions through the dereferenced iterator.

  Unlike its sequential form, the parallel overload of *for_each* does not return a copy of its *Function* parameter, since parallelization may not permit efficient state accumulation.

  The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size**: The type of the argument specifying the number of elements to apply \( f \) to.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *for_each* requires \( F \) to meet the requirements of *CopyConstructible*.

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• \textbf{count}: Refers to the number of elements starting at \textit{first} the algorithm will be applied to.

• \textbf{f}: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\textit{first}, \textit{last})\). The signature of this predicate should be equivalent to:

\[
\texttt{\langle ignored\rangle \ pred(const \ Type \ &a);}\]

The signature does not need to have \texttt{const&}. The type \texttt{Type} must be such that an object of type \texttt{FwdIter} can be dereferenced and then implicitly converted to \texttt{Type}.

The application of function objects in parallel algorithm invoked with an execution policy object of type \texttt{parallel\_policy} or \texttt{parallel\_task\_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The \texttt{for\_each\_n} algorithm returns a \texttt{hpx::future<FwdIter>} if the execution policy is of type \texttt{sequenced\_task\_policy} or \texttt{parallel\_task\_policy} and returns \texttt{FwdIter} otherwise. It returns \texttt{first + count} for non-negative values of \texttt{count} and \texttt{first} for negative values.

\begin{verbatim}
namespace hpx

Functions

template<typename I, typename ...Args>
void for_loop(typename std::decay<I>::type first, I last, Args&&... args)
{
    The for_loop implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

    The execution of for_loop without specifying an execution policy is equivalent to specifying \texttt{hpx::execution::seq} as the execution policy.

    Requires: \textit{I} shall be an integral type or meet the requirements of an input iterator type. The \textit{args} parameter pack shall have at least one element, comprising objects returned by invocations of \texttt{reduction} and/or \texttt{induction} function templates followed by exactly one element invocable element-access function, \textit{f}. \textit{f} shall meet the requirements of \texttt{MoveConstructible}.

    Template Parameters
    \begin{itemize}
        \item \textbf{I}: The type of the iteration variable. This could be an (forward) iterator type or an integral type.
        \item \textbf{Args}: A parameter pack, it’s last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.
    \end{itemize}

    Parameters
    \begin{itemize}
        \item \textbf{first}: Refers to the beginning of the sequence of elements the algorithm will be applied to.
        \item \textbf{last}: Refers to the end of the sequence of elements the algorithm will be applied to.
        \item \textbf{args}: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by \([\textit{first}, \textit{last})\) should expose a signature equivalent to:

\[
\texttt{\langle ignored\rangle \ pred(I \ const\% \ a, \ ...);}\]
\end{itemize}
\end{verbatim}
The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

Effects: Applies \( f \) to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the \( \text{args} \) parameter pack. The length of the input sequence is \( \text{last} - \text{first} \).

The first element in the input sequence is specified by \( \text{first} \). Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the \( \text{args} \) parameter pack excluding \( f \), an additional argument is passed to each application of \( f \) as follows:

**Note** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

**Note** The order of the elements of the input sequence is important for determining ordinal position of an application of \( f \), even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of \( f \) in the input sequence.

Complexity: Applies \( f \) exactly once for each element of the input sequence.

Remarks: If \( f \) returns a result, the result is ignored.

```cpp
template<typename ExPolicy, typename I, typename ...Args>
util::detail::algorithm_result<ExPolicy>::type for_loop(ExPolicy &&policy, typename std::decay<I>::type first, I last, Args&&... args)
```

The for_loop implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

Requires: \( I \) shall be an integral type or meet the requirements of an input iterator type. The \( \text{args} \) parameter pack shall have at least one element, comprising objects returned by invocations of \textit{reduction} and/or \textit{induction} function templates followed by exactly one element invocable element-access function, \( f \). \( f \) shall meet the requirements of MoveConstructible.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **I**: The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- **Args**: A parameter pack, it’s last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
• **args**: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)` should expose a signature equivalent to:

```cpp
<ignored> pred(I const & a, ...);
```

The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Effects**: Applies `f` to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the `args` parameter pack. The length of the input sequence is `last - first`.

The first element in the input sequence is specified by `first`. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the `args` parameter pack excluding `f`, an additional argument is passed to each application of `f` as follows:

**Note** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

**Note** The order of the elements of the input sequence is important for determining ordinal position of an application of `f`, even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of `f` in the input sequence.

**Complexity**: Applies `f` exactly once for each element of the input sequence.

**Remarks**: If `f` returns a result, the result is ignored.

**Return** The `for_loop` algorithm returns a `hpx::future<void>` if the execution policy is of type `hpx::execution::sequenced_task_policy` or `hpx::execution::parallel_task_policy` and returns `void` otherwise.

```cpp
template<typename I, typename S, typename ...Args>
void for_loop_strided(typename std::decay<I>::type first, I last, S stride, Args&&... args)
```

The `for_loop_strided` implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of `for_loop` without specifying an execution policy is equivalent to specifying `hpx::execution::seq` as the execution policy.

**Requires**: `I` shall be an integral type or meet the requirements of an input iterator type. The `args` parameter pack shall have at least one element, comprising objects returned by invocations of `reduction` and/or `induction` function templates followed by exactly one element invocable element-access function, `f`. `f` shall meet the requirements of `MoveConstructible`.

**Template Parameters**

- **I**: The type of the iteration variable. This could be an (forward) iterator type or an integral type.
• **S**: The type of the stride variable. This should be an integral type.

• **Args**: A parameter pack, it’s last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**

• **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **last**: Refers to the end of the sequence of elements the algorithm will be applied to.

• **stride**: Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if I has integral type or meets the requirements of a bidirectional iterator.

• **args**: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

```cpp
<ignored> pred(I const & a, ...);
```

The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Effects**: Applies \( f \) to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the \( args \) parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by \( first \). Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the \( args \) parameter pack excluding \( f \), an additional argument is passed to each application of \( f \) as follows:

**Note** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

**Note** The order of the elements of the input sequence is important for determining ordinal position of an application of \( f \), even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of \( f \) in the input sequence.

**Complexity**: Applies \( f \) exactly once for each element of the input sequence.

**Remarks**: If \( f \) returns a result, the result is ignored.

```cpp
template<typename ExPolicy, typename I, typename S, typename ... Args>
util::detail::algorithm_result<ExPolicy>::type for_loop_strided(ExPolicy &&policy, typename std::decay<I>::type first, I last, S stride, Args&&... args)
```

The for_loop_strided implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

**Requires**: \( I \) shall be an integral type or meet the requirements of an input iterator type. The \( args \) parameter pack shall have at least one element, comprising objects returned by invocations of reduction and/or
induction function templates followed by exactly one element invocable element-access function, \( f \). \( f \) shall meet the requirements of MoveConstructible.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **I**: The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- **S**: The type of the stride variable. This should be an integral type.
- **Args**: A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **stride**: Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if I has integral type or meets the requirements of a bidirectional iterator.
- **args**: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

\[
\text{<ignored> \ pred(I \ const\& a, \ldots)};
\]

The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Effects**: Applies \( f \) to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the args parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by first. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the args parameter pack excluding \( f \), an additional argument is passed to each application of \( f \) as follows:

**Note** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

**Note** The order of the elements of the input sequence is important for determining ordinal position of an application of \( f \), even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of \( f \) in the input sequence.

**Complexity**: Applies \( f \) exactly once for each element of the input sequence.

**Remarks**: If \( f \) returns a result, the result is ignored.
**Return** The `for_loop_strided` algorithm returns a `hpx::future<void>` if the execution policy is of type `hpx::execution::sequenced_task_policy` or `hpx::execution::parallel_task_policy` and returns `void` otherwise.

```cpp
template<typename I, typename Size, typename ...Args>
void for_loop_n(I first, Size size, Args&&... args)
```

The `for_loop_n` implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of `for_loop_n` without specifying an execution policy is equivalent to specifying `hpx::execution::seq` as the execution policy.

Requires: `I` shall be an integral type or meet the requirements of an input iterator type. The `args` parameter pack shall have at least one element, comprising objects returned by invocations of `reduction` and/or `induction` function templates followed by exactly one element invocable element-access function. `f` shall meet the requirements of `MoveConstructible`.

**Template Parameters**
- `I`: The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- `Size`: The type of a non-negative integral value specifying the number of items to iterate over.
- `Args`: A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**
- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `size`: Refers to the number of items the algorithm will be applied to.
- `args`: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)` should expose a signature equivalent to:

```cpp
<ignored> pred(I const& a, ...);
```

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Effects**: Applies `f` to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the `args` parameter pack. The length of the input sequence is `last - first`.

The first element in the input sequence is specified by `first`. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the `args` parameter pack excluding `f`, an additional argument is passed to each application of `f` as follows:

**Note** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

**Note** The order of the elements of the input sequence is important for determining ordinal position of an application of `f`, even though the applications themselves may be unordered.
If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of $f$ in the input sequence.

Complexity: Applies $f$ exactly once for each element of the input sequence.

Remarks: If $f$ returns a result, the result is ignored.

```cpp
template<typename ExPolicy, typename I, typename Size, typename ...Args>
util::detail::algorithm_result<ExPolicy>::type for_loop_n(ExPolicy &&policy, I first, Size size, Args&&... args)
```

The for_loop_n implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

Requires: $I$ shall be an integral type or meet the requirements of an input iterator type. The args parameter pack shall have at least one element, comprising objects returned by invocations of reduction and/or induction function templates followed by exactly one element invocable element-access function, $f$. $f$ shall meet the requirements of MoveConstructible.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **$I$**: The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- **Size**: The type of a non-negative integral value specifying the number of items to iterate over.
- **Args**: A parameter pack, it’s last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **size**: Refers to the number of items the algorithm will be applied to.
- **args**: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

```cpp
<ignored> pred(I const& a, ...);
```

The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Effects**: Applies $f$ to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the args parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by first. Each subsequent element is generated by incrementing the previous element.
Along with an element from the input sequence, for each member of the \textit{args} parameter pack excluding \textit{f},
an additional argument is passed to each application of \textit{f} as follows:

\textbf{Note} As described in the C++ standard, arithmetic on non-random-access iterators is performed using
advance and distance.

\textbf{Note} The order of the elements of the input sequence is important for determining ordinal position of an
application of \textit{f}, even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the
additional argument is a reference to a view of that reduction object. If the pack member is an object
returned by a call to induction, then the additional argument is the induction value for that induction object
corresponding to the position of the application of \textit{f} in the input sequence.

Complexity: Applies \textit{f} exactly once for each element of the input sequence.

Remarks: If \textit{f} returns a result, the result is ignored.

\textbf{Return} The \textit{for\_loop\_n} algorithm returns a \texttt{hpx::future<void>} if the execution policy is of type
\texttt{hpx::execution::sequenced\_task\_policy} or \texttt{hpx::execution::parallel\_task\_policy} and returns \texttt{void}
otherwise.

\begin{verbatim}
template<typename I, typename Size, typename S, typename ...Args>
void for_loop_n_strided(I first, Size size, S stride, Args&&... args)
{
    for (typename I::iterator it = first; it != first + size; it += stride)
    {
        // Call f with the additional arguments...
    }
}
\end{verbatim}

The \textit{for\_loop\_n\_strided} implements loop functionality over a range specified by integral or iterator bounds.
For the iterator case, these algorithms resemble \textit{for\_each} from the Parallelism TS, but leave to the program-
er when and if to dereference the iterator.

The execution of \textit{for\_loop} without specifying an execution policy is equivalent to specifying
\texttt{hpx::execution::seq} as the execution policy.

Requires: \textit{I} shall be an integral type or meet the requirements of an input iterator type. The \textit{args} param-
eter pack shall have at least one element, comprising objects returned by invocations of \textit{reduction} and/or
\textit{induction} function templates followed by exactly one element invocable element-access function, \textit{f}. \textit{f} shall
meet the requirements of MoveConstructible.

\textbf{Template Parameters}

- \textit{I}: The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- \textit{Size}: The type of a non-negative integral value specifying the number of items to iterate over.
- \textit{S}: The type of the stride variable. This should be an integral type.
- \textit{Args}: A parameter pack, it's last element is a function object to be invoked for each iteration,
  the others have to be either conforming to the induction or reduction concept.

\textbf{Parameters}

- \textit{first}: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- \textit{size}: Refers to the number of items the algorithm will be applied to.
- \textit{stride}: Refers to the stride of the iteration steps. This shall have non-zero value and shall be
  negative only if \textit{I} has integral type or meets the requirements of a bidirectional iterator.
- \textit{args}: The last element of this parameter pack is the function (object) to invoke, while the re-
  maining elements of the parameter pack are instances of either induction or reduction objects.
  The function (or function object) which will be invoked for each of the elements in the sequence
  specified by \texttt{[first, last]} should expose a signature equivalent to:
The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

Effects: Applies \( f \) to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the \( \text{args} \) parameter pack. The length of the input sequence is \( \text{last} - \text{first} \).

The first element in the input sequence is specified by \( \text{first} \). Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the \( \text{args} \) parameter pack excluding \( f \), an additional argument is passed to each application of \( f \) as follows:

Note As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

Note The order of the elements of the input sequence is important for determining ordinal position of an application of \( f \), even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of \( f \) in the input sequence.

Complexity: Applies \( f \) exactly once for each element of the input sequence.

Remarks: If \( f \) returns a result, the result is ignored.

```cpp
<ignored> pred(I const& a, ...);
```

The for_loop_n_strided implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

Requires: \( I \) shall be an integral type or meet the requirements of an input iterator type. The \( \text{args} \) parameter pack shall have at least one element, comprising objects returned by invocations of reduction and/or induction function templates followed by exactly one element invocable element-access function, \( f \). \( f \) shall meet the requirements of MoveConstructible.

Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **I**: The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- **Size**: The type of a non-negative integral value specifying the number of items to iterate over.
- **S**: The type of the stride variable. This should be an integral type.
- **Args**: A parameter pack, it’s last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

Parameters
• **policy**: The execution policy to use for the scheduling of the iterations.

• **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **size**: Refers to the number of items the algorithm will be applied to.

• **stride**: Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if `I` has integral type or meets the requirements of a bidirectional iterator.

• **args**: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)` should expose a signature equivalent to:

```
<ignored> pred(I const & a, ...);
```

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

Effects: Applies `f` to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the `args` parameter pack. The length of the input sequence is `last - first`.

The first element in the input sequence is specified by `first`. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the `args` parameter pack excluding `f`, an additional argument is passed to each application of `f` as follows:

**Note** As described in the C++ standard, arithmetic on non-random-access iterators is performed using `advance` and `distance`.

**Note** The order of the elements of the input sequence is important for determining ordinal position of an application of `f`, even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of `f` in the input sequence.

Complexity: Applies `f` exactly once for each element of the input sequence.

Remarks: If `f` returns a result, the result is ignored.

**Return** The `for_loop_n_strided` algorithm returns a `hpx::future<void>` if the execution policy is of type `hpx::execution::sequenced_task_policy` or `hpx::execution::parallel_task_policy` and returns `void` otherwise.

```cpp
namespace hpx
{

namespace parallel
{
The function template returns an induction object of unspecified type having a value type and encapsulating an initial value value of that type and, optionally, a stride.

For each element in the input range, a looping algorithm over input sequence S computes an induction value from an induction variable and ordinal position p within S by the formula i + p * stride if a stride was specified or i + p otherwise. This induction value is passed to the element access function.

If the value argument to induction is a non-const lvalue, then that lvalue becomes the live-out object for the returned induction object. For each induction object that has a live-out object, the looping algorithm assigns the value of i + n * stride to the live-out object upon return, where n is the number of elements in the input range.

**Return** This returns an induction object with value type T, initial value value, and (if specified) stride stride. If T is an lvalue of non-const type, value is used as the live-out object for the induction object; otherwise there is no live-out object.

**Template Parameters**
- T: The value type to be used by the induction object.

**Parameters**
- value: [in] The initial value to use for the induction object
- stride: [in] The (optional) stride to use for the induction object (default: 1)

```cpp
namespace hpx

namespace parallel

Functions

template<
typename T>
constexpr detail::induction_stride_helper<T> induction (T &&value, std::size_t stride)

The function template returns an induction object of unspecified type having a value type and encapsulating an initial value value of that type and, optionally, a stride.

For each element in the input range, a looping algorithm over input sequence S computes an induction value from an induction variable and ordinal position p within S by the formula i + p * stride if a stride was specified or i + p otherwise. This induction value is passed to the element access function.

If the value argument to induction is a non-const lvalue, then that lvalue becomes the live-out object for the returned induction object. For each induction object that has a live-out object, the looping algorithm assigns the value of i + n * stride to the live-out object upon return, where n is the number of elements in the input range.

**Return** This returns an induction object with value type T, initial value value, and (if specified) stride stride. If T is an lvalue of non-const type, value is used as the live-out object for the induction object; otherwise there is no live-out object.

**Template Parameters**
- T: The value type to be used by the induction object.

**Parameters**
- value: [in] The initial value to use for the induction object
- stride: [in] The (optional) stride to use for the induction object (default: 1)

```cpp
namespace hpx

namespace parallel

Functions

template<
typename T, typename Op>
constexpr detail::reduction_helper<T, typename std::decay<Op>::type> reduction (T &var, const T &identity, Op &&combiner)

The function template returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, a combiner function object, and a live-out object from which the initial value is obtained and into which the final value is stored.

A parallel algorithm uses reduction objects by allocating an unspecified number of instances, called views, of the reduction’s value type. Each view is initialized with the reduction object’s identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function, ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.

Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the
reduction object’s combiner operation until a single value remains, which is then assigned back to the live-out object.

T shall meet the requirements of CopyConstructible and MoveAssignable. The expression var = combiner(var, var) shall be well formed.

**Template Parameters**
- **T**: The value type to be used by the induction object.
- **Op**: The type of the binary function (object) used to perform the reduction operation.

**Parameters**
- **var**: [in,out] The life-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing.
- **identity**: [in] The identity value to use for the reduction operation.
- **combiner**: [in] The binary function (object) used to perform a pairwise reduction on the elements.

**Note** In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation. For example if the combiner is plus<T>, incrementing the view would be consistent with the combiner but doubling it or assigning to it would not.

**Return** This returns a reduction object of unspecified type having a value type of T. When the return value is used by an algorithm, the reference to var is used as the live-out object, new views are initialized to a copy of identity, and views are combined by invoking the copy of combiner, passing it the two views to be combined.

```cpp
namespace hpx {

Functions

template<typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result<ExPolicy, FwdIter>::type generate(ExPolicy &&policy, FwdIter first, FwdIter last, F &&f)
    Assign each element in range [first, last) a value generated by the given function object f

The assignments in the parallel generate algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Exactly distance(first, last) invocations of f and assignments.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of equal requires F to meet the requirements of CopyConstructible.

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
```
• last: Refers to the end of the sequence of elements the algorithm will be applied to.

• f: generator function that will be called. Signature of function should be equivalent to the following:

RET fun();

The type RET must be such that an object of type FwdIter can be dereferenced and assigned a value of type RET.

The assignments in the parallel generate algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The replace_if algorithm returns a hpx::future<FwdIter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter otherwise. It returns last.

template<typename ExPolicy, typename FwdIter, typename Size, typename F>
util::detail::algorithm_result<ExPolicy, FwdIter>::type generate_n (ExPolicy &&policy, FwdIter first, Size count, F &&f)

Assigns each element in range [first, first+count) a value generated by the given function object g.

The assignments in the parallel generate_n algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Exactly count invocations of f and assignments, for count > 0.

**Template Parameters**

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• FwdIter: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

• F: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of equal requires F to meet the requirements of CopyConstructible.

**Parameters**

• policy: The execution policy to use for the scheduling of the iterations.

• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.

• count: Refers to the number of elements in the sequence the algorithm will be applied to.

• f: Refers to the generator function object that will be called. The signature of the function should be equivalent to

RET fun();

The type RET must be such that an object of type OutputIt can be dereferenced and assigned a value of type RET.

The assignments in the parallel generate_n algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
**Return** The `replace_if` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. It returns `last`.

```cpp
namespace hpx

Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::less>
util::detail::algorithm_result<ExPolicy, bool>::type::type
includes(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, Pred &&op
= Pred())
```

Returns true if every element from the sorted range `[first2, last2)` is found within the sorted range `[first1, last1)`. Also returns true if `[first2, last2)` is empty. The version expects both ranges to be sorted with the user supplied binary predicate `f`.

The comparison operations in the parallel `includes` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** At most \(2^{*}(N1+N2-1)\) comparisons, where \(N1 = \text{std::distance(first1, last1)}\) and \(N2 = \text{std::distance(first2, last2)}\).

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `includes` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2**: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2**: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op**: The binary predicate which returns true if the elements should be treated as includes. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```
The signature does not need to have const &, but the function must not modify the objects passed to it. The types \texttt{Type1} and \texttt{Type2} must be such that objects of types \texttt{FwdIter1} and \texttt{FwdIter2} can be dereferenced and then implicitly converted to \texttt{Type1} and \texttt{Type2} respectively.

The comparison operations in the parallel \texttt{includes} algorithm invoked with an execution policy object of type \texttt{parallel\_policy} or \texttt{parallel\_task\_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The \texttt{includes} algorithm returns a \texttt{hpx::future<bool>} if the execution policy is of type \texttt{sequenced\_task\_policy} or \texttt{parallel\_task\_policy} and returns \texttt{bool} otherwise. The \texttt{includes} algorithm returns true every element from the sorted range \([\text{first2}, \text{last2})\) is found within the sorted range \([\text{first1}, \text{last1})\). Also returns true if \([\text{first2}, \text{last2})\) is empty.

```cpp
namespace hpx

namespace parallel

Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Op, typename T>
util::detail::algorithm_result<ExPolicy, FwdIter2>::type inclusive_scan(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest, Op &&op, T init)
```

Assigns through each iterator \(i\) in \([\text{result}, \text{result} + (\text{last} - \text{first}))\) the value of \texttt{GENERALIZED\_NONCOMMUTATIVE\_SUM(op, init, *first, \ldots, *(first + (i - result)))}.

The reduce operations in the parallel \texttt{inclusive\_scan} algorithm invoked with an execution policy object of type \texttt{sequenced\_policy} execute in sequential order in the calling thread.

**Note** Complexity: \(O(\text{last} - \text{first})\) applications of the predicate \(op\).

**Template Parameters**
- \texttt{ExPolicy}: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- \texttt{FwdIter1}: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- \texttt{FwdIter2}: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- \texttt{T}: The type of the value to be used as initial (and intermediate) values (deduced).
- \texttt{Op}: The type of the binary function object used for the reduction operation.

**Parameters**
- \texttt{policy}: The execution policy to use for the scheduling of the iterations.
- \texttt{first}: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- \texttt{last}: Refers to the end of the sequence of elements the algorithm will be applied to.
- \texttt{dest}: Refers to the beginning of the destination range.
- \texttt{init}: The initial value for the generalized sum.
- \texttt{op}: Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:
Ret fun(const Type1 &a, const Type1 &b);

The signature does not need to have const&, but the function must not modify the objects passed to it. The types Type1 and Ret must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

The reduce operations in the parallel inclusive_scan algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between exclusive_scan and inclusive_scan is that inclusive_scan includes the ith input element in the ith sum. If op is not mathematically associative, the behavior of inclusive_scan may be non-deterministic.

**Return** The inclusive_scan algorithm returns a hpx::future<FwdIter2> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter2 otherwise. The inclusive_scan algorithm returns the output iterator to the element in the destination range, one past the last element copied.

**Note** GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, . . . , aN) is defined as:
- a1 when N is 1
- op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, . . . , aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, . . . , aN)) where 1 < K+1 = M <= N.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Op>
util::detail::algorithm_result<ExPolicy, FwdIter2>::type inclusive_scan(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest, Op &&op)
```

Assigns through each iterator i in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(op, *first, . . . , *(first + (i - result))).

The reduce operations in the parallel inclusive_scan algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: O(last - first) applications of the predicate op.

**Template Parameters**
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- FwdIter1: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- FwdIter2: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- Op: The type of the binary function object used for the reduction operation.

**Parameters**
- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last: Refers to the end of the sequence of elements the algorithm will be applied to.
- dest: Refers to the beginning of the destination range.
- op: Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:
Ret fun(const Type1 &a, const Type1 &b);

The signature does not need to have const&, but the function must not modify the objects passed to it. The types Type1 and Ret must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

The reduce operations in the parallel `inclusive_scan` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `exclusive_scan` and `inclusive_scan` is that `inclusive_scan` includes the ith input element in the ith sum.

**Return** The `inclusive_scan` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `inclusive_scan` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

**Note** GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, …, aN) is defined as:

- a1 when N is 1
- GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, …, aK)
  - GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, …, aN) where 1 < K+1 = M <= N.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
std::enable_if<hpx::is_execution_policy<ExPolicy>::value, typename util::detail::algorithm_result<ExPolicy, FwdIter2>::type>::type
inclusive_scan(ExPolicy&& policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest)
```

Assigns through each iterator i in [result, result + (last - first)) the value of gENERALIZED_NONCOMMUTATIVE_SUM(+, *first, …, *(first + (i - result))).

The reduce operations in the parallel `inclusive_scan` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: `O(last - first)` applications of the predicate `op`.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.

The reduce operations in the parallel `inclusive_scan` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
The difference between exclusive_scan and inclusive_scan is that inclusive_scan includes the ith input element in the ith sum.

**Return** The inclusive_scan algorithm returns a hpx::future<FwdIter2> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter2 otherwise. The inclusive_scan algorithm returns the output iterator to the element in the destination range, one past the last element copied.

**Note** GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, . . . , aN) is defined as:

- a1 when N is 1
- GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, . . . , aK)
  - GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, . . . , aN) where 1 < K+1 = M <= N.

namespace hpx

**Functions**

template<typename ExPolicy, typename RandIter, typename Comp = detail::less>
util::detail::algorithm_result<ExPolicy, bool>::type
   is_heap(ExPolicy &&policy, RandIter first, RandIter last, Comp &comp = Comp())

Returns whether the range is max heap. That is, true if the range is max heap, false otherwise. The function uses the given comparison function object comp (defaults to using operator<()).

*comp* has to induce a strict weak ordering on the values.

**Note** Complexity: Performs at most N applications of the comparison comp, at most 2 * N applications of the projection proj, where N = last - first.

**Template Parameters**

- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- RandIter: The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.

- Comp: The type of the function/function object to use (deduced).

**Parameters**

- policy: The execution policy to use for the scheduling of the iterations.

- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.

- last: Refers to the end of the sequence of elements the algorithm will be applied to.

- comp: *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.

The application of function objects in parallel algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
Return The \texttt{is_heap} algorithm returns a \texttt{hpx::future<bool>} if the execution policy is of type \texttt{sequenced_task_policy} or \texttt{parallel_task_policy} and returns \texttt{bool} otherwise. The \texttt{is_heap} algorithm returns whether the range is max heap. That is, true if the range is max heap, false otherwise.

```cpp
template<typename ExPolicy, typename RandIter, typename Comp = detail::less>
util::detail::algorithm_result<ExPolicy, RandIter>::type is_heap_until(ExPolicy &&policy, RandIter first, RandIter last, Comp &&comp = Comp())
```

Returns the upper bound of the largest range beginning at \textit{first} which is a max heap. That is, the last iterator \textit{it} for which range \([\text{first}, \text{it})\) is a max heap. The function uses the given comparison function object \textit{comp} (defaults to using \texttt{operator<()}).

\textit{comp} has to induce a strict weak ordering on the values.

Note Complexity: Performs at most N applications of the comparison \textit{comp}, at most 2 * N applications of the projection \textit{proj}, where N = \textit{last} - \textit{first}.

Template Parameters

- \textit{ExPolicy}: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- \textit{RandIter}: The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- \textit{Comp}: The type of the function/function object to use (deduced).

Parameters

- \textit{policy}: The execution policy to use for the scheduling of the iterations.
- \textit{first}: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- \textit{last}: Refers to the end of the sequence of elements the algorithm will be applied to.
- \textit{comp}: \textit{comp} is a callable object. The return value of the \texttt{invoke} operation applied to an object of type \textit{Comp}, when contextually converted to \texttt{bool}, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that \textit{comp} will not apply any non-constant function through the dereferenced iterator.

The application of function objects in parallel algorithm invoked with an execution policy object of type \texttt{sequenced_policy} execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type \texttt{parallel_policy} or \texttt{parallel_task_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The \texttt{is_heap_until} algorithm returns a \texttt{hpx::future<RandIter>} if the execution policy is of type \texttt{sequenced_task_policy} or \texttt{parallel_task_policy} and returns \texttt{RandIter} otherwise. The \texttt{is_heap_until} algorithm returns the upper bound of the largest range beginning at \textit{first} which is a max heap. That is, the last iterator \textit{it} for which range \([\text{first}, \text{it})\) is a max heap.

\texttt{namespace hpx}
Functions

template<typename FwdIter, typename Pred>
bool is_partitioned(FwdIter first, FwdIter last, Pred &&pred)
    Determines if the range [first, last) is partitioned.

Note  Complexity: at most (N) predicate evaluations where \( N = \text{distance(} \text{first, last)} \).

Return  The is_partitioned algorithm returns bool. The is_partitioned algorithm returns true if each element in the sequence for which pred returns true precedes those for which pred returns false. Otherwise is_partitioned returns false. If the range [first, last) contains less than two elements, the function is always true.

Template Parameters
- FwdIter: The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- Pred: The type of the function/function object to use (deduced).

Parameters
- first: Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- last: Refers to the end of the sequence of elements of that the algorithm will be applied to.
- pred: Refers to the unary predicate which returns true for elements expected to be found in the beginning of the range. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type Type must be such that objects of types FwdIter can be dereferenced and then implicitly converted to Type.

template<typename ExPolicy, typename FwdIter, typename Pred>
util::detail::algorithm_result<ExPolicy, bool>::type is_partitioned(ExPolicy &&policy, FwdIter first, FwdIter last, Pred &&pred)
    Determines if the range [first, last) is partitioned.

The predicate operations in the parallel is_partitioned algorithm invoked with an execution policy object of type sequenced_policy executes in sequential order in the calling thread.

Note  Complexity: at most (N) predicate evaluations where \( N = \text{distance(} \text{first, last)} \).

Template Parameters
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- FwdIter: The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- Pred: The type of the function/function object to use (deduced). Pred must be CopyConstructible when using a parallel policy.
Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred**: Refers to the unary predicate which returns true for elements expected to be found in the beginning of the range. The signature of the function should be equivalent to

  ```cpp
  bool pred(const Type &a);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.

The comparison operations in the parallel `is_partitioned` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `is_partitioned` algorithm returns a `hpx::future<bool>` if the execution policy is of type `task_execution_policy` and returns `bool` otherwise. The `is_partitioned` algorithm returns true if each element in the sequence for which `pred` returns true precedes those for which `pred` returns false. Otherwise `is_partitioned` returns false. If the range `[first, last)` contains less than two elements, the function is always true.

```cpp
namespace hpx

Functions

template<typename FwdIter, typename Pred = hpx::parallel::v1::detail::less>
bool is_sorted(FwdIter first, FwdIter last, Pred &&pred = Pred())
```

Determines if the range `[first, last)` is sorted. Uses `pred` to compare elements.

The comparison operations in the parallel `is_sorted` algorithm executes in sequential order in the calling thread.

**Note** Complexity: at most \((N+S-1)\) comparisons where \(N = \text{distance(first, last)}\). \(S\) = number of partitions

**Template Parameters**

- **FwdIter**: The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred**: The type of an optional function/function object to use.

**Parameters**

- **first**: Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred**: Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to
bool pred(const Type &a, const Type &b);

The signature does not need to have const &, but the function must not modify the objects passed to it. The type Type must be such that objects of types FwdIter can be dereferenced and then implicitly converted to Type.

Return The is_sorted algorithm returns a bool. The is_sorted algorithm returns true if each element in the sequence [first, last) satisfies the predicate passed. If the range [first, last) contains less than two elements, the function always returns true.

template<typename ExPolicy, typename FwdIter, typename Pred = hpx::parallel::v1::detail::less> hpx::parallel::util::detail::algorithm_result<ExPolicy, bool>::type is_sorted(ExPolicy &&policy, FwdIter first, FwdIter last, Pred &&pred = Pred())

Determines if the range [first, last) is sorted. Uses pred to compare elements.

The comparison operations in the parallel is_sorted algorithm invoked with an execution policy object of type sequenced_policy executes in sequential order in the calling thread.

Note Complexity: at most (N+S-1) comparisons where N = distance(first, last). S = number of partitions

Template Parameters
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- FwdIter: The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- Pred: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of is_sorted requires Pred to meet the requirements of CopyConstructible. This defaults to std::less<>.

Parameters
- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- last: Refers to the end of the sequence of elements of that the algorithm will be applied to.
- pred: Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

bool pred(const Type &a, const Type &b);

The signature does not need to have const &, but the function must not modify the objects passed to it. The type Type must be such that objects of types FwdIter can be dereferenced and then implicitly converted to Type.

The comparison operations in the parallel is_sorted algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
Return The `is_sorted` algorithm returns a `hpx::future<bool>` if the execution policy is of type `task_execution_policy` and returns `bool` otherwise. The `is_sorted` algorithm returns a `bool` if each element in the sequence `[first, last)` satisfies the predicate passed. If the range `[first, last)` contains less than two elements, the function always returns true.

```cpp
template<typename FwdIter, typename Pred = hpx::parallel::v1::detail::less>
FwdIter is_sorted_until (FwdIter first, FwdIter last, Pred &&pred = Pred())
```

Returns the first element in the range `[first, last)` that is not sorted. Uses a predicate to compare elements or the less than operator.

The comparison operations in the parallel `is_sorted_until` algorithm execute in sequential order in the calling thread.

Note Complexity: at most (N+S-1) comparisons where N = distance(first, last). S = number of partitions

Template Parameters

- FwdIter: The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- Pred: The type of an optional function/function object to use.

Parameters

- `first`: Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- `last`: Refers to the end of the sequence of elements of that the algorithm will be applied to.
- `pred`: Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```cpp
template<
   typename Type
>
bool pred(const Type &a, const Type &b);
```

The signature does not need to have const &,

Return The `is_sorted_until` algorithm returns a `FwdIter`. The `is_sorted_until` algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, last is returned.

```cpp
hpx::parallel::util::detail::algorithm_result<
   ExPolicy, FwdIter>
::type is_sorted_until (ExPolicy &&policy,
   FwdIter first,
   FwdIter last, Pred &&pred = Pred())
```

Returns the first element in the range `[first, last)` that is not sorted. Uses a predicate to compare elements or the less than operator.

The comparison operations in the parallel `is_sorted_until` algorithm invoked with an execution policy object of type `sequenced_policy` executes in sequential order in the calling thread.

2.8. API reference 1025
Note  Complexity: at most \((N+S-1)\) comparisons where \(N = \text{distance(first, last)}\). \(S = \text{number of partitions}\)

Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter**: The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.

- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `is_sorted_until` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.

- **first**: Refers to the beginning of the sequence of elements of that the algorithm will be applied to.

- **last**: Refers to the end of the sequence of elements of that the algorithm will be applied to.

- **pred**: Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

  ```cpp
  bool pred(const Type &a, const Type &b);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.

  The comparison operations in the parallel `is_sorted_until` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return  The `is_sorted_until` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `is_sorted_until` algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, last is returned.

```
namespace hpx

namespace parallel

Functions
```

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::less>
```
std::enable_if<hpx::is_execution_policy<ExPolicy>::value, typename util::detail::algorithm_result<ExPolicy, bool>::type>::type

Checks if the first range [first1, last1) is lexicographically less than the second range [first2, last2). Uses a provided predicate to compare elements.

The comparison operations in the parallel lexicographical_compare algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: At most 2 * min(N1, N2) applications of the comparison operation, where N1 = std::distance(first1, last) and N2 = std::distance(first2, last2).

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of lexicographical_compare requires Pred to meet the requirements of CopyConstructible. This defaults to std::less<>

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2**: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2**: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **pred**: Refers to the comparison function that the first and second ranges will be applied to.

The comparison operations in the parallel lexicographical_compare algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note** Lexicographical comparison is an operation with the following properties
- Two ranges are compared element by element
- The first mismatching element defines which range is lexicographically less or greater than the other
- If one range is a prefix of another, the shorter range is lexicographically less than the other
• If two ranges have equivalent elements and are of the same length, then the ranges are lexicographically equal
• An empty range is lexicographically less than any non-empty range
• Two empty ranges are lexicographically equal

Return  The lexicographically_compare algorithm returns a hpx::future<bool> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns bool otherwise. The lexicographically_compare algorithm returns true if the first range is lexicographically less, otherwise it returns false. range [first2, last2), it returns false.

namespace hpx

Functions

template<typename ExPolicy, typename RndIter, typename Comp>
util::detail::algorithm_result<ExPolicy>::type make_heap(ExPolicy &&policy, RndIter first, RndIter last, Comp &&comp)

Constructs a max heap in the range [first, last).

The predicate operations in the parallel make_heap algorithm invoked with an execution policy object of type sequential_execution_policy executes in sequential order in the calling thread.

Note  Complexity: at most (3*N) comparisons where N = distance(first, last).

Template Parameters

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• RndIter: The type of the source iterators used for algorithm. This iterator must meet the requirements for a random access iterator.

Parameters

• first: Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
• last: Refers to the end of the sequence of elements of that the algorithm will be applied to.
• comp: Refers to the binary predicate which returns true if the first argument should be treated as less than the second. The signature of the function should be equivalent to

```cpp
bool comp(const Type &a, const Type &b);
```

The signature does not need to have const &,. but the function must not modify the objects passed to it. The type Type must be such that objects of types RndIter can be dereferenced and then implicitly converted to Type.

The comparison operations in the parallel make_heap algorithm invoked with an execution policy object of type parallel_execution_policy or parallel_task_execution_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return  The make_heap algorithm returns a hpx::future<void> if the execution policy is of type task_execution_policy and returns void otherwise.

template<typename ExPolicy, typename RndIter>
The predicate operations in the parallel `make_heap` algorithm invoked with an execution policy object of type `parallel_execution_policy` execute in sequential order in the calling thread.

**Note** Complexity: at most (3*N) comparisons where N = distance(first, last).

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RndIter**: The type of the source iterators used for algorithm. This iterator must meet the requirements for a random access iterator.

**Parameters**
- **first**: Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of that the algorithm will be applied to.

The comparison operations in the parallel `make_heap` algorithm invoked with an execution policy object of type `parallel_execution_policy` or `parallel_task_execution_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `make_heap` algorithm returns a `hpx::future<void>` if the execution policy is of type `task_execution_policy` and returns `void` otherwise.

**namespace hpx**

**Functions**

```
template<typename ExPolicy, typename RandIter1, typename RandIter2, typename RandIter3, typename Comp = detail::less>
util::detail::algorithm_result<ExPolicy, RandIter3>::type merge(ExPolicy &&policy, RandIter1 first1, RandIter1 last1, RandIter2 first2, RandIter2 last2, RandIter3 dest, Comp &&comp = Comp())
```

Merges two sorted ranges [first1, last1) and [first2, last2) into one sorted range beginning at `dest`. The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. The destination range cannot overlap with either of the input ranges.

The assignments in the parallel `merge` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs O(std::distance(first1, last1) + std::distance(first2, last2)) applications of the comparison `comp` and the each projection.

**Template Parameters**
• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **RandIter1**: The type of the source iterators used (deduced) representing the first sorted range. This iterator type must meet the requirements of an random access iterator.

• **RandIter2**: The type of the source iterators used (deduced) representing the second sorted range. This iterator type must meet the requirements of an random access iterator.

• **RandIter3**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an random access iterator.

• **Comp**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `merge` requires `Comp` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the first range of elements the algorithm will be applied to.
- **last1**: Refers to the end of the first range of elements the algorithm will be applied to.
- **first2**: Refers to the beginning of the second range of elements the algorithm will be applied to.
- **last2**: Refers to the end of the second range of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **comp**: `comp` is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```cpp
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `RandIter1` and `RandIter2` can be dereferenced and then implicitly converted to both `Type1` and `Type2`.

The assignments in the parallel `merge` algorithm invoked with an execution policy object of type `sequenced_task_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

#### Return

The `merge` algorithm returns a `hpx::future<RandIter3>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `tagged_tuple<RandIter3>` otherwise. The `merge` algorithm returns the destination iterator to the end of the `dest` range.

```cpp
template<
typename ExPolicy, typename RandIter, typename Comp = detail::less>
util::detail::algorithm_result<ExPolicy>::type inplace_merge(ExPolicy &&policy, RandIter first, RandIter middle, RandIter last, Comp &&comp = Comp())
```

Merges two consecutive sorted ranges `[first, middle)` and `[middle, last)` into one sorted range `[first, last)`. The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range.

The assignments in the parallel `inplace_merge` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.
**Note** Complexity: Performs $O(\text{std::distance}(\text{first}, \text{last}))$ applications of the comparison $\text{comp}$ and the each projection.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **RandIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.

- **Comp**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `inplace_merge` requires $\text{Comp}$ to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.

- **first**: Refers to the beginning of the first sorted range the algorithm will be applied to.

- **middle**: Refers to the end of the first sorted range and the beginning of the second sorted range the algorithm will be applied to.

- **last**: Refers to the end of the second sorted range the algorithm will be applied to.

- **comp**: $\text{comp}$ is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```cpp
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types $\text{Type1}$ and $\text{Type2}$ must be such that objects of types `RandIter` can be dereferenced and then implicitly converted to both $\text{Type1}$ and $\text{Type2}$.

The assignments in the parallel `inplace_merge` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `inplace_merge` algorithm returns a `hpx::future<void>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns void otherwise. The `inplace_merge` algorithm returns the source iterator `last`.

```cpp
namespace hpx

namespace parallel

Functions

template<typename ExPolicy, typename FwdIter, typename Proj = util::projection_identity, typename F = detail::less>
util::detail::algorithm_result<ExPolicy, FwdIter>::type min_element (ExPolicy &&policy,
    FwdIter first, FwdIter last,
    F &&f = F(), Proj &&proj
    = Proj())
```

Finds the smallest element in the range [first, last) using the given comparison function $f$. 

---

**2.8. API reference** 1031
The comparisons in the parallel *min_element* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

**Note** Complexity: Exactly $\max(N-1, 0)$ comparisons, where $N = \text{std::distance}(\text{first}, \text{last})$.

**Template Parameters**
- *ExPolicy*: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- *FwdIter*: The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- *F*: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *min_element* requires *F* to meet the requirements of *CopyConstructible*.
- *Proj*: The type of an optional projection function. This defaults to util::projection_identity

**Parameters**
- *policy*: The execution policy to use for the scheduling of the iterations.
- *first*: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- *last*: Refers to the end of the sequence of elements the algorithm will be applied to.
- *f*: The binary predicate which returns true if the the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.
- *proj*: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The comparisons in the parallel *min_element* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The *min_element* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter* otherwise. The *min_element* algorithm returns the iterator to the smallest element in the range [first, last). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```cpp
template<typename ExPolicy, typename FwdIter, typename Proj = util::projection_identity, typename F = detail::less>
util::detail::algorithm_result<ExPolicy, FwdIter>::type
max_element(ExPolicy &&policy, FwdIter first, FwdIter last, F &&f = F(), Proj &&proj = Proj())
```

Finds the greatest element in the range [first, last) using the given comparison function *f*.

The comparisons in the parallel *max_element* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

**Note** Complexity: Exactly $\max(N-1, 0)$ comparisons, where $N = \text{std::distance}(\text{first}, \text{last})$.

**Template Parameters**
- *ExPolicy*: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- *FwdIter*: The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- *F*: The type of the function/function object to use (deduced). Unlike its sequential form, the
parallel overload of `max_element` requires `F` to meet the requirements of `CopyConstructible`.

- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **f**: The binary predicate which returns true if the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The comparisons in the parallel `max_element` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `max_element` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `max_element` algorithm returns the iterator to the smallest element in the range `[first, last)`. If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```cpp
template<typename ExPolicy, typename FwdIter, typename Proj = util::projection_identity, typename F = detail::less>
util::detail::algorithm_result<ExPolicy, hpx::util::tagged_pair<tag::min(FwdIter), tag::max FwdIter>>, type minmax_element ExPolicy &&policy, FwdIter first, FwdIter last, F &&f = F(), Proj &&proj = Proj() finds the greatest element in the range [first, last) using the given comparison function `f`.
```

The comparisons in the parallel `minmax_element` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: At most \(\text{max}(\text{floor}(3/2^*(N-1)), 0)\) applications of the predicate, where \(N = \text{std::distance(first, last)}\).

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `minmax_element` requires `F` to meet the requirements of `CopyConstructible`.
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **f**: The binary predicate which returns true if the left argument is less than the right element. This argument is optional and defaults to `std::less`. The signature of the predicate function should be equivalent to the following:
bool pred(const Type1 &a, const Type1 &b);

The signature does not need to have const &, but the function must not modify the objects passed to it. The type Type1 must be such that objects of type FwdIter can be dereferenced and then implicitly converted to Type1.

• proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The comparisons in the parallel minmax_element algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The minmax_element algorithm returns a hpx::future<tagged_pair<tag::min(FwdIter), tag::max(FwdIter)> > if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns tagged_pair<tag::min(FwdIter), tag::max(FwdIter)> otherwise. The minmax_element algorithm returns a pair consisting of an iterator to the smallest element as the first element and an iterator to the greatest element as the second. Returns std::make_pair(first, first) if the range is empty. If several elements are equivalent to the smallest element, the iterator to the first such element is returned. If several elements are equivalent to the largest element, the iterator to the last such element is returned.

namespace hpx

Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result<ExPolicy, std::pair<FwdIter1, FwdIter2>>::type mismatch (ExPolicy &&policy,
FwdIter1 first1,
FwdIter1 last1,
FwdIter2 first2,
FwdIter2 last2, Pred &&op = Pred())

Returns true if the range [first1, last1) is mismatch to the range [first2, last2), and false otherwise.

The comparison operations in the parallel mismatch algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: At most min(last1 - first1, last2 - first2) applications of the predicate f. If FwdIter1 and FwdIter2 meet the requirements of RandomAccessIterator and (last1 - first1) != (last2 - first2) then no applications of the predicate f are made.

Template Parameters

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• FwdIter1: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
• **FwdIter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

• **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `mismatch` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`

### Parameters

• **policy**: The execution policy to use for the scheduling of the iterations.

• **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

• **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

• **first2**: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

• **last2**: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

• **op**: The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

The comparison operations in the parallel `mismatch` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

### Note

The two ranges are considered mismatch if, for every iterator `i` in the range `[first1,last1)`, *(i mismatches *(first2 + (i - first1))). This overload of `mismatch` uses `operator==` to determine if two elements are mismatch.

### Return

The `mismatch` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `mismatch` algorithm returns true if the elements in the two ranges are mismatch, otherwise it returns false. If the length of the range `[first1, last1) does not mismatch the length of the range `[first2, last2), it returns false.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result<ExPolicy, std::pair<FwdIter1, FwdIter2>>::type mismatch(ExPolicy &&policy,
  FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, Pred &&op = Pred())
```

Returns `std::pair` with iterators to the first two non-equivalent elements.
The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: At most `last1 - first1` applications of the predicate `f`.

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter1`: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- `FwdIter2`: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- `Pred`: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *mismatch* requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`

**Parameters**

- `policy`: The execution policy to use for the scheduling of the iterations.
- `first1`: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- `last1`: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- `first2`: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- `op`: The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The *mismatch* algorithm returns a `hpx::future<std::pair<FwdIter1, FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `std::pair<FwdIter1, FwdIter2>` otherwise. The *mismatch* algorithm returns the first mismatching pair of elements from two ranges: one defined by `[first1, last1)` and another defined by `[first2, last2).`
Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
util::detail::algorithm_result<ExPolicy, FwdIter2>::type move(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest)

Moves the elements in the range [first, last), to another range beginning at dest. After this operation the elements in the moved-from range will still contain valid values of the appropriate type, but not necessarily the same values as before the move.

The move assignments in the parallel move algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Performs exactly last - first move assignments.

Template Parameters
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the move assignments.
- FwdIter1: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- FwdIter2: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters
- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last: Refers to the end of the sequence of elements the algorithm will be applied to.
- dest: Refers to the beginning of the destination range.

The move assignments in the parallel move algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The move algorithm returns a hpx::future<tagged_pair<tag::in(FwdIter1), tag::out(FwdIter2)>> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns tagged_pair<tag::in(FwdIter1), tag::out(FwdIter2)>> otherwise. The move algorithm returns the pair of the input iterator last and the output iterator to the element in the destination range, one past the last element moved.

namespace hpx

2.8. API reference 1037
Functions

```cpp
template<
    typename RandIter,
    typename ExPolicy
>
util::detail::algorithm_result<ExPolicy>::type partial_sort(
    ExPolicy &&policy,
    RandIter first,
    RandIter middle,
    RandIter last
)
```

Places the first middle - first elements from the range [first, last) as sorted with respect to comp into the range [first, middle). The rest of the elements in the range [middle, last) are placed in an unspecified order.

**Note** Complexity: Approximately (last - first) * log(middle - first) comparisons.

**Return** The `partial_sort` algorithm returns a `hpx::future<void>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns void otherwise.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **RandIter**: The type of the source begin, middle, and end iterators used (deduced). This iterator type must meet the requirements of a random access iterator.

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **middle**: Refers to the middle of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.

```cpp
namespace hpx

namespace parallel

Functions

```cpp
template<
    typename ExPolicy,
    typename BidirIter,
    typename F,
    typename Proj = util::projection_identity
>
util::detail::algorithm_result<ExPolicy, BidirIter>::type stable_partition(
    ExPolicy &&policy,
    BidirIter first,
    BidirIter last,
    F &&f,
    Proj &&proj
)
```

Permutes the elements in the range [first, last) such that there exists an iterator i such that for every iterator j in the range [first, i) \(\text{INVOK}(f, \text{INVOK}(\text{proj}, *j)) \neq \text{false} \), and for every iterator k in the range [i, last), \(\text{INVOK}(f, \text{INVOK}(\text{proj}, *k)) \neq \text{false} \)

The invocations of \(f\) in the parallel `stable_partition` algorithm invoked with an execution policy object of type `sequenced_policy` executes in sequential order in the calling thread.

**Note** Complexity: At most (last - first) * log(last - first) swaps, but only linear number of swaps if there is enough extra memory. Exactly `last - first` applications of the predicate and projection.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of \(f\).
**BidirIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.

**F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `transform` requires `F` to meet the requirements of `CopyConstructible`.

**Proj**: The type of an optional projection function. This defaults to `util::projection_identity`.

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **f**: Unary predicate which returns true if the element should be ordered before other elements. Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. The signature of this predicate should be equivalent to:

  ```cpp
def fun(const Type &a);
```

The signature does not need to have `const&`. The type `Type` must be such that an object of type `BidirIter` can be dereferenced and then implicitly converted to `Type`.

- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate `f` is invoked.

The invocations of `f` in the parallel `stable_partition` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

### Return

The `stable_partition` algorithm returns an iterator `i` such that for every iterator `j` in the range `[first, i)`, `f(*j) != false` and `INVOKE(f, INVOKE(proj, *j)) != false`, and for every iterator `k` in the range `[i, last)`, `f(*k) == false` and `INVOKE(f, INVOKE(proj, *k)) == false`. The relative order of the elements in both groups is preserved. If the execution policy is of type `parallel_task_policy` the algorithm returns a `future<>` referring to this iterator.

```cpp
template<typename ExPolicy, typename FwdIter, typename Pred, typename Proj = util::projection_identity
util::detail::algorithm_result<ExPolicy, FwdIter>::type partition(ExPolicy &&policy, FwdIter first, FwdIter last, Pred &&pred, Proj &&proj = Proj())
```

Reorders the elements in the range `[first, last) in such a way that all elements for which the predicate `pred` returns true precede the elements for which the predicate `pred` returns false. Relative order of the elements is not preserved.

The assignments in the parallel `partition` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequentially order in the calling thread.

### Note

Complexity: At most `2 * (last - first)` swaps. Exactly `last - first` applications of the predicate and projection.

### Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `partition` requires `Pred` to meet the requirements of `CopyConstructible`.
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`.

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
• **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
• **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `InIter` can be dereferenced and then implicitly converted to `Type`.

• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate `pred` is invoked.

The assignments in the parallel `partition` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

### Return

The `partition` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `parallel_task_policy` and returns `FwdIter` otherwise. The `partition` algorithm returns the iterator to the first element of the second group.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, hpx::util::tagged_tuple<tag::in(FwdIter1), tag::out1 FwdIter2, tag::out2FwdIter3>>:type partition_copy(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest_true, FwdIter3 dest_false, Pred &&pred, Proj &&proj = Proj())Copies the elements in the range, defined by [first, last), to two different ranges depending on the value returned by the predicate `pred`. The elements, that satisfy the predicate `pred`, are copied to the range beginning at `dest_true`. The rest of the elements are copied to the range beginning at `dest_false`. The order of the elements is preserved.
```

The assignments in the parallel `partition_copy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

### Note

Complexity: Performs not more than `last - first` assignments, exactly `last - first` applications of the predicate `f`.

### Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the iterator representing the destination range for the elements that satisfy the predicate `pred` (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter3**: The type of the iterator representing the destination range for the elements that don’t satisfy the predicate `pred` (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `partition_copy` requires `Pred` to meet the requirements of `CopyConstructible`.
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`
• **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
• **dest_true**: Refers to the beginning of the destination range for the elements that satisfy the predicate `pred`.
• **dest_false**: Refers to the beginning of the destination range for the elements that don’t satisfy the predicate `pred`.
• **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`.
• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel `partition_copy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `partition_copy` algorithm returns a `hpx::future<tagged_tuple<tag::in(InIter), tag::out1(OutIter1), tag::out2(OutIter2)>>` if the execution policy is of type `parallel_task_policy` and returns `tagged_tuple<tag::in(InIter), tag::out1(OutIter1), tag::out2(OutIter2)>>` otherwise. The `partition_copy` algorithm returns the tuple of the source iterator `last`, the destination iterator to the end of the `dest_true` range, and the destination iterator to the end of the `dest_false` range.

```cpp
namespace hpx

Functions

template<typename ExPolicy, typename FwdIter, typename T, typename F>
util::detail::algorithm_result<ExPolicy, T>::type reduce(ExPolicy &&policy, FwdIter first, FwdIter last, T init, F &&f)
```

Returns `GENERALIZED_SUM(f, init, *first, ..., *(first + (last - first) - 1))`.

The `reduce` operations in the parallel `reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: O(`last - first`) applications of the predicate `f`.

**Template Parameters**

• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• **FwdIter**: The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
• **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `copy_if` requires `F` to meet the requirements of `CopyConstructible`.
• **T**: The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**
• **policy**: The execution policy to use for the scheduling of the iterations.

• **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **last**: Refers to the end of the sequence of elements the algorithm will be applied to.

• **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature of this predicate should be equivalent to:

```cpp
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&. The types `Type1 Ret` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to any of those types.

• **init**: The initial value for the generalized sum.

The reduce operations in the parallel `copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `reduce` and `accumulate` is that the behavior of `reduce` may be non-deterministic for non-associative or non-commutative binary predicate.

**Return** The `reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `T` otherwise. The `reduce` algorithm returns the result of the generalized sum over the elements given by the input range [first, last).

**Note** GENERALIZED_SUM(op, a1, . . . , aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(op, b1, . . . , bK), GENERALIZED_SUM(op, bM, . . . , bN)), where:
  - b1, . . . , bN may be any permutation of a1, . . . , aN and
  - 1 < K+1 = M <= N.

```cpp
template<typename ExPolicy, typename FwdIter, typename T>
util::detail::algorithm_result<ExPolicy, T>::type reduce(ExPolicy &&policy, FwdIter first, FwdIter last, T init)
```

Returns GENERALIZED_SUM(+, init, *first, . . . , *(first + (last - first) - 1)).

The reduce operations in the parallel `reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: O(last - first) applications of the operator+().

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter**: The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

- **T**: The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• last: Refers to the end of the sequence of elements the algorithm will be applied to.
• init: The initial value for the generalized sum.

The reduce operations in the parallel `copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `reduce` and `accumulate` is that the behavior of `reduce` may be non-deterministic for non-associative or non-commutative binary predicate.

**Return** The `reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_policy` or `parallel_task_policy` and returns `T` otherwise. The `reduce` algorithm returns the result of the generalized sum (applying operator+) over the elements given by the input range `[first, last).

**Note** GENERALIZED_SUM(+, a1, . . . , aN) is defined as follows:

• a1 when N is 1
• op(GENERALIZED_SUM(+, b1, . . . , bK), GENERALIZED_SUM(+, bM, . . . , bN)), where:
  – b1, . . . , bN may be any permutation of a1, . . . , aN and
  – 1 < K+1 = M <= N.

```cpp
template<typename ExPolicy, typename FwdIter>
util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<FwdIter>::value_type>::type reduce(
    ExPolicy&& policy,
    FwdIter first,
    FwdIter last)
```

Returns GENERALIZED_SUM(+, T(), *first, . . . , *(first + (last - first) - 1)).

The reduce operations in the parallel `reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: O(last - first) applications of the operator+().

**Template Parameters**

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• FwdIter: The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

• policy: The execution policy to use for the scheduling of the iterations.
• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• last: Refers to the end of the sequence of elements the algorithm will be applied to.
The reduce operations in the parallel `copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `reduce` and `accumulate` is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

**Return** The `reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `T` otherwise (where `T` is the `value_type` of `FwdIter`). The `reduce` algorithm returns the result of the generalized sum (applying `operator+()` over the elements given by the input range [first, last]).

**Note** The type of the initial value (and the result type) `T` is determined from the `value_type` of the used `FwdIter`.

**Note** `GENERALIZED_SUM(+, a1, …, aN)` is defined as follows:

- `a1` when `N` is `1`
- `op(GENERALIZED_SUM(+, b1, …, bK), GENERALIZED_SUM(+, bM, …, bN))`, where:
  - `b1, …, bN` may be any permutation of `a1, …, aN` and
  - `1 < K+1 = M <= N`.

```cpp
namespace hpx
{
  namespace parallel
  {

    Functions

    template<
typename ExPolicy, typename RanIter, typename RanIter2, typename FwdIter1, typen
Reduce by Key performs an inclusive scan reduction operation on elements supplied in key/value pairs. The algorithm produces a single output value for each set of equal consecutive keys in \([key\_first, key\_last)\). The value being the GENERALIZED_NONCOMMUTATIVE_SUM(op, init, *first, . . . , *(first + (i - result))). for the run of consecutive matching keys. The number of keys supplied must match the number of values.

\[comp\] has to induce a strict weak ordering on the values.

**Note** Complexity: \(O(last - first)\) applications of the predicate \(op\).

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **RanIter**: The type of the key iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **RanIter2**: The type of the value iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **FwdIter1**: The type of the iterator representing the destination key range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the iterator representing the destination value range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Compare**: The type of the optional function/function object to use to compare keys (deduced). Assumed to be std::equal_to otherwise.
- **Func**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \(copy\_if\) requires \(F\) to meet the requirements of CopyConstructible.

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **key\_first**: Refers to the beginning of the sequence of key elements the algorithm will be
applied to.

- `key_last`: Refers to the end of the sequence of key elements the algorithm will be applied to.
- `values_first`: Refers to the beginning of the sequence of value elements the algorithm will be applied to.
- `keys_output`: Refers to the start output location for the keys produced by the algorithm.
- `values_output`: Refers to the start output location for the values produced by the algorithm.
- `comp`: `comp` is a callable object. The return value of the `INVOKE` operation applied to an object of type `Comp`, when contextually converted to `bool`, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator.
- `func`: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is a binary predicate. The signature of this predicate should be equivalent to:

```cpp
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`. The types `Type1 Ret` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to any of those types.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `reduce_by_key` algorithm returns a `hpx::future<pair<Iter1,Iter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `pair<Iter1,Iter2>` otherwise.

```cpp
namespace hpx
{

Functions

template<typename FwdIter, typename T>
FwdIter remove(FwdIter first, FwdIter last, T const &value)

Removes all elements satisfying specific criteria from the range `[first, last)` and returns a past-the-end iterator for the new end of the range. This version removes all elements that are equal to `value`.

The assignments in the parallel `remove` algorithm execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than `last - first` assignments, exactly `last - first` applications of the operator `==()`.

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter`: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
• **T**: The type of the value to remove (deduced). This value type must meet the requirements of `CopyConstructible`.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **value**: Specifies the value of elements to remove.

**Return** The `remove` algorithm returns a `FwdIter`. The `remove` algorithm returns the iterator to the new end of the range.

```cpp
template<typename ExPolicy, typename FwdIter, typename T>
util::detail::algorithm_result<ExPolicy, FwdIter>::type remove(ExPolicy &&policy, FwdIter first, FwdIter last, T const &value)
```

Removes all elements satisfying specific criteria from the range `[first, last)` and returns a past-the-end iterator for the new end of the range. This version removes all elements that are equal to `value`.

The assignments in the parallel `remove` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than `last-first` assignments, exactly `last-first` applications of the operator==().

**Template Parameters**

- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T**: The type of the value to remove (deduced). This value type must meet the requirements of `CopyConstructible`.

**Parameters**

- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **value**: Specifies the value of elements to remove.

The assignments in the parallel `remove` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `remove` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `remove` algorithm returns the iterator to the new end of the range.

```cpp
template<typename FwdIter, typename Pred>
FwdIter remove_if(FwdIter first, FwdIter last, Pred &&pred)
```

Removes all elements satisfying specific criteria from the range `[first, last)` and returns a past-the-end iterator for the new end of the range. This version removes all elements for which predicate `pred` returns true.
The assignments in the parallel `remove_if` algorithm execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than `last - first` assignments, exactly `last - first` applications of the predicate `pred`.

### Template Parameters
- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `remove_if` requires `Pred` to meet the requirements of `CopyConstructible`.

### Parameters
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

### Return
The `remove_if` algorithm returns a `FwdIter`. The `remove_if` algorithm returns the iterator to the new end of the range.

```cpp
template<typename ExPolicy, typename FwdIter, typename Pred>
util::detail::algorithm_result<ExPolicy, FwdIter>::type remove_if (ExPolicy &&policy, FwdIter first, FwdIter last, Pred &&pred)
```

Removes all elements satisfying specific criteria from the range `[first, last)` and returns a past-the-end iterator for the new end of the range. This version removes all elements for which predicate `pred` returns `true`.

The assignments in the parallel `remove_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than `last - first` assignments, exactly `last - first` applications of the predicate `pred`.

### Template Parameters
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `remove_if` requires `Pred` to meet the requirements of `CopyConstructible`.

### Parameters
- **policy**: The execution policy to use for the scheduling of the iterations.
first: Refers to the beginning of the sequence of elements the algorithm will be applied to.

last: Refers to the end of the sequence of elements the algorithm will be applied to.

pred: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\). This is an unary predicate which returns \(true\) for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have \(\text{const}\&\), but the function must not modify the objects passed to it. The type \(\text{Type}\) must be such that an object of type \(\text{FwdIter}\) can be dereferenced and then implicitly converted to \(\text{Type}\).

The assignments in the parallel remove_if algorithm invoked with an execution policy object of type \(\text{parallel_policy}\) or \(\text{parallel_task_policy}\) are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The remove_if algorithm returns a \(\text{hpx::future<FwdIter>}\) if the execution policy is of type \(\text{sequenced_task_policy}\) or \(\text{parallel_task_policy}\) and returns \(\text{FwdIter}\) otherwise. The remove_if algorithm returns the iterator to the new end of the range.

namespace hpx

Functions

template<typename InIter, typename OutIter, typename T>
FwdIter remove_copy (InIter first, InIter last, OutIter dest, T const &value)

Copies the elements in the range, defined by \([\text{first}, \text{last})\), to another range beginning at \(\text{dest}\). Copies only the elements for which the comparison operator returns false when compare to value. The order of the elements that are not removed is preserved.

Effects: Copies all the elements referred to by the iterator \(\text{it}\) in the range \([\text{first},\text{last})\) for which the following corresponding conditions do not hold: \(*\text{it} == \text{value}\)

The assignments in the parallel remove_copy algorithm execute in sequential order in the calling thread.

Note Complexity: Performs not more than \(\text{last} - \text{first}\) assignments, exactly \(\text{last} - \text{first}\) applications of the predicate \(f\).

Template Parameters

- \(\text{InIter}\): The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.

- \(\text{OutIter}\): The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

- \(T\): The type that the result of dereferencing \(\text{FwdIter1}\) is compared to.

Parameters

- \(\text{first}\): Refers to the beginning of the sequence of elements the algorithm will be applied to.

- \(\text{last}\): Refers to the end of the sequence of elements the algorithm will be applied to.

- \(\text{dest}\): Refers to the beginning of the destination range.

- \(\text{val}\): Value to be removed.
Return The remove_copy algorithm returns an OutIter. The remove_copy algorithm returns the iterator to the element past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename T>
FwdIter remove_copy (ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest, T const &val)
```

Copies the elements in the range, defined by [first, last), to another range beginning at dest. Copies only the elements for which the comparison operator returns false when compare to value. The order of the elements that are not removed is preserved.

Effects: Copies all the elements referred to by the iterator it in the range [first,last) for which the following corresponding conditions do not hold: *it == value

The assignments in the parallel remove_copy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Performs not more than last - first assignments, exactly last - first applications of the predicate f.

Template Parameters

- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- FwdIter1: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- FwdIter2: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- T: The type that the result of dereferencing FwdIter1 is compared to.

Parameters

- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last: Refers to the end of the sequence of elements the algorithm will be applied to.
- dest: Refers to the beginning of the destination range.
- val: Value to be removed.

The assignments in the parallel remove_copy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The remove_copy algorithm returns a hpx::future<FwdIter2> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter2 otherwise. The remove_copy algorithm returns the iterator to the element past the last element copied.

```cpp
template<typename InIter, typename OutIter, typename Pred>
FwdIter remove_copy_if (InIter first, InIter last, OutIter dest, Pred &&pred)
```

Copies the elements in the range, defined by [first, last), to another range beginning at dest. Copies only the elements for which the predicate f returns false. The order of the elements that are not removed is preserved.
Effects: Copies all the elements referred to by the iterator it in the range [first,last) for which the following corresponding conditions do not hold: INVOKE(pred, *it) != false.

The assignments in the parallel remove_copy_if algorithm execute in sequential order in the calling thread.

Note Complexity: Performs not more than last - first assignments, exactly last - first applications of the predicate f.

Template Parameters
- **InIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter**: The type of the iterator representing the destination range (deduced).
- **Pred**: The type of the function/function object to use (deduced).

Parameters
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns true for the elements to be removed. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type InIter can be dereferenced and then implicitly converted to Type.

Return The remove_copy_if algorithm returns an OutIter. The remove_copy_if algorithm returns the iterator to the element past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred>
FwdIter remove_copy_if(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest, Pred &&pred)
```

Copies the elements in the range, defined by [first, last), to another range beginning at dest. Copies only the elements for which the predicate f returns false. The order of the elements that are not removed is preserved.

Effects: Copies all the elements referred to by the iterator it in the range [first,last) for which the following corresponding conditions do not hold: INVOKE(pred, *it) != false.

The assignments in the parallel remove_copy_if algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Performs not more than last - first assignments, exactly last - first applications of the predicate f.

Template Parameters
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• **FwdIter1**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

• **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

• **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `remove_copy_if` requires `Pred` to meet the requirements of `CopyConstructible`.

**Parameters**

• **policy**: The execution policy to use for the scheduling of the iterations.

• **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **last**: Refers to the end of the sequence of elements the algorithm will be applied to.

• **dest**: Refers to the beginning of the destination range.

• **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns `true` for the elements to be removed. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`.

The assignments in the parallel `remove_copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `remove_copy_if` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `remove_copy_if` algorithm returns the iterator to the element past the last element copied.

```cpp
namespace hpx
{

Functions

template<typename InIter, typename T>
void replace(InIter first, InIter last, T const &old_value, T const &new_value)
    Replaces all elements satisfying specific criteria with `new_value` in the range [first, last).

    Effects: Substitutes elements referred by the iterator `it` in the range [first, last) with `new_value`, when the following corresponding conditions hold: `*it == old_value`

    The assignments in the parallel `replace` algorithm execute in sequential order in the calling thread.

    **Note** Complexity: Performs exactly `last - first` assignments.

Template Parameters

• **InIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.

• **T**: The type of the old and new values to replace (deduced).
```
Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **old_value**: Refers to the old value of the elements to replace.
- **new_value**: Refers to the new value to use as the replacement.

**Return** The `replace` algorithm returns a `void`.

```
template<typename ExPolicy, typename FwdIter, typename T>
parallel::util::detail::algorithm_result<ExPolicy, void>::type replace(ExPolicy &&policy, FwdIter first, FwdIter last, T const &old_value, T const &new_value)
```

Replaces all elements satisfying specific criteria with `new_value` in the range `[first, last)`.

Effects: Substitutes elements referred by the iterator `it` in the range `[first, last)` with `new_value`, when the following corresponding conditions hold: 

```
*it == old_value
```

The assignments in the parallel `replace` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `last - first` assignments.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **T**: The type of the old and new values to replace (deduced).

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **old_value**: Refers to the old value of the elements to replace.
- **new_value**: Refers to the new value to use as the replacement.

The assignments in the parallel `replace` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `replace` algorithm returns a `hpx::future<void>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `void` otherwise.

```
template<typename Iter, typename Pred, typename T>
```
void replace_if (Iter first, Iter last, Pred &&pred, T const &new_value)
Replaces all elements satisfying specific criteria (for which predicate f returns true) with new_value in the range [first, last).

Effects: Substitutes elements referred by the iterator it in the range [first, last) with new_value, when the following corresponding conditions hold: INVOKE(f, *it) != false

The assignments in the parallel replace_if algorithm execute in sequential order in the calling thread.

Note Complexity: Performs exactly last - first applications of the predicate.

Template Parameters

- Iter: The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- Pred: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of equal requires Pred to meet the requirements of CopyConstructible. (deduced).
- T: The type of the new values to replace (deduced).

Parameters

- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last: Refers to the end of the sequence of elements the algorithm will be applied to.
- pred: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns true for the elements which need to replaced. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type InIter can be dereferenced and then implicitly converted to Type.
- new_value: Refers to the new value to use as the replacement.

Return The replace_if algorithm returns void.

template<
typename ExPolicy, typename FwdIter, typename Pred, typename T>
parallel::util::detail::algorithm_result<ExPolicy, void>::type replace_if (ExPolicy &&policy,
FwdIter first, FwdIter last, Pred &&pred, T const &new_value)
Replaces all elements satisfying specific criteria (for which predicate f returns true) with new_value in the range [first, last).

Effects: Substitutes elements referred by the iterator it in the range [first, last) with new_value, when the following corresponding conditions hold: INVOKE(f, *it) != false

The assignments in the parallel replace_if algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Performs exactly last - first applications of the predicate.
Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

- **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible` (deduced).

- **T**: The type of the new values to replace (deduced).

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.

- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.

- **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the elements which need to replaced. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **new_value**: Refers to the new value to use as the replacement.

The assignments in the parallel `replace_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `replace_if` algorithm returns a `hpx::future<void>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `void` otherwise.

```
template<
  typename InIter,
  typename OutIter,
  typename T
>
OutIter replace_copy(InIter first, InIter last, OutIter dest, T const &old_value, T const &new_value)
```

Copies the all elements from the range `[first, last)` to another range beginning at `dest` replacing all elements satisfying a specific criteria with `new_value`.

Effects: Assigns to every iterator it in the range `[result, result + (last - first))` either `new_value` or `*(first + (it - result))` depending on whether the following corresponding condition holds: `*(first + (i - result)) == old_value`.

The assignments in the parallel `replace_copy` algorithm execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `last - first` applications of the predicate. of the algorithm may be parallelized and the manner in which it executes the assignments.

Template Parameters
• **InIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.

• **OutIter**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

• **T**: The type of the old and new values (deduced).

**Parameters**

• **policy**: The execution policy to use for the scheduling of the iterations.

• **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **last**: Refers to the end of the sequence of elements the algorithm will be applied to.

• **dest**: Refers to the beginning of the destination range.

• **old_value**: Refers to the old value of the elements to replace.

• **new_value**: Refers to the new value to use as the replacement.

**Return** The replace_copy algorithm returns an **OutIter**. The replace_copy algorithm returns the Iterator to the element past the last element copied.

template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename T>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter2> replace_copy(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest, T const &old_value, T const &new_value)

Copies all elements from the range [first, last) to another range beginning at dest replacing all elements satisfying a specific criteria with new_value.

Effects: Assigns to every iterator it in the range [result, result + (last - first)) either new_value or *(first + (it - result)) depending on whether the following corresponding condition holds: *(first + (i - result)) == old_value

The assignments in the parallel replace_copy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly last - first applications of the predicate.

**Template Parameters**

• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **FwdIter1**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

• **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

• **T**: The type of the old and new values (deduced).
• policy: The execution policy to use for the scheduling of the iterations.
• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• last: Refers to the end of the sequence of elements the algorithm will be applied to.
• dest: Refers to the beginning of the destination range.
• old_value: Refers to the old value of the elements to replace.
• new_value: Refers to the new value to use as the replacement.

The assignments in the parallel replace_copy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The replace_copy algorithm returns a hpx::future<FwdIter2> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter2 otherwise. The replace_copy algorithm returns the Iterator to the element past the last element copied.

template<typename InIter, typename OutIter, typename Pred, typename T>
OutIter replace_copy_if(InIter first, InIter last, OutIter dest, Pred &&pred, T const &new_value)

Copies the all elements from the range [first, last) to another range beginning at dest replacing all elements satisfying a specific criteria with new_value.

Effects: Assigns to every iterator it in the range [result, result + (last - first)) either new_value or *(first + (it - result)) depending on whether the following corresponding condition holds: INVOKE(f, *(first + (i - result()))) != false

The assignments in the parallel replace_copy_if algorithm execute in sequential order in the calling thread.

Note Complexity: Performs exactly last - first applications of the predicate.

Template Parameters
• InIter: The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
• OutIter: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
• Pred: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of equal requires Pred to meet the requirements of CopyConstructible. (deduced).
• T: The type of the new values to replace (deduced).

Parameters
• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• last: Refers to the end of the sequence of elements the algorithm will be applied to.
• dest: Refers to the beginning of the destination range.
• pred: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns true for the elements which need to replaced. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```
The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type InIter can be dereferenced and then implicitly converted to Type.

- new_value: Refers to the new value to use as the replacement.

Return The replace_copy_if algorithm returns an OutIter. The replace_copy_if algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred, typename T>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type replace_copy_if (ExPolicy &&policy,
                                      FwdIter1 first,
                                      FwdIter1 last,
                                      FwdIter2 dest,
                                      Pred &&pred,
                                      T const &&new_value)
```

Copies the all elements from the range [first, last) to another range beginning at dest replacing all elements satisfying a specific criteria with new_value.

Effects: Assigns to every iterator it in the range [result, result + (last - first)) either new_value or *(first + (it - result)) depending on whether the following corresponding condition holds: INVOKE(f, *(first + (i - result))) != false

The assignments in the parallel replace_copy_if algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Performs exactly last - first applications of the predicate.

Template Parameters
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- FwdIter1: The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- FwdIter2: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- Pred: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of equal requires F to meet the requirements of CopyConstructible. (deduced).
- T: The type of the new values to replace (deduced).

Parameters
- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last: Refers to the end of the sequence of elements the algorithm will be applied to.
- dest: Refers to the beginning of the destination range.
- pred: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns true for the elements which need to replaced. The signature of this predicate should be equivalent to:
bool pred(const Type &a);

The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type FwdIter1 can be dereferenced and then implicitly converted to Type.

• new_value: Refers to the new value to use as the replacement.

The assignments in the parallel replace_copy_if algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The replace_copy_if algorithm returns a hpx::future<FwdIter2> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter2 otherwise. The replace_copy_if algorithm returns the iterator to the element in the destination range, one past the last element copied.

namespace hpx

namespace parallel

**Functions**

```cpp
template<typename ExPolicy, typename BidirIter>
util::detail::algorithm_result<ExPolicy, BidirIter>::type reverse(ExPolicy &&policy, BidirIter first, BidirIter last)
```

Reverses the order of the elements in the range [first, last). Behaves as if applying std::iter_swap to every pair of iterators first+i, (last-i) - 1 for each non-negative i < (last-first)/2.

The assignments in the parallel reverse algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Linear in the distance between first and last.

**Template Parameters**

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• BidirIter: The type of the source iterators used (deduced). This iterator type must meet the requirements of an bidirectional iterator.

**Parameters**

• policy: The execution policy to use for the scheduling of the iterations.

• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.

• last: Refers to the end of the sequence of elements the algorithm will be applied to.

The assignments in the parallel reverse algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The reverse algorithm returns a hpx::future<BidirIter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns BidirIter otherwise. It returns last.

```cpp
template<typename ExPolicy, typename BidirIter, typename FwdIter>
```
util::detail::algorithm_result<ExPolicy, util::in_out_result<BidirIter, FwdIter>>::type reverse_copy (ExPolicy &&policy, BidirIter first, BidirIter last, FwdIter dest_first)

Copies the elements from the range [first, last) to another range beginning at dest_first in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment *(dest_first + (last - first) - 1 - i) = *(first + i) once for each non-negative i < (last - first) If the source and destination ranges (that is, [first, last) and [dest_first, dest_first+(last-first)) respectively) overlap, the behavior is undefined.

The assignments in the parallel reverse_copy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly last - first assignments.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **BidirIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an bidirectional iterator.
- **FwdIter**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest_first**: Refers to the begin of the destination range.

The assignments in the parallel reverse_copy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The reverse_copy algorithm returns a hpx::future<tagged_pair<tag::in(BidirIter), tag::out(FwdIter)>> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns tagged_pair<tag::in(BidirIter), tag::out(FwdIter)>> otherwise. The copy algorithm returns the pair of the input iterator forwarded to the first element after the last in the input sequence and the output iterator to the element in the destination range, one past the last element copied.

namespace hpx

namespace parallel
Functions

```cpp
template<typename ExPolicy, typename FwdIter>
util::detail::algorithm_result<ExPolicy, util::in_out_result<FwdIter>>::type rotate (ExPolicy &&policy, FwdIter first, FwdIter new_first, FwdIter last)
```

Performs a left rotation on a range of elements. Specifically, rotate swaps the elements in the range [first, last) in such a way that the element new_first becomes the first element of the new range and new_first - 1 becomes the last element.

The assignments in the parallel rotate algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Linear in the distance between first and last.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **new_first**: Refers to the element that should appear at the beginning of the rotated range.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.

The assignments in the parallel rotate algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note** The type of dereferenced FwdIter must meet the requirements of MoveAssignable and MoveConstructible.

**Return** The rotate algorithm returns a `hpx::future<tagged_pair<tag::begin(FwdIter), tag::end(FwdIter)>>` if the execution policy is of type parallel_task_policy and returns `tagged_pair<tag::begin(FwdIter), tag::end(FwdIter)>>` otherwise. The rotate algorithm returns the iterator equal to pair(first + (last - new_first), last).

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
util::detail::algorithm_result<ExPolicy, util::in_out_result<FwdIter1, FwdIter2>>::type rotate_copy (ExPolicy &&policy, FwdIter1 first, FwdIter1 new_first, FwdIter1 last, FwdIter2 dest_first)
```

2.8. API reference 1061
Copies the elements from the range \([\text{first}, \text{last})\), to another range beginning at \(\text{dest_first}\) in such a way, that the element \(\text{new_first}\) becomes the first element of the new range and \(\text{new_first} - 1\) becomes the last element.

The assignments in the parallel \(\text{rotate\_copy}\) algorithm invoked with an execution policy object of type \(\text{sequenced\_policy}\) execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly \(\text{last} - \text{first}\) assignments.

**Template Parameters**
- \(\text{ExPolicy}\) The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- \(\text{FwdIter1}\) The type of the source iterators used (deduced). This iterator type must meet the requirements of an bidirectional iterator.
- \(\text{FwdIter2}\) The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**
- \(\text{policy}\) The execution policy to use for the scheduling of the iterations.
- \(\text{first}\) Refers to the beginning of the sequence of elements the algorithm will be applied to.
- \(\text{new\_first}\) Refers to the element that should appear at the beginning of the rotated range.
- \(\text{last}\) Refers to the end of the sequence of elements the algorithm will be applied to.
- \(\text{dest\_first}\) Refers to the begin of the destination range.

The assignments in the parallel \(\text{rotate\_copy}\) algorithm invoked with an execution policy object of type \(\text{parallel\_policy}\) or \(\text{parallel\_task\_policy}\) are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The \(\text{rotate\_copy}\) algorithm returns a \(\text{hpx\::future<tagged\_pair<tag::in(\text{FwdIter1}), tag::out(\text{FwdIter2})>}>\) if the execution policy is of type \(\text{parallel\_task\_policy}\) and returns \(\text{tagged\_pair<tag::in(\text{FwdIter1}), tag::out(\text{FwdIter2})>}\) otherwise. The \(\text{rotate\_copy}\) algorithm returns the output iterator to the element past the last element copied.

```cpp
namespace hpx
{

Functions

template<typename FwdIter, typename FwdIter2, typename Pred = detail::equal_to>
FwdIter search(FwdIter first, FwdIter last, FwdIter2 s_first, FwdIter2 s_last, Pred && op = Pred())
{

Searches the range \([\text{first}, \text{last})\) for any elements in the range \([\text{s\_first}, \text{s\_last})\). Uses a provided predicate to compare elements.

The comparison operations in the parallel \(\text{search}\) algorithm execute in sequential order in the calling thread.

**Note** Complexity: at most \((S*N)\) comparisons where \(S = \text{distance(s\_first, s\_last)}\) and \(N = \text{distance(first, last)}\).

**Template Parameters**
- \(\text{FwdIter}\) The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- \(\text{FwdIter2}\) The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

}```
• **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`.

**Parameters**

- **first**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s_first**: Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last**: Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op**: Refers to the binary predicate which returns true if the elements should be treated as equal.

The signature of the function should be equivalent to:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

**Return** The `search` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `search` algorithm returns an iterator to the beginning of the first subsequence `[s_first, s_last)` in range `[first, last)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, last)`, `last` is returned. Additionally if the size of the subsequence is empty `first` is returned. If no subsequence is found, `last` is returned.

```cpp
template<typename ExPolicy, typename FwdIter, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result<ExPolicy, FwdIter>::type search(ExPolicy &&policy, FwdIter first, FwdIter last, FwdIter2 s_first, FwdIter2 s_last, Pred &&op = Pred())
```

Searches the range `[first, last)` for any elements in the range `[s_first, s_last)`. Uses a provided predicate to compare elements.

The comparison operations in the parallel `search` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: at most \((S*N)\) comparisons where \(S = \text{distance}(s_{\text{first}}, s_{\text{last}})\) and \(N = \text{distance}(\text{first}, \text{last})\).

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
• **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `<std::equal_to<>`

**Parameters**

• **policy**: The execution policy to use for the scheduling of the iterations.

• **first**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

• **last**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

• **s_first**: Refers to the beginning of the sequence of elements the algorithm will be searching for.

• **s_last**: Refers to the end of the sequence of elements of the algorithm will be searching for.

• **op**: Refers to the binary predicate which returns true if the elements should be treated as equal. The signature of the function should be equivalent to

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

The comparison operations in the parallel `search` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `search` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `search` algorithm returns an iterator to the beginning of the first subsequence `[s_first, s_last)` in range `[first, last)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, last)`, `last` is returned. Additionally if the size of the subsequence is empty `first` is returned. If no subsequence is found, `last` is returned.

```cpp
template<typename FwdIter, typename FwdIter2, typename Pred = detail::equal_to>
FwdIter search_n (FwdIter first, std::size_t count, FwdIter2 s_first, FwdIter2 s_last, Pred &&op = Pred())
```

Searches the range `[first, last)` for any elements in the range `[s_first, s_last)`. Uses a provided predicate to compare elements.

The comparison operations in the parallel `search_n` algorithm execute in sequential order in the calling thread.

**Note** Complexity: at most \((S*N)\) comparisons where \(S = \text{distance}(s\_first, s\_last)\) and \(N = \text{count}\).

**Template Parameters**

• **FwdIter**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

• **FwdIter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
• **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`.

**Parameters**

- **first**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **count**: Refers to the range of elements of the first range the algorithm will be applied to.
- **s_first**: Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last**: Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op**: Refers to the binary predicate which returns true if the elements should be treated as equal. The signature of the function should be equivalent to

  ```cpp
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

**Return** The `search_n` algorithm returns `FwdIter`. The `search_n` algorithm returns an iterator to the beginning of the last subsequence `[s_first, s_last)` in range `[first, first+count)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, first+count)`, `first` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `first` is also returned.

```cpp
template<typename ExPolicy, typename FwdIter, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result<ExPolicy, FwdIter>::type search_n(
    ExPolicy &&policy,
    FwdIter first,
    std::size_t count,
    FwdIter2 s_first,
    FwdIter2 s_last,
    Pred &&op = Pred())
```

Searches the range `[first, last)` for any elements in the range `[s_first, s_last)`. Uses a provided predicate to compare elements.

The comparison operations in the parallel `search_n` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: at most \((S*N)\) comparisons where \(S = \text{distance}(s\text{\_first}, s\text{\_last})\) and \(N = \text{count}\).

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`.  

2.8. API reference 1065
Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **count**: Refers to the range of elements of the first range the algorithm will be applied to.
- **s_first**: Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last**: Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op**: Refers to the binary predicate which returns true if the elements should be treated as equal. The signature of the function should be equivalent to

\[
\text{bool \ pred(const Type1 &a, const Type2 &b);}
\]

The signature does not need to have const &, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

The comparison operations in the parallel search_n algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The search_n algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The search_n algorithm returns an iterator to the beginning of the last subsequence `[s_first, s_last)` in range `[first, first+count)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, first+count), first` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `first` is also returned.

namespace hpx

**Functions**

```cpp
namespace hpx

template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred = detail::less>
util::detail::algorithm_result<ExPolicy, FwdIter3>::type::type set_difference(ExPolicy &&policy,
FwdIter1 first1,
FwdIter1 last1,
FwdIter2 first2,
FwdIter2 last2,
FwdIter3 dest, Pred &op = Pred())
```

Constructs a sorted range beginning at dest consisting of all elements present in the range `[first1, last1)` and not present in the range `[first2, last2)`. This algorithm expects both input ranges to be sorted with the given binary predicate \(f\).

Equivalent elements are treated individually, that is, if some element is found \(m\) times in `[first1, last1)` and \(n\) times in `[first2, last2)`, it will be copied to `dest` exactly `std::max(m-n, 0)` times. The resulting range cannot overlap with either of the input ranges.

**Note** Complexity: At most \(2*(N1 + N2 - 1)\) comparisons, where \(N1\) is the length of the first sequence and \(N2\) is the length of the second sequence.
The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (sequenced_policy) or in a single new thread spawned from the current thread (for sequenced_task_policy).

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

- **FwdIter1**: The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.

- **FwdIter2**: The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.

- **FwdIter3**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of set_difference requires Pred to meet the requirements of CopyConstructible. This defaults to std::less<>

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.

- **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

- **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

- **first2**: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

- **last2**: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

- **dest**: Refers to the beginning of the destination range.

- **op**: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`.

The application of function objects in parallel algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The set_difference algorithm returns a hpx::future<FwdIter3> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter3 otherwise. The set_difference algorithm returns the output iterator to the element in the destination range, one past the last element copied.
namespace hpx

Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred = detail::less>
util::detail::algorithm_result<ExPolicy, FwdIter3>::type set_intersection(
    ExPolicy &&policy,
    FwdIter1 first1,
    FwdIter1 last1,
    FwdIter2 first2,
    FwdIter2 last2,
    FwdIter3 dest,
    Pred &&op = Pred())

Constructs a sorted range beginning at dest consisting of all elements present in both sorted ranges [first1, last1) and [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate f.

If some element is found m times in [first1, last1) and n times in [first2, last2), the first std::min(m, n) elements will be copied from the first range to the destination range. The order of equivalent elements is preserved. The resulting range cannot overlap with either of the input ranges.

Note  Complexity: At most 2*(N1 + N2 - 1) comparisons, where N1 is the length of the first sequence and N2 is the length of the second sequence.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (sequenced_policy) or in a single new thread spawned from the current thread (for sequenced_task_policy).

Template Parameters

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

• FwdIter1: The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.

• FwdIter2: The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.

• FwdIter3: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

• Pred: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of set_intersection requires Pred to meet the requirements of CopyConstructible. This defaults to std::less<>

Parameters

• policy: The execution policy to use for the scheduling of the iterations.

• first1: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

• last1: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
• **first2**: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

• **last2**: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

• **dest**: Refers to the beginning of the destination range.

• **op**: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `set_intersection` algorithm returns a `hpx::future<FwdIter3>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter3` otherwise. The `set_intersection` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
amespace hpx

Functions
```

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred = detail::less>
util::detail::algorithm_result<ExPolicy, FwdIter3>::type set_symmetric_difference(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, FwdIter3 dest, Pred &&op = Pred())
```

Constructs a sorted range beginning at `dest` consisting of all elements present in either of the sorted ranges `[first1, last1)` and `[first2, last2)`, but not in both of them are copied to the range beginning at `dest`. The resulting range is also sorted. This algorithm expects both input ranges to be sorted with the given binary predicate `f`. 
If some element is found \( m \) times in \([\text{first1}, \text{last1})\) and \( n \) times in \([\text{first2}, \text{last2})\), it will be copied to \( \text{dest} \) exactly \( \text{std::abs}(m-n) \) times. If \( m>n \), then the last \( m-n \) of those elements are copied from \([\text{first1},\text{last1})\), otherwise the last \( n-m \) elements are copied from \([\text{first2},\text{last2})\). The resulting range cannot overlap with either of the input ranges.

**Note** Complexity: At most \( 2\times(N1 + N2 - 1) \) comparisons, where \( N1 \) is the length of the first sequence and \( N2 \) is the length of the second sequence.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (\( \text{sequenced\_policy} \)) or in a single new thread spawned from the current thread (for \( \text{sequenced\_task\_policy} \)).

**Template Parameters**

- \( \text{ExPolicy} \): The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

- \( \text{FwdIter1} \): The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.

- \( \text{FwdIter2} \): The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.

- \( \text{FwdIter3} \): The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

- \( \text{Pred} \): The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of \( \text{set\_symmetric\_difference} \) requires \( \text{Pred} \) to meet the requirements of \( \text{Copy\_Constructible} \). This defaults to \( \text{std::less<} \)

**Parameters**

- \( \text{policy} \): The execution policy to use for the scheduling of the iterations.

- \( \text{first1} \): Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

- \( \text{last1} \): Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

- \( \text{first2} \): Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

- \( \text{last2} \): Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

- \( \text{dest} \): Refers to the beginning of the destination range.

- \( \text{op} \): The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

  ```cpp
  bool pred(const Type1 &a, const Type1 &b);
  ```

The signature does not need to have \( \text{const} \ & \), but the function must not modify the objects passed to it. The type \( \text{Type1} \) must be such that objects of type \( \text{InIter} \) can be dereferenced and then implicitly converted to \( \text{Type1} \).
The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `set_symmetric_difference` algorithm returns a `hpx::future<FwdIter3>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter3` otherwise. The `set_symmetric_difference` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
namespace hpx
{

Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred = detail::less>
util::detail::algorithm_result<ExPolicy, FwdIter3>::type::type set_union(
    ExPolicy &&policy,
    FwdIter1 first1, FwdIter1 last1,
    FwdIter2 first2, FwdIter2 last2,
    FwdIter3 dest, Pred &&op = Pred())
```

Constructs a sorted range beginning at `dest` consisting of all elements present in one or both sorted ranges `[first1, last1)` and `[first2, last2)`. This algorithm expects both input ranges to be sorted with the given binary predicate `f`.

If some element is found `m` times in `[first1, last1)` and `n` times in `[first2, last2)`, then all `m` elements will be copied from `[first1, last1)` to `dest`, preserving order, and then exactly `std::max(n-m, 0)` elements will be copied from `[first2, last2)` to `dest`, also preserving order.

**Note** Complexity: At most `2*(N1 + N2 - 1)` comparisons, where `N1` is the length of the first sequence and `N2` is the length of the second sequence.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (`sequenced_policy`) or in a single new thread spawned from the current thread (for `sequenced_task_policy`).

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

- **FwdIter1**: The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.

- **FwdIter2**: The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.

- **FwdIter3**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

- **Op**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_union` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>

---

2.8. API reference
Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2**: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2**: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **op**: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `set_union` algorithm returns a `hpx::future<FwdIter3>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter3` otherwise. The `set_union` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
namespace hpx

namespace parallel

Functions

template<typename ExPolicy, typename RandomIt, typename Comp = detail::less, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, RandomIt>::type sort(ExPolicy &&policy, RandomIt first, RandomIt last, Comp &&comp = Comp(), Proj &&proj = Proj())
```

Sorts the elements in the range `[first, last)` in ascending order. The order of equal elements is not guaranteed to be preserved. The function uses the given comparison function object `comp` (defaults to using `operator<()`).

A sequence is sorted with respect to a comparator `comp` and a projection `proj` if for every iterator `i` pointing to the sequence and every non-negative integer `n` such that `i + n` is a valid iterator pointing to an element of the sequence, and `INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false.

**Note** Complexity: $O(N\log(N))$, where $N = \text{std::distance}(first, last)$ comparisons.
comp has to induce a strict weak ordering on the values.

Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Iter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp**: The type of the function/function object to use (deduced).
- **Proj**: The type of an optional projection function. This defaults to util::projection_identity

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp**: comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.
- **proj**: Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate comp is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return

The sort algorithm returns a hpx::future<RandomIt> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns RandomIt otherwise. The algorithm returns an iterator pointing to the first element after the last element in the input sequence.

```cpp
namespace hpx

namespace parallel

Functions

template<typename ExPolicy, typename KeyIter, typename ValueIter, typename Compare = detail::less>
util::detail::algorithm_result<ExPolicy, hpx::util::tagged_pair<tag::in1(KeyIter), tag::in2 ValueIter>>::type sort_by_key
ExPolicy &&policy, KeyIter key_first, KeyIter key_last, ValueIter value_first, Compare &&comp = Compare()Sorts one range of data using keys supplied in another range. The key elements in the range [key_first, key_last) are sorted in ascending order with the corresponding elements in the value range moved to follow the sorted order. The algorithm is not stable, the order of equal elements is not guaranteed to be preserved. The function uses the given comparison function object comp (defaults to using operator<()).

A sequence is sorted with respect to a comparator comp and a projection proj if for every iterator i pointing to the sequence and every non-negative integer n such that i + n is a valid iterator pointing to an element of the sequence, and INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false.

Note Complexity: O(Nlog(N)), where N = std::distance(first, last) comparisons. comp has to induce a strict weak ordering on the values.

Template Parameters
• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

• **KeyIter**: The type of the key iterators used (deduced). This iterator type must meet the requirements of a random access iterator.

• **ValueIter**: The type of the value iterators used (deduced). This iterator type must meet the requirements of a random access iterator.

• **Comp**: The type of the function/function object to use (deduced).

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **key_first**: Refers to the beginning of the sequence of key elements the algorithm will be applied to.
- **key_last**: Refers to the end of the sequence of key elements the algorithm will be applied to.
- **value_first**: Refers to the beginning of the sequence of value elements the algorithm will be applied to, the range of elements must match [key_first, key_last)
- **comp**: comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

### Return

The `sort_by-key` algorithm returns a `hpx::future<tagged_pair<tag::in1(KeyIter), tag::in2(ValueIter)>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns otherwise. The algorithm returns a pair holding an iterator pointing to the first element after the last element in the input key sequence and an iterator pointing to the first element after the last element in the input value sequence.

```cpp
namespace hpx

namespace parallel

Functions

template<
    typename ExPolicy, 
    typename RandomIt, 
    typename Sentinel, 
    typename Proj = util::projection_identity,
    typename Compare = detail::less>
util::detail::algorithm_result<ExPolicy, RandomIt>::type stable_sort(ExPolicy &&policy, RandomIt first, Sentinel last, Compare &&comp = Compare(), Proj &&proj = Proj())
```

Sorts the elements in the range `first`, `last`) in ascending order. The relative order of equal elements is preserved. The function uses the given comparison function object `comp` (defaults to using `operator<()`).

A sequence is sorted with respect to a comparator `comp` and a projection `proj` if for every iterator `i` pointing to the sequence and every non-negative integer `n` such that `i` + `n` is a valid iterator pointing
to an element of the sequence, and INVoke(comp, INVoke(proj, *(i + n)), INVoke(proj, *i)) == false.

**Note** Complexity: O(Nlog(N)), where N = std::distance(first, last) comparisons.

*comp* has to induce a strict weak ordering on the values.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **RandomIt**: The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Sentinel**: The type of the end iterators used (deduced). This iterator type must meet the requirements of a random access iterator and must be a valid sentinel type for RandomIt.
- **Comp**: The type of the function/function object to use (deduced).
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp**: `comp` is a callable object. The return value of the INVoke operation applied to an object of type `Comp`, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator.
- **proj**: Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate `comp` is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `stable_sort` algorithm returns a `hpx::future<RandomIt>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `RandomIt` otherwise. The algorithm returns an iterator pointing to the first element after the last element in the input sequence.

```cpp
namespace hpx

namespace parallel

Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
std::enable_if<hpx::is_execution_policy<ExPolicy>::value, typename util::detail::algorithm_result<ExPolicy, FwdIter2>::type>::type
```

Exchanges elements between range [first1, last1) and another range starting at `first2`.  

2.8. API reference
The swap operations in the parallel `swap_ranges` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Linear in the distance between `first1` and `last1`

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the swap operations.
- `FwdIter1`: The type of the first range of iterators to swap (deduced). This iterator type must meet the requirements of an forward iterator.
- `FwdIter2`: The type of the second range of iterators to swap (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

- `policy`: The execution policy to use for the scheduling of the iterations.
- `first1`: Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- `last1`: Refers to the end of the first sequence of elements the algorithm will be applied to.
- `first2`: Refers to the beginning of the second sequence of elements the algorithm will be applied to.

The swap operations in the parallel `swap_ranges` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `swap_ranges` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `parallel_task_policy` and returns `FwdIter2` otherwise. The `swap_ranges` algorithm returns iterator to the element past the last element exchanged in the range beginning with `first2`.

```cpp
namespace hpx {

Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename F>
util::detail::algorithm_result<ExPolicy, util::in_out_result<FwdIter1, FwdIter2>>::type transform(ExPolicy &&policy,
FwdIter1 first,
FwdIter1 last,
FwdIter2 dest,
F &&f)

Applies the given function `f` to the range `[first, last)` and stores the result in another range, beginning at `dest`.

The invocations of `f` in the parallel `transform` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Exactly `last - first` applications of `f`

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which
the execution of the algorithm may be parallelized and the manner in which it executes the invocations of $f$.

- **FwdIter1**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `transform` requires $F$ to meet the requirements of `CopyConstructible`.

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate. The signature of this predicate should be equivalent to:

```cpp
Ret fun(const Type &a);
```

The signature does not need to have `const&`. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`. The type `Ret` must be such that an object of type `FwdIter2` can be dereferenced and assigned a value of type `Ret`.

The invocations of $f$ in the parallel `transform` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

### Return

The `transform` algorithm returns a `hpx::future<in_out_result<FwdIter1, FwdIter2>>` if the execution policy is of type `parallel_task_policy` and returns `in_out_result<FwdIter1, FwdIter2>` otherwise. The `transform` algorithm returns a tuple holding an iterator referring to the first element after the input sequence and the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename F
util::detail::algorithm_result<ExPolicy, util::in_in_out_result<FwdIter1, FwdIter2, FwdIter3>>::type transform(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter3 dest, F &&f)
```

Applies the given function $f$ to pairs of elements from two ranges: one defined by [first1, last1) and the other beginning at first2, and stores the result in another range, beginning at dest.
The invocations of $f$ in the parallel transform algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Exactly last - first applications of $f$

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of $f$.
- **FwdIter1**: The type of the source iterators for the first range used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the source iterators for the second range used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter3**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of transform requires $F$ to meet the requirements of CopyConstructible.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- **last1**: Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2**: Refers to the beginning of the second sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature of this predicate should be equivalent to:

```cpp
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&. The types Type1 and Type2 must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively. The type Ret must be such that an object of type FwdIter3 can be dereferenced and assigned a value of type Ret.

The invocations of $f$ in the parallel transform algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The transform algorithm returns a hpx::future<in_in_out_result<FwdIter1, FwdIter2, FwdIter3>> if the execution policy is of type parallel_task_policy and returns in_in_out_result<FwdIter1, FwdIter2, FwdIter3> otherwise. The transform algorithm returns a tuple holding an iterator referring to the first element after the first input sequence, an iterator referring to the first element after the second input sequence, and the output iterator referring to the element in the destination range, one past the last element copied.
namespace hpx

namespace parallel

Functions

template<
typename ExPolicy,
typename FwdIter1,
typename FwdIter2,
typename T,
typename Op,
typename Conv
>
util::detail::algorithm_result<
ExPolicy,
FwdIter1
>::type
transform_exclusive_scan(
ExPolicy &&policy,
FwdIter1 first,
FwdIter1 last,
FwdIter2 dest,
T init,
Op &&op,
Conv &&conv)

Assigns through each iterator \(i\) in \([\text{result}, \text{result} + (\text{last} - \text{first}))\) the value of GENERALIZED_NONCOMMUTATIVE_SUM(binary_op, init, conv(*first), \ldots, conv(*\((\text{first} + (i - \text{result}) - 1))\)).

The reduce operations in the parallel \textit{transform\_exclusive\_scan} algorithm invoked with an execution policy object of type \textit{sequenced\_policy} execute in sequential order in the calling thread.

\textbf{Note} Complexity: \(O(\text{last} - \text{first})\) applications of the predicates \textit{op} and \textit{conv}.

Template Parameters

\begin{itemize}
  \item \textit{ExPolicy}: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
  \item \textit{FwdIter1}: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
  \item \textit{FwdIter2}: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
  \item \textit{Conv}: The type of the unary function object used for the conversion operation.
  \item \textit{T}: The type of the value to be used as initial (and intermediate) values (deduced).
  \item \textit{Op}: The type of the binary function object used for the reduction operation.
\end{itemize}

Parameters

\begin{itemize}
  \item \textit{policy}: The execution policy to use for the scheduling of the iterations.
  \item \textit{first}: Refers to the beginning of the sequence of elements the algorithm will be applied to.
  \item \textit{last}: Refers to the end of the sequence of elements the algorithm will be applied to.
  \item \textit{dest}: Refers to the beginning of the destination range.
  \item \textit{conv}: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\). This is a unary predicate. The signature of this predicate should be equivalent to:

\begin{verbatim}
R fun(const Type &a);
\end{verbatim}

The signature does not need to have const&, but the function must not modify the objects passed to it. The type \textit{Type} must be such that an object of type \textit{FwdIter1} can be dereferenced.
and then implicitly converted to Type. The type \( R \) must be such that an object of this type can
be implicitly converted to \( T \).

- \textbf{init}: The initial value for the generalized sum.
- \textbf{op}: Specifies the function (or function object) which will be invoked for each of the values
of the input sequence. This is a binary predicate. The signature of this predicate should be
equivalent to:

\[
\text{Ret fun}(\text{const} \text{ Type1 &a, const} \text{ Type1 &b});
\]

The signature does not need to have \text{const}&, but the function must not modify the objects
passed to it. The types \text{Type1} and \text{Ret} must be such that an object of a type as given by the input
sequence can be implicitly converted to any of those types.

The reduce operations in the parallel \text{transform_exclusive_scan} algorithm invoked with an execution
policy object of type \text{parallel_policy} or \text{parallel_task_policy} are permitted to execute in an unordered
fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither \text{conv} nor \text{op} shall invalidate iterators or subranges, or modify elements in the ranges \([\text{first}, \text{last})\)
or \([\text{result}, \text{result} + (\text{last} - \text{first}))\).

\textbf{Return} The \text{transform_exclusive_scan} algorithm returns a \text{hpx::future<\text{FwdIter2}>} if the execution
policy is of type \text{sequenced_task_policy} or \text{parallel_task_policy} and returns \text{FwdIter2} otherwise.
The \text{transform_exclusive_scan} algorithm returns the output iterator to the element in the destination
range, one past the last element copied.

\textbf{Note} \text{GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, . . . , aN)} is defined as:

- \( a1 \) when \( N \) is 1
- \( \text{op}(\text{GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, . . . , aK)}, \text{GENERAL-
IZED_NONCOMMUTATIVE_SUM(op, aM, . . . , aN)}) \) where \( 1 < K+1 = M < N \).

The behavior of \text{transform_exclusive_scan} may be non-deterministic for a non-associative predicate.

\begin{verbatim}
namespace hpx
namespace parallel

Functions

\end{verbatim}

\begin{verbatim}
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Op, typename Conv, 
type T> 
util::detail::algorithm_result<ExPolicy, FwdIter2>::type transform_inclusive_scan(ExPolicy 
&\&policy, 
FwdIter1 first, 
FwdIter1 last, 
FwdIter2 dest, 
Op &\&op, 
Conv &\&conv, 
T init)
\end{verbatim}

Assigns through each iterator \( i \) in \([\text{result}, \text{result} + (\text{last} - \text{first}))\) the value of \text{GENERALIZED_NONCOMMUTATIVE_SUM(op, init, conv(*first), . . . , conv(*}(i - \text{result}))}).

1080 Chapter 2. What’s so special about HPX?
The reduce operations in the parallel `transform_inclusive_scan` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: $O(last - first)$ applications of the predicate $op$.

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter1`: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- `FwdIter2`: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- `Conv`: The type of the unary function object used for the conversion operation.
- `T`: The type of the value to be used as initial (and intermediate) values (deduced).
- `Op`: The type of the binary function object used for the reduction operation.

**Parameters**
- `policy`: The execution policy to use for the scheduling of the iterations.
- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last`: Refers to the end of the sequence of elements the algorithm will be applied to.
- `dest`: Refers to the beginning of the destination range.
- `conv`: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is a unary predicate. The signature of this predicate should be equivalent to:

\[ R \text{ fun}(\text{const Type } &a); \]

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`. The type `R` must be such that an object of this type can be implicitly converted to `T`.
- `init`: The initial value for the generalized sum.
- `op`: Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

\[ Ret \text{ fun}(\text{const Type1 } &a, \text{ const Type1 } &b); \]

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Ret` must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

The reduce operations in the parallel `transform_inclusive_scan` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither `conv` nor `op` shall invalidate iterators or subranges, or modify elements in the ranges `[first,last)` or `[result,result + (last - first))`.

**Return** The `transform_inclusive_scan` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `transform_inclusive_scan` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

**Note** `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, \ldots, aN)` is defined as:
- `a1` when `N` is `1`
The difference between exclusive_scan and transform_inclusive_scan is that transform_inclusive_scan includes the ith input element in the ith sum. If op is not mathematically associative, the behavior of transform_inclusive_scan may be non-deterministic.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Conv, typename Op>
util::detail::algorithm_result<ExPolicy, FwdIter2>::type transform_inclusive_scan(
    ExPolicy&& policy,
    FwdIter1 first,
    FwdIter1 last,
    FwdIter2 dest,
    Op&& op,
    Conv&& conv)
```

Assigns through each iterator i in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(op, conv(*first), . . . , conv(*(first + (i - result)))).

The reduce operations in the parallel transform_inclusive_scan algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: O(last - first) applications of the predicate op.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Conv**: The type of the unary function object used for the conversion operation.
- **T**: The type of the value to be used as initial (and intermediate) values (deduced).
- **Op**: The type of the binary function object used for the reduction operation.

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **conv**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```cpp
R fun(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type FwdIter1 can be dereferenced and then implicitly converted to Type. The type R must be such that an object of this type can be implicitly converted to T.
- **op**: Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be
equivalent to:

```cpp
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types `Type1` and `Ret` must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

The reduce operations in the parallel `transform_inclusive_scan` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither `conv` nor `op` shall invalidate iterators or subrange, or modify elements in the ranges `[first,last)` or `[result, result + (last - first))`.

**Return** The `transform_inclusive_scan` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise.

The `transform_inclusive_scan` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

**Note** `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, . . . , aN)` is defined as:
- `a1` when `N` is 1
- `op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, . . . , aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, . . . , aN))` where `1 < K+1 = M <= N`.

The difference between `exclusive_scan` and `transform_inclusive_scan` is that `transform_inclusive_scan` includes the ith input element in the ith sum.

```cpp
namespace hpx

Functions

template<typename ExPolicy, typename FwdIter, typename T, typename Reduce, typename Convert>
util::detail::algorithm_result<ExPolicy, T>::type transform_reduce(ExPolicy &&policy, FwdIter first, FwdIter last, T init, Reduce &&red_op, Convert &&conv_op)
```

Returns `GENERALIZED_SUM(red_op, init, conv_op(*first), . . . , conv_op(*((first + (last - first) - 1))))`.

The reduce operations in the parallel `transform_reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: `O(last - first)` applications of the predicates `red_op` and `conv_op`.

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter`: The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- `T`: The type of the value to be used as initial (and intermediate) values (deduced).
- `Reduce`: The type of the binary function object used for the reduction operation.
• **Convert**: The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

**Parameters**

• **policy**: The execution policy to use for the scheduling of the iterations.
• **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
• **conv_op**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\). This is a unary predicate. The signature of this predicate should be equivalent to:

\[
\text{R fun}(\text{const Type } \&a);
\]

The signature does not need to have const&, but the function must not modify the objects passed to it. The type **Type** must be such that an object of type **FwdIter** can be dereferenced and then implicitly converted to **Type**. The type **R** must be such that an object of this type can be implicitly converted to **T**.
• **init**: The initial value for the generalized sum.
• **red_op**: Specifies the function (or function object) which will be invoked for each of the values returned from the invocation of **conv_op**. This is a binary predicate. The signature of this predicate should be equivalent to:

\[
\text{Ret fun}(\text{const Type1 } \&a, \text{const Type2 } \&b);
\]

The signature does not need to have const&, but the function must not modify the objects passed to it. The types **Type1**, **Type2**, and **Ret** must be such that an object of a type as returned from **conv_op** can be implicitly converted to any of those types.

The reduce operations in the parallel **transform_reduce** algorithm invoked with an execution policy object of type **parallel_policy** or **parallel_task_policy** are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between **transform_reduce** and **accumulate** is that the behavior of **transform_reduce** may be non-deterministic for non-associative or non-commutative binary predicate.

**Return** The **transform_reduce** algorithm returns **hpx::future<T>** if the execution policy is of type **parallel_task_policy** and returns **T** otherwise. The **transform_reduce** algorithm returns the result of the generalized sum over the values returned from **conv_op** when applied to the elements given by the input range \([\text{first}, \text{last})\).

**Note** GENERALIZED_SUM(op, a1, \ldots, aN) is defined as follows:

• a1 when N is 1
• op(GENERALIZED_SUM(op, b1, \ldots, bK), GENERALIZED_SUM(op, bM, \ldots, bN)), where:
  – b1, \ldots, bN may be any permutation of a1, \ldots, aN and
  – 1 < K+1 = M <= N.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename T>
```
util::detail::algorithm_result<ExPolicy, T>::type `transform_reduce` (ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, T init)

Returns the result of accumulating init with the inner products of the pairs formed by the elements of two ranges starting at first1 and first2.

The operations in the parallel `transform_reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: $O(last - first)$ applications of the predicate $op2$.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the first source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the second source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T**: The type of the value to be used as return) values (deduced).

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the first sequence of elements the result will be calculated with.
- **last1**: Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2**: Refers to the beginning of the second sequence of elements the result will be calculated with.
- **init**: The initial value for the sum.

The operations in the parallel `transform_reduce` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `transform_reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns $T$ otherwise.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename T, typename Reduce, typename Convert>
util::detail::algorithm_result<ExPolicy, T>::type `transform_reduce` (ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, T init, Reduce &&red_op, Convert &&conv_op)
```

Returns the result of accumulating init with the inner products of the pairs formed by the elements of two ranges starting at first1 and first2.

The operations in the parallel `transform_reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: $O(last - first)$ applications of the predicate $op2$. 

2.8. API reference 1085
Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter1**: The type of the first source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

- **FwdIter2**: The type of the second source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

- **T**: The type of the value to be used as return) values (deduced).

- **Reduce**: The type of the binary function object used for the multiplication operation.

- **Convert**: The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.

- **first1**: Refers to the beginning of the first sequence of elements the result will be calculated with.

- **last1**: Refers to the end of the first sequence of elements the algorithm will be applied to.

- **first2**: Refers to the beginning of the second sequence of elements the result will be calculated with.

- **init**: The initial value for the sum.

- **red_op**: Specifies the function (or function object) which will be invoked for the initial value and each of the return values of op2. This is a binary predicate. The signature of this predicate should be equivalent to:

  ```c++
  Ret fun(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type Ret must be such that it can be implicitly converted to a type of T.

- **conv_op**: Specifies the function (or function object) which will be invoked for each of the input values of the sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

  ```c++
  Ret fun(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type Ret must be such that it can be implicitly converted to an object for the second argument type of op1.

The operations in the parallel transform_reduce algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The transform_reduce algorithm returns a hpx::future<T> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns T otherwise.

namespace hpx
namespace parallel

Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
std::enable_if<hpx::is_execution_policy<ExPolicy>::value, typename util::detail::algorithm_result<ExPolicy, FwdIter2>>::type
uninitialized_copy(
    ExPolicy &&policy,
    FwdIter1 first,
    FwdIter1 last,
    FwdIter2 dest)

Copies the elements in the range, defined by [first, last), to an uninitialized memory area beginning at dest. If an exception is thrown during the copy operation, the function has no effects.

The assignments in the parallel uninitialized_copy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Performs exactly last - first assignments.

Template Parameters
• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• FwdIter1: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
• FwdIter2: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters
• policy: The execution policy to use for the scheduling of the iterations.
• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• last: Refers to the end of the sequence of elements the algorithm will be applied to.
• dest: Refers to the beginning of the destination range.

The assignments in the parallel uninitialized_copy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The uninitialized_copy algorithm returns a hpx::future<FwdIter2>, if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter2 otherwise. The uninitialized_copy algorithm returns the output iterator to the element in the destination range, one past the last element copied.
Copies the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest. If an exception is thrown during the copy operation, the function has no effects.

The assignments in the parallel uninitialized_copy_n algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly count assignments, if count > 0, no assignments otherwise.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Size**: The type of the argument specifying the number of elements to apply f to.
- **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count**: Refers to the number of elements starting at first the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.

The assignments in the parallel uninitialized_copy_n algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The uninitialized_copy_n algorithm returns a hpx::future<FwdIter2> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter2 otherwise. The uninitialized_copy_n algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
namespace hpx

namespace parallel

Functions

```template<typename ExPolicy, typename FwdIter>
util::detail::algorithm_result<ExPolicy>::type uninitialized_default_construct(ExPolicy &&policy, FwdIter first, FwdIter last)
``` Constructs objects of type typename iterator_traits<ForwardIt>::value_type in the uninitialized storage designated by the range [first, last) by default-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel uninitialized_default_construct algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly last - first assignments.
Template Parameters
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.

The assignments in the parallel `uninitialized_default_construct` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return

The `uninitialized_default_construct` algorithm returns a `hpx::future<void>`, if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `void` otherwise.

```cpp
template<typename ExPolicy, typename FwdIter, typename Size>
util::detail::algorithm_result<ExPolicy, FwdIter>::type
uninitialized_default_construct_n(ExPolicy &&policy,
FwdIter first, Size count)
```

Constructs objects of type typename iterator_traits<ForwardIt>::value_type in the uninitialized storage designated by the range [first, first + count) by default-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel `uninitialized_default_construct_n` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

Note Complexity: Performs exactly `count` assignments, if `count > 0`, no assignments otherwise.

Template Parameters
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size**: The type of the argument specifying the number of elements to apply to.

Parameters
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count**: Refers to the number of elements starting at `first` the algorithm will be applied to.

The assignments in the parallel `uninitialized_default_construct_n` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return

The `uninitialized_default_construct_n` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `uninitialized_default_construct_n` algorithm returns the iterator to the element in the source range, one past the last element constructed.
namespace parallel

Functions

template<typename ExPolicy, typename FwdIter, typename T>
std::enable_if<hpx::is_execution_policy<ExPolicy>::value, typename util::detail::algorithm_result<ExPolicy>::type>::type
uninitialized_fill(
    ExPolicy&& policy,
    FwdIter first, FwdIter last,
    T const& value)

Copies the given value to an uninitialized memory area, defined by the range [first, last). If an exception is thrown during the initialization, the function has no effects.

The initializations in the parallel uninitialized_fill algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

*Note*  Complexity: Linear in the distance between first and last

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T**: The type of the value to be assigned (deduced).

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **value**: The value to be assigned.

The initializations in the parallel uninitialized_fill algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return**  The uninitialized_fill algorithm returns a hpx::future<void>, if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns nothing otherwise.

```cpp
template<typename ExPolicy, typename FwdIter, typename Size, typename T>
std::enable_if<hpx::is_execution_policy<ExPolicy>::value, typename util::detail::algorithm_result<ExPolicy>::type>::type
uninitialized_fill_n(
    ExPolicy&& policy,
    FwdIter first, Size count,
    T const& value)
```

1090 Chapter 2. What’s so special about HPX?
Copies the given value value to the first count elements in an uninitialized memory area beginning at first. If an exception is thrown during the initialization, the function has no effects.

The initializations in the parallel uninitialized_fill_n algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly count assignments, if count > 0, no assignments otherwise.

**Template Parameters**
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- FwdIter: The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- Size: The type of the argument specifying the number of elements to apply f to.
- T: The type of the value to be assigned (deduced).

**Parameters**
- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- count: Refers to the number of elements starting at first the algorithm will be applied to.
- value: The value to be assigned.

The initializations in the parallel uninitialized_fill_n algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The uninitialized_fill_n algorithm returns a hpx::future<void>, if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns nothing otherwise.

namespace hpx

namespace parallel

**Functions**

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
util::detail::algorithm_result<ExPolicy, FwdIter2>::type uninitialized_move(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest)
```

Moves the elements in the range, defined by [first, last), to an uninitialized memory area beginning at dest. If an exception is thrown during the initialization, some objects in [first, last) are left in a valid but unspecified state.

The assignments in the parallel uninitialized_move algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly last - first move operations.

**Template Parameters**
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- FwdIter1: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
• FwdIter2: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters
• policy: The execution policy to use for the scheduling of the iterations.
• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• last: Refers to the end of the sequence of elements the algorithm will be applied to.
• dest: Refers to the beginning of the destination range.

The assignments in the parallel uninitialized_move algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The uninitialized_move algorithm returns a hpx::future<FwdIter2>, if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter2 otherwise. The uninitialized_move algorithm returns the output iterator to the element in the destination range, one past the last element moved.

template<typename ExPolicy, typename FwdIter1, typename Size, typename FwdIter2>
util::detail::algorithm_result<ExPolicy, hpx::util::tagged_pair<
in (FwdIter1), tag::out
FwdIter2>>, type uninitialized_move_n ExPolicy &&policy, FwdIter1 first, Size count, FwdIter2 dest Moves the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest. If an exception is thrown during the initialization, some objects in [first, first + count) are left in a valid but unspecified state.

The assignments in the parallel uninitialized_move_n algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Performs exactly count movements, if count > 0, no move operations otherwise.

Template Parameters
• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• FwdIter1: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
• Size: The type of the argument specifying the number of elements to apply f to.
• FwdIter2: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters
• policy: The execution policy to use for the scheduling of the iterations.
• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• count: Refers to the number of elements starting at first the algorithm will be applied to.
• dest: Refers to the beginning of the destination range.

The assignments in the parallel uninitialized_move_n algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The uninitialized_move_n algorithm returns a hpx::future<std::pair<FwdIter1, FwdIter2>> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns std::pair<FwdIter1, FwdIter2> otherwise. The uninitialized_move_n algorithm returns the pair of the input iterator to the element past in the source range and an output iterator to the element in the destination range, one past the last element moved.
namespace parallel

Functions

```cpp
template<typename ExPolicy, typename FwdIter>
util::detail::algorithm_result<ExPolicy>::type uninitialized_value_construct (ExPolicy &&policy, FwdIter first, FwdIter last)
```

Constructs objects of type typename iterator_traits<ForwardIt>::value_type in the uninitialized storage designated by the range [first, last) by default-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel `uninitialized_value_construct` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `last - first` assignments.

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter`: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**
- `policy`: The execution policy to use for the scheduling of the iterations.
- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last`: Refers to the end of the sequence of elements the algorithm will be applied to.

The assignments in the parallel `uninitialized_value_construct` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `uninitialized_value_construct` algorithm returns a `hpx::future<void>`, if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `void` otherwise.

```cpp
template<typename ExPolicy, typename FwdIter, typename Size>
util::detail::algorithm_result<ExPolicy, FwdIter>::type uninitialized_value_construct_n (ExPolicy &&policy, FwdIter first, Size count)
```

Constructs objects of type typename iterator_traits<ForwardIt>::value_type in the uninitialized storage designated by the range [first, first + count) by default-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel `uninitialized_value_construct_n` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `count` assignments, if `count > 0`, no assignments otherwise.
Template Parameters
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size**: The type of the argument specifying the number of elements to apply \( f \) to.

Parameters
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count**: Refers to the number of elements starting at **first** the algorithm will be applied to.

The assignments in the parallel `uninitialized_value_construct_n` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return
The `uninitialized_value_construct_n` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `uninitialized_value_construct_n` algorithm returns the iterator to the element in the source range, one past the last element constructed.

```cpp
namespace hpx

namespace parallel

Functions

```template<typename ExPolicy, typename FwdIter, typename Pred = detail::equal_to, typename Proj = util::projection_identity>

util::detail::algorithm_result<ExPolicy, FwdIter>::type
unique(ExPolicy &&policy,
    FwdIter first,
    FwdIter last,
    Pred &&pred = Pred(),
    Proj &&proj = Proj())
``` Eliminates all but the first element from every consecutive group of equivalent elements from the range \([first, last)\) and returns a past-the-end iterator for the new logical end of the range.

The assignments in the parallel `unique` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than \( last - first \) assignments, exactly \( last - first - 1 \) applications of the predicate **pred** and no more than twice as many applications of the projection **proj**.

Template Parameters
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `unique` requires **Pred** to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>

- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

Parameters
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
• **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

```cpp
cbool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to both `Type1` and `Type2`.

• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel `unique` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `unique` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `unique` algorithm returns the iterator to the new end of the range.

The assignments in the parallel `unique_copy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than `last - first` assignments, exactly `last - first` - 1 applications of the predicate `pred` and no more than twice as many applications of the projection `proj`.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `unique_copy` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`
The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type FwdIter1 can be dereferenced and then implicitly converted to Type.

- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel unique_copy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The unique_copy algorithm returns a hpx::future<tagged_pair<tag::in(FwdIter1), tag::out(FwdIter2)>> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns tagged_pair<tag::in(FwdIter1), tag::out(FwdIter2)> otherwise. The unique_copy algorithm returns the pair of the source iterator to last, and the destination iterator to the end of the dest range.

namespace hpx

namespace ranges

### Functions

```cpp
template<typename FwdIter, typename Sent, typename Proj = hpx::parallel::util::projection_identity, typename Pred = detail::equal_to>
FwdIter adjacent_find(FwdIter first, Sent last, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Searches the range [first, last) for two consecutive identical elements.

**Note** Complexity: Exactly the smaller of (result - first) + 1 and (last - first) - 1 application of the predicate where result is the value returned

**Return** The adjacent_find algorithm returns an iterator to the first of the identical elements. If no such elements are found, last is returned.

**Template Parameters**

- **FwdIter**: The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent**: The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **Proj**: The type of an optional projection function. This defaults to util::projection_identity
- **Pred**: The type of an optional function/function object to use.

**Parameters**

- **first**: Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **pred**: The binary predicate which returns true if the elements should be treated as equal. The signature should be equivalent to the following:

  ```cpp
  bool pred(const Type1 &a, const Type1 &b);
  ```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 must be such that objects of type FwdIter can be dereferenced and then implicitly converted to Type1.

- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.
template<typename ExPolicy, typename FwdIter, typename Sent, typename Proj = hpx::parallel::util::projection_identity, 
util::detail::algorithm_result<ExPolicy, FwdIter>::type adjacent_find(ExPolicy &&policy, 
    FwdIter first, Sent last, 
    Pred &&pred = Pred(), 
    Proj &&proj = Proj())

Searches the range [first, last) for two consecutive identical elements. This version uses the given
binary predicate pred.

The comparison operations in the parallel adjacent_find invoked with an execution policy object of
type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Exactly the smaller of (result - first) + 1 and (last - first) - 1 application of the
predicate where result is the value returned

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in
  which the execution of the algorithm may be parallelized and the manner in which it executes
  the assignments.
- **FwdIter**: The type of the source iterators used for the range (deduced). This iterator type
  must meet the requirements of an forward iterator.
- **Sent**: The type of the source sentinel (deduced). This sentinel type must be a sentinel for
  InIter.
- **Proj**: The type of an optional projection function. This defaults to util::projection_identity
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form,
  the parallel overload of adjacent_find requires Pred to meet the requirements of CopyCon-
  structible. This defaults to std::equal_to<>.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements of the range the algorithm will
  be applied to.
- **last**: Refers to the end of the sequence of elements of the range the algorithm will be applied
  to.
- **pred**: The binary predicate which returns true if the elements should be treated as equal. The
  signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects
passed to it. The types Type1 must be such that objects of type FwdIter can be dereferenced
and then implicitly converted to Type1.
- **proj**: Specifies the function (or function object) which will be invoked for each of the ele-
  ments as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel adjacent_find invoked with an execution policy object of
type sequenced_policy or parallel_task_policy are permitted to execute in an unordered fashion in un-
specified threads, and indeterminately sequenced within each thread.

This overload of adjacent_find is available if the user decides to provide their algorithm their own
binary predicate pred.

**Return** The adjacent_find algorithm returns a hpx::future<InIter> if the execution policy is of type
sequenced_task_policy or parallel_task_policy and returns InIter otherwise. The adjacent_find
algorithm returns an iterator to the first of the identical elements. If no such elements are found,
last is returned.
hpx::traits::range_traits<Rng>::iterator_type adjacent_find(ExPolicy &&policy, Rng &&rng, Pred &&pred = Pred(), Proj &&proj = Proj())

Searches the range rng for two consecutive identical elements.

**Note**  Complexity: Exactly the smaller of \((\text{result} - \text{std::begin(rng)}) + 1\) and \((\text{std::begin(rng)} - \text{std::end(rng)}) - 1\) applications of the predicate where \text{result} is the value returned

**Return**  The `adjacent_find` algorithm returns an iterator to the first of the identical elements. If no such elements are found, `last` is returned.

**Template Parameters**

- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`
- **Pred**: The type of an optional function/function object to use.

**Parameters**

- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **pred**: The binary predicate which returns `true` if the elements should be treated as equal. The signature should be equivalent to the following:

  ```cpp
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

```
template<typename ExPolicy, typename Rng, typename Proj = hpx::parallel::util::projection_identity, typename Pred = detail::equal_to>
util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_traits<Rng>::iterator_type>::type
adjacent_find(ExPolicy &&policy, Rng &&rng, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Searches the range rng for two consecutive identical elements.

The comparison operations in the parallel `adjacent_find` invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note**  Complexity: Exactly the smaller of \((\text{result} - \text{std::begin(rng)}) + 1\) and \((\text{std::begin(rng)} - \text{std::end(rng)}) - 1\) applications of the predicate where \text{result} is the value returned

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
• Proj: The type of an optional projection function. This defaults to `util::projection_identity`.
• Pred: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`.

Parameters
• policy: The execution policy to use for the scheduling of the iterations.
• rng: Refers to the sequence of elements the algorithm will be applied to.
• pred: The binary predicate which returns `true` if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.
• proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel `adjacent_find` invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of `adjacent_find` is available if the user decides to provide their algorithm their own binary predicate `pred`.

Return The `adjacent_find` algorithm returns a `hpx::future<InIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `InIter` otherwise. The `adjacent_find` algorithm returns an iterator to the first of the identical elements. If no such elements are found, `last` is returned.

namespace hpx

namespace ranges

Functions

```cpp
template<typename ExPolicy, typename Rng, typename F, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, bool>::type none_of(ExPolicy &&policy, Rng &&rng, F &&f, Proj &&&proj = Proj())
```

Checks if unary predicate `f` returns true for no elements in the range `rng`.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

Note Complexity: At most std::distance(begin(rng), end(rng)) applications of the predicate `f`

Template Parameters
• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
• Rng: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
• F: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `none_of` requires `F` to meet the requirements of `CopyConstructible`.
• Proj: The type of an optional projection function. This defaults to `util::projection_identity`.
Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type FwdIter can be dereferenced and then implicitly converted to Type.

- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return**

The none_of algorithm returns a hpx::future<bool> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns bool otherwise. The none_of algorithm returns true if the unary predicate f returns true for no elements in the range, false otherwise. It returns true if the range is empty.

```cpp
template<typename ExPolicy, typename Rng, typename F, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, bool>::type any_of(ExPolicy &&policy, Rng &&rng, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate f returns true for at least one element in the range rng.

The application of function objects in parallel algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: At most std::distance(begin(rng), end(rng)) applications of the predicate f

Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of none_of requires F to meet the requirements of CopyConstructible.
- **Proj**: The type of an optional projection function. This defaults to util::projection_identity

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type FwdIter can be dereferenced and then implicitly converted to Type.

- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in
unspecified threads, and indeterminately sequenced within each thread.

**Return** The `any_of` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `any_of` algorithm returns true if the unary predicate `f` returns true for at least one element in the range, false otherwise. It returns false if the range is empty.

template<typename ExPolicy, typename Rng, typename F, typename Proj = std::projection_identity> hpx::util::detail::algorithm_result<ExPolicy, bool>::type any_of(ExPolicy&& policy, Rng&& rng, F&& f, Proj&& proj = Proj())

Checks if unary predicate `f` returns true for all elements in the range `rng`.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate `f`

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- `F`: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `none_of` requires `F` to meet the requirements of `CopyConstructible`.
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**
- `policy`: The execution policy to use for the scheduling of the iterations.
- `rng`: Refers to the sequence of elements the algorithm will be applied to.
- `f`: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- `proj`: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `all_of` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `all_of` algorithm returns true if the unary predicate `f` returns true for all elements in the range, false otherwise. It returns true if the range is empty.

```cpp
namespace hpx

namespace ranges
```
Functions

template<typename ExPolicy, typename Iter1, typename Sent1, typename FwdIter>

hpx::parallel::util::detail::algorithm_result<ExPolicy, hpx::ranges::copy_result<Iter1, Iter>>::type

copy((ExPolicy &&policy, Iter1 &&iter, Sent1 &&sent, FwdIter &&dest))

Copies the elements in the range, defined by [first, last), to another range beginning at dest.

The assignments in the parallel copy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Performs exactly last - first assignments.

Template Parameters

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• Iter1: The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
• Sent1: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
• FwdIter: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

• policy: The execution policy to use for the scheduling of the iterations.
• iter: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• sent: Refers to the end of the sequence of elements the algorithm will be applied to.
• dest: Refers to the beginning of the destination range.

The assignments in the parallel copy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The copy algorithm returns a hpx::future<hpx::ranges::copy_result<FwdIter1, FwdIter>> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns hpx::ranges::copy_result<FwdIter1, FwdIter> otherwise. The copy algorithm returns the pair of the input iterator last and the output iterator to the element in the destination range, one past the last element copied.

template<typename ExPolicy, typename Rng, typename FwdIter>

hpx::parallel::util::detail::algorithm_result<ExPolicy, hpx::ranges::copy_result<typename hpx::traits::range_traits<Rng>::iterator_type, FwdIter>>::type

hpx::ranges::copy_result<FwdIter1, FwdIter> copy((ExPolicy &&policy, Rng &&rng, FwdIter &&dest))

Copies the elements in the range rng to another range beginning at dest.
The assignments in the parallel `copy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `std::distance(begin(rng), end(rng))` assignments.

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- `FwdIter`: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**
- `policy`: The execution policy to use for the scheduling of the iterations.
- `rng`: Refers to the sequence of elements the algorithm will be applied to.
- `dest`: Refers to the beginning of the destination range.

The assignments in the parallel `copy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `copy` algorithm returns a `hpx::future<ranges::copy_result<iterator_t<Rng>, FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::copy_result<iterator_t<Rng>, FwdIter2>` otherwise. The `copy` algorithm returns the pair of the input iterator `last` and the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename Size, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result<ExPolicy, hpx::ranges::copy_n_result<FwdIter1, FwdIter2>>::type copy_n(
    ExPolicy&& policy, FwdIter1 first, Size count, FwdIter2 dest)
```

Copies the elements in the range `[first, first + count)`, starting from first and proceeding to first + count - 1, to another range beginning at dest.

The assignments in the parallel `copy_n` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `count` assignments, if `count > 0`, no assignments otherwise.

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter1`: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- `Size`: The type of the argument specifying the number of elements to apply `f` to.
- `FwdIter2`: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**
- `policy`: The execution policy to use for the scheduling of the iterations.
- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
count: Refers to the number of elements starting at first the algorithm will be applied to.
dest: Refers to the beginning of the destination range.
The assignments in the parallel copy_n algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The copy_n algorithm returns a hpx::future<ranges::copy_n_result<FwdIter1, FwdIter2>> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns ranges::copy_n_result<FwdIter1, FwdIter2> otherwise. The copy algorithm returns the pair of the input iterator forwarded to the first element after the last in the input sequence and the output iterator to the element in the destination range, one past the last element copied.

Copies the elements in the range, defined by [first, last) to another range beginning at dest. Copies only the elements for which the predicate f returns true. The order of the elements that are not removed is preserved.

The assignments in the parallel copy_if algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Performs not more than std::distance(begin(rng), end(rng)) assignments, exactly std::distance(begin(rng), end(rng)) applications of the predicate f.

Template Parameters
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- FwdIter1: The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- Sent1: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for FwdIter1.
- FwdIter: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- F: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of copy_if requires F to meet the requirements of CopyConstructible.
- Proj: The type of an optional projection function. This defaults to util::projection_identity

Parameters
- policy: The execution policy to use for the scheduling of the iterations.
- iter: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- sent: Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\). This is an unary predicate which returns \textit{true} for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have \texttt{const\&}, but the function must not modify the objects passed to it. The type \texttt{Type} must be such that an object of type \texttt{InIter} can be dereferenced and then implicitly converted to \texttt{Type}.

- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel \texttt{copy_if} algorithm invoked with an execution policy object of type \texttt{parallel_policy} or \texttt{parallel_task_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The \texttt{copy_if} algorithm returns a \texttt{hpx::future<ranges::copy_if_result<iterator_t<Rng>, FwdIter2>}} if the execution policy is of type \texttt{sequenced_task_policy} or \texttt{parallel_task_policy} and returns \texttt{ranges::copy_if_result<iterator_t<Rng>, FwdIter2>} otherwise. The \texttt{copy_if} algorithm returns the pair of the input iterator \texttt{last} and the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename Rng, typename OutIter, typename F, typename Proj = hpx::parallel::util::projection_identity>
std::pair<OutIter, ranges::copy_if_result<typename hpx::traits::range_traits<Rng>::iterator_type, OutIter>>
copy_if(ExPolicy &&policy, Rng &&rng, OutIter dest, F &&f, Proj &&proj);
```

Copies the elements in the range \texttt{rng} to another range beginning at \texttt{dest}. Copies only the elements for which the predicate \texttt{f} returns true. The order of the elements that are not removed is preserved.

The assignments in the parallel \texttt{copy_if} algorithm invoked with an execution policy object of type \texttt{sequenced_policy} execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than \texttt{std::distance(begin(rng), end(rng))} assignments, exactly \texttt{std::distance(begin(rng), end(rng))} applications of the predicate \texttt{f}.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **OutIter**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the
parallel overload of `copy_if` requires `F` to meet the requirements of `CopyConstructible`.

- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

### Parameters
- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

  ```cpp
def bool pred(const Type &a);
  ```

  The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `InIter` can be dereferenced and then implicitly converted to `Type`.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel `copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

### Return
The `copy_if` algorithm returns a `hpx::future<ranges::copy_if_result<iterator_t<Rng>, FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::copy_if_result<iterator_t<Rng>, FwdIter2>` otherwise. The `copy_if` algorithm returns the pair of the input iterator `last` and the output iterator to the element in the destination range, one past the last element copied.

```cpp
namespace hpx

namespace ranges

Functions
```

- template<typename ExPolicy, typename Rng, typename T, typename Proj = util::projection_identity>
- `util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<typename hpx::traits::range_traits<Rng>::iterator_t>::difference_type>::type count(ExPolicy &&policy, Rng &&rng, T const &value, Proj &&proj = Proj())`

  Returns the number of elements in the range `[first, last)` satisfying a specific criteria. This version counts the elements that are equal to the given `value`.

  The comparisons in the parallel `count` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

  **Note**: Complexity: Performs exactly `last - first` comparisons.
**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the comparisons.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **T**: The type of the value to search for (deduced).
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **value**: The value to search for.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Note** The comparisons in the parallel `count` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `count` algorithm returns a `hpx::future<difference_type>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `difference_type` otherwise (where `difference_type` is defined by `std::iterator_traits<FwdIter>::difference_type`). The `count` algorithm returns the number of elements satisfying the given criteria.

```
template<typename ExPolicy, typename Rng, typename F, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<Rng>::difference_type>
count_if(ExPolicy&& policy, Rng&& rng, F&& f, Proj&& proj = Proj())
```

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts elements for which predicate `f` returns true.

**Note** Complexity: Performs exactly `last - first` applications of the predicate.

**Note** The assignments in the parallel `count_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** The assignments in the parallel `count_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `count_if` algorithm returns `hpx::future<difference_type>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `difference_type` otherwise (where `difference_type` is defined by `std::iterator_traits<FwdIter>::difference_type`). The `count_if` algorithm returns the number of elements satisfying the given criteria.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the comparisons.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `count_if` requires `F` to meet the requirements of `CopyConstructible`.

- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`.

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

```cpp
namespace hpx

namespace ranges

Functions

template<typename ExPolicy>
util::detail::algorithm_result<ExPolicy, typename traits::range_iterator<Rng>::type>::type destroy(ExPolicy &&policy, Rng &&rng)
```

Destroys objects of type typename iterator_traits<ForwardIt>::value_type in the range `[first, last)`.

The operations in the parallel `destroy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `last - first` operations.

### Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.

The operations in the parallel `destroy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `destroy` algorithm returns a `hpx::future<void>`, if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `void` otherwise.
The operations in the parallel `destroy_n` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.  

**Note** Complexity: Performs exactly `count` operations, if `count > 0`, no assignments otherwise.

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter`: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- `Size`: The type of the argument specifying the number of elements to apply this algorithm to.

**Parameters**
- `policy`: The execution policy to use for the scheduling of the iterations.
- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `count`: Refers to the number of elements starting at `first` the algorithm will be applied to.

The operations in the parallel `destroy_n` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `destroy_n` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `destroy_n` algorithm returns the iterator to the element in the source range, one past the last element constructed.

```cpp
namespace hpx

namespace ranges

Functions

```cpp
template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Pred = ranges::equal_to, typename Proj1 = util::projection_identity, typename Proj2 = util::projection_identity>
util::detail::algorithm_result<ExPolicy, bool>::type equal
(ExPolicy &&policy, Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Pred &&op = Pred(), Proj1 &&&proj1 = Proj1(), Proj2 &&&proj2 = Proj2())
```

Returns true if the range `[first1, last1)` is equal to the range `[first2, last2)`, and false otherwise.

The comparison operations in the parallel `equal` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.  

**Note** Complexity: At most `min(last1 - first1, last2 - first2)` applications of the predicate `f`.

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Iter1`: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- `Sent1`: The type of the source iterators used for the end of the first range (deduced).
Iter2: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

Sent2: The type of the source iterators used for the end of the second range (deduced).

Pred: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of equal requires Pred to meet the requirements of CopyConstructible. This defaults to std::equal_to<>

Proj1: The type of an optional projection function applied to the first range. This defaults to util::projection_identity

Proj2: The type of an optional projection function applied to the second range. This defaults to util::projection_identity

Parameters

- policy: The execution policy to use for the scheduling of the iterations.
- first1: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- last1: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- first2: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- last2: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- op: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The comparison operations in the parallel equal algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note The two ranges are considered equal if, for every iterator i in the range [first1, last1), *(first2 + (i - first1)). This overload of equal uses operator== to determine if two elements are equal.

Return The equal algorithm returns a hpx::future<bool> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns bool otherwise. The equal algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range [first1, last1) does not equal the length of the range [first2, last2), it returns false.

```cpp
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred = ranges::equal_to, typename Proj1 = util::projection_identity, typename Proj2 = util::projection_identity>
util::detail::algorithm_result<ExPolicy, bool>::type equal(ExPolicy &&policy, Rng1 &&rng1, Rng2 &&rng2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Returns true if the range [first1, last1) is equal to the range starting at first2, and false otherwise.

The comparison operations in the parallel equal algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.
Note Complexity: At most last1 - first1 applications of the predicate f.

Template Parameters

- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- Rng1: The type of the first source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- Rng2: The type of the second source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- Pred: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of equal requires Pred to meet the requirements of CopyConstructible. This defaults to std::equal_to<>.
- Proj1: The type of an optional projection function applied to the first range. This defaults to util::projection_identity.
- Proj2: The type of an optional projection function applied to the second range. This defaults to util::projection_identity.

Parameters

- policy: The execution policy to use for the scheduling of the iterations.
- rng1: Refers to the first sequence of elements the algorithm will be applied to.
- rng2: Refers to the second sequence of elements the algorithm will be applied to.
- op: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &`, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively.

- proj1: Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate is invoked.
- proj2: Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel equal algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note The two ranges are considered equal if, for every iterator i in the range [first1,last1), *i equals *(first2 + (i - first1)). This overload of equal uses operator== to determine if two elements are equal.

Return The equal algorithm returns a hpx::future<bool> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns bool otherwise. The equal algorithm returns true if the elements in the two ranges are equal, otherwise it returns false.

```cpp
namespace hpx
```
Functions

```cpp
template<typename ExPolicy, typename Rng, typename T>
util::detail::algorithm_result<ExPolicy>::type fill(ExPolicy &&policy, Rng &&rng, T const &value)
Assigns the given value to the elements in the range [first, last).
```

The comparisons in the parallel `fill` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `last - first` assignments.

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- `T`: The type of the value to be assigned (deduced).

**Parameters**

- `policy`: The execution policy to use for the scheduling of the iterations.
- `rng`: Refers to the sequence of elements the algorithm will be applied to.
- `value`: The value to be assigned.

The comparisons in the parallel `fill` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `fill` algorithm returns a `hpx::future<void>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `difference_type` otherwise (where `difference_type` is defined by `void`).

```cpp
template<typename ExPolicy, typename Iterator, typename Size, typename T>
util::detail::algorithm_result<ExPolicy, Iterator>::type fill_n(ExPolicy &&policy, Iterator first, Size count, T const &value)
Assigns the given value value to the first count elements in the range beginning at first if count > 0. Does nothing otherwise.
```

The comparisons in the parallel `fill_n` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `count` assignments, for `count > 0`.

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Iterator`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Size**: The type of the argument specifying the number of elements to apply \( f \) to.
- **T**: The type of the value to be assigned (deduced).

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count**: Refers to the number of elements starting at `first` the algorithm will be applied to.
- **value**: The value to be assigned.

The comparisons in the parallel `fill_n` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

### Return

The `fill_n` algorithm returns a `hpx::future<void>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `difference_type` otherwise (where `difference_type` is defined by `void`).

```cpp
namespace hpx

namespace ranges

### Functions

```cpp
template<typename ExPolicy, typename Iter, typename Sent, typename T, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, Iter>::type find(ExPolicy &&policy, Iter first, Sent last, T const &val, Proj &&proj = Proj())
```

Returns the first element in the range `[first, last)` that is equal to `val`.

The comparison operations in the parallel `find` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: At most `last - first` applications of the operator `==`.

### Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter**: The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent**: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for `Iter`.
- **T**: The type of the value to find (deduced).
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`.

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **val**: The value to compare the elements to.
• proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel `find` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `find` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `find` algorithm returns the first element in the range `[first,last)` that is equal to `val`. If no such element in the range of `[first,last)` is equal to `val`, then the algorithm returns `last`.

```cpp
template<typename ExPolicy, typename Rng, typename T, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, Iter>::type find(ExPolicy &&policy, Rng &&rng, T const &val, Proj &&proj = Proj())
```

Returns the first element in the range `[first, last)` that is equal to `val`.

The comparison operations in the parallel `find` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: At most last - first applications of the operator `==`().

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- `T`: The type of the value to find (deduced).
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`.

**Parameters**
- `policy`: The execution policy to use for the scheduling of the iterations.
- `rng`: Refers to the sequence of elements the algorithm will be applied to.
- `val`: The value to compare the elements to.
- `proj`: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel `find` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `find` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `find` algorithm returns the first element in the range `[first,last)` that is equal to `val`. If no such element in the range of `[first,last)` is equal to `val`, then the algorithm returns `last`.

```cpp
template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Pred = ranges::equal_to, typename Proj1 = util::projection_identity, typename Proj2 = util::projection_identity>
```
util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng1>::type>::type find_end(ExPolicy &&policy, Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())

Returns the last subsequence of elements [first2, last2) found in the range [first1, last1) using the given predicate \( f \) to compare elements.

The comparison operations in the parallel \textit{find\_end} algorithm invoked with an execution policy object of type \textit{sequenced\_policy} execute in sequential order in the calling thread.

\textbf{Note} Complexity: at most \( S^*N - S + 1 \) comparisons where \( S = \text{distance}(\text{first2}, \text{last2}) \) and \( N = \text{distance}(	ext{first1}, \text{last1}) \).

\textbf{Template Parameters}
- \texttt{ExPolicy}: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- \texttt{Iter1}: The type of the begin source iterators for the first sequence used (deduced). This iterator type must meet the requirements of an forward iterator.
- \texttt{Sent1}: The type of the end source iterators for the first sequence used (deduced). This iterator type must meet the requirements of an sentinel for \texttt{Iter1}.
- \texttt{Iter2}: The type of the begin source iterators for the second sequence used (deduced). This iterator type must meet the requirements of an forward iterator.
- \texttt{Sent2}: The type of the end source iterators for the second sequence used (deduced). This iterator type must meet the requirements of an sentinel for \texttt{Iter2}.
- \texttt{Pred}: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of \textit{replace} requires \texttt{Pred} to meet the requirements of \textit{CopyConstructible}. This defaults to \texttt{std::equal\_to<>}
- \texttt{Proj1}: The type of an optional projection function applied to the first sequence. This defaults to \texttt{util::projection\_identity}
- \texttt{Proj2}: The type of an optional projection function applied to the second sequence. This defaults to \texttt{util::projection\_identity}

\textbf{Parameters}
- \texttt{policy}: The execution policy to use for the scheduling of the iterations.
- \texttt{first1}: Refers to the beginning of the first sequence of elements the algorithm will be applied to.
• last1: Refers to the end of the first sequence of elements the algorithm will be applied to.
• first2: Refers to the beginning of the second sequence of elements the algorithm will be applied to.
• last2: Refers to the end of the second sequence of elements the algorithm will be applied to.
• op: The binary predicate which returns true if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types `iterator_t<Rng>` and `iterator_t<Rng2>` can be dereferenced and then implicitly converted to Type1 and Type2 respectively.

• proj1: Specifies the function (or function object) which will be invoked for each of the elements of the first range of type dereferenced `iterator_t<Rng1>` as a projection operation before the function `op` is invoked.
• proj2: Specifies the function (or function object) which will be invoked for each of the elements of the second range of type dereferenced `iterator_t<Rng2>` as a projection operation before the function `op` is invoked.

The comparison operations in the parallel `find_end` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of `find_end` is available if the user decides to provide the algorithm their own predicate `op`.

**Return** The `find_end` algorithm returns a `hpx::future<iterator_t<Rng>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `iterator_t<Rng>` otherwise. The `find_end` algorithm returns an iterator to the beginning of the last subsequence `rng2` in range `rng`. If the length of the subsequence `rng2` is greater than the length of the range `rng`, `end(rng)` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `end(rng)` is also returned.

```cpp
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred = ranges::equal_to, typename Proj1 = util::projection_identity, typename Proj2 = util::projection_identity>
util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng1>::type>::type find_end(ExPolicy &&policy, Rng1 &&rng, Rng2 &&rng2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Returns the last subsequence of elements `rng2` found in the range `rng` using the given predicate `f` to compare elements.
The comparison operations in the parallel `find_end` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: at most \( S*(N-S+1) \) comparisons where \( S = \text{distance}(\text{begin}(rng2), \text{end}(rng2)) \) and \( N = \text{distance}(\text{begin}(rng), \text{end}(rng)) \).

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Rng1`: The type of the first source range (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- `Rng2`: The type of the second source range (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- `Pred`: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `replace` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`.
- `Proj1`: The type of an optional projection function applied to the first sequence. This defaults to `util::projection_identity`.
- `Proj2`: The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`.

**Parameters**
- `policy`: The execution policy to use for the scheduling of the iterations.
- `rng`: Refers to the first sequence of elements the algorithm will be applied to.
- `rng2`: Refers to the second sequence of elements the algorithm will be applied to.
- `op`: The binary predicate which returns `true` if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `iterator_t<Rng>` and `iterator_t<Rng2>` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.
- `proj1`: Specifies the function (or function object) which will be invoked for each of the elements of the first range of type dereferenced `iterator_t<Rng1>` as a projection operation before the function `op` is invoked.
- `proj2`: Specifies the function (or function object) which will be invoked for each of the elements of the second range of type dereferenced `iterator_t<Rng2>` as a projection operation before the function `op` is invoked.

The comparison operations in the parallel `find_end` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of `find_end` is available if the user decides to provide the algorithm their own predicate `op`.

**Return** The `find_end` algorithm returns a `hpx::future<iterator_t<Rng>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `iterator_t<Rng>` otherwise. The `find_end` algorithm returns an iterator to the beginning of the last subsequence `rng2` in range `rng`. If the length of the subsequence `rng2` is greater than the length of the range `rng`, `end(rng)` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `end(rng)` is also returned.
util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng1>::type>::type find_first_of (ExPolicy&& policy, Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Pred&& op = Pred(), Proj1&& proj1 = Proj1(), Proj2&& proj2 = Proj2())

Searches the range [first1, last1) for any elements in the range [first2, last2). Uses binary predicate \( p \) to compare elements.

The comparison operations in the parallel find_first_of algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: at most \((S \times N)\) comparisons where \( S = \text{distance(first2, last2)} \) and \( N = \text{distance(first1, last1)} \).

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter1**: The type of the begin source iterators for the first sequence used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1**: The type of the end source iterators for the first sequence used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2**: The type of the begin source iterators for the second sequence used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2**: The type of the end source iterators for the second sequence used (deduced). This iterator type must meet the requirements of an sentinel for Iter2.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of replace requires \( \text{Pred} \) to meet the requirements of CopyConstructible. This defaults to std::equal_to<>
- **Proj1**: The type of an optional projection function. This defaults to util::projection_identity and is applied to the elements in rng1.
- **Proj2**: The type of an optional projection function. This defaults to util::projection_identity and is applied to the elements in rng2.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the first sequence of elements the algorithm will be applied to.
• last1: Refers to the end of the first sequence of elements the algorithm will be applied to.
• first2: Refers to the beginning of the second sequence of elements the algorithm will be applied to.
• last2: Refers to the end of the second sequence of elements the algorithm will be applied to.
• op: The binary predicate which returns true if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types iterator_t<Rng1> and iterator_t<Rng2> can be dereferenced and then implicitly converted to Type1 and Type2 respectively.

• proj1: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced iterator_t<Rng1> before the function op is invoked.
• proj2: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced iterator_t<Rng2> before the function op is invoked.

The comparison operations in the parallel find_first_of algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of find_first_of is available if the user decides to provide the algorithm their own predicate op.

Return The find_end algorithm returns a hpx::future<iterator_t<Rng1>> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns iterator_t<Rng1> otherwise. The find_first_of algorithm returns an iterator to the first element in the range rng1 that is equal to an element from the range rng2. If the length of the subsequence rng2 is greater than the length of the range rng1, end(rng1) is returned. Additionally if the size of the subsequence is empty or no subsequence is found, end(rng1) is also returned.

```cpp
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred = ranges::equal_to, typename Proj1 = util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng1>::type>::type, typename Proj2 = util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng2>::type>::type>
util::detail::algorithm_result<ExPolicy, types::range_iterator<Rng1>::type>::type find_first_of(ExPolicy &&policy, Rng1 &&rng1, Rng2 &&rng2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Searches the range rng1 for any elements in the range rng2. Uses binary predicate p to compare elements.
The comparison operations in the parallel `find_first_of` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: at most \((S \times N)\) comparisons where \(S = \text{distance(begin(rng2), end(rng2))}\) and \(N = \text{distance(begin(rng1), end(rng1))}\).

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Rng1`: The type of the first source range (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- `Rng2`: The type of the second source range (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- `Pred`: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `replace` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>
- `Proj1`: The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements in `rng1`.
- `Proj2`: The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements in `rng2`.

**Parameters**
- `policy`: The execution policy to use for the scheduling of the iterations.
- `rng1`: Refers to the first sequence of elements the algorithm will be applied to.
- `rng2`: Refers to the second sequence of elements the algorithm will be applied to.
- `op`: The binary predicate which returns `true` if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `iterator_t<Rng1>` and `iterator_t<Rng2>` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.
- `proj1`: Specifies the function (or function object) which will be invoked for each of the elements of type `iterator_t<Rng1>` before the function `op` is invoked.
- `proj2`: Specifies the function (or function object) which will be invoked for each of the elements of type `iterator_t<Rng2>` before the function `op` is invoked.

The comparison operations in the parallel `find_first_of` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of `find_first_of` is available if the user decides to provide the algorithm their own predicate `op`.

**Return** The `find_end` algorithm returns a `hpx::future<iterator_t<Rng1>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `iterator_t<Rng1>` otherwise. The `find_first_of` algorithm returns an iterator to the first element in the range `rng1` that is equal to an element from the range `rng2`. If the length of the subsequence `rng2` is greater than the length of the range `rng1`, `end(rng1)` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `end(rng1)` is also returned.

```cpp
namespace hpx
{
    namespace ranges
    {

```
Functions

```cpp
template<typename InIter, typename Sent, typename F, typename Proj = util::projection_identity>
hpx::ranges::for_each_result<InIter, F> for_each (InIter first, Sent last, F &&f, Proj &&proj = Proj())
```

Applies `f` to the result of dereferencing every iterator in the range `[first, last)`.

If `f` returns a result, the result is ignored.

**Note** Complexity: Applies `f` exactly `last - first` times.

If the type of `first` satisfies the requirements of a mutable iterator, `f` may apply non-constant functions through the dereferenced iterator.

Applies `f` to the result of dereferencing every iterator in the range `[first, first + count)`, starting from `first` and proceeding to `first + count - 1`.

**Return** `{last, std::move(f)}` where `last` is the iterator corresponding to the input sentinel `last`.

**Template Parameters**

- `InIter`: The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an input iterator.
- `Sent`: The type of the source sentinel (deduced). This sentinel type must be a sentinel for `InIter`.
- `F`: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `for_each` requires `F` to meet the requirements of `CopyConstructible`.
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last`: Refers to the end of the sequence of elements the algorithm will be applied to.
- `f`: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. The signature of this predicate should be equivalent to:

```cpp
<ignored> pred(const Type &a);
```

The signature does not need to have const&. The type `Type` must be such that an object of type `InIter` can be dereferenced and then implicitly converted to `Type`.
- `proj`: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

If `f` returns a result, the result is ignored.

**Note** Complexity: Applies `f` exactly `last - first` times.

If the type of `first` satisfies the requirements of a mutable iterator, `f` may apply non-constant functions through the dereferenced iterator.

**Return** `{first + count, std::move(f)}`

**Template Parameters**

- `InIter`: The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an input iterator.
- `Size`: The type of the argument specifying the number of elements to apply `f` to.
- `F`: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `for_each` requires `F` to meet the requirements of `CopyConstructible`.
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **count**: Refers to the number of elements starting at `first` the algorithm will be applied to.
• **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. The signature of this predicate should be equivalent to:

```
<ignored> pred(const Type &a);
```

The signature does not need to have `const&`. The type `Type` must be such that an object of type `InIter` can be dereferenced and then implicitly converted to Type.
• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

```
template<typename ExPolicy, typename FwdIter, typename Sent, typename F, typename Proj = util::projection_identity>
FwdIter for_each (ExPolicy &&policy, FwdIter first, Sent last, F &&f, Proj &&proj = Proj())
Applies `f` to the result of dereferencing every iterator in the range `[first, last)`.
```

If `f` returns a result, the result is ignored.

**Note** Complexity: Applies `f` exactly `last - first` times.

If the type of `first` satisfies the requirements of a mutable iterator, `f` may apply non-constant functions through the dereferenced iterator.

Unlike its sequential form, the parallel overload of `for_each` does not return a copy of its `Function` parameter, since parallelization may not permit efficient state accumulation.

**Return** The `for_each` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. It returns `last`.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter**: The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent**: The type of the source sentinel (deduced). This sentinel type must be a sentinel for `InIter`.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `for_each` requires `F` to meet the requirements of `CopyConstructible`.
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`.

**Parameters**
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. The signature of this predicate should be equivalent to:

```
<ignored> pred(const Type &a);
```

The signature does not need to have `const&`. The type `Type` must be such that an object of type `InIter` can be dereferenced and then implicitly converted to Type.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

```
template<typename Rng, typename F, typename Proj = util::projection_identity>
```
Applies $f$ to the result of dereferencing every iterator in the given range $rng$.

If $f$ returns a result, the result is ignored.

**Note** Complexity: Applies $f$ exactly $size(rng)$ times.

If the type of $first$ satisfies the requirements of a mutable iterator, $f$ may apply non-constant functions through the dereferenced iterator.

**Return** {std::end(rng), std::move(f)}

**Template Parameters**

- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of for_each requires $F$ to meet the requirements of CopyConstructible.
- **Proj**: The type of an optional projection function. This defaults to util::projection_identity

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```cpp
<ignored> pred(const Type &a);
```

The signature does not need to have const&. The type $Type$ must be such that an object of type $InIter$ can be dereferenced and then implicitly converted to $Type$.

- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

```cpp
template<typename ExPolicy, typename Rng, typename F, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng>::type>::type for_each (ExPolicy &&policy,
  Rng &&rng,
  F &&f,
  Proj &&proj
  = Proj())
```

Applies $f$ to the result of dereferencing every iterator in the given range $rng$. 

2.8. API reference 1123
If \( f \) returns a result, the result is ignored.

**Note** Complexity: Applies \( f \) exactly \( \text{size(rng)} \) times.

If the type of \( \text{first} \) satisfies the requirements of a mutable iterator, \( f \) may apply non-constant functions through the dereferenced iterator.

Unlike its sequential form, the parallel overload of \( \text{for_each} \) does not return a copy of its \( \text{Function} \) parameter, since parallelization may not permit efficient state accumulation.

The application of function objects in parallel algorithm invoked with an execution policy object of type \( \text{sequenced_policy} \) execute in sequential order in the calling thread.

**Template Parameters**

- \( \text{ExPolicy} \): The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- \( \text{Rng} \): The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- \( F \): The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \( \text{for_each} \) requires \( F \) to meet the requirements of \( \text{CopyConstructible} \).
- \( \text{Proj} \): The type of an optional projection function. This defaults to \( \text{util::projection_identity} \)

**Parameters**

- \( \text{policy} \): The execution policy to use for the scheduling of the iterations.
- \( \text{rng} \): Refers to the sequence of elements the algorithm will be applied to.
- \( f \): Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\). The signature of this predicate should be equivalent to:

```cpp
<\text{ignored}> \text{pred}(\text{const Type } \&a);
```

The signature does not need to have \( \text{const} \& \). The type \( \text{Type} \) must be such that an object of type \( \text{InIter} \) can be dereferenced and then implicitly converted to \( \text{Type} \).
- \( \text{proj} \): Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type \( \text{parallel_policy} \) or \( \text{parallel_task_policy} \) are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The \( \text{for_each} \) algorithm returns a \( \text{hpx::future<\text{FwdIter}>} \) if the execution policy is of type \( \text{sequenced_task_policy} \) or \( \text{parallel_task_policy} \) and returns \( \text{FwdIter} \) otherwise. It returns \( \text{last} \).

```cpp
template<\text{typename ExPolicy, typename FwdIter, typename Size, typename F, typename Proj = util::projection_identity> util::detail::algorithm_result<ExPolicy, FwdIter>::type for_each_n(ExPolicy &&policy, FwdIter first, Size count, F &&f, Proj &&proj = Proj())
```

Applies \( f \) to the result of dereferencing every iterator in the range \([\text{first}, \text{first} + \text{count})\), starting from \( \text{first} \) and proceeding to \( \text{first} + \text{count} - 1 \).

If \( f \) returns a result, the result is ignored.

**Note** Complexity: Applies \( f \) exactly \( \text{count} \) times.

If the type of \( \text{first} \) satisfies the requirements of a mutable iterator, \( f \) may apply non-constant functions through the dereferenced iterator.

Unlike its sequential form, the parallel overload of \( \text{for_each} \) does not return a copy of its \( \text{Function} \) parameter, since parallelization may not permit efficient state accumulation.
The for_each algorithm returns a hpx::future<FwdIter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter otherwise. It returns last.

Template Parameters
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- FwdIter: The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- Size: The type of the argument specifying the number of elements to apply f to.
- F: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of for_each requires F to meet the requirements of CopyConstructible.
- Proj: The type of an optional projection function. This defaults to util::projection_identity

Parameters
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- count: Refers to the number of elements starting at first the algorithm will be applied to.
- f: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

  ```cpp
  <ignored> pred(const Type &a);
  ```

  The signature does not need to have const&. The type Type must be such that an object of type InIter can be dereferenced and then implicitly converted to Type.
- proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

namespace hpx

namespace ranges

Functions

template<typename Iter, typename Sent, typename ...Args>
void for_loop (Iter first, Sent last, Args&&... args)

The for_loop implements loop functionality over a range specified by iterator bounds. These algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of for_loop without specifying an execution policy is equivalent to specifying hpx::execution::seq as the execution policy.

Requires: Iter shall meet the requirements of an input iterator type. The args parameter pack shall have at least one element, comprising objects returned by invocations of reduction and/or induction function templates followed by exactly one element invocable element-access function, f. f shall meet the requirements of MoveConstructible.

Template Parameters
- Iter: The type of the iteration variable (input iterator).
- Sent: The type of the source sentinel (deduced). This sentinel type must be a sentinel for Iter.
- Args: A parameter pack, it’s last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

Parameters
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last: Refers to the end of the sequence of elements the algorithm will be applied to.
• **args**: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

```cpp
<ignored> pred(Iter const& a, ...);
```

The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Effects**: Applies `f` to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the `args` parameter pack. The length of the input sequence is `last - first`.

The first element in the input sequence is specified by `first`. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the `args` parameter pack excluding `f`, an additional argument is passed to each application of `f` as follows:

- **Note**: As described in the C++ standard, arithmetic on non-random-access iterators is performed using `advance` and `distance`.

- **Note**: The order of the elements of the input sequence is important for determining ordinal position of an application of `f`, even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of `f` in the input sequence.

**Complexity**: Applies `f` exactly once for each element of the input sequence.

**Remarks**: If `f` returns a result, the result is ignored.

```cpp
template<typename ExPolicy, typename Iter, typename Sent, typename ...Args>
util::detail::algorithm_result<ExPolicy>::type for_loop(ExPolicy &&policy, Iter first, Sent last, Args&&... args)
```

The `for_loop` implements loop functionality over a range specified by iterator bounds. These algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

**Requires**: `Iter` shall meet the requirements of a forward iterator type. The `args` parameter pack shall have at least one element, comprising objects returned by invocations of `reduction` and/or `induction` function templates followed by exactly one element invocable element-access function. `f`, `f` shall meet the requirements of MoveConstructible.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Iter**: The type of the iteration variable (forward iterator).
- **Sent**: The type of the source sentinel (forward iterator). This sentinel type must be a sentinel for `Iter`.
- **Args**: A parameter pack, it’s last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• last: Refers to the end of the sequence of elements the algorithm will be applied to.
• args: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

\[
\text{<ignored> pred(Iter const a, ...);}
\]

The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

Effects: Applies \( f \) to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the args parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by first. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the args parameter pack excluding \( f \), an additional argument is passed to each application of \( f \) as follows:

**Note** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

**Note** The order of the elements of the input sequence is important for determining ordinal position of an application of \( f \), even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of \( f \) in the input sequence.

Complexity: Applies \( f \) exactly once for each element of the input sequence.

Remarks: If \( f \) returns a result, the result is ignored.

**Return** The for_loop algorithm returns a hpx::future<void> if the execution policy is of type hpx::execution::sequenced_task_policy or hpx::execution::parallel_task_policy and returns void otherwise.

```cpp
template<typename Rng, typename ...Args>
void for_loop (Rng &&rng, Args&&... args)
```

The for_loop implements loop functionality over a range specified by a range. These algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of for_loop without specifying an execution policy is equivalent to specifying hpx::execution::seq as the execution policy.

Requires: Rng::iterator shall meet the requirements of an input iterator type. The args parameter pack shall have at least one element, comprising objects returned by invocations of reduction and/or induction function templates followed by exactly one element invocable element-access function, \( f \). \( f \) shall meet the requirements of MoveConstructible.

**Template Parameters**
- Rng: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
• **Args**: A parameter pack, it’s last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**

• **rng**: Refers to the sequence of elements the algorithm will be applied to.
• **args**: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects.

The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

```cpp
<ignored> pred(Rng::iterator const & a, ...);
```

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Effects**: Applies `f` to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the `args` parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by `first`. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the `args` parameter pack excluding `f`, an additional argument is passed to each application of `f` as follows:

**Note** As described in the C++ standard, arithmetic on non-random-access iterators is performed using `advance` and `distance`.

**Note** The order of the elements of the input sequence is important for determining ordinal position of an application of `f`, even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of `f` in the input sequence.

**Complexity**: Applies `f` exactly once for each element of the input sequence.

**Remarks**: If `f` returns a result, the result is ignored.

```cpp
template<
    typename ExPolicy, 
    typename Rng, 
    typename ...Args>
util::detail::algorithm_result<ExPolicy>::type
for_loop(ExPolicy && policy, Rng && rng, 
        Args&& ... args)
```

The `for_loop` implements loop functionality over a range specified by a range. These algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

**Requires**: `Rng::iterator` shall meet the requirements of a forward iterator type. The `args` parameter pack shall have at least one element, comprising objects returned by invocations of `reduction` and/or `induction` function templates followed by exactly one element invocable element-access function, `f`. `f` shall meet the requirements of `MoveConstructible`.

**Template Parameters**

• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

• **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
• **Args**: A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**

• **policy**: The execution policy to use for the scheduling of the iterations.
• **rng**: Refers to the sequence of elements the algorithm will be applied to.
• **args**: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects.

The function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\) should expose a signature equivalent to:

```cpp
<\text{ignored}> \text{pred}(\text{Rng::iterator} \ \text{const} \ a, ...);
```

The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Effects**: Applies \(f\) to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the `args` parameter pack. The length of the input sequence is `last - first`.

The first element in the input sequence is specified by `first`. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the `args` parameter pack excluding `f`, an additional argument is passed to each application of `f` as follows:

**Note** As described in the C++ standard, arithmetic on non-random-access iterators is performed using `advance` and `distance`.

**Note** The order of the elements of the input sequence is important for determining ordinal position of an application of `f`, even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of `f` in the input sequence.

**Complexity**: Applies `f` exactly once for each element of the input sequence.

**Remarks**: If `f` returns a result, the result is ignored.

**Return**: The `for_loop` algorithm returns a `hpx::future<void>` if the execution policy is of type `hpx::execution::sequenced_task_policy` or `hpx::execution::parallel_task_policy` and returns `void` otherwise.

```cpp
template<typename Iter, typename Sent, typename S, typename ..Args>
void for_loop_strided(Iter first, Sent last, S stride, Args&& ... args)
```

The `for_loop_strided` implements loop functionality over a range specified by iterator bounds. These algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of `for_loop_strided` without specifying an execution policy is equivalent to specifying `hpx::execution::seq` as the execution policy.

**Requires**: `Iter` shall meet the requirements of an input iterator type. The `args` parameter pack shall have at least one element, comprising objects returned by invocations of `reduction` and/or `induction` function templates followed by exactly one element invocable element-access function. `f`, `f` shall meet the requirements of `MoveConstructible`.

---

2.8. API reference 1129
Template Parameters

- **Iter**: The type of the iteration variable (input iterator).
- **Sent**: The type of the source sentinel (deduced). This sentinel type must be a sentinel for Iter.
- **S**: The type of the stride variable. This should be an integral type.
- **Args**: A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

Parameters

- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **stride**: Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if Iter meets the requirements a bidirectional iterator.
- **args**: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

  ```cpp
  <ignored> pred(Iter const & a, ...);
  ```

The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

Effects: Applies \( f \) to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the **args** parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by **first**. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the **args** parameter pack excluding \( f \), an additional argument is passed to each application of \( f \) as follows:

**Note** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

**Note** The order of the elements of the input sequence is important for determining ordinal position of an application of \( f \), even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of \( f \) in the input sequence.

Complexity: Applies \( f \) exactly once for each element of the input sequence.

Remarks: If \( f \) returns a result, the result is ignored.

```cpp
template<typename ExPolicy, typename Iter, typename Sent, typename S, typename... Args>
util::detail::algorithm_result<ExPolicy>::type hpx::ranges::for_loop_strided(ExPolicy && policy, Iter first, Sent last, S stride Args &&... args)
```

The **for_loop_strided** implements loop functionality over a range specified by iterator bounds. These algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

**Requires**: **Iter** shall meet the requirements of a forward iterator type. The **args** parameter pack shall have at least one element, comprising objects returned by invocations of **reduction** and/or **induction** function templates followed by exactly one element invocable element-access function, \( f \). \( f \) shall meet the requirements of MoveConstructible.

**Template Parameters**
ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

Iter: The type of the iteration variable (forward iterator).

Sent: The type of the source sentinel (deduced). This sentinel type must be a sentinel for Iter.

S: The type of the stride variable. This should be an integral type.

Args: A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

Parameters

- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last: Refers to the end of the sequence of elements the algorithm will be applied to.
- stride: Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if Iter meets the requirements a bidirectional iterator.
- args: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

```cpp
<ignored> pred(Iter const& a, ...);
```

The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

Effects: Applies \( f \) to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the args parameter pack. The length of the input sequence is last-first.

The first element in the input sequence is specified by first. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the args parameter pack excluding \( f \), an additional argument is passed to each application of \( f \) as follows:

Note As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

Note The order of the elements of the input sequence is important for determining ordinal position of an application of \( f \), even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of \( f \) in the input sequence.

Complexity: Applies \( f \) exactly once for each element of the input sequence.

Remarks: If \( f \) returns a result, the result is ignored.

Return The for_loop_strided algorithm returns a hpx::future<void> if the execution policy is of type hpx::execution::sequenced_task_policy or hpx::execution::parallel_task_policy and returns void otherwise.

template<typename Rng, typename S, typename ...Args>
void for_loop_strided(Rng &&rng, S stride, Args&&... args)

The for_loop_strided implements loop functionality over a range specified by a range. These algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.
The execution of `for_loop_strided` without specifying an execution policy is equivalent to specifying `hpx::execution::seq` as the execution policy.

Requires: `Rng::iterator` shall meet the requirements of an input iterator type. The `args` parameter pack shall have at least one element, comprising objects returned by invocations of `reduction` and/or `induction` function templates followed by exactly one element invocable element-access function, `f`. `f` shall meet the requirements of MoveConstructible.

**Template Parameters**
- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- `S`: The type of the stride variable. This should be an integral type.
- `Args`: A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**
- `rng`: Refers to the sequence of elements the algorithm will be applied to.
- `stride`: Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if `Rng::iterator` meets the requirements a bidirectional iterator.
- `args`: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)` should expose a signature equivalent to:

```cpp
<ignored> pred(Rng::iterator const & a, ...);
```

The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Effects**: Applies `f` to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the `args` parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by `first`. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the `args` parameter pack excluding `f`, an additional argument is passed to each application of `f` as follows:

**Note** As described in the C++ standard, arithmetic on non-random-access iterators is performed using `advance` and `distance`.

**Note** The order of the elements of the input sequence is important for determining ordinal position of an application of `f`, even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of `f` in the input sequence.

**Complexity**: Applies `f` exactly once for each element of the input sequence.

**Remarks**: If `f` returns a result, the result is ignored.

```cpp
template<typename ExPolicy, typename Rng, typename S, typename ...Args>
util::detail::algorithm_result<ExPolicy>::type for_loop_strided(ExPolicy &&policy, Rng &&rng, S stride, Args&&... args)
```

The `for_loop_strided` implements loop functionality over a range specified by a range. These al-
algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

Requires: `Rng::iterator` shall meet the requirements of a forward iterator type. The `args` parameter pack shall have at least one element, comprising objects returned by invocations of `reduction` and/or `induction` function templates followed by exactly one element invocable element-access function, `f`. `f` shall meet the requirements of MoveConstructible.

Template Parameters
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- `S`: The type of the stride variable. This should be an integral type.
- `Args`: A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

Parameters
- `policy`: The execution policy to use for the scheduling of the iterations.
- `rng`: Refers to the sequence of elements the algorithm will be applied to.
- `stride`: Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if `Rng::iterator` meets the requirements a bidirectional iterator.
- `args`: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)` should expose a signature equivalent to:

```cpp
<ignored> pred(Rng::iterator const& a, ...);
```

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

Effects: Applies `f` to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the `args` parameter pack. The length of the input sequence is `last - first`.

The first element in the input sequence is specified by `first`. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the `args` parameter pack excluding `f`, an additional argument is passed to each application of `f` as follows:

**Note** As described in the C++ standard, arithmetic on non-random-access iterators is performed using `advance` and `distance`.

**Note** The order of the elements of the input sequence is important for determining ordinal position of an application of `f`, even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of `f` in the input sequence.

Complexity: Applies `f` exactly once for each element of the input sequence.

Remarks: If `f` returns a result, the result is ignored.
**Return** The *for_loop_strided* algorithm returns a `hpx::future<void>` if the execution policy is of type `hpx::execution::sequenced_task_policy` or `hpx::execution::parallel_task_policy` and returns `void` otherwise.

```cpp
namespace hpx

namespace ranges

Functions

```template<typename ExPolicy, typename Rng, typename F>
util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng>::type>::type
generate(ExPolicy &&policy, Rng &&rng, F &&f)
``` Assign each element in range `[first, last)` a value generated by the given function object `f`

The assignments in the parallel `generate` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Exactly `distance(first, last)` invocations of `f` and assignments.

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- `F`: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `F` to meet the requirements of `CopyConstructible`.

**Parameters**
- `policy`: The execution policy to use for the scheduling of the iterations.
- `rng`: Refers to the sequence of elements the algorithm will be applied to.
- `f`: generator function that will be called. signature of function should be equivalent to the following:

```cpp
Ret fun();
```

The type `Ret` must be such that an object of type `FwdIter` can be dereferenced and assigned a value of type `Ret`.

The assignments in the parallel `generate` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `replace_if` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. It returns `last`.

```template<typename ExPolicy, typename Iter, typename Sent, typename F>
util::detail::algorithm_result<ExPolicy, Iter>::type
generate(ExPolicy &&policy, Iter first, Sent last, F &&f)
``` Assign each element in range `[first, last)` a value generated by the given function object `f`
The assignments in the parallel `generate` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Exactly $distance(first, last)$ invocations of $f$ and assignments.

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Iter`: The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- `Sent`: The type of the source end iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- `F`: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires $F$ to meet the requirements of `CopyConstructible`.

**Parameters**
- `policy`: The execution policy to use for the scheduling of the iterations.
- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last`: Refers to the end of the sequence of elements the algorithm will be applied to.
- `f`: generator function that will be called. signature of function should be equivalent to the following:

```cpp
Ret fun();
```

The type $Ret$ must be such that an object of type $FwdIter$ can be dereferenced and assigned a value of type $Ret$.

The assignments in the parallel `generate` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `replace_if` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. It returns `last`.

```cpp
template<typename ExPolicy, typename FwdIter, typename Size, typename F>
util::detail::algorithm_result<ExPolicy, FwdIter>::type generate_n(ExPolicy &&policy, FwdIter first, Size count, F &&f)
```

Assigns each element in range `[first, first+count)` a value generated by the given function object $g$.

The assignments in the parallel `generate_n` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Exactly $count$ invocations of $f$ and assignments, for $count > 0$.

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter`: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- `F`: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires $F$ to meet the requirements of `CopyConstructible`.

**Parameters**
- `policy`: The execution policy to use for the scheduling of the iterations.
- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `count`: Refers to the number of elements in the sequence the algorithm will be applied to.
f: Refers to the generator function object that will be called. The signature of the function should be equivalent to

```
Ret fun();
```

The type Ret must be such that an object of type OutputIt can be dereferenced and assigned a value of type Ret.

The assignments in the parallel `generate_n` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The replace_if algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. It returns `last`.

```cpp
namespace hpx

namespace ranges

Functions

template<
    typename ExPolicy,
    typename Iter1,
    typename Sent1,
    typename Iter2,
    typename Sent2,
    typename Pred = detail::less,
    typename Proj1 = util::projection_identity,
    typename Proj2 = util::projection_identity>

util::detail::algorithm_result<
    ExPolicy && policy,
    Iter1 first1, last1,
    Iter2 first2,
    Sent2 last2,
    Pred && op = Pred(),
    Proj1 && proj1 = Proj1(),
    Proj2 && proj2 = Proj2()> includes

Returns true if every element from the sorted range [first2, last2) is found within the sorted range [first1, last1). Also returns true if [first2, last2) is empty. The version expects both ranges to be sorted with the user supplied binary predicate f.

The comparison operations in the parallel `includes` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** At most \(2^*(N1+N2-1)\) comparisons, where \(N1 = \text{std::distance(first1, last1)}\) and \(N2 = \text{std::distance(first2, last2)}\).

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter1**: The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent1**: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2**: The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent2**: The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for Iter2.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `includes` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>
- **Proj1**: The type of an optional projection function applied to the first sequence. This defaults to `util::projection_identity`
• **Proj2**: The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the sequence of elements of the first range that the algorithm will be applied to.
- **last1**: Refers to the end of the sequence of elements of the first range that the algorithm will be applied to.
- **first2**: Refers to the beginning of the sequence of elements of the second range that the algorithm will be applied to.
- **last2**: Refers to the end of the sequence of elements of the second range that the algorithm will be applied to.
- **op**: The binary predicate which returns true if the elements should be treated as includes. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

The comparison operations in the parallel `includes` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `includes` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `includes` algorithm returns true every element from the sorted range `[first2, last2)` is found within the sorted range `[first1, last1)`. Also returns true if `[first2, last2)` is empty. The version expects both ranges to be sorted with the user supplied binary predicate `f`.

```cpp
template<
  typename ExPolicy, typename Rng1, typename Rng2,
  typename Pred = detail::less,
  typename Proj1 = util::projection_identity,
  typename Proj2 = util::projection_identity>
util::detail::algorithm_result<ExPolicy, bool>::type
includes(ExPolicy &&policy, Rng1 &&rng1, Rng2 &&rng2,
  Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2());```

Returns true if every element from the sorted range `[first2, last2)` is found within the sorted range `[first1, last1)`. Also returns true if `[first2, last2)` is empty. The version expects both ranges to be sorted with the user supplied binary predicate `f`.

The comparison operations in the parallel `includes` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** At most \(2*(N1+N2-1)\) comparisons, where \(N1 = \text{std::distance}(\text{first1}, \text{last1})\) and \(N2 = \text{std::distance}(\text{first2}, \text{last2})\).

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1**: The type of the source range used (deduced). The iterators extracted from this range
type must meet the requirements of an input iterator.

- **Rng2**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `includes` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`

- **Proj1**: The type of an optional projection function applied to the first sequence. This defaults to `util::projection_identity`

- **Proj2**: The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng1**: Refers to the first sequence of elements the algorithm will be applied to.
- **rng2**: Refers to the second sequence of elements the algorithm will be applied to.
- **op**: The binary predicate which returns true if the elements should be treated as includes. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.

- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

The comparison operations in the parallel `includes` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

### Return

The `includes` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `includes` algorithm returns true every element from the sorted range `[first2, last2)` is found within the sorted range `[first1, last1)`. Also returns true if `[first2, last2)` is empty.

### Functions

```cpp
template<typename ExPolicy, typename Iter, typename Sent, typename Comp = detail::less, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, bool>::type is_heap(ExPolicy &&policy, Iter first, Sent last,
    Comp &&comp = Comp(), Proj &&proj = Proj())
```

Returns whether the range is max heap. That is, true if the range is max heap, false otherwise. The function uses the given comparison function object `comp` (defaults to using `operator<()`).

`comp` has to induce a strict weak ordering on the values.

### Note

Complexity: Performs at most N applications of the comparison `comp`, at most 2 * N applications of the projection `proj`, where N = last - first.
**ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

**Iter**: The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

**Sent**: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.

**Comp**: The type of the function/function object to use (deduced).

**Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **iter**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp**: `comp` is a callable object. The return value of the INVOKE operation applied to an object of type `Comp`, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

### Return

The `is_heap` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `is_heap` algorithm returns whether the range is max heap. That is, true if the range is max heap, false otherwise. The function uses the given comparison function object `comp` (defaults to using operator<()).

`comp` has to induce a strict weak ordering on the values.

**Note** Complexity: Performs at most N applications of the comparison `comp`, at most 2 * N applications of the projection `proj`, where N = last - first.

### Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
• Comp: The type of the function/function object to use (deduced).

• Proj: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

• policy: The execution policy to use for the scheduling of the iterations.

• rng: Refers to the sequence of elements the algorithm will be applied to.

• comp: `comp` is a callable object. The return value of the `INVOKE` operation applied to an object of type `Comp`, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator.

• proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return**

The `is_heap` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `is_heap` algorithm returns whether the range is max heap. That is, true if the range is max heap, false otherwise.

```cpp
template<typename ExPolicy, typename Iter, typename Sent, typename Comp = detail::less, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, Iter>::type is_heap_until(ExPolicy &&policy,
                    Iter first, Sent sent,
                    Comp &&comp = Comp(), Proj &&proj = Proj())
```

Returns the upper bound of the largest range beginning at `first` which is a max heap. That is, the last iterator `it` for which range `[first, it)` is a max heap. The function uses the given comparison function object `comp` (defaults to using operator<()).

`comp` has to induce a strict weak ordering on the values.

**Note** Complexity: Performs at most N applications of the comparison `comp`, at most 2 * N applications of the projection `proj`, where N = last - first.

**Template Parameters**

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• Iter: The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

• Sent: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for `Iter1`.

• Comp: The type of the function/function object to use (deduced).

• Proj: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

• policy: The execution policy to use for the scheduling of the iterations.

• iter: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **sent**: Refers to the end of the sequence of elements the algorithm will be applied to.

• **comp**: *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that *comp* will not apply any non-constant function through the dereferenced iterator.

• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The *is_heap_until* algorithm returns a *hpx::future<RandIter>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *RandIter* otherwise. The *is_heap_until* algorithm returns the upper bound of the largest range beginning at first which is a max heap. That is, the last iterator *it* for which range *[first, it)* is a max heap. The function uses the given comparison function object *comp* (defaults to using operator<()).

*comp* has to induce a strict weak ordering on the values.

**Note** Complexity: Performs at most N applications of the comparison *comp*, at most 2 * N applications of the projection proj, where N = last - first.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.

- **Comp**: The type of the function/function object to use (deduced).

- **Proj**: The type of an optional projection function. This defaults to *util::projection_identity*

**Parameters**
• **policy**: The execution policy to use for the scheduling of the iterations.

• **rng**: Refers to the sequence of elements the algorithm will be applied to.

• **comp**: comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.

• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The is_heap_until algorithm returns a hpx::future<RandIter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns RandIter otherwise. The is_heap_until algorithm returns the upper bound of the largest range beginning at first which is a max heap. That is, the last iterator it for which range [first, it) is a max heap.

```cpp
namespace hpx

namespace ranges

Functions

template<
    typename FwdIter,
    typename Sent,
    typename Pred = hpx::parallel::v1::detail::less,
    typename Proj = hpx::parallel::util::projection_identity>

bool is_sorted(FwdIter first, Sent last, Pred &&pred = Pred(), Proj &&proj = Proj())

Determines if the range [first, last) is sorted. Uses pred to compare elements.
```

The comparison operations in the parallel is_sorted algorithm executes in sequential order in the calling thread.

**Note** Complexity: at most (N+S-1) comparisons where N = distance(first, last). S = number of partitions

**Template Parameters**

- **FwdIter**: The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred**: The type of an optional function/function object to use.
- **Proj**: The type of an optional projection function. This defaults to util::projection_identity

**Parameters**

- **first**: Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred**: Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a, const Type &b);
```
The signature does not need to have const &, but the function must not modify the objects passed to it. The type Type must be such that objects of types FwdIter can be dereferenced and then implicitly converted to Type.

- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Return**  
The `is_sorted` algorithm returns a `bool`. The `is_sorted` algorithm returns true if each element in the sequence [first, last) satisfies the predicate passed. If the range [first, last) contains less than two elements, the function always returns true.

```cpp
template<typename ExPolicy, typename FwdIter, typename Sent, typename Pred = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>

hpx::parallel::util::detail::algorithm_result<ExPolicy, bool>::type

is_sorted(ExPolicy &&policy, FwdIter first, Sent last, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Determines if the range [first, last) is sorted. Uses pred to compare elements.

The comparison operations in the parallel `is_sorted` algorithm invoked with an execution policy object of type `sequenced_policy` executes in sequential order in the calling thread.

**Note**  
Complexity: at most (N+S-1) comparisons where N = distance(first, last). S = number of partitions

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `is_sorted` requires Pred to meet the requirements of CopyConstructible. This defaults to std::less<>
- **Proj**: The type of an optional projection function. This defaults to util::projection_identity

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred**: Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```cpp

bool pred(const Type &a, const Type &b);
```

The comparison operations in the parallel `is_sorted` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return**  
The `is_sorted` algorithm returns a `hpx::future<bool>` if the execution policy is of type
task_execution_policy and returns bool otherwise. The is_sorted algorithm returns a bool if each element in the sequence [first, last) satisfies the predicate passed. If the range [first, last) contains less than two elements, the function always returns true.

template<typename Rng, typename Pred = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>
bool is_sorted(ExPolicy &&policy, Rng &&rng, Pred &&pred = Pred(), Proj &&proj = Proj())
Determines if the range rng is sorted. Uses pred to compare elements.

The comparison operations in the parallel is_sorted algorithm executes in sequential order in the calling thread.  

**Note** Complexity: at most (N+S-1) comparisons where N = size(rng). S = number of partitions

**Template Parameters**

- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred**: The type of an optional function/function object to use.
- **Proj**: The type of an optional projection function. This defaults to util::projection_identity

**Parameters**

- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **pred**: Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

  ```cpp
  bool pred(const Type &a, const Type &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type **Type** must be such that objects of types FwdIter can be dereferenced and then implicitly converted to **Type**.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Return** The is_sorted algorithm returns a bool. The is_sorted algorithm returns true if each element in the rng satisfies the predicate passed. If the range rng contains less than two elements, the function always returns true.

template<typename ExPolicy, typename Rng, typename Pred = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::detail::algorithm_result<ExPolicy, bool>::type>
bool is_sorted(ExPolicy &&policy, Rng &&rng, Pred &&pred = Pred(), Proj &&proj = Proj())

Determines if the range rng is sorted. Uses pred to compare elements.

The comparison operations in the parallel is_sorted algorithm invoked with an execution policy object of type sequenced_policy executes in sequential order in the calling thread.  

**Note** Complexity: at most (N+S-1) comparisons where N = size(rng). S = number of partitions

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of is_sorted requires Pred to meet the requirements of CopyConstructible. This defaults to std::less<>
• **Proj:** The type of an optional projection function. This defaults to `util::projection_identity`.

**Parameters**
- **policy:** The execution policy to use for the scheduling of the iterations.
- **rng:** Refers to the sequence of elements the algorithm will be applied to.
- **pred:** Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a, const Type &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- **proj:** Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel `is_sorted` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return**
The `is_sorted` algorithm returns a `hpx::future<bool>` if the execution policy is of type `task_execution_policy` and returns `bool` otherwise. The `is_sorted` algorithm returns a `bool` if each element in the range `rng` satisfies the predicate passed. If the range `rng` contains less than two elements, the function always returns true.

```cpp
template<typename FwdIter, typename Sent, typename Pred = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>
FwdIter is_sorted_until(FwdIter first, Sent last, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Returns the first element in the range `[first, last)` that is not sorted. Uses a predicate to compare elements or the less than operator.

The comparison operations in the parallel `is_sorted_until` algorithm execute in sequential order in the calling thread.

**Note**
Complexity: at most (N+S-1) comparisons where \(N = \text{distance(first, last)}\). \(S = \text{number of partitions}\)

**Template Parameters**
- **FwdIter:** The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred:** The type of an optional function/function object to use.
- **Proj:** The type of an optional projection function. This defaults to `util::projection_identity`.

**Parameters**
- **first:** Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last:** Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred:** Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a, const Type &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- **proj:** Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.
Return The `is_sorted_until` algorithm returns a `FwdIter`. The `is_sorted_until` algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, last is returned.

```cpp
template<typename ExPolicy, typename FwdIter, typename Sent, typename Pred = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>

hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type

is_sorted_until(ExPolicy&& policy, FwdIter first, Sent last, Pred&& pred = Pred(), Proj&& proj = Proj());
```

Returns the first element in the range `[first, last)` that is not sorted. Uses a predicate to compare elements or the less than operator.

The comparison operations in the parallel `is_sorted_until` algorithm invoked with an execution policy object of type `sequenced_policy` executes in sequential order in the calling thread.

Note Complexity: at most \((N+S-1)\) comparisons where \(N = \text{distance}(\text{first}, \text{last})\). \(S = \text{number of partitions}\)

Template Parameters

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter`: The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- `Pred`: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `is_sorted_until` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`

Parameters

- `policy`: The execution policy to use for the scheduling of the iterations.
- `first`: Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- `last`: Refers to the end of the sequence of elements of that the algorithm will be applied to.
- `pred`: Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a, const Type &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- `proj`: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel `is_sorted_until` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion.
in unspecified threads, and indeterminately sequenced within each thread.

Return The `is_sorted_until` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `is_sorted_until` algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, last is returned.

```cpp
template<typename Rng, typename Pred = hpx::parallel::util::projection_identity, typename Proj = hpx::parallel::util::projection_identity>
int is_sorted_until(ExPolicy &&policy, Rng &&rng, Pred &&pred = Pred(), Proj &&proj = Proj());
```

Returns the first element in the range `rng` that is not sorted. Uses a predicate to compare elements or the less than operator.

The comparison operations in the parallel `is_sorted_until` algorithm execute in sequential order in the calling thread.

**Note** Complexity: at most (N+S-1) comparisons where N = size(rng). S = number of partitions

Template Parameters

- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- `Pred`: The type of an optional function/function object to use.
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`

Parameters

- `rng`: Refers to the sequence of elements the algorithm will be applied to.
- `pred`: Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a, const Type &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to Type.
- `proj`: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate `is` invoked.

Return The `is_sorted_until` algorithm returns a `FwdIter`. The `is_sorted_until` algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, last is returned.

```cpp
template<typename ExPolicy, typename Rng, typename Pred = hpx::parallel::util::less, typename Proj = hpx::parallel::util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng>::type>::type>
```

Returns the first element in the range `rng` that is not sorted. Uses a predicate to compare elements or
The comparison operations in the parallel \texttt{is\_sorted\_until} algorithm invoked with an execution policy object of type \texttt{sequenced\_policy} executes in sequential order in the calling thread.

\textbf{Note} Complexity: at most \((N+S-1)\) comparisons where \(N = \text{size(rng)}\). \(S = \text{number of partitions}\)

\textbf{Template Parameters}

- \texttt{ExPolicy}: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- \texttt{Rng}: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- \texttt{Pred}: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of \texttt{is\_sorted\_until} requires \texttt{Pred} to meet the requirements of \texttt{CopyConstructible}. This defaults to \texttt{std::less<>.}
- \texttt{Proj}: The type of an optional projection function. This defaults to \texttt{util::projection\_identity}

\textbf{Parameters}

- \texttt{policy}: The execution policy to use for the scheduling of the iterations.
- \texttt{rng}: Refers to the sequence of elements the algorithm will be applied to.
- \texttt{pred}: Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

\begin{verbatim}
bool pred(const Type &a, const Type &b);
\end{verbatim}

The signature does not need to have \texttt{const &}, but the function must not modify the objects passed to it. The type \texttt{Type} must be such that objects of types \texttt{FwdIter} can be dereferenced and then implicitly converted to \texttt{Type}.

- \texttt{proj}: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate \texttt{is} invoked.

The comparison operations in the parallel \texttt{is\_sorted\_until} algorithm invoked with an execution policy object of type \texttt{parallel\_policy} or \texttt{parallel\_task\_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

\textbf{Return} The \texttt{is\_sorted\_until} algorithm returns a \texttt{hpx::future<FwdIter>} if the execution policy is of type \texttt{task\_execution\_policy} and returns \texttt{FwdIter} otherwise. The \texttt{is\_sorted\_until} algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, last is returned.

\begin{verbatim}
namespace hpx

namespace ranges

Functions

template<typename ExPolicy, typename Rng, typename Comp, typename Proj = util::projection_identity>
\end{verbatim}
Constructs a max heap in the range [first, last).

The predicate operations in the parallel make_heap algorithm invoked with an execution policy object of type sequential_execution_policy executes in sequential order in the calling thread.

Note Complexity: at most (3*N) comparisons where $N = \text{distance(first, last)}$.

Template Parameters
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- Rng: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- Comp: The type of the function/function object to use (deduced).
- Proj: The type of an optional projection function. This defaults to util::projection_identity

Parameters
- rng: Refers to the sequence of elements the algorithm will be applied to.
- comp: Refers to the binary predicate which returns true if the first argument should be treated as less than the second. The signature of the function should be equivalent to

```cpp
define bool comp(const Type &a, const Type &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type Type must be such that objects of types RndIter can be dereferenced and then implicitly converted to Type.
- proj: Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate comp is invoked.

The comparison operations in the parallel make_heap algorithm invoked with an execution policy object of type parallel_execution_policy or parallel_task_execution_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The make_heap algorithm returns a hpx::future<Iter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns Iter otherwise. It returns last.
Constructs a max heap in the range [first, last). Uses the operator < for comparisons.

The predicate operations in the parallel make_heap algorithm invoked with an execution policy object of type sequential_execution_policy executes in sequential order in the calling thread.

**Note**  Complexity: at most \((3*N)\) comparisons where \(N = \text{distance}(\text{first}, \text{last})\).

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Proj**: The type of an optional projection function. This defaults to util::projection_identity

**Parameters**

- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **proj**: Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate \(\text{comp}\) is invoked.

The comparison operations in the parallel make_heap algorithm invoked with an execution policy object of type parallel_execution_policy or parallel_task_execution_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return**  The make_heap algorithm returns a hpx::future<void> if the execution policy is of type task_execution_policy and returns void otherwise.

```cpp
namespace hpx
{
namespace ranges
{

Functions

template<typename ExPolicy, typename Iter1, typename Sent, typename Iter2, typename Sent2, typename Iter3, typename Comp = hpx::ranges::less, typename Proj1 = util::projection_identity, typename Proj2 = util::projection_identity>
```
util::detail::algorithm_result<ExPolicy, hpx::ranges::merge_result<Iter1, Iter2, Iter3>>::type merge (ExPolicy &&policy, Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Iter3 dest, Comp &&comp = Comp(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())

Merges two sorted ranges [first1, last1) and [first2, last2) into one sorted range beginning at dest. The order of equivalent elements in each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. The destination range cannot overlap with either of the input ranges.

The assignments in the parallel merge algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Performs O(std::distance(first1, last1) + std::distance(first2, last2)) applications of the comparison comp and the each projection.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter1**: The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an random access iterator.
- **Sent1**: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2**: The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an random access iterator.
- **Sent2**: The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for Iter2.
- **Iter3**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an random access iterator.
- **Comp**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of merge requires Comp to meet the requirements of CopyConstructible. This defaults to std::less<>
- **Proj1**: The type of an optional projection function to be used for elements of the first range. This defaults to util::projection_identity
• **Proj2**: The type of an optional projection function to be used for elements of the second range. This defaults to `util::projection_identity`

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2**: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2**: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **comp**: `comp` is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```cpp
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `RandIter1` and `RandIter2` can be dereferenced and then implicitly converted to both `Type1` and `Type2`

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual comparison `comp` is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual comparison `comp` is invoked.

The assignments in the parallel `merge` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `merge` algorithm returns a `hpx::future<merge_result<Iter1, Iter2, Iter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `merge_result<Iter1, Iter2, Iter3>` otherwise. The `merge` algorithm returns the tuple of the source iterator `last1`, the source iterator `last2`, the destination iterator to the end of the `dest` range.

```cpp
template<typename ExPolicy, typename Rng1, typename Rng2, typename RandIter3, typename Comp = hpx::range_v3::less>
```
Merges two sorted ranges \([\text{first1}, \text{last1})\) and \([\text{first2}, \text{last2})\) into one sorted range beginning at \(\text{dest}\). The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. The destination range cannot overlap with either of the input ranges.

The assignments in the parallel \textit{merge} algorithm invoked with an execution policy object of type \textit{sequenced\_policy} execute in sequential order in the calling thread.

\textbf{Note} Complexity: Performs \(O(\text{std::distance(\text{first1}, \text{last1}) + std::distance(\text{first2}, \text{last2}))}\) applications of the comparison \(\text{comp}\) and the each projection.

**Template Parameters**

- \textit{ExPolicy}: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- \textit{Rng1}: The type of the first source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- \textit{Rng2}: The type of the second source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- \textit{RandIter3}: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an random access iterator.
- \textit{Comp}: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \textit{merge} requires \textit{Comp} to meet the requirements of \textit{CopyConstructible}. This defaults to \textit{std::less<>

- \textit{Proj1}: The type of an optional projection function to be used for elements of the first range. This defaults to \textit{util::projection\_identity}
- \textit{Proj2}: The type of an optional projection function to be used for elements of the second range. This defaults to \textit{util::projection\_identity}

**Parameters**

- \textit{policy}: The execution policy to use for the scheduling of the iterations.
- \textit{rng1}: Refers to the first range of elements the algorithm will be applied to.
- \textit{rng2}: Refers to the second range of elements the algorithm will be applied to.
- \textit{dest}: Refers to the beginning of the destination range.
• **comp**: `comp` is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```cpp
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `RandIter1` and `RandIter2` can be dereferenced and then implicitly converted to both `Type1` and `Type2`.

• **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual comparison `comp` is invoked.

• **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual comparison `comp` is invoked.

The assignments in the parallel `merge` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The `merge` algorithm returns a `hpx::future<merge_result<RandIter1, RandIter2, RandIter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `merge_result<RandIter1, RandIter2, RandIter3>` otherwise. The `merge` algorithm returns the tuple of the source iterator `last1`, the source iterator `last2`, the destination iterator to the end of the `dest` range.

```cpp
template<typename ExPolicy, typename Iter, typename Sent, typename Comp = hpx::ranges::less, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, Iter>::type
inplace_merge(ExPolicy &&policy, Iter first, Iter middle, Sent last, Comp &&comp = Comp(), Proj &&proj = Proj())
```

Merges two consecutive sorted ranges `[first, middle)` and `[middle, last)` into one sorted range `[first, last)`. The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range.

The assignments in the parallel `inplace_merge` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs $O(\text{std::distance(first, last)})$ applications of the comparison `comp` and the each projection.

**Template Parameters**

• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **Iter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an random access iterator.

• **Sent**: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for `Iter1`.

• **Comp**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `inplace_merge` requires `Comp` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`

• **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

• **policy**: The execution policy to use for the scheduling of the iterations.

• **first**: Refers to the beginning of the first sorted range the algorithm will be applied to.

• **middle**: Refers to the end of the first sorted range and the beginning of the second sorted
range the algorithm will be applied to.

- **last**: Refers to the end of the second sorted range the algorithm will be applied to.
- **comp**: 
  
  `comp` is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

  ```cpp
  bool comp(const Type1 &a, const Type2 &b);
  ```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `RandIter` can be dereferenced and then implicitly converted to both `Type1` and `Type2`.

- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel `inplace_merge` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `inplace_merge` algorithm returns a `hpx::future<Iter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `Iter` otherwise. The `inplace_merge` algorithm returns the source iterator `last`.

```cpp
template<typename ExPolicy, typename Rng, typename RandIter, typename Comp = hpx::ranges::less, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, RandIter>::type inplace_merge(ExPolicy &&policy,
    Rng &&rng, RandIter middle, Comp &&comp = Comp(),
    Proj &&proj = Proj())
```

Merges two consecutive sorted ranges `[first, middle)` and `[middle, last)` into one sorted range `[first, last)`. The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range.

The assignments in the parallel `inplace_merge` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs O(std::distance(first, last)) applications of the comparison `comp` and the each projection.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- **RandIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an random access iterator.
- **Comp**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `inplace_merge` requires `Comp` to meet the requirements of `CopyConstructible`. This defaults to std::less<>
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the range of elements the algorithm will be applied to.
- **middle**: Refers to the end of the first sorted range and the beginning of the second sorted range the algorithm will be applied to.
- **comp**: `comp` is a callable object which returns true if the first argument is less than the second,
and false otherwise. The signature of this comparison should be equivalent to:

```cpp
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types RandIter can be dereferenced and then implicitly converted to both Type1 and Type2.

- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel inplace_merge algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The inplace_merge algorithm returns a hpx::future<RandIter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns RandIter otherwise. The inplace_merge algorithm returns the source iterator last.

namespace hpx

namespace parallel

### Functions

```
template<

typename ExPolicy, typename Rng, typename Proj = util::projection_identity,

typename F = detail::less>
util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_traits<Rng>::iterator_type>::type
min_element(
    ExPolicy &&policy,
    Rng &&rng,
    F &&f = F(),
    Proj &&proj = Proj())
```

Finds the smallest element in the range [first, last) using the given comparison function f.

The comparisons in the parallel min_element algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Exactly max(N-1, 0) comparisons, where N = std::distance(first, last).

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of min_element requires F to meet the requirements of CopyConstructible.
- **Proj**: The type of an optional projection function. This defaults to util::projection_identity

**Parameters**
• **policy**: The execution policy to use for the scheduling of the iterations.
• **rng**: Refers to the sequence of elements the algorithm will be applied to.
• **f**: The binary predicate which returns true if the the left argument is less than the right element.
   The signature of the predicate function should be equivalent to the following:

   ```cpp
   bool pred(const Type1 &a, const Type1 &b);
   ```

   The signature does not need to have const & but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.
   
   • **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The comparisons in the parallel `min_element` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `min_element` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `min_element` algorithm returns the iterator to the smallest element in the range `[first, last)`. If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```cpp
template<typename ExPolicy, typename Rng, typename Proj = util::projection_identity, typename F = detail::less>
util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_traits<Rng>::iterator_type>::type
util::max_element(ExPolicy &&policy, Rng &&rng, F &&f = F(), Proj &&proj = Proj());
```

Finds the greatest element in the range `[first, last)` using the given comparison function `f`.

The comparisons in the parallel `max_element` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Exactly `max(N-1, 0)` comparisons, where `N = std::distance(first, last)`.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `max_element` requires `F` to meet the requirements of `CopyConstructible`.
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
• **f**: The binary predicate which returns true if the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const & but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The comparisons in the parallel `max_element` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return**: The `max_element` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `max_element` algorithm returns the iterator to the smallest element in the range `[first, last)`. If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```cpp
.template<typename ExPolicy, typename Rng, typename Proj = util::projection_identity, typename F = detail::less>
util::detail::algorithm_result<ExPolicy, hpx::util::tagged_pair<tag::min,typename hpx::traits::range_traits<Rng>::iterator_type>, tag::max
typename hpx::traits::range_traits<Rng>::iterator_type> ::type
minmax_element(ExPolicy &&policy, Rng &&rng, F &&f = F(), Proj &&proj = Proj())
```

The comparisons in the parallel `minmax_element` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note**: Complexity: At most \( \max(\floor{3/2*(N-1)}, 0) \) applications of the predicate, where \( N = \text{std::distance}(\text{first}, \text{last}) \).

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `minmax_element` requires `F` to meet the requirements of `CopyConstructible`.
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **f**: The binary predicate which returns true if the left argument is less than the right element. This argument is optional and defaults to `std::less`. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.
• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The comparisons in the parallel `minmax_element` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `minmax_element` algorithm returns a `hpx::future<tagged_pair<tag::min(FwdIter), tag::max(FwdIter)>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `tagged_pair<tag::min(FwdIter), tag::max(FwdIter)>>` otherwise. The `minmax_element` algorithm returns a pair consisting of an iterator to the smallest element as the first element and an iterator to the greatest element as the second. Returns `std::make_pair(first, first)` if the range is empty. If several elements are equivalent to the smallest element, the iterator to the first such element is returned. If several elements are equivalent to the largest element, the iterator to the last such element is returned.

```cpp
namespace hpx

namespace ranges

Functions

template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Pred = ranges::equal_to, typename Proj1 = util::projection_identity, typename Proj2 = util::projection_identity>
util::detail::algorithm_result<ExPolicy, ranges::mismatch_result<FwdIter1, FwdIter2>>::type mismatch(ExPolicy&& policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, Pred&& op = Pred(), Proj1&& proj1 = Proj1(), Proj2&& proj2 = Proj2())
```

Returns true if the range `[first1, last1)` is mismatch to the range `[first2, last2)`, and false otherwise.

The comparison operations in the parallel `mismatch` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: At most `min(last1 - first1, last2 - first2)` applications of the predicate `f`. If `FwdIter1` and `FwdIter2` meet the requirements of `RandomAccessIterator` and `(last1 - first1) != (last2 - first2)` then no applications of the predicate `f` are made.
Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter1**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1**: The type of the source iterators used for the end of the first range (deduced).
- **Iter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2**: The type of the source iterators used for the end of the second range (deduced).
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `mismatch` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`.
- **Proj1**: The type of an optional projection function applied to the first range. This defaults to `util::projection_identity`.
- **Proj2**: The type of an optional projection function applied to the second range. This defaults to `util::projection_identity`.

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2**: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2**: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op**: The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

  ```cpp
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel `mismatch` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note

The two ranges are considered mismatch if, for every iterator `i` in the range `[first1,last1), *(i) mismatches *(first2 + (i - first1))`. This overload of `mismatch` uses operator `==` to determine if two elements are mismatch.

Return

The `mismatch` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `mismatch` algorithm returns true if the elements in the two ranges are mismatch, otherwise it returns false. If the length of the range `[first1, last1)` does not mismatch the length of the range `[first2, last2)`, it returns false.

```cpp
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred = ranges::equal_to, typename Proj1 = util::projection_identity, typename Proj2 = util::projection_identity>
```
util::detail::algorithm_result<ExPolicy, ranges::mismatch_result<FwdIter1, FwdIter2>>::type mismatch

Returns std::pair with iterators to the first two non-equivalent elements.

The comparison operations in the parallel mismatch algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: At most last1 - first1 applications of the predicate \( f \).

Template Parameters

- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- Rng1: The type of the first source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- Rng2: The type of the second source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- Pred: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of mismatch requires \( \text{Pred} \) to meet the requirements of CopyConstructible. This defaults to std::equal_to<>.
- Proj1: The type of an optional projection function applied to the first range. This defaults to util::projection_identity
- Proj2: The type of an optional projection function applied to the second range. This defaults to util::projection_identity

Parameters

- policy: The execution policy to use for the scheduling of the iterations.
- rng1: Refers to the first sequence of elements the algorithm will be applied to.
- rng2: Refers to the second sequence of elements the algorithm will be applied to.
- op: The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const & but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively.

- proj1: Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate is invoked.

---

2.8. API reference 1161
• proj2: Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate is invoked. The comparison operations in the parallel mismatch algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The mismatch algorithm returns a hpx::future<std::pair<FwdIter1, FwdIter2>> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns std::pair<FwdIter1, FwdIter2> otherwise. The mismatch algorithm returns the first mismatching pair of elements from two ranges: one defined by [first1, last1) and another defined by [first2, last2).

```cpp
class hpx

namespace hpx

Functions

template<typename ExPolicy, typename FwdIter1, typename Sent1, typename FwdIter>
util::detail::algorithm_result<ExPolicy, ranges::move_result<FwdIter1, FwdIter>>::type move(ExPolicy &&policy, FwdIter1 iter, Sent1 sent, FwdIter dest)
```

Moves the elements in the range rng to another range beginning at dest. After this operation the elements in the moved-from range will still contain valid values of the appropriate type, but not necessarily the same values as before the move.

The assignments in the parallel copy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly std::distance(begin(rng), end(rng)) assignments.

**Template Parameters**
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- FwdIter1: The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- Sent1: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for FwdIter1.
- FwdIter: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**
- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last: Refers to the end of the sequence of elements the algorithm will be applied to.
\* dest: Refers to the beginning of the destination range.

The assignments in the parallel \textit{copy} algorithm invoked with an execution policy object of type \textit{parallel_policy} or \textit{parallel_task_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The move algorithm returns a \texttt{hpx::future\langle \texttt{ranges::move_result\langle iterator_t\langle Rng \rangle, FwdIter2 \rangle} \rangle} if the execution policy is of type \textit{sequenced_task_policy} or \textit{parallel_task_policy} and returns \texttt{ranges::move_result\langle iterator_t\langle Rng \rangle, FwdIter2 \rangle} otherwise. The move algorithm returns the pair of the input iterator \texttt{last} and the output iterator to the element in the destination range, one past the last element moved.

\begin{verbatim}
template\langle typename ExPolicy, typename Rng, typename FwdIter \rangle
tool::detail::algorithm_result\langle ExPolicy, ranges::move_result\langle typename hpx::traits::range_traits\langle Rng \rangle::iterator_type, FwdIter \rangle\rangle
\end{verbatim}

Moves the elements in the range \texttt{rng} to another range beginning at \texttt{dest}. After this operation the elements in the moved-from range will still contain valid values of the appropriate type, but not necessarily the same values as before the move.

The assignments in the parallel \textit{copy} algorithm invoked with an execution policy object of type \textit{sequenced_policy} execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly \texttt{std::distance(begin(rng), end(rng))} assignments.

**Template Parameters**

\begin{itemize}
  \item \texttt{ExPolicy}: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
  \item \texttt{Rng}: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
  \item \texttt{FwdIter}: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
\end{itemize}

**Parameters**

\begin{itemize}
  \item \texttt{policy}: The execution policy to use for the scheduling of the iterations.
  \item \texttt{rng}: Refers to the sequence of elements the algorithm will be applied to.
  \item \texttt{dest}: Refers to the beginning of the destination range.
\end{itemize}

The assignments in the parallel \textit{copy} algorithm invoked with an execution policy object of type \textit{parallel_policy} or \textit{parallel_task_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The move algorithm returns a \texttt{hpx::future\langle \texttt{ranges::move_result\langle iterator_t\langle Rng \rangle, FwdIter2 \rangle} \rangle} if the execution policy is of type \textit{sequenced_task_policy} or \textit{parallel_task_policy} and returns \texttt{ranges::move_result\langle iterator_t\langle Rng \rangle, FwdIter2 \rangle} otherwise. The move algorithm returns the pair
of the input iterator \texttt{last} and the output iterator to the element in the destination range, one past the last element moved.

\begin{verbatim}

Functions

template<typename ExPolicy, typename Rng, typename Pred, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng>::type>::type
\textbf{partition} (ExPolicy &&policy, Rng &&rng, Pred &&pred, Proj &&proj = Proj())
\end{verbatim}

Reorders the elements in the range \texttt{rng} in such a way that all elements for which the predicate \texttt{pred} returns true precede the elements for which the predicate \texttt{pred} returns false. Relative order of the elements is not preserved.

The assignments in the parallel partition algorithm invoked with an execution policy object of type \texttt{sequenced_policy} execute in sequential order in the calling thread.

\textbf{Note} Complexity: Performs at most 2 \* N swaps, exactly N applications of the predicate and projection, where \(N = \text{std:}:\text{distance}(	ext{begin(rng)}, \text{end(rng)})\).

\textbf{Template Parameters}
- \texttt{ExPolicy}: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- \texttt{Rng}: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- \texttt{Pred}: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of partition requires \texttt{Pred} to meet the requirements of \texttt{CopyConstructible}.
- \texttt{Proj}: The type of an optional projection function. This defaults to util::projection_identity

\textbf{Parameters}
- \texttt{policy}: The execution policy to use for the scheduling of the iterations.
- \texttt{rng}: Refers to the sequence of elements the algorithm will be applied to.
- \texttt{pred}: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by the range \texttt{rng}. This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

\begin{verbatim}
bool pred(const Type &a);
\end{verbatim}

The signature does not need to have \texttt{const\&}, but the function must not modify the objects passed to it. The type \texttt{Type} must be such that an object of type \texttt{FwdIter} can be dereferenced and then implicitly converted to \texttt{Type}.
- \texttt{proj}: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate \texttt{is} invoked.
The assignments in the parallel partition algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The partition algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type parallel_task_policy and returns `FwdIter` otherwise. The partition algorithm returns the iterator to the first element of the second group.

```cpp
template<typename ExPolicy, typename Rng, typename FwdIter2, typename FwdIter3, typename Pred, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, hpx::util::tagged_tuple<tag::in<typename hpx::traits::range_iterator<Rng>::type>, tag::out1 FwdIter2, tag::out2 FwdIter3>>::type partition_copy(ExPolicy &&policy, Rng &&rng, FwdIter2 dest_true, FwdIter3 dest_false, Pred &&pred, Proj &&proj = Proj())
```

Copies the elements in the range `rng`, to two different ranges depending on the value returned by the predicate `pred`. The elements, that satisfy the predicate `pred`, are copied to the range beginning at `dest_true`. The rest of the elements are copied to the range beginning at `dest_false`. The order of the elements is preserved.

The assignments in the parallel partition_copy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than N assignments, exactly N applications of the predicate `pred`, where N = std::distance(begin(rng), end(rng)).

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- `FwdIter2`: The type of the iterator representing the destination range for the elements that satisfy the predicate `pred` (deduced). This iterator type must meet the requirements of an forward iterator.
- `FwdIter3`: The type of the iterator representing the destination range for the elements that don’t satisfy the predicate `pred` (deduced). This iterator type must meet the requirements of an forward iterator.
- `Pred`: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of partition_copy requires `Pred` to meet the requirements of CopyConstructible.
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`.

**Parameters**
- `policy`: The execution policy to use for the scheduling of the iterations.
- `rng`: Refers to the sequence of elements the algorithm will be applied to.
- `dest_true`: Refers to the beginning of the destination range for the elements that satisfy the predicate `pred`.
- `dest_false`: Refers to the beginning of the destination range for the elements that don’t satisfy the predicate `pred`.
- `pred`: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by the range `rng`. This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced.
and then implicitly converted to Type.

- proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel partition_copy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The partition_copy algorithm returns a hpx::future<tagged_tuple<tag::in(InIter), tag::out1(OutIter1), tag::out2(OutIter2)>> if the execution policy is of type parallel_task_policy and returns tagged_tuple<tag::in(InIter), tag::out1(OutIter1), tag::out2(OutIter2)>> otherwise. The partition_copy algorithm returns the tuple of the source iterator last, the destination iterator to the end of the dest_true range, and the destination iterator to the end of the dest_false range.

namespace ranges

Functions

template<typename ExPolicy, typename FwdIter, typename Sent, typename T, typename F>
util::detail::algorithm_result<ExPolicy, T>::type reduce(ExPolicy &&policy, FwdIter first, Sent last, T init, F &&f)
Returns GENERALIZED_SUM(f, init, *first, . . . , *(first + (last - first) - 1)).

The reduce operations in the parallel reduce algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: O(last - first) applications of the predicate f.

Template Parameters

- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- FwdIter: The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- Sent: The type of the source sentinel used (deduced). This iterator type must meet the requirements of an forward iterator.
- F: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of copy_if requires F to meet the requirements of CopyConstructible.
- T: The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last: Refers to the end of the sequence of elements the algorithm will be applied to.
- f: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature of this predicate should be equivalent to:

  ```cpp
  Ret fun(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const&. The types Type1 Ret must be such that an object of type FwdIterB can be dereferenced and then implicitly converted to any of those types.
- init: The initial value for the generalized sum.
The reduce operations in the parallel `copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `reduce` and `accumulate` is that the behavior of `reduce` may be non-deterministic for non-associative or non-commutative binary predicate.

**Return** The `reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `T` otherwise. The `reduce` algorithm returns the result of the generalized sum over the elements given by the input range `[first, last)`.  

**Note** `GENERATED_SUM(op, a1, ..., aN)` is defined as follows:
- `a1` when `N` is 1
- `op(GENERALIZED_SUM(op, b1, ..., bK), GENERALIZED_SUM(op, bM, ..., bN))`, where:
  - `b1`, ..., `bN` may be any permutation of `a1`, ..., `aN` and
  - `1 < K+1 = M <= N`.

```cpp
template<typename ExPolicy, typename FwdIter, typename Sent, typename T>
util::detail::algorithm_result<ExPolicy, T>::type reduce
(ExPolicy&& policy, FwdIter first, Sent last, T init)
```

Returns `GENERALIZED_SUM(+, init, *first, ..., *(first + (last - first) - 1))`.  

The reduce operations in the parallel `reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.  

**Note** Complexity: `O(last - first)` applications of the operator+().

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter`: The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- `Sent`: The type of the source sentinel used (deduced). This iterator type must meet the requirements of an forward iterator.
- `T`: The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**
- `policy`: The execution policy to use for the scheduling of the iterations.
- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last`: Refers to the end of the sequence of elements the algorithm will be applied to.
- `init`: The initial value for the generalized sum.

The reduce operations in the parallel `copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `reduce` and `accumulate` is that the behavior of `reduce` may be non-deterministic for non-associative or non-commutative binary predicate.

**Return** The `reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `T` otherwise. The `reduce` algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range `[first, last)`.  

**Note** `GENERATED_SUM(+, a1, ..., aN)` is defined as follows:
- `a1` when `N` is 1
- `op(GENERALIZED_SUM(+, b1, ..., bK), GENERALIZED_SUM(+, bM, ..., bN))`, where:
template<typename ExPolicy, typename FwdIter, typename Sent>
util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<FwdIter>::value_type>::type
reduce(
    ExPolicy&& policy,
    FwdIter first,
    Sent last)
Returns GENERALIZED_SUM(+, T(), *(first + (last - first) - 1)).

The reduce operations in the parallel reduce algorithm invoked with an execution policy object of type
sequenced_policy execute in sequential order in the calling thread.

Note Complexity: \(O(last - first)\) applications of the operator+().

Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in
  which the execution of the algorithm may be parallelized and the manner in which it executes
  the assignments.
- **FwdIter**: The type of the source begin iterator used (deduced). This iterator type must meet
  the requirements of an forward iterator.
- **Sent**: The type of the source sentinel used (deduced). This iterator type must meet the re-
  quirements of an forward iterator.

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.

The reduce operations in the parallel copy_if algorithm invoked with an execution policy object of
type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in un-
specified threads, and indeterminately sequenced within each thread.

The difference between reduce and accumulate is that the behavior of reduce may be non-deterministic
for non-associative or non-commutative binary predicate.

Return The reduce algorithm returns a hpx::future<T> if the execution policy is of type se-
quenced_task_policy or parallel_task_policy and returns T otherwise (where T is the value_type
of FwdIterB). The reduce algorithm returns the result of the generalized sum (applying operator+() over
the elements given by the input range [first, last]).

Note The type of the initial value (and the result type) T is determined from the value_type of the
used FwdIterB.

Note GENERALIZED_SUM(+, a1, ..., aN) is defined as follows:
- a1 when N is 1
- op(GENERALIZED_SUM(+, b1, ..., bK), GENERALIZED_SUM(+, bM, ..., bN)), where:
  - b1, ..., bN may be any permutation of a1, ..., aN and
  - 1 < K+1 = M <= N.

template<typename ExPolicy, typename Rng, typename T, typename F>
util::detail::algorithm_result<ExPolicy, T>::type
reduce(ExPolicy &&policy, Rng &&rng, T init, F &&f)
Returns GENERALIZED_SUM(f, init, *(first + (last - first) - 1)).
The reduce operations in the parallel `reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: \(O(last - first)\) applications of the predicate \(f\).

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- `F`: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `copy_if` requires \(F\) to meet the requirements of `CopyConstructible`.
- `T`: The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**
- `policy`: The execution policy to use for the scheduling of the iterations.
- `rng`: Refers to the sequence of elements the algorithm will be applied to.
- `f`: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([first, last)\). This is a binary predicate. The signature of this predicate should be equivalent to:

```cpp
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&. The types `Type1 Ret` must be such that an object of type `FwdIterB` can be dereferenced and then implicitly converted to any of those types.
- `init`: The initial value for the generalized sum.

The reduce operations in the parallel `copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `reduce` and `accumulate` is that the behavior of `reduce` may be non-deterministic for non-associative or non-commutative binary predicate.

**Return** The `reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns \(T\) otherwise. The `reduce` algorithm returns the result of the generalized sum over the elements given by the input range \([first, last)\).

**Note** `GENERALIZED_SUM(op, a1, \ldots, aN)` is defined as follows:
- \(a1\) when \(N = 1\)
- \(op(GENERALIZED_SUM(op, b1, \ldots, bK), GENERALIZED_SUM(op, bM, \ldots, bN))\), \(\)where:
  - \(b1, \ldots, bN\) may be any permutation of \(a1, \ldots, aN\) and
  - \(1 < K+1 = M \leq N\).

```cpp
template<typename ExPolicy, typename Rng, typename T>
util::detail::algorithm_result<ExPolicy, T>::type reduce (ExPolicy &&policy, Rng &&rng, T init)
Returns GENERALIZED_SUM(+, init, *first, \ldots, *(first + (last - first) - 1)).
```

The reduce operations in the parallel `reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: \(O(last - first)\) applications of the operator\(+()\).

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
• T: The type of the value to be used as initial (and intermediate) values (deduced).

Parameters
• policy: The execution policy to use for the scheduling of the iterations.
• rng: Refers to the sequence of elements the algorithm will be applied to.
• init: The initial value for the generalized sum.

The reduce operations in the parallel `copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `reduce` and `accumulate` is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Return The `reduce` algorithm returns an `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `T` otherwise. The `reduce` algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range `[first, last)`.

Note GENERALIZED_SUM(+, a1, . . . , aN) is defined as follows:
• a1 when N is 1
• op(GENERALIZED_SUM(+, b1, . . . , bK), GENERALIZED_SUM(+, bM, . . . , bN)), where:
  – b1, . . . , bN may be any permutation of a1, . . . , aN and
  – 1 < K+1 = M <= N.

```template<typename ExPolicy, typename Rng>
util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<typename hpx::traits::range_traits<Rng>::iterator_type>::value_type>::type
reduce((ExPolicy &&)policy, (Rng &&)rng)
```

Returns GENERALIZED_SUM(+, T(), *(first), . . . , *(first + (last - first) - 1)).

The reduce operations in the parallel `reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

Note Complexity: \(O(last - first)\) applications of the operator+().

Template Parameters
• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• Rng: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

Parameters
• policy: The execution policy to use for the scheduling of the iterations.
• rng: Refers to the sequence of elements the algorithm will be applied to.

The reduce operations in the parallel `copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `reduce` and `accumulate` is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Return The `reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `T` otherwise (where `T` is the value_type of `FwdIterB`). The `reduce` algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range `[first, last)`.
The type of the initial value (and the result type) $T$ is determined from the value_type of the used `FwdIterB`.

**Note** GENERALIZED_SUM(+, $a_1, \ldots, a_N$) is defined as follows:
- $a_1$ when $N$ is 1
- $\text{op}(\text{GENERALIZED_SUM}(+, b_1, \ldots, b_K), \text{GENERALIZED_SUM}(+, b_M, \ldots, b_N))$, where:
  - $b_1, \ldots, b_N$ may be any permutation of $a_1, \ldots, a_N$ and
  - $1 < K+1 = M <= N$.

```cpp
namespace hpx

Functions

template<typename FwdIter, typename Sent, typename T, typename Proj = util::projection_identity>
subrange_t<FwdIter, Sent> remove (FwdIter first, Sent last, T const &value, Proj &&proj = Proj())

Removes all elements that are equal to value from the range [first, last) and and returns a subrange [ret, last), where ret is a past-the-end iterator for the new end of the range.

The assignments in the parallel `remove` algorithm execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than `last - first` assignments, exactly `last - first` applications of the operator `==()` and the projection `proj`.

**Template Parameters**
- `FwdIter`: The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- `Sent`: The type of the end iterators used (deduced). This sentinel type must be a sentinel for `FwdIter`.
- `T`: The type of the value to remove (deduced). This value type must meet the requirements of `CopyConstructible`.
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**
- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last`: Refers to the end of the sequence of elements the algorithm will be applied to.
- `value`: Specifies the value of elements to remove.
- `proj`: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Return** The `remove` algorithm returns a `subrange_t<FwdIter, Sent>`. The `remove` algorithm returns an object `{ret, last}`, where ret is a past-the-end iterator for a new subrange of the values all in valid but unspecified state.
Removes all elements that are equal to value from the range [first, last) and and returns a subrange [ret, last), where ret is a past-the-end iterator for the new end of the range.

The assignments in the parallel remove algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than last - first assignments, exactly last - first applications of the operator==() and the projection proj.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter**: The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.

- **Sent**: The type of the end iterators used (deduced). This sentinel type must be a sentinel for FwdIter.

- **T**: The type of the value to remove (deduced). This value type must meet the requirements of CopyConstructible.

- **Proj**: The type of an optional projection function. This defaults to util::projection_identity

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.

- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.

- **value**: Specifies the value of elements to remove.

- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel remove algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The remove algorithm returns a hpx::future<subrange_t<FwdIter, Sent>>. The remove algorithm returns an object {ret, last}, where ret is a past-the-end iterator for a new subrange of the values all in valid but unspecified state.
subrange_t<
typename hpx::traits::range_iterator<Rng>::type> remove(Rng &&rng, T const &value, Proj &&proj = Proj())

Removes all elements that are equal to \textit{value} from the range \textit{rng} and and returns a subrange \([\text{ret}, \text{util::end(rng)})\), where \text{ret} is a past-the-end iterator for the new end of the range.

The assignments in the parallel \textit{remove} algorithm execute in sequential order in the calling thread.

\textbf{Note} Complexity: Performs not more than \text{util::end(rng)}

- \text{util::begin(rng)} assignments, exactly \text{util::end(rng)} - \text{util::begin(rng)} applications of the operator\(==()\) and the projection \text{proj}.

\textbf{Template Parameters}

- \textit{Rng}: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- \textit{T}: The type of the value to remove (deduced). This value type must meet the requirements of \text{CopyConstructible}.
- \textit{Proj}: The type of an optional projection function. This defaults to \text{util::projection_identity}

\textbf{Parameters}

- \textit{rng}: Refers to the sequence of elements the algorithm will be applied to.
- \textit{value}: Specifies the value of elements to remove.
- \textit{proj}: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate \text{is} invoked.

\textbf{Return} The \textit{remove} algorithm returns a \text{subrange_t<typename hpx::traits::range_iterator<Rng>::type>}. The \textit{remove} algorithm returns an object \([\text{ret, last})\), where \text{ret} is a past-the-end iterator for a new subrange of the values all in valid but unspecified state.

\begin{verbatim}
template<typename ExPolicy, typename Rng, typename T, typename Proj = util::projection_identity>
parallel::util::detail::algorithm_result<ExPolicy, subrange_t<
typename hpx::traits::range_iterator<Rng>::type>::type> remove(ExPolicy &&policy, Rng &&rng, T const &value, Proj &&proj = Proj())
\end{verbatim}

Removes all elements that are equal to \textit{value} from the range \textit{rng} and and returns a subrange \([\text{ret}, \text{util::end(rng)})\), where \text{ret} is a past-the-end iterator for the new end of the range.

The assignments in the parallel \textit{remove} algorithm invoked with an execution policy object of type \text{sequenced_policy} execute in sequential order in the calling thread.

\textbf{Note} Complexity: Performs not more than \text{util::end(rng)}
• `util::begin(rng)` assignments, exactly `util::end(rng) - util::begin(rng)` applications of the operator==() and the projection `proj`.

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- `T`: The type of the value to remove (deduced). This value type must meet the requirements of `CopyConstructible`.
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`.

**Parameters**

- `policy`: The execution policy to use for the scheduling of the iterations.
- `rng`: Refers to the sequence of elements the algorithm will be applied to.
- `value`: Specifies the value of elements to remove.
- `proj`: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel `remove` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `remove` algorithm returns a `hpx::future< subrange_t<typename hpx::traits::range_iterator<Rng>::type>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `remove` algorithm returns the iterator to the new end of the range.

```cpp
template<typename FwdIter, typename Sent, typename Pred, typename Proj = hpx::parallel::util::projection_identity>
subrange_t<FwdIter, Sent> remove_if (FwdIter first, Sent sent, Pred &&pred, Proj &&proj = Proj())
```

Removes all elements for which predicate `pred` returns true from the range `[first, last)` and returns a sub-range `[ret, last)`, where ret is a past-the-end iterator for the new end of the range.

The assignments in the parallel `remove_if` algorithm execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than `last - first` assignments, exactly `last - first` applications of the predicate `pred` and the projection `proj`.

**Template Parameters**

- `FwdIter`: The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- `Sent`: The type of the end iterators used (deduced). This sentinel type must be a sentinel for `FwdIter`.
- `Pred`: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `remove_if` requires `Pred` to meet the requirements of `CopyConstructible`.
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`.

**Parameters**
• **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **last**: Refers to the end of the sequence of elements the algorithm will be applied to.

• **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Return** The `remove_if` algorithm returns a `subrange_t<FwdIter, Sent>`. The `remove_if` algorithm returns an object `{ret, last}`, where ret is a past-the-end iterator for a new subrange of the values all in valid but unspecified state.

```cpp
template<
    typename ExPolicy,
    typename FwdIter,
    typename Sent,
    typename Pred,
    typename Proj = hpx::parallel::util::projection_identity>
parallel::util::detail::algorithm_result<ExPolicy, subrange_t<FwdIter, Sent>>::type remove_if(
    ExPolicy &&policy,
    FwdIter first,
    Sent sent,
    Pred &&pred,
    Proj &&proj = Proj())
```

Removes all elements for which predicate `pred` returns true from the range `[first, last)` and returns a subrange `[ret, last)`, where ret is a past-the-end iterator for the new end of the range.

The assignments in the parallel `remove_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than `last - first` assignments, exactly `last - first` applications of the predicate `pred` and the projection `proj`.

**Template Parameters**

• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **FwdIter**: The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.

• **Sent**: The type of the end iterators used (deduced). This sentinel type must be a sentinel for `FwdIter`. 

2.8. API reference 1175
**Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `remove_if` requires `Pred` to meet the requirements of `CopyConstructible`.

**Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel `remove_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `remove_if` algorithm returns a `hpx::future<subrange_t<FwdIter, Sent>>`. The `remove_if` algorithm returns an object `{ret, last}`, where `ret` is a past-the-end iterator for a new subrange of the values all in valid but unspecified state.

```cpp
template<
typename Rng,
typename T,
typename Proj = util::projection_identity>
subrange_t<hpx::traits::range_iterator<Rng>::type> remove_if (Rng &&rng, Pred &&pred, Proj &&proj = Proj())
```

Removes all elements that are equal to `value` from the range `rng` and and returns a subrange `[ret, util::end(rng))`, where `ret` is a past-the-end iterator for the new end of the range.

The assignments in the parallel `remove_if` algorithm execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than `util::end(rng)`

- `util::begin(rng) assignments`, exactly `util::end(rng) - util::begin(rng)` applications of the operator `==()` and the projection `proj`.

### Template Parameters

- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.

- **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `remove_if` requires `Pred` to meet the requirements of `CopyConstructible`.

- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

### Parameters

- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Return** The `remove_if` algorithm returns a `subrange_t<typename hpx::traits::range_iterator<Rng>::type>`. The `remove_if` algorithm returns an object `{ret, last}`, where `ret` is a past-the-end iterator for a new subrange of the values all in valid but unspecified state.

```cpp
template<typename ExPolicy, typename Rng, typename Pred, typename Proj = util::projection_identity>
parallel::util::detail::algorithm_result<ExPolicy, subrange_t<typename hpx::traits::range_iterator<Rng>::type>>::type
remove_if(
  ExPolicy &&policy,
  Rng &&rng,
  Pred &&pred,
  Proj &&proj = Proj() )
```

Removes all elements that are equal to `value` from the range `rng` and and returns a subrange `[ret, util::end(rng))`, where `ret` is a past-the-end iterator for the new end of the range.

The assignments in the parallel `remove_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than `util::end(rng)`

- `util::begin(rng)` assignments, exactly `util::end(rng) - util::begin(rng)` applications of the operator `==()` and the projection `proj`.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.

- **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `remove_if` requires `Pred` to meet the requirements of `CopyConstructible`.

- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
• **rng**: Refers to the sequence of elements the algorithm will be applied to.

• **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\). This is an unary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

```cpp
template<typename T>
bool pred(const T &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `T` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel `remove_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `remove_if` algorithm returns a `hpx::future`<subrange_t<typename hpx::traits::range_iterator<Rng>::type>> if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `remove_if` algorithm returns an object `{ret, last}`, where ret is a past-the-end iterator for a new subrange of the values all in valid but unspecified state.

```cpp	namespace hpx

Functions

template<typename Iter, typename Sent, typename T1, typename T2, typename Proj = hpx::parallel::util::projection_identity>
Iter replace(Iter first, Sent sent, T1 const &old_value, T2 const &new_value, Proj &&proj = Proj())

Replaces all elements satisfying specific criteria with `new_value` in the range \([\text{first}, \text{last})\).

Effects: Substitutes elements referred by the iterator `it` in the range \([\text{first}, \text{last})\) with `new_value`, when the following corresponding conditions hold: `INVOKE(proj, *i) == old_value`

**Note** Complexity: Performs exactly `last - first` assignments.

The assignments in the parallel `replace` algorithm execute in sequential order in the calling thread.

**Template Parameters**

- **Iter**: The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.

- **Sent**: The type of the end iterators used (deduced). This sentinel type must be a sentinel for `Iter`.

- **T1**: The type of the old value to replace (deduced).

- **T2**: The type of the new values to replace (deduced).

- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
**Return** The `replace` algorithm returns an `Iter`.

```
template<typename Rng, typename T1, typename T2, typename Proj = hpx::parallel::util::projection_identity>
    hpx::traits::range_iterator<Rng>::type replace (Rng &&rng, T1 const &old_value, T2 const &new_value, Proj &&proj = Proj())
```

Replaces all elements satisfying specific criteria with `new_value` in the range `rng`.

Effects: Substitutes elements referred by the iterator `it` in the range `rng` with `new_value`, when the following corresponding conditions hold: `INVOKE(proj, *i) == old_value`

**Note** Complexity: Performs exactly `util::end(rng) - util::begin(rng)` assignments.

The assignments in the parallel `replace` algorithm execute in sequential order in the calling thread.

**Template Parameters**

- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- `T1`: The type of the old value to replace (deduced).
- `T2`: The type of the new values to replace (deduced).
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- `rng`: Refers to the sequence of elements the algorithm will be applied to.
- `old_value`: Refers to the old value of the elements to replace.
- `new_value`: Refers to the new value to use as the replacement.
- `proj`: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate `is` invoked.

**Return** The `replace` algorithm returns an `hpx::traits::range_iterator<Rng>::type`.

```
template<typename ExPolicy, typename Iter, typename Sent, typename T1, typename T2, typename Proj = hpx::parallel::util::detail::algorithm_result<ExPolicy, Iter>::type replace (ExPolicy &&policy, Iter first, Sent sent, T1 const &old_value, T2 const &new_value, Proj &&proj = Proj())
```

Replaces all elements satisfying specific criteria with `new_value` in the range `[first, last)`.

Effects: Substitutes elements referred by the iterator `it` in the range `[first, last)` with `new_value`, when the following corresponding conditions hold: `INVOKE(proj, *i) == old_value`
Note Complexity: Performs exactly last - first assignments.

The assignments in the parallel replace algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter**: The type of the source iterator used (deduced). The iterator type must meet the requirements of a forward iterator.
- **Sent**: The type of the end iterators used (deduced). This sentinel type must be a sentinel for Iter.
- **T1**: The type of the old value to replace (deduced).
- **T2**: The type of the new values to replace (deduced).
- **Proj**: The type of an optional projection function. This defaults to util::projection_identity

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **old_value**: Refers to the old value of the elements to replace.
- **new_value**: Refers to the new value to use as the replacement.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel replace algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The replace algorithm returns a hpx::future<Iter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns Iter otherwise.

```cpp
template<typename ExPolicy, typename Rng, typename T1, typename T2, typename Proj = hpx::parallel::util::projection_identity>
parallel::util::detail::algorithm_result<ExPolicy, hpx::traits::range_iterator<Rng>::type>::type
replace(ExPolicy&& policy, Rng&& rng, T1 const& old_value, T2 const& new_value, Proj&& proj = Proj())
```
Replaces all elements satisfying specific criteria with `new_value` in the range `rng`.

Effects: Substitutes elements referred by the iterator `it` in the range `rng` with `new_value`, when the following corresponding conditions hold: `INVOKE(proj, *i) == old_value`

**Note** Complexity: Performs exactly `util::end(rng) - util::begin(rng)` assignments.

The assignments in the parallel `replace` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **T1**: The type of the old value to replace (deduced).
- **T2**: The type of the new values to replace (deduced).
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **old_value**: Refers to the old value of the elements to replace.
- **new_value**: Refers to the new value to use as the replacement.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked. The assignments in the parallel `replace` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Return** The `replace` algorithm returns an `hpx::future<hpx::traits::range_iterator<Rng>::type>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `hpx::traits::range_iterator<Rng>::type` otherwise.

```cpp
template<typename Iter, typename Sent, typename Pred, typename T, typename Proj = hpx::parallel::util::projection_identity>
Iter replace_if(Iter first, Sent sent, Pred &&pred, T const &new_value, Proj &&proj = Proj())
```

Replaces all elements satisfying specific criteria (for which predicate `f` returns true) with `new_value` in the range `[first, sent)`.

Effects: Substitutes elements referred by the iterator `it` in the range `[first, sent)` with `new_value`, when the following corresponding conditions hold: `INVOKE(f, INVOKE(proj, *it)) != false`

**Note** Complexity: Performs exactly `sent - first` applications of the predicate.

The assignments in the parallel `replace_if` algorithm execute in sequential order in the calling thread.
Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter**: The type of the source iterator used (deduced). The iterator type must meet the requirements of a forward iterator.
- **Sent**: The type of the end iterators used (deduced). This sentinel type must be a sentinel for Iter.
- **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `F` to meet the requirements of `CopyConstructible` (deduced).
- **T**: The type of the new values to replace (deduced).
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`.

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last]. This is an unary predicate which returns `true` for the elements which need to replaced. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `Iter` can be dereferenced and then implicitly converted to `Type`.
- **new_value**: Refers to the new value to use as the replacement.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Return The `replace_if` algorithm returns an `Iter`. It returns `last`.

Template Parameters

```cpp
template<typename Rng, typename Pred, typename T, typename Proj = hpx::parallel::util::projection_identity>
hpx::traits::range_iterator<Rng>::type replace_if(Rng &&rng, Pred &&pred, T const &&new_value, Proj &&proj = Proj())
```

Replaces all elements satisfying specific criteria (for which predicate `pred` returns true) with `new_value` in the range `rng`.

Effects: Substitutes elements referred by the iterator it in the range rng with new_value, when the following corresponding conditions hold: `INVOKE(f, INVOKE(proj, *it)) != false`

Note Complexity: Performs exactly `util::end(rng) - util::begin(rng)` applications of the predicate.

The assignments in the parallel `replace` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.
• Rng: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.

• Pred: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `F` to meet the requirements of `CopyConstructible`. (deduced).

• T: The type of the new values to replace (deduced).

• Proj: The type of an optional projection function. This defaults to `util::projection_identity`

Parameters

• rng: Refers to the sequence of elements the algorithm will be applied to.

• pred: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by rng. This is an unary predicate which returns `true` for the elements which need to replaced. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

• new_value: Refers to the new value to use as the replacement.

• proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel `replace` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return

The `replace_if` algorithm returns an `hpx::traits::range_iterator<Rng>::type` It returns `last`.

```
template<typename ExPolicy, typename Iter, typename Sent, typename Pred, typename T, typename Proj = ... t>
```

Replaces all elements satisfying specific criteria (for which predicate `pred` returns true) with `new_value` in the range `rng`.

Effects: Substitutes elements referred by the iterator `it` in the range `rng` with `new_value`, when the following corresponding conditions hold: `INVOKE(f, INVOKE(proj, *it)) != false`

Note Complexity: Performs exactly `util::end(rng) - util::begin(rng)` applications of the predicate.

The assignments in the parallel `replace_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

Template Parameters

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• Iter: The type of the source iterator used (deduced). The iterator type must meet the requirements of a forward iterator.

• Sent: The type of the end iterators used (deduced). This sentinel type must be a sentinel for Iter.
• **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible`. (deduced).

• **T**: The type of the new values to replace (deduced).

• **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the elements which need to replaced. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **new_value**: Refers to the new value to use as the replacement.

- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel `replace_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

### Return

The `replace_if` algorithm returns a `hpx::future<Iter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy`. It returns `last`.

```cpp
template<typename ExPolicy, typename Rng, typename Pred, typename T, typename Proj = hpx::parallel::util::projection_identity>
parallel::util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng>::type>::type
replace_if(ExPolicy &&policy, Rng &&rng, Pred &&pred,
T const &new_value, Proj &&proj = Proj())
```

Replaces all elements satisfying specific criteria (for which predicate `pred` returns true) with `new_value` in the range `rng`.

Effects: Substitutes elements referred by the iterator `it` in the range `rng` with `new_value`, when the following corresponding conditions hold: `INVOKE(f, INVOKE(proj, *it)) != false`
Note Complexity: Performs exactly \texttt{util::end(rng)} - \texttt{util::begin(rng)} applications of the predicate.

The assignments in the parallel replace algorithm invoked with an execution policy object of type \texttt{sequenced\_policy} execute in sequential order in the calling thread.

**Template Parameters**

- \texttt{ExPolicy}: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- \texttt{Rng}: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- \texttt{Pred}: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \texttt{equal} requires \texttt{F} to meet the requirements of \texttt{CopyConstructible}. (deduced).
- \texttt{T}: The type of the new values to replace (deduced).
- \texttt{Proj}: The type of an optional projection function. This defaults to \texttt{util::projection\_identity}

**Parameters**

- \texttt{policy}: The execution policy to use for the scheduling of the iterations.
- \texttt{rng}: Refers to the sequence of elements the algorithm will be applied to.
- \texttt{pred}: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \texttt{rng}. This is an unary predicate which returns \texttt{true} for the elements which need to replaced. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have \texttt{const\&}, but the function must not modify the objects passed to it. The type \texttt{Type} must be such that an object of type \texttt{FwdIter} can be dereferenced and then implicitly converted to \texttt{Type}.
- \texttt{new\_value}: Refers to the new value to use as the replacement.
- \texttt{proj}: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel replace algorithm invoked with an execution policy object of type \texttt{parallel\_policy} or \texttt{parallel\_task\_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return**

The replace_if algorithm returns a \texttt{hpx::future<typename hpx::traits::range\_iterator<Rng>::type>} if the execution policy is of type \texttt{sequenced\_task\_policy} or \texttt{parallel\_task\_policy}. It returns last.

```cpp
template<typename InIter, typename Sent, typename OutIter, typename T1, typename T2, typename Proj = hpx::parallel::util::projection_identity>
replace_copy_result<InIter, OutIter> replace_copy(InIter first, Sent sent, OutIter dest, T1 const &old_value, T2 const &new_value, Proj &&proj = Proj())
```

Copies the all elements from the range [first, sent) to another range beginning at dest replacing all elements satisfying a specific criteria with new_value.

Effects: Assigns to every iterator it in the range [result, result + (sent - first)) either new_value or *(first + (it - result)) depending on whether the following corresponding condition holds: \texttt{INVOKE(proj, *(first + (i - result))) \text{== \text{old\_value}}
The assignments in the parallel `replace_copy` algorithm execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `sent - first` applications of the predicate.

**Template Parameters**

- `Iter`: The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- `Sent`: The type of the end iterators used (deduced). This sentinel type must be a sentinel for `Iter`.
- `OutIter`: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- `T1`: The type of the old value to replace (deduced).
- `T2`: The type of the new values to replace (deduced).
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `sent`: Refers to the end of the sequence of elements the algorithm will be applied to.
- `dest`: Refers to the beginning of the destination range.
- `old_value`: Refers to the old value of the elements to replace.
- `new_value`: Refers to the new value to use as the replacement.
- `proj`: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Return** The `replace_copy` algorithm returns an `in_out_result<InIter, OutIter>`. The `copy` algorithm returns the pair of the input iterator `last` and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename Rng, typename OutIter, typename T1, typename T2, typename Proj = hpx::parallel::util::projection_identity>
replace_copy_result<
typename hpx::traits::range_iterator<Rng>::type,
OutIter
> replace_copy(
    Rng &&rng,
    OutIter dest,
    T1 const &old_value,
    T2 const &new_value,
    Proj &&proj
)
```

Copies the all elements from the range rbh to another range beginning at `dest` replacing all elements satisfying a specific criteria with `new_value`.  

1186 Chapter 2. What’s so special about HPX?
Effects: Assigns to every iterator \( \text{it} \) in the range \([\text{result}, \text{result} + (\text{util}::\text{end}(rng) - \text{util}::\text{begin}(rng)))\) either \( \text{new\_value} \) or \( *(\text{first} + (\text{it} - \text{result})) \) depending on whether the following corresponding condition holds:

\[
\text{INVOLVE}(\text{proj}, *(\text{first} + (\text{i} - \text{result}))) == \text{old\_value}
\]

The assignments in the parallel replace copy algorithm execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly \( \text{util}::\text{end}(rng) - \text{util}::\text{begin}(rng) \) applications of the predicate.

**Template Parameters**

- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **OutIter**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **T1**: The type of the old value to replace (deduced).
- **T2**: The type of the new values to replace (deduced).
- **Proj**: The type of an optional projection function. This defaults to \text{util}::projection_identity

**Parameters**

- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **old_value**: Refers to the old value of the elements to replace.
- **new_value**: Refers to the new value to use as the replacement.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Return** The replace_copy algorithm returns an \text{in\_out\_result<typename hpx::traits::range\_iterator<Rng>::type, OutIter>}\. The copy algorithm returns the pair of the input iterator \text{last} and the output iterator to the element in the destination range, one past the last element copied.
Caches the all elements from the range \([\text{first}, \text{sent})\) to another range beginning at \(\text{dest}\) replacing all elements satisfying a specific criteria with \(\text{new\_value}\).

Effects: Assigns to every iterator \(i\) in the range \([\text{result}, \text{result} + (\text{sent} - \text{first}))\) either \(\text{new\_value}\) or \(*((\text{first} + (i - \text{result})))\) depending on whether the following corresponding condition holds: \(\text{INVOKE}((\text{proj} \cdot *((\text{first} + (i - \text{result})))) == \text{old\_value})\)

The assignments in the parallel \(\text{replace\_copy}\) algorithm invoked with an execution policy object of type \(\text{sequenced\_policy}\) execute in sequential order in the calling thread.

Note Complexity: Performs exactly \(\text{sent} - \text{first}\) applications of the predicate.

Template Parameters

- \(\text{ExPolicy}\): The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- \(\text{FwdIter1}\): The type of the source iterator used (deduced). The iterator type must meet the requirements of an forward iterator.
- \(\text{Sent}\): The type of the end iterators used (deduced). This sentinel type must be a sentinel for \(\text{Iter}\).
- \(\text{FwdIter2}\): The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- \(\text{T1}\): The type of the old value to replace (deduced).
- \(\text{T2}\): The type of the new values to replace (deduced).
- \(\text{Proj}\): The type of an optional projection function. This defaults to \(\text{util\_\_projection\_identity}\)

Parameters

- \(\text{policy}\): The execution policy to use for the scheduling of the iterations.
- \(\text{first}\): Refers to the beginning of the sequence of elements the algorithm will be applied to.
- \(\text{sent}\): Refers to the end of the sequence of elements the algorithm will be applied to.
- \(\text{dest}\): Refers to the beginning of the destination range.
- \(\text{old\_value}\): Refers to the old value of the elements to replace.
- \(\text{new\_value}\): Refers to the new value to use as the replacement.
- \(\text{proj}\): Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate \(\text{is}\) invoked.

The assignments in the parallel \(\text{replace\_copy}\) algorithm invoked with an execution policy object of type \(\text{parallel\_policy}\) or \(\text{parallel\_task\_policy}\) are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The \(\text{replace\_copy}\) algorithm returns a \(\text{hpx\_\_future}\langle\text{in\_out\_result}\langle\text{FwdIter1, FwdIter2}\rangle\rangle\) if the execution policy is of type \(\text{sequenced\_task\_policy}\) or \(\text{parallel\_task\_policy}\) and returns \(\text{in\_out\_result}\langle\text{FwdIter1, FwdIter2}\rangle\) otherwise. The \(\text{copy}\) algorithm returns the pair of the forward iterator \(\text{last}\) and the output iterator to the element in the destination range, one past the last element copied.
parallel::util::detail::algorithm_result<ExPolicy, replace_copy_result<typename hpx::traits::range_iterator<Rng>::type, FwdIter>>::type

replace_copy(
  ExPolicy &&policy,
  Rng &&rng,
  FwdIter dest,
  T1 const &old_value,
  T2 const &new_value,
  Proj &&proj = Proj()
)

Copies the all elements from the range rbg to another range beginning at dest replacing all elements satisfying a specific criteria with new_value.

Effects: Assigns to every iterator it in the range [result, result + (util::end(rng) - util::begin(rng))) either new_value or *(first + (i - result)) depending on whether the following corresponding condition holds:

\text{INVOKED(proj, *(first + (i - result))) == old_value}

The assignments in the parallel replace_copy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Performs exactly util::end(rng) - util::begin(rng) applications of the predicate.

Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **FwdIter**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T1**: The type of the old value to replace (deduced).
- **T2**: The type of the new values to replace (deduced).
- **Proj**: The type of an optional projection function. This defaults to util::projection_identity

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **old_value**: Refers to the old value of the elements to replace.
- **new_value**: Refers to the new value to use as the replacement.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.
The assignments in the parallel `replace_copy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `replace_copy` algorithm returns a `hpx::future<in_out_result<

```cpp
typename traits::range_iterator<Rng>::type, FwdIter>>
```

if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns

```cpp
in_out_result<
```

```cpp
typename traits::range_iterator<Rng>::type, FwdIter>>
```

The `copy` algorithm returns the pair of the input iterator `last` and the forward iterator to the element in the destination range, one past the last element copied.

```cpp
template<

typename InIter, typename Sent, typename OutIter, typename Pred, typename T, typename Proj = hpx::parallel::util::projection_identity> replace_copy_if_result<
```

```cpp
InIter, OutIter>
```

```cpp
replace_copy_if(InIter first, Sent sent, OutIter dest, Pred
```

```cpp
&&pred, T const &new_value, Proj
```

```cpp
&&proj = Proj())
```

Copies the all elements from the range `[first, sent)` to another range beginning at `dest` replacing all elements satisfying a specific criteria with `new_value`.

Effects: Assigns to every iterator `it` in the range `[result, result + (sent - first))` either `new_value` or `*(first + (i - result))` depending on whether the following corresponding condition holds: `INVOKE(f, INVOKE(proj, *(first + (i - result)))) != false`

The assignments in the parallel `replace_copy_if` algorithm execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `sent - first` applications of the predicate.

**Template Parameters**

- `InIter`: The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- `Sent`: The type of the end iterators used (deduced). This sentinel type must be a sentinel for `InIter`.
- `OutIter`: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- `Pred`: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible`. (deduced).
- `T`: The type of the new values to replace (deduced).
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `sent`: Refers to the end of the sequence of elements the algorithm will be applied to.
- `dest`: Refers to the beginning of the destination range.
- `pred`: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the elements which need to be replaced. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```
The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type FwdIter can be dereferenced and then implicitly converted to Type.

- new_value: Refers to the new value to use as the replacement.
- proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Return** The replace_copy_if algorithm returns a in_out_result<InIter, OutIter>. The replace_copy_if algorithm returns the input iterator last and the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<
    typename Rng, typename OutIter, typename Pred, typename T, typename Proj = hpx::parallel::util::projection_identity
>
replace_copy_if_result<
    typename hpx::traits::range_iterator<Rng>::type,
    OutIter>
replace_copy_if(
    Rng &&rng,
    OutIter dest,
    Pred &&pred,
    T const &new_value,
    Proj &&proj = Proj()
)
```

Copies the all elements from the range rng to another range beginning at dest replacing all elements satisfying a specific criteria with new_value.

Effects: Assigns to every iterator it in the range [result, result + (util::end(rng) - util::begin(rng))) either new_value or *(first + (i - result)) depending on whether the following corresponding condition holds: INVOKE(f, INVOKE(proj, *(first + (i - result)))) != false

The assignments in the parallel replace_copy_if algorithm execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly util::end(rng) - util::begin(rng) applications of the predicate.

**Template Parameters**
- Rng: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- OutIter: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- Pred: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of equal requires Pred to meet the requirements of CopyConstructible. (deduced).
- T: The type of the new values to replace (deduced).
- Proj: The type of an optional projection function. This defaults to util::projection_identity

**Parameters**
- rng: Refers to the sequence of elements the algorithm will be applied to.
• **dest**: Refers to the beginning of the destination range.

• **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns *true* for the elements which need to be replaced. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

• **new_value**: Refers to the new value to use as the replacement.

• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Return** The `replace_copy_if` algorithm returns an `in_out_result<typename hpx::traits::range_iterator<Rng>::type, OutIter>`. The `replace_copy_if` algorithm returns the input iterator `last` and the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename Sent, typename FwdIter2, typename Pred, typename T, typename Proj = hpx::parallel::util::projection_identity>
parallel::util::detail::algorithm_result<ExPolicy, replace_copy_if_result<FwdIter1, FwdIter2>::type>
replace_copy_if(ExPolicy &&policy, FwdIter1 first, Sent sent, FwdIter2 dest, Pred &&pred, T const &new_value, Proj &&proj = Proj())
```

Copies the all elements from the range `[first, sent)` to another range beginning at `dest` replacing all elements satisfying a specific criteria with `new_value`.

Effects: Assigns to every iterator `it` in the range `[result, result + (sent - first))` either `new_value` or `*(first + (it - result))` depending on whether the following corresponding condition holds: `INVOKE(f, INVOKE(proj, *(first + (i - result)))) != false`

The assignments in the parallel `replace_copy_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `sent - first` applications of the predicate.

**Template Parameters**
• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **FwdIter1**: The type of the source iterator used (deduced). The iterator type must meet the requirements of a forward iterator.

• **Sent**: The type of the end iterators used (deduced). This sentinel type must be a sentinel for InIter.

• **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

• **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible`. (deduced).

• **T**: The type of the new values to replace (deduced).

• **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the elements which need to replaced. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **new_value**: Refers to the new value to use as the replacement.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel `replace_copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

### Return

The `replace_copy_if` algorithm returns an `hpx::future<FwdIter1, FwdIter2>`. The `replace_copy_if` algorithm returns the input iterator `last` and the output iterator to the element in the destination range, one past the last element copied.
Copies the all elements from the range rng to another range beginning at dest replacing all elements satisfying a specific criteria with new_value.

Effects: Assigns to every iterator it in the range [result, result + (util::end(rng) - util::begin(rng))) either new_value or *(first + (it - result)) depending on whether the following corresponding condition holds: INVOKE(f, INVOKE(proj, *(first + (i - result)))) != false

The assignments in the parallel replace_copy_if algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note  Complexity: Performs exactly util::end(rng) - util::begin(rng) applications of the predicate.

Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **OutIter**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of equal requires Pred to meet the requirements of CopyConstructible. (deduced).
- **T**: The type of the new values to replace (deduced).
- **Proj**: The type of an optional projection function. This defaults to util::projection_identity

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns true for the elements which need to replaced. The signature of this predicate should be equivalent to:
The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type FwdIter can be dereferenced and then implicitly converted to Type.

- **new_value**: Refers to the new value to use as the replacement.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel replace_copy_if algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The replace_copy_if algorithm returns an hpx::future<hpx::traits::range_iterator<Rng>::type, OutIter>>. The replace_copy_if algorithm returns the input iterator last and the output iterator to the element in the destination range, one past the last element copied.

```cpp
namespace hpx

namespace parallel

Functions

```template<typename ExPolicy, typename Rng>
util::detail::algorithm_result<ExPolicy, hpx::traits::range_iterator<Rng>::type>::type reverse(ExPolicy &&policy, Rng &&rng)
```

Reverses the order of the elements in the range [first, last). Behaves as if applying std::iter_swap to every pair of iterators first+i, (last-i) - 1 for each non-negative i < (last-first)/2. The assignments in the parallel reverse algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Linear in the distance between first and last.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a bidirectional iterator.

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.

The assignments in the parallel reverse algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
**Return** The `reverse` algorithm returns a `hpx::future<BidirIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `BidirIter` otherwise. It returns `last`.

The assignments in the parallel `reverse_copy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `last - first` assignments.

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a bidirectional iterator.
- `OutIter`: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

**Parameters**
- `policy`: The execution policy to use for the scheduling of the iterations.
- `rng`: Refers to the sequence of elements the algorithm will be applied to.
- `dest_first`: Refers to the begin of the destination range.

The assignments in the parallel `reverse_copy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `reverse_copy` algorithm returns a `hpx::future<in_out_result<BidirIter, OutIter>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `in_out_result<BidirIter, OutIter>` otherwise. The `copy` algorithm returns the pair of the input iterator forwarded to the first element after the last in the input sequence and the output iterator to the element in the destination range, one past the last element copied.

```cpp	namespace hpx

namespace parallel
```
Functions

template<typename ExPolicy, typename Rng>
util::detail::algorithm_result<ExPolicy, util::in_out_result<typename hpx::traits::range_iterator<Rng>::type, typename hpx::traits::range_iterator<Rng>::type>>::type
rotate(
    ExPolicy&& policy,
    Rng&& rng,
    typename hpx::traits::range_iterator<Rng>::type middle)

Performs a left rotation on a range of elements. Specifically, `rotate` swaps the elements in the range `[first, last)` in such a way that the element `new_first` becomes the first element of the new range and `new_first - 1` becomes the last element.

The assignments in the parallel `rotate` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Linear in the distance between `first` and `last`.

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.

**Parameters**
- `policy`: The execution policy to use for the scheduling of the iterations.
- `rng`: Refers to the sequence of elements the algorithm will be applied to.
- `middle`: Refers to the element that should appear at the beginning of the rotated range.

The assignments in the parallel `rotate` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note** The type of dereferenced `FwdIter` must meet the requirements of `MoveAssignable` and `MoveConstructible`.

**Return** The `rotate` algorithm returns a `hpx::future<tag::begin(FwdIter), tag::end(FwdIter)>>` if the execution policy is of type `parallel_task_policy` and returns `tagged_pair<tag::begin(FwdIter), tag::end(FwdIter)>>` otherwise. The `rotate` algorithm returns the iterator equal to pair(first + (last - new_first), last).

template<typename ExPolicy, typename Rng, typename OutIter>
util::detail::algorithm_result<ExPolicy, util::in_out_result<typename hpx::traits::range_iterator<Rng>::type, OutIter>>::type
rotate_copy(
    ExPolicy&& policy,
    Rng&& rng,
    typename hpx::traits::range_iterator<Rng>::type middle,
    OutIter dest_first)
Copies the elements from the range \([\text{first}, \text{last})\), to another range beginning at \(\text{dest}\_\text{first}\) in such a way, that the element \(\text{new}\_\text{first}\) becomes the first element of the new range and \(\text{new}\_\text{first} - 1\) becomes the last element.

The assignments in the parallel \(\text{rotate}\_\text{copy}\) algorithm invoked with an execution policy object of type \(\text{sequenced}\_\text{policy}\) execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly \(\text{last} - \text{first}\) assignments.

**Template Parameters**
- \(\text{ExPolicy}\): The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- \(\text{Rng}\): The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- \(\text{OutIter}\): The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

**Parameters**
- \(\text{policy}\): The execution policy to use for the scheduling of the iterations.
- \(\text{rng}\): Refers to the sequence of elements the algorithm will be applied to.
- \(\text{middle}\): Refers to the element that should appear at the beginning of the rotated range.
- \(\text{dest}\_\text{first}\): Refers to the begin of the destination range.

The assignments in the parallel \(\text{rotate}\_\text{copy}\) algorithm invoked with an execution policy object of type \(\text{parallel}\_\text{policy}\) or \(\text{parallel}\_\text{task}\_\text{policy}\) are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The \(\text{rotate}\_\text{copy}\) algorithm returns a \(\text{hpx}\::\text{future}\langle\text{tagged}\_\text{pair}\langle\text{tag}\_\text{in}\langle\text{FwdIter}\rangle, \text{tag}\_\text{out}\langle\text{OutIter}\rangle]\rangle\) if the execution policy is of type \(\text{parallel}\_\text{task}\_\text{policy}\) and returns \(\text{tagged}\_\text{pair}\langle\text{tag}\_\text{in}\langle\text{FwdIter}\rangle, \text{tag}\_\text{out}\langle\text{OutIter}\rangle]\rangle\) otherwise. The \(\text{rotate}\_\text{copy}\) algorithm returns the output iterator to the element past the last element copied.

```cpp
namespace hpx
{
namespace ranges
{

Functions

template<
    typename FwdIter,
    typename Sent,
    typename FwdIter2,
    typename Sent2,
    typename Pred = std::equal_to<typename std::iterator_traits<FwdIter>::value_type>,
    typename Proj1 = std::identity,
    typename Proj2 = std::identity>
FwdIter search(FwdIter first, Sent last, FwdIter2 s_first, Sent2 s_last, Pred && op = Pred(), Proj1 && proj1 = Proj1(), Proj2 && proj2 = Proj2())

Searches the range \([\text{first}, \text{last})\) for any elements in the range \([\text{s}\_\text{first}, \text{s}\_\text{last})\). Uses a provided predicate to compare elements.

The comparison operations in the parallel \(\text{search}\) algorithm execute in sequential order in the calling thread.

**Note** Complexity: at most \((S*N)\) comparisons where \(S = \text{distance}(\text{s}\_\text{first}, \text{s}\_\text{last})\) and \(N = \text{distance}(\text{first}, \text{last})\).

**Template Parameters**
- \(\text{FwdIter}\): The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- \(\text{Sent}\): The type of the source sentinel used for the first range (deduced). This iterator type must meet the requirements of an sentinel.
```
• **FwdIter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
• **Sent2**: The type of the source sentinel used for the second range (deduced). This iterator type must meet the requirements of an sentinel.
• **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>
• **Proj1**: The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements of type dereferenced `FwdIter`.
• **Proj2**: The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements of type dereferenced `FwdIter2`.

### Parameters
- **first**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s_first**: Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last**: Refers to the end of the sequence of elements the algorithm will be searching for.
- **op**: Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `FwdIter1` as a projection operation before the actual predicate is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `FwdIter2` as a projection operation before the actual predicate is invoked.

### Return
The `search` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `search` algorithm returns an iterator to the beginning of the first subsequence (`s_first, s_last`) in range (`first, last`). If the length of the subsequence (`s_first, s_last`) is greater than the length of the range (`first, last`), `last` is returned. Additionally if the size of the subsequence is empty `first` is returned. If no subsequence is found, `last` is returned.

The comparison operations in the parallel `search` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

### Note
Complexity: at most (S*N) comparisons where S = distance(`s_first, s_last`) and N = distance(`first, last`).

```cpp
template<typename ExPolicy, typename FwdIter, typename Sent, typename FwdIter2, typename Sent2,
          util::detail::algorithm_result<ExPolicy, FwdIter>::type search
            (ExPolicy &&policy, FwdIter first,
            Sent last, FwdIter2 s_first, Sent2
            s_last, Pred &&op = Pred(),
            Proj1 &&proj1 = Proj1(), Proj2
            &&proj2 = Proj2())
```

Searches the range (`first, last`) for any elements in the range (`s_first, s_last`). Uses a provided predicate to compare elements.
Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent**: The type of the source sentinel used for the first range (deduced). This iterator type must meet the requirements of an sentinel.
- **FwdIter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2**: The type of the source sentinel used for the second range (deduced). This iterator type must meet the requirements of an sentinel.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`
- **Proj1**: The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements of type dereferenced `FwdIter`.
- **Proj2**: The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements of type dereferenced `FwdIter2`.

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s_first**: Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last**: Refers to the end of the sequence of elements the algorithm will be searching for.
- **op**: Refers to the binary predicate which returns true if the elements should be treated as equal. The signature of the function should be equivalent to

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively
- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `FwdIter1` as a projection operation before the actual predicate is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `FwdIter2` as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel search algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The search algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The search algorithm returns an iterator to the beginning of the first subsequence `[s_first, s_last)` in range `[first, last)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, last)`, `last` is returned. Additionally if the size of the subsequence is empty `first` is returned. If no subsequence is found, `last` is returned.

template<
typename Rng1,
typename Rng2,
typename Pred = hpx::ranges::equal_to,
typename Proj1 = hpx::parallel::util::projection_identity,
typename Proj2 = hpx::parallel::util::projection_identity>

Chapter 2. What’s so special about HPX?
hpx::traits::range_iterator<Rng1>::type search(Rng1 &&rng1, Rng2 &&rng2, Pred &&&op = Pred(), Proj1 &&&proj1 = Proj1(), Proj2 &&&proj2 = Proj2())

Searches the range [first, last) for any elements in the range [s_first, s_last). Uses a provided predicate to compare elements.

The comparison operations in the parallel search algorithm execute in sequential order in the calling thread.

**Note** Complexity: at most (S*N) comparisons where S = distance(s_first, s_last) and N = distance(first, last).

**Template Parameters**
- Rng1: The type of the examine range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- Rng2: The type of the search range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- Pred: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of adjacent_find requires Pred to meet the requirements of CopyConstructible. This defaults to std::equal_to<>.
- Proj1: The type of an optional projection function. This defaults to util::projection_identity and is applied to the elements of Rng1.
- Proj2: The type of an optional projection function. This defaults to util::projection_identity and is applied to the elements of Rng2.

**Parameters**
- rng1: Refers to the sequence of elements the algorithm will be examining.
- rng2: Refers to the sequence of elements the algorithm will be searching for.
- op: Refers to the binary predicate which returns true if the elements should be treated as equal. The signature of the function should be equivalent to

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively.

- proj1: Specifies the function (or function object) which will be invoked for each of the elements of rng1 as a projection operation before the actual predicate is invoked.
- proj2: Specifies the function (or function object) which will be invoked for each of the elements of rng2 as a projection operation before the actual predicate is invoked.

**Return** The search algorithm returns a hpx::future<FwdIter> if the execution policy is of type task_execution_policy and returns FwdIter otherwise. The search algorithm returns an iterator to the beginning of the first subsequence [s_first, s_last) in range [first, last). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, last), last is returned. Additionally if the size of the subsequence is empty first is returned. If no subsequence is found, last is returned.
Searches the range [first, last) for any elements in the range [s_first, s_last). Uses a provided predicate to compare elements.

The comparison operations in the parallel search algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread. 

**Note** Complexity: at most \( (S+N) \) comparisons where \( S = \text{distance}(s\_first, s\_last) \) and \( N = \text{distance}(\text{first}, \text{last}) \).

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1**: The type of the examine range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2**: The type of the search range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of adjacent_find requires Pred to meet the requirements of CopyConstructible. This defaults to std::equal_to<>
- **Proj1**: The type of an optional projection function. This defaults to util::projection_identity and is applied to the elements of Rng1.
- **Proj2**: The type of an optional projection function. This defaults to util::projection_identity and is applied to the elements of Rng2.

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng1**: Refers to the sequence of elements the algorithm will be examining.
- **rng2**: Refers to the sequence of elements the algorithm will be searching for.
- **op**: Refers to the binary predicate which returns true if the elements should be treated as equal. The signature of the function should be equivalent to

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively.
• **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of \(rng1\) as a projection operation before the actual predicate is invoked.
• **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of \(rng2\) as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel `search` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `search` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `search` algorithm returns an iterator to the beginning of the first subsequence \([s_{\text{first}}, s_{\text{last}})\) in range \([\text{first}, \text{last})\). If the length of the subsequence \([s_{\text{first}}, s_{\text{last}})\) is greater than the length of the range \([\text{first}, \text{last})\), \(\text{last}\) is returned. Additionally if the size of the subsequence is empty \(\text{first}\) is returned. If no subsequence is found, \(\text{last}\) is returned.

```cpp
template<typename FwdIter, typename FwdIter2, typename Sent2, typename Pred = hpx::ranges::equal_to, typename Proj1 = parallel::util::projection_identity, typename Proj2 = parallel::util::projection_identity>
FwdIter search_n(
    ExPolicy &&policy,
    FwdIter first,
    std::size_t count,
    FwdIter2 s_first, Sent2 s_last,
    Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Searches the range \([\text{first}, \text{last})\) for any elements in the range \([s_{\text{first}}, s_{\text{last}})\). Uses a provided predicate to compare elements.

The comparison operations in the parallel `search_n` algorithm execute in sequential order in the calling thread.

**Note** Complexity: at most \((S*N)\) comparisons where \(S = \text{distance}(s_{\text{first}}, s_{\text{last}})\) and \(N = \text{count}\).

**Template Parameters**
- **FwdIter**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2**: The type of the source sentinel used for the second range (deduced). This iterator type must meet the requirements of an sentinel.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`

**Parameters**
- **first**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **count**: Refers to the range of elements of the first range the algorithm will be applied to.
- **s_first**: Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last**: Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op**: Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `FwdIter1` as a projection operation before the actual predicate is invoked.
• proj2: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced FwdIter2 as a projection operation before the actual predicate is invoked.

**Return** The search_n algorithm returns FwdIter. The search_n algorithm returns an iterator to the beginning of the last subsequence [s_first, s_last) in range [first, first+count). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, first+count), first is returned. Additionally if the size of the subsequence is empty or no subsequence is found, first is also returned.

```cpp
template<typename ExPolicy, typename FwdIter, typename FwdIter2, typename Sent2, typename Pred = hpx::ranges::equal_to, typename Proj1 = parallel::util::projection_identity, typename Proj2 = parallel::util::projection_identity>
util::detail::algorithm_result<ExPolicy, FwdIter>::type search_n(
    ExPolicy &&policy, FwdIter first, std::size_t count, FwdIter2 s_first, Sent2 s_last, 
    Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Searches the range [first, last) for any elements in the range [s_first, s_last). Uses a provided predicate to compare elements.

The comparison operations in the parallel search_n algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: at most $(S*N)$ comparisons where $S = \text{distance}(s\_first, s\_last)$ and $N = \text{count}$.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2**: The type of the source sentinel used for the second range (deduced). This iterator type must meet the requirements of an sentinel.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of adjacent_find requires Pred to meet the requirements of CopyConstructible. This defaults to std::equal_to<>.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **count**: Refers to the range of elements of the first range the algorithm will be applied to.
- **s_first**: Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last**: Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op**: Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively.

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced FwdIter1 as a projection operation before the actual predicate is invoked.
invoked.

- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `FwdIter2` as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel `search_n` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return**  The `search_n` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `search_n` algorithm returns an iterator to the beginning of the last subsequence `[s_first, s_last)` in range `[first, first+count)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, first+count)`, `first` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `first` is also returned.

```cpp
template<
    typename Rng1, typename Rng2, typename Pred = hpx::ranges::equal_to,
    typename Proj1 = hpx::parallel::util::projection_identity,
    typename Proj2 = hpx::parallel::util::projection_identity
>
auto search_n(
    Rng1 &&rng1,
    std::size_t count,
    Rng2 &&rng2,
    Pred &&op = Pred(),
    Proj1 &&proj1 = Proj1(),
    Proj2 &&proj2 = Proj2())
{
    // Implementation...
}
```

Searches the range `[first, last)` for any elements in the range `[s_first, s_last)` uses a provided predicate to compare elements.

The comparison operations in the parallel `search` algorithm execute in sequential order in the calling thread.

**Note** Complexity: at most $(S*N)$ comparisons where $S = \text{distance}(s\_first, s\_last)$ and $N = \text{distance}(\text{first}, \text{last})$.

**Template Parameters**
- **Rng1**: The type of the examine range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2**: The type of the search range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>

  ```cpp
  bool pred(const Type1 &a, const Type2 &b);
  ```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.
- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of `rng1` as a projection operation before the actual predicate is invoked.
• **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of `rng2` as a projection operation before the actual predicate is invoked.

**Return** The `search` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `search` algorithm returns an iterator to the beginning of the first subsequence `[s_first, s_last)` in range `[first, last)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, last)`, `last` is returned. Additionally if the size of the subsequence is empty `first` is returned. If no subsequence is found, `last` is returned.

```cpp
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred = hpx::ranges::equal_to, typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 = hpx::parallel::util::projection_identity>

hpx::parallel::util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng1>::type>::type search_n(ExPolicy&& policy, Rng1&& rng1, std::size_t count, Rng2&& rng2, Pred&& op = Pred(), Proj1&& proj1 = Proj1(), Proj2&& proj2 = Proj2())
```

Searches the range `[first, last)` for any elements in the range `[s_first, s_last)`. Uses a provided predicate to compare elements.

The comparison operations in the parallel `search` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: at most \((S \times N)\) comparisons where \(S = \text{distance}(s\_first, s\_last)\) and \(N = \text{distance}(first, last)\).

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1**: The type of the examine range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2**: The type of the search range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Pred**: The type of the optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`.
- **Proj1**: The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements of `Rng1`.
- **Proj2**: The type of an optional projection function. This defaults to `util::projection_identity`
and is applied to the elements of Rng2.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng1**: Refers to the sequence of elements the algorithm will be examining.
- **count**: The number of elements to apply the algorithm on.
- **rng2**: Refers to the sequence of elements the algorithm will be searching for.
- **op**: Refers to the binary predicate which returns true if the elements should be treated as equal. The signature of the function should be equivalent to

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively.

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of rng1 as a projection operation before the actual predicate is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of rng2 as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel search algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The search algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type task_execution_policy and returns FwdIter otherwise. The search algorithm returns an iterator to the beginning of the first subsequence [s_first, s_last) in range [first, last). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, last), last is returned. Additionally if the size of the subsequence is empty first is returned. If no subsequence is found, last is returned.

```cpp
namespace hpx

namespace ranges

Functions
```

```cpp
template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3, typename Proj1 = util::projection_identity, typename Proj2 = util::projection_identity>
```

2.8. API reference 1207
Constructs a sorted range beginning at dest consisting of all elements present in the range [first1, last1) and not present in the range [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate \( f \).

Equivalent elements are treated individually, that is, if some element is found \( m \) times in [first1, last1) and \( n \) times in [first2, last2), it will be copied to dest exactly \( \max(m-n, 0) \) times. The resulting range cannot overlap with either of the input ranges.

**Note** Complexity: At most \( 2 \times (N1 + N2 - 1) \) comparisons, where \( N1 \) is the length of the first sequence and \( N2 \) is the length of the second sequence.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (sequence_policy) or in a single new thread spawned from the current thread (for sequenced_task_policy).

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Iter1**: The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent1**: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2**: The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent2**: The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for Iter2.
- **Iter3**: The type of the iterator representing the destination range (deduced). This iterator
**type** must meet the requirements of an output iterator.

- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_difference` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`
- **Proj1**: The type of an optional projection function applied to the first sequence. This defaults to `util::projection_identity`
- **Proj2**: The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2**: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2**: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **op**: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
def bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `set_difference` algorithm returns a `hpx::future<ranges::set_difference_result<Iter1, Iter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::set_difference_result<Iter1, Iter3>` otherwise. The `set_difference` algorithm returns the output iterator to the element in the destination range, one past the last element copied.
Constructs a sorted range beginning at `dest` consisting of all elements present in the range `[first1, last1)` and not present in the range `[first2, last2)`. This algorithm expects both input ranges to be sorted with the given binary predicate `f`.

Equivalent elements are treated individually, that is, if some element is found `m` times in `[first1, last1)` and `n` times in `[first2, last2)`, it will be copied to `dest` exactly `std::max(m-n, 0)` times. The resulting range cannot overlap with either of the input ranges.

**Note** Complexity: At most `2*(N1 + N2 - 1)` comparisons, where `N1` is the length of the first sequence and `N2` is the length of the second sequence.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (`sequenced_policy`) or in a single new thread spawned from the current thread (for `sequenced_task_policy`).

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- `Rng1`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- `Rng2`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- `Iter3`: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- `Pred`: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_difference` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`.
- `Proj1`: The type of an optional projection function applied to the first sequence. This defaults to `util::projection_identity`.
- `Proj2`: The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`.
Parameters

• **policy**: The execution policy to use for the scheduling of the iterations.
• **rng1**: Refers to the first sequence of elements the algorithm will be applied to.
• **rng2**: Refers to the second sequence of elements the algorithm will be applied to.
• **dest**: Refers to the beginning of the destination range.
• **op**: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &; but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`

• **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.
• **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `set_difference` algorithm returns a `hpx::future<ranges::set_difference_result<Iter1, Iter3>>` if the execution policy is of type `sequenced_task_policy` and returns `ranges::set_difference_result<Iter1, Iter3>` otherwise. where `Iter1` is `range_iterator_t<Rng1>` and `Iter2` is `range_iterator_t<Rng2>` The `set_difference` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
namespace hpx

namespace ranges

Functions

template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3, typename Proj1 = util::projection_identity, typename Proj2 = util::projection_identity>
```
Constructs a sorted range beginning at dest consisting of all elements present in both sorted ranges [first1, last1) and [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate \( f \).

If some element is found \( m \) times in [first1, last1) and \( n \) times in [first2, last2), the first std::min(m, n) elements will be copied from the first range to the destination range. The order of equivalent elements is preserved. The resulting range cannot overlap with either of the input ranges.

**Note** Complexity: At most \( 2*(N1 + N2 - 1) \) comparisons, where \( N1 \) is the length of the first sequence and \( N2 \) is the length of the second sequence.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (sequenced_policy) or in a single new thread spawned from the current thread (for sequenced_task_policy).

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Iter1**: The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent1**: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2**: The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent2**: The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for Iter2.
- **Iter3**: The type of the iterator representing the destination range (deduced). This iterator
type must meet the requirements of an output iterator.

- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_intersection` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>

- **Proj1**: The type of an optional projection function applied to the first sequence. This defaults to `util::projection_identity`

- **Proj2**: The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2**: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2**: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **op**: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `set_intersection` algorithm returns a `hpx::future<ranges::set_intersection_result<Iter1, Iter2, Iter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::set_intersection_result<Iter1, Iter2, Iter3>` otherwise. The `set_intersection` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<
    typename ExPolicy, typename Rng1, typename Rng2, typename Iter3,
    typename Pred = detail::less, typename
```
Constructs a sorted range beginning at dest consisting of all elements present in both sorted ranges [first1, last1) and [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate $f$.

If some element is found $m$ times in [first1, last1) and $n$ times in [first2, last2), the first std::min(m, n) elements will be copied from the first range to the destination range. The order of equivalent elements is preserved. The resulting range cannot overlap with either of the input ranges.

Note: Complexity: At most $2^*(N_1 + N_2 - 1)$ comparisons, where $N_1$ is the length of the first sequence and $N_2$ is the length of the second sequence.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (sequenced_policy) or in a single new thread spawned from the current thread (for sequenced_task_policy).

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Rng1**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Iter3**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of set_intersection requires $Pred$ to meet the requirements of CopyConstructible. This defaults to std::less<>.
- **Proj1**: The type of an optional projection function applied to the first sequence. This defaults to util::projection_identity
- **Proj2**: The type of an optional projection function applied to the second sequence. This defaults to util::projection_identity
Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng1**: Refers to the first sequence of elements the algorithm will be applied to.
- **rng2**: Refers to the second sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **op**: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`.

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return

The `set_intersection` algorithm returns a `hpx::future<ranges::set_intersection_result<Iter1, Iter2, Iter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::set_intersection_result<Iter1, Iter2, Iter3>` otherwise. where Iter1 is `range_iterator_t<Rng1>` and Iter2 is `range_iterator_t<Rng2>` The `set_intersection` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
namespace hpx
namespace ranges

Functions

template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3, typename Pred = detail::less, typename Proj1 = util::projection_identity, typename Proj2 = util::projection_identity>
```
Constructs a sorted range beginning at `dest` consisting of all elements present in either of the sorted ranges `[first1, last1)` and `[first2, last2)`, but not in both of them are copied to the range beginning at `dest`. The resulting range is also sorted. This algorithm expects both input ranges to be sorted with the given binary predicate `f`.

If some element is found `m` times in `[first1, last1)` and `n` times in `[first2, last2)`, it will be copied to `dest` exactly `std::abs(m-n)` times. If `m>n`, then the last `m-n` of those elements are copied from `[first1,last1)`, otherwise the last `n-m` elements are copied from `[first2,last2)`. The resulting range cannot overlap with either of the input ranges.

**Note** Complexity: At most `2*(N1 + N2 - 1)` comparisons, where `N1` is the length of the first sequence and `N2` is the length of the second sequence. The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (`sequenced_policy`) or in a single new thread spawned from the current thread (`sequenced_task_policy`).

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- `Iter1`: The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- `Sent1`: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for `Iter1`.
- `Iter2`: The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
- `Sent2`: The type of the end source iterators used (deduced) representing the second sequence.
This iterator type must meet the requirements of an sentinel for Iter2.

- **Iter3**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_symmetric_difference` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>
- **Proj1**: The type of an optional projection function applied to the first sequence. This defaults to `util::projection_identity`
- **Proj2**: The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2**: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2**: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **op**: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return**

The `set_symmetric_difference` algorithm returns a `hpx::future<ranges::set_symmetric_difference_result<Iter1, Iter2, Iter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::set_symmetric_difference_result<Iter1, Iter2, Iter3>` otherwise. The `set_symmetric_difference` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<
    typename ExPolicy, 
    typename Rng1, 
    typename Rng2, 
    typename Iter3, 
    typename Pred = detail::less, 
    typename Proj1 = util::projection_identity, 
    typename Proj2 = util::projection_identity
> 
```

2.8. API reference 1217
HPX Documentation, master

util::detail::algorithm_result<ExPolicy, ranges::set_symmetric_difference_result<
typename traits::range_iterator<Rng1>::type,
typename traits::range_iterator<Rng2>::type,
Iter3>::type

set_symmetric_difference(ExPolicy &&policy,
Rng1 &&rng1,
Rng2 &&rng2,
Iter3 dest,
Pred &&op = Pred(),
Proj1 &&proj1 = Proj1(),
Proj2 &&proj2 = Proj2())

Constructs a sorted range beginning at dest consisting of all elements present in either of the sorted
ranges [first1, last1) and [first2, last2), but not in both of them are copied to the range beginning at
dest. The resulting range is also sorted. This algorithm expects both input ranges to be sorted with the
given binary predicate f.

If some element is found m times in [first1, last1) and n times in [first2, last2), it will be copied to dest
exactly std::abs(m-n) times. If m>n, then the last m-n of those elements are copied from [first1,last1),
otherwise the last n-m elements are copied from [first2,last2). The resulting range cannot overlap with
either of the input ranges.

Note Complexity: At most 2*(N1 + N2 - 1) comparisons, where N1 is the length of the first sequence
and N2 is the length of the second sequence.
The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy
object execute in sequential order in the calling thread (sequenced_policy) or in a single new thread
spawned from the current thread (for sequenced_task_policy).

Template Parameters

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in
which the execution of the algorithm may be parallelized and the manner in which it applies
user-provided function objects.
• Rng1: The type of the source range used (deduced). The iterators extracted from this range
type must meet the requirements of an input iterator.
• Rng2: The type of the source range used (deduced). The iterators extracted from this range
type must meet the requirements of an input iterator.
• Iter3: The type of the iterator representing the destination range (deduced). This iterator
type must meet the requirements of an output iterator.
• Pred: The type of an optional function/function object to use. Unlike its sequential form,
the parallel overload of set_symmetric_difference requires Pred to meet the requirements
of CopyConstructible. This defaults to std::less<>
• Proj1: The type of an optional projection function applied to the first sequence. This defaults
to util::projection_identity
• **Proj2**: The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng1**: Refers to the first sequence of elements the algorithm will be applied to.
- **rng2**: Refers to the second sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **op**: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &; but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`.

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `set_symmetric_difference` algorithm returns a `hpx::future<ranges::set_symmetric_difference_result<Iter1, Iter2, Iter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::set_symmetric_difference_result<Iter1, Iter2, Iter3>` otherwise. Where `Iter1` is `range_iterator_t<Rng1>` and `Iter2` is `range_iterator_t<Rng2>`. The `set_symmetric_difference` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
namespace hpx

namespace ranges

Functions

template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3, typename Pred = detail::less, typename Proj1 = util::projection_identity, typename Proj2 = util::projection_identity>
```

Constructs a sorted range beginning at dest consisting of all elements present in one or both sorted ranges \([\text{first}_1, \text{last}_1)\) and \([\text{first}_2, \text{last}_2)\). This algorithm expects both input ranges to be sorted with the given binary predicate \(f\).

If some element is found \(m\) times in \([\text{first}_1, \text{last}_1)\) and \(n\) times in \([\text{first}_2, \text{last}_2)\), then all \(m\) elements will be copied from \([\text{first}_1, \text{last}_1)\) to dest, preserving order, and then exactly \(\text{std::max}(n-m, 0)\) elements will be copied from \([\text{first}_2, \text{last}_2)\) to dest, also preserving order.

**Note** Complexity: At most \(2\times(N_1 + N_2 - 1)\) comparisons, where \(N_1\) is the length of the first sequence and \(N_2\) is the length of the second sequence.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (\(\text{sequenced\_policy}\)) or in a single new thread spawned from the current thread (for \(\text{sequenced\_task\_policy}\)).

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Iter1**: The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent1**: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2**: The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent2**: The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for Iter2.
- **Iter3**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
type must meet the requirements of an output iterator.

- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_union` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`
- **Proj1**: The type of an optional projection function applied to the first sequence. This defaults to `util::projection_identity`
- **Proj2**: The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2**: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2**: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **op**: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `set_union` algorithm returns a `hpx::future<ranges::set_union_result<Iter1, Iter2, Iter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::set_union_result<Iter1, Iter2, Iter3>` otherwise. The `set_union` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<
type::ExPolicy, typename Rng1, typename Rng2, type::Iter3, typename Pred = detail::less, typename...`
```
Constructs a sorted range beginning at dest consisting of all elements present in one or both sorted ranges [first1, last1) and [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate \( f \).

If some element is found \( m \) times in [first1, last1) and \( n \) times in [first2, last2), then all \( m \) elements will be copied from [first1, last1) to dest, preserving order, and then exactly std::max(n-m, 0) elements will be copied from [first2, last2) to dest, also preserving order.

**Note** Complexity: At most \( 2 \times (N1 + N2 - 1) \) comparisons, where \( N1 \) is the length of the first sequence and \( N2 \) is the length of the second sequence.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (sequenced_policy) or in a single new thread spawned from the current thread (for sequenced_task_policy).

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Rng1**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Iter3**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of set_union requires Pred to meet the requirements of CopyConstructible. This defaults to std::less<>
- **Proj1**: The type of an optional projection function applied to the first sequence. This defaults to util::projection_identity
- **Proj2**: The type of an optional projection function applied to the second sequence. This defaults to util::projection_identity
Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng1**: Refers to the first sequence of elements the algorithm will be applied to.
- **rng2**: Refers to the second sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **op**: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`.

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `set_union` algorithm returns a `hpx::future<ranges::set_union_result<Iter1, Iter2, Iter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::set_union_result<Iter1, Iter2, Iter3>` otherwise. where `Iter1` is `range_iterator_t<Rng1>` and `Iter2` is `range_iterator_t<Rng2>` The `set_union` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
namespace hpx

namespace parallel

Functions

```cpp
template<typename ExPolicy, typename Rng, typename Compare = v1::detail::less, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng>::type>::type sort(ExPolicy &&policy, Rng &&rng, Compare &&comp = Compare(), Proj &&proj = Proj())
```

Sorts the elements in the range `rng` in ascending order. The order of equal elements is not guaranteed to be preserved. The function uses the given comparison function object `comp` (defaults to using operator<()).
A sequence is sorted with respect to a comparator `comp` and a projection `proj` if for every iterator `i` pointing to the sequence and every non-negative integer `n` such that `i + n` is a valid iterator pointing to an element of the sequence, and `INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false.`

**Note** Complexity: O(Nlog(N)), where N = `std::distance(begin(rng), end(rng))` comparisons.

`comp` has to induce a strict weak ordering on the values.

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- `Comp`: The type of the function/function object to use (deduced).
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**
- `policy`: The execution policy to use for the scheduling of the iterations.
- `rng`: Refers to the sequence of elements the algorithm will be applied to.
- `comp`: `comp` is a callable object. The return value of the `INVOKE` operation applied to an object of type `Comp`, when contextually converted to `bool`, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator.
- `proj`: Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate `comp` is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `sort` algorithm returns a `hpx::future<Iter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `Iter` otherwise. It returns `last`.

```cpp
namespace hpx
{
    namespace parallel
    {
}
}
```
Functions

template<typename ExPolicy, typename Rng, typename Compare = v1::detail::less, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng>::type>::type stable_sort(
    ExPolicy &&policy,
    Rng &&rng,
    Compare &&comp = Compare(),
    Proj &&proj = Proj())

Sorts the elements in the range [first, last) in ascending order. The relative order of equal elements is preserved. The function uses the given comparison function object comp (defaults to using operator<()).

A sequence is sorted with respect to a comparator comp and a projection proj if for every iterator i pointing to the sequence and every non-negative integer n such that i + n is a valid iterator pointing to an element of the sequence, and INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false.

Note Complexity: O(Nlog(N)), where N = std::distance(first, last) comparisons. comp has to induce a strict weak ordering on the values.

Template Parameters
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Comp**: The type of the function/function object to use (deduced).
- **Proj**: The type of an optional projection function. This defaults to util::projection_identity

Parameters
- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **comp**: comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.
- **proj**: Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate comp is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The stable_sort algorithm returns a hpx::future<RandomIt> if the execution policy is of type
sequenced_task_policy or parallel_task_policy and returns RandomIt otherwise. The algorithm returns an iterator pointing to the first element after the last element in the input sequence.

namespace hpx

Functions

template<typename ExPolicy, typename Rng, typename OutIter, typename F, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, ranges::unary_transform_result<typename hpx::traits::range_iterator<Rng>::type, OutIter>> transform(ExPolicy&& policy, Rng&& rng, OutIter dest, F&& f, Proj&& proj = Proj())
Applies the given function f to the given range rng and stores the result in another range, beginning at dest.

The invocations of f in the parallel transform algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note  Complexity: Exactly size(rng) applications of f

Template Parameters

- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of f.
- Rng: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- OutIter: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- F: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of transform requires F to meet the requirements of CopyConstructible.
- Proj: The type of an optional projection function. This defaults to util::projection_identity

Parameters

- policy: The execution policy to use for the scheduling of the iterations.
- rng: Refers to the sequence of elements the algorithm will be applied to.
- dest: Refers to the beginning of the destination range.
- f: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last]. This is an unary predicate. The signature of this predicate should be equivalent to:
Ret fun(const Type &a);

The signature does not need to have const&. The type Type must be such that an object of type range_iterator<Rng>::type can be dereferenced and then implicitly converted to Type. The type Ret must be such that an object of type OutIter can be dereferenced and assigned a value of type Ret.

• proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate f is invoked.

The invocations of f in the parallel transform algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The transform algorithm returns a hpx::future<ranges::unary_transform_result<range_iterator<Rng>::type, OutIter>> if the execution policy is of type parallel_task_policy and returns ranges::unary_transform_result<range_iterator<Rng>::type, OutIter> otherwise. The transform algorithm returns a tuple holding an iterator referring to the first element after the input sequence and the output iterator to the element in the destination range, one past the last element copied.

Applies the given function f to the given range rng and stores the result in another range, beginning at dest.

The invocations of f in the parallel transform algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Exactly size(rng) applications of f

Template Parameters

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of f.

• FwdIter1: The type of the source iterators for the first range used (deduced). This iterator type must meet the requirements of an forward iterator.

• Sent1: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for FwdIter1.
- **FwdIter2**: The type of the source iterators for the first range used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `transform` requires `F` to meet the requirements of `CopyConstructible`.
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type &a);
  ```

  The signature does not need to have `const&`. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`. The type `Ret` must be such that an object of type `FwdIter2` can be dereferenced and assigned a value of type `Ret`.

- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate `f` is invoked.

  The invocations of `f` in the parallel `transform` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

### Return

The `transform` algorithm returns a `hpx::future<ranges::unary_transform_result<FwdIter1, FwdIter2>>` if the execution policy is of type `parallel_task_policy` and returns `ranges::unary_transform_result<FwdIter1, FwdIter2>` otherwise. The `transform` algorithm returns a tuple holding an iterator referring to the first element after the input sequence and the output iterator to the element in the destination range, one past the last element copied.
Applies the given function \( f \) to pairs of elements from two ranges: one defined by \( rng \) and the other beginning at \( \text{first2} \), and stores the result in another range, beginning at \( \text{dest} \).

The invocations of \( f \) in the parallel transform algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Exactly size(rng) applications of \( f \)

**Template Parameters**

- \( \text{ExPolicy} \): The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of \( f \).
- \( \text{FwdIter1} \): The type of the source iterators for the first range used (deduced). This iterator type must meet the requirements of an forward iterator.
- \( \text{Sent1} \): The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for \( \text{FwdIter1} \).
- \( \text{FwdIter2} \): The type of the source iterators for the first range used (deduced). This iterator type must meet the requirements of an forward iterator.
- \( \text{Sent2} \): The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for \( \text{FwdIter2} \).
- \( \text{FwdIter3} \): The type of the source iterators for the first range used (deduced). This iterator type must meet the requirements of an forward iterator.
- \( \text{F} \): The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of transform requires \( F \) to meet the requirements of CopyConstructible.
- \( \text{Proj1} \): The type of an optional projection function to be used for elements of the first sequence. This defaults to \text{util::projection_identity}
• Proj2: The type of an optional projection function to be used for elements of the second sequence. This defaults to `util::projection_identity`

**Parameters**

• policy: The execution policy to use for the scheduling of the iterations.

• first1: Refers to the beginning of the first sequence of elements the algorithm will be applied to.

• last1: Refers to the end of the first sequence of elements the algorithm will be applied to.

• first2: Refers to the beginning of the second sequence of elements the algorithm will be applied to.

• last2: Refers to the end of the second sequence of elements the algorithm will be applied to.

• dest: Refers to the beginning of the destination range.

• f: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is a binary predicate. The signature of this predicate should be equivalent to:

```cpp
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively. The type `Ret` must be such that an object of type `FwdIter3` can be dereferenced and assigned a value of type `Ret`.

• proj1: Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `f` is invoked.

• proj2: Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `f` is invoked.

The invocations of `f` in the parallel `transform` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `transform` algorithm returns a `hpx::future<ranges::binary_transform_result<FwdIter1, FwdIter2, FwdIter3>>` if the execution policy is of type `parallel_task_policy` and returns `ranges::binary_transform_result<FwdIter1, FwdIter2, FwdIter3>` otherwise. The `transform` algorithm returns a tuple holding an iterator referring to the first element after the first input sequence, an iterator referring to the first element after the second input sequence, and the output iterator referring to the element in the destination range, one past the last element copied.

```cpp
namespace hpx
```
Functions

template<typename ExPolicy, typename Rng, typename T, typename Reduce, typename Convert>
util::detail::algorithm_result<ExPolicy, T>::type transform_reduce(ExPolicy &&policy, Rng &&rng, T init, Reduce &&red_op, Convert &&conv_op)

Returns GENERALIZED_SUM(red_op, init, conv_op(*first), ..., conv_op(*(first + (last - first) - 1))).

The reduce operations in the parallel transform_reduce algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: O(last - first) applications of the predicates red_op and conv_op.

Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `copy_if` requires `F` to meet the requirements of `CopyConstructible`.
- **T**: The type of the value to be used as initial (and intermediate) values (deduced).
- **Reduce**: The type of the binary function object used for the reduction operation.
- **Convert**: The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **init**: The initial value for the generalized sum.
- **red_op**: Specifies the function (or function object) which will be invoked for each of the values returned from the invocation of `conv_op`. This is a binary predicate. The signature of this predicate should be equivalent to:

```cpp
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types `Type1`, `Type2`, and `Ret` must be such that an object of a type as returned from `conv_op` can be implicitly converted to any of those types.

- **conv_op**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is a unary predicate. The signature of this predicate should be equivalent to:

```cpp
R fun(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `Iter` can be dereferenced and then implicitly converted to `Type`. The type `R` must be such that an object of this type can be implicitly converted to `T`.

2.8. API reference
The reduce operations in the parallel `transform_reduce` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `transform_reduce` and `accumulate` is that the behavior of `transform_reduce` may be non-deterministic for non-associative or non-commutative binary predicate.

**Return** The `transform_reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `parallel_task_policy` and returns `T` otherwise. The `transform_reduce` algorithm returns the result of the generalized sum over the values returned from `conv_op` when applied to the elements given by the input range `[first, last)`.

**Note** GENERALIZED_SUM(op, a1, . . . , aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(op, b1, . . . , bK), GENERALIZED_SUM(op, bM, . . . , bN)), where:
  - b1, . . . , bN may be any permutation of a1, . . . , aN and
  - 1 < K+1 = M <= N.

```cpp
template<typename ExPolicy, typename Rng1, typename FwdIter2, typename T>
util::detail::algorithm_result<ExPolicy, T>::type transform_reduce(ExPolicy &&policy, Rng1 &&rng1, FwdIter2 first2, T init)
```

Returns the result of accumulating `init` with the inner products of the pairs formed by the elements of two ranges starting at `first1` and `first2`.

The operations in the parallel `transform_reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: O(last - first) applications of the predicate `op2`.

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- `Rng1`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

- `FwdIter2`: The type of the second source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

- `T`: The type of the value to be used as return) values (deduced).

**Parameters**

- `policy`: The execution policy to use for the scheduling of the iterations.

- `rng1`: Refers to the sequence of elements the algorithm will be applied to.

- `first2`: Refers to the beginning of the second sequence of elements the result will be calculated with.

- `init`: The initial value for the sum.
The operations in the parallel transform_reduce algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The transform_reduce algorithm returns a hpx::future<T> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns T otherwise.

template<typename ExPolicy, typename Rng1, typename FwdIter2, typename T, typename Reduce, typename Convert> util::detail::algorithm_result<ExPolicy, T>::type transform_reduce(ExPolicy &&policy, Rng1 &&rng1, FwdIter2 first2, T init, Reduce &&red_op, Convert &&&conv_op)

Returns the result of accumulating init with the inner products of the pairs formed by the elements of two ranges starting at first1 and first2.

The operations in the parallel transform_reduce algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: O(last - first) applications of the predicate op2.

**Template Parameters**
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- Rng1: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- FwdIter2: The type of the second source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- T: The type of the value to be used as return) values (deduced).
- Reduce: The type of the binary function object used for the multiplication operation.
- Convert: The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

**Parameters**
- policy: The execution policy to use for the scheduling of the iterations.
- rng1: Refers to the sequence of elements the algorithm will be applied to.
- first2: Refers to the beginning of the second sequence of elements the result will be calculated with.
- init: The initial value for the sum.
- red_op: Specifies the function (or function object) which will be invoked for the initial value and each of the return values of op2. This is a binary predicate. The signature of this predicate should be equivalent to should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type Ret must be such that it can be implicitly converted to a type of T.
• **conv_op**: Specifies the function (or function object) which will be invoked for each of the input values of the sequence. This is a binary predicate. The signature of this predicate should be equivalent to

```cpp
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Ret` must be such that it can be implicitly converted to an object for the second argument type of `op1`.

The operations in the parallel `transform_reduce` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `transform_reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `T` otherwise.

```cpp
namespace hpx
{

namespace parallel
{

Functions

```cpp
template<typename ExPolicy, typename Rng, typename Pred = detail::equal_to, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng>::type>::type unique(
    ExPolicy &&policy,
    Rng &&rng,
    Pred &&pred = Pred(),
    Proj &&proj = Proj())
```

Eliminates all but the first element from every consecutive group of equivalent elements from the range `rng` and returns a past-the-end iterator for the new logical end of the range.

The assignments in the parallel `unique` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than N assignments, exactly N - 1 applications of the predicate `pred` and no more than twice as many applications of the projection `proj`, where N = std::distance(begin(rng), end(rng)).

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
• **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `unique` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`
• **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an binary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

  ```cpp
  bool pred(const Type &a, const Type &b);
  ```

  The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

  The assignments in the parallel `unique` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return**

The `unique` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `unique` algorithm returns the iterator to the new end of the range.

```cpp
template<
  typename ExPolicy,
  typename Rng,
  typename FwdIter2
>
util::detail::algorithm_result<
  typename traits::range_iterator<Rng>::type,
  tag::out
>
unique_copy(ExPolicy &&policy, Rng &&rng, FwdIter2 dest, Pred &&pred = Pred(), Proj &&proj = Proj())
``` 

Copies the elements from the range `rng`, to another range beginning at `dest` in such a way that there are no consecutive equal elements. Only the first element of each group of equal elements is copied.

The assignments in the parallel `unique_copy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note**

Complexity: Performs not more than N assignments, exactly N - 1 applications of the predicate `pred`, where `N` = `std::distance(begin(rng), end(rng))`.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `unique_copy` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
• rng: Refers to the sequence of elements the algorithm will be applied to.
• dest: Refers to the beginning of the destination range.
• pred: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by the range rng. This is a binary predicate which returns true for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a, const Type &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type FwdIter1 can be dereferenced and then implicitly converted to Type.

• proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel unique_copy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The unique_copy algorithm returns a hpx::future<tagged_pair<tag::in(FwdIter1), tag::out(FwdIter2)>> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns tagged_pair<tag::in(FwdIter1), tag::out(FwdIter2)> otherwise. The unique_copy algorithm returns the pair of the source iterator to last, and the destination iterator to the end of the dest range.

Functions

template<typename Value, typename ...Args>
void construct_object (Value *ptr, Args&&... args)
create an object in the memory specified by ptr

Template Parameters
  • Value:: typename of the object to create
  • Args:: parameters for the constructor

Parameters
  • [in] ptr:: pointer to the memory where to create the object
  • [in] args:: arguments to the constructor

template<typename Value>
void destroy_object (Value *ptr)
destroy an object in the memory specified by ptr

Template Parameters
  • Value:: typename of the object to create

Parameters
  • [in] ptr:: pointer to the object to destroy

template<typename Iter, typename Sent>
void init (Iter first, Sent last, typename std::iterator_traits<Iter>::value_type &val)
Initialize a range of objects with the object val moving across them

Return range initialized

Parameters
  • [in] r:: range of elements not initialized
  • [in] val:: object used for the initialization

template<typename Value, typename ...Args>
void construct (Value *ptr, Args&&... args)
create an object in the memory specified by ptr

Template Parameters
  • Value:: typename of the object to create
  • Args:: parameters for the constructor

Parameters
  • [in] ptr:: pointer to the memory where to create the object
  • [in] args:: arguments to the constructor

template<typename Iter1, typename Sent1, typename Iter2>
Iter2 init_move (Iter2 it_dest, Iter1 first, Sent1 last)
Move objects.

Template Parameters
  • Iter1:: iterator to the elements
  • Value:: typename of the object to create

Parameters
  • [in] itdest:: iterator to the final place of the objects
template<typename Iter, typename Sent, typename Value = typename std::iterator_traits<Iter>::value_type>
Value *uninit_move (Value *ptr, Iter first, Sent last)
Move objects to uninitialized memory.

Template Parameters
• Iter:: iterator to the elements
• Value:: typename of the object to construct

Parameters
• [in] ptr:: pointer to the memory where to create the object
• [in] R:: range to move

template<typename Iter, typename Sent>
void destroy (Iter first, Sent last)
Move objects to uninitialized memory.

Template Parameters
• Iter:: iterator to the elements
• Value:: typename of the object to construct

Parameters
• [in] ptr:: pointer to the memory where to construct the object
• [in] R:: range to move

template<typename Iter1, typename Sent1, typename Iter2, typename Compare>
Iter2 full_merge (Iter1 buf1, Sent1 end_buf1, Iter1 buf2, Sent1 end_buf2, Iter2 buf_out, Compare comp)
Merge two contiguous buffers pointed by buf1 and buf2, and put in the buffer pointed by buf_out.

Parameters
• [in] buf1:: iterator to the first element in the first buffer
• [in] end_buf1:: final iterator of first buffer
• [in] buf2:: iterator to the first iterator to the second buffer
• [in] end_buf2:: final iterator of the second buffer
• [in] buf_out:: buffer where move the elements merged
• [in] comp:: comparison object

template<typename Iter, typename Sent, typename Value, typename Compare>
Value *uninit_full_merge (Iter first1, Sent last1, Iter first2, Sent last2, Value *it_out, Compare comp)
Merge two contiguous buffers pointed by first1 and first2, and put in the uninitialized buffer pointed by it_out.

Parameters
• [in] first1:: iterator to the first element in the first buffer
• [in] last:: last iterator of the first buffer
• [in] first2:: iterator to the first element to the second buffer
• [in] last2:: final iterator of the second buffer
• [in] it_out:: uninitialized buffer where move the elements merged
• [in] comp:: comparison object
Iter2 `half_merge` ([Iter1 buf1, Sent1 end_buf1, Iter2 buf2, Sent2 end_buf2, Iter2 buf_out, Compare comp])

- Merge two buffers. The first buffer is in a separate memory. The second buffer have a empty space before buf2 of the same size than the (end_buf1 - buf1)

**Remark** The elements pointed by Iter1 and Iter2 must be the same

**Parameters**
- `[in]` `buf1`: iterator to the first element of the first buffer
- `[in]` `end_buf1`: iterator to the last element of the first buffer
- `[in]` `buf2`: iterator to the first element of the second buffer
- `[in]` `end_buf2`: iterator to the last element of the second buffer
- `[in]` `buf_out`: iterator to the first element to the buffer where put the result
- `[in]` `comp`: object for Compare two elements of the type pointed by the Iter1 and Iter2

```cpp
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3, typename Compare>
bool in_place_merge_uncontiguous (Iter1 src1, Sent1 end_src1, Iter2 src2, Sent2 end_src2, Iter3 aux, Compare comp)
```

- Merge two non contiguous buffers, placing the results in the buffers for to do this use an auxiliary buffer pointed by aux

**Parameters**
- `[in]` `src1`: iterator to the first element of the first buffer
- `[in]` `end_src1`: last iterator of the first buffer
- `[in]` `src2`: iterator to the first element of the second buffer
- `[in]` `end_src2`: last iterator of the second buffer
- `[in]` `aux`: iterator to the first element of the auxiliary buffer
- `[in]` `comp`: object for to Compare elements

**Exceptions**

```cpp
template<typename Iter1, typename Sent1, typename Iter2, typename Compare>
bool in_place_merge (Iter1 src1, Iter1 src2, Sent1 end_src2, Iter2 buf, Compare comp)
```

- Merge two contiguous buffers, using an auxiliary buffer pointed by buf

**Parameters**
- `[in]` `src1`: iterator to the first position of the first buffer
- `[in]` `src2`: final iterator of the first buffer and first iterator of the second buffer
- `[in]` `end_src2`: final iterator of the second buffer
- `[in]` `buf`: iterator to buffer used as auxiliary memory
- `[in]` `comp`: object for to Compare elements

**Exceptions**

```cpp
namespace hpx
```

```cpp
namespace parallel
```

```cpp
namespace util
```
Functions

```cpp
template<typename Iter, typename Sent, typename Compare>
bool less_range (Iter it1, std::uint32_t pos1, Sent it2, std::uint32_t pos2, Compare comp)
```

Compare the elements pointed by it1 and it2, and if they are equals, compare their position, doing a stable comparison.

Return result of the comparison

Parameters
- [in] it1: iterator to the first element
- [in] pos1: position of the object pointed by it1
- [in] it2: iterator to the second element
- [in] pos2: position of the element pointed by it2
- [in] comp: comparison object

```cpp
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Compare>
util::range<Iter1, Sent1> full_merge4 (util::range<Iter1, Sent1> &dest, util::range<Iter2, Sent2> vrange_input[4], std::uint32_t nrange_input, Compare comp)
```

Merge four ranges.

Return range with all the elements move with the size adjusted

Parameters
- [in] dest: range where move the elements merged. Their size must be greater or equal than the sum of the sizes of the ranges in the array R
- [in] R: array of ranges to merge
- [in] nrange_input: number of ranges in R
- [in] comp: comparison object

```cpp
template<typename Value, typename Iter, typename Sent, typename Compare>
util::range<Value*> uninit_full_merge4 (util::range<Value*> const &dest, util::range<Iter, Sent> vrange_input[4], std::uint32_t nrange_input, Compare comp)
```

Merge four ranges and put the result in uninitialized memory.

Return range with all the elements move with the size adjusted

Parameters
- [in] dest: range where create and move the elements merged. Their size must be greater or equal than the sum of the sizes of the ranges in the array R
- [in] R: array of ranges to merge
- [in] nrange_input: number of ranges in vrange_input
- [in] comp: comparison object

namespace hpx

namespace parallel

namespace util
Functions

template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Compare>
void merge_level4 (util::range<Iter1, Sent1> dest, std::vector<util::range<Iter2, Sent2>> &v_input, std::vector<util::range<Iter1, Sent1>> &v_output, Compare comp)
Merge the ranges in the vector v_input using full_merge4. The v_output vector is used as auxiliary
memory in the internal process The final results is in the dest range. All the ranges of v_output
are inside the range dest

Return range with all the elements moved

Parameters
• [in] dest:: range where move the elements merged
• [in] v_input:: vector of ranges to merge
• [in] v_output:: vector of ranges obtained
• [in] comp:: comparison object

template<typename Value, typename Iter, typename Sent, typename Compare>
void uninit_merge_level4 (util::range<Value*> dest, std::vector<util::range<Iter, Sent>> &v_input, std::vector<util::range<Value*>> &v_output, Compare comp)
Merge the ranges over uninitialized memory in the vector v_input using full_merge4. The
v_output vector is used as auxiliary memory in the internal process. The final results is in the
dest range. All the ranges of v_output are inside the range dest

Return range with all the elements moved

Parameters
• [in] dest:: range where move the elements merged
• [in] v_input:: vector of ranges to merge
• [in] v_output:: vector of ranges obtained
• [in] comp:: comparison object

template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Compare>
util::range<Iter2, Sent2> merge_vector4 (util::range<Iter1, Sent1> range_input,
util::range<Iter2, Sent2> range_output,
std::vector<util::range<Iter1, Sent1>> &v_input,
std::vector<util::range<Iter2, Sent2>> &v_output,
Compare comp)
Merge the ranges in the vector v_input using merge_level4. The v_output vector is used as auxiliary
memory in the internal process The final results is in the range_output range. All the ranges of v_output
are inside the range range_output All the ranges of v_input are inside the range
range_input

Parameters
• [in] range_input:: range including all the ranges of v_input

namespace hpx

namespace parallel

namespace util
 Functions

 constexpr std::uint32_t nbits32 (std::uint32_t num)
 Obtain the number of bits equal or greater than num.

 Return  Number of bits
 Parameters
  • [in] num : Number to examine
 Exceptions
  • none:

 constexpr std::uint64_t nbits64 (std::uint64_t num)
 Obtain the number of bits equal or greater than num.

 Return  Number of bits
 Parameters
  • [in] num : Number to examine
 Exceptions
  • none:

 Variables

template<typename Iterator, typename Sentinel = Iterator>
using range = hpx::util::iterator_range<Iterator, Sentinel>

Functions

template<typename Iter, typename Sent>
range<Iter, Sent> concat (range<Iter, Sent> const &it1, range<Iter, Sent> const &it2)
concatenate two contiguous ranges

Return range resulting of the concatenation
Parameters
• [in] it1:: first range
• [in] it2:: second range

template<typename Iter1, typename Sent1, typename Iter2, typename Sent2>
range<Iter2, Iter2> init_move (range<Iter2, Sent2> const &dest, range<Iter1, Sent1> const &src)
Move objects from the range src to dest.

Return range with the objects moved and the size adjusted
Parameters
• [in] dest:: range where move the objects
• [in] src:: range from where move the objects

template<typename Iter1, typename Sent1, typename Iter2, typename Sent2>
range<Iter2, Sent2> uninit_move (range<Iter2, Sent2> const & dest, range<Iter1, Sent1> const & src)

Move objects from the range src creating them in dest.

Return range with the objects moved and the size adjusted
Parameters
• [in] dest:: range where move and create the objects
• [in] src:: range from where move the objects

template<typename Iter, typename Sent>
void destroy_range (range<Iter, Sent> r)

destroy a range of objects

Parameters
• [in] r:: range to destroy

template<typename Iter, typename Sent>
range<Iter, Sent> init (range<Iter, Sent> const & r, typename std::iterator_traits<Iter>::value_type & val)

initialize a range of objects with the object val moving across them

Return range initialized
Parameters
• [in] r:: range of elements not initialized
• [in] val:: object used for the initialization

template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Compare>
bool is_mergeable (range<Iter1, Sent1> const & src1, range<Iter2, Sent2> const & src2, Compare comp)

: indicate if two ranges have a possible merge

Parameters
• [in] src1:: first range
• [in] src2:: second range
• [in] comp:: object for to compare elements

Exceptions
•

template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3, typename Sent3>
range<Iter3, Sent3> full_merge (range<Iter3, Sent3> const & dest, range<Iter1, Sent1> const & src1, range<Iter2, Sent2> const & src2, Compare comp)

Merge two contiguous ranges src1 and src2 , and put the result in the range dest, returning the range merged.

Return range with the elements merged and the size adjusted
Parameters
• [in] dest:: range where locate the elements merged. the size of dest must be greater or equal than the sum of the sizes of src1 and src2
• [in] src1:: first range to merge
• [in] src2: second range to merge
• [in] comp: comparison object

template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Value, typename Compare>
range<Value*> uninit_full_merge(const range<Value*> &dest, range<Iter1, Sent1> const &src1, range<Iter2, Sent2> const &src2, Compare comp)

Merge two contiguous ranges src1 and src2, and create and move the result in the uninitialized range dest, returning the range merged.

Return range with the elements merged and the size adjusted

Parameters
• [in] dest: range where locate the elements merged. the size of dest must be greater or equal than the sum of the sizes of src1 and src2. Initially is uninitialize memory
• [in] src1: first range to merge
• [in] src2: second range to merge
• [in] comp: comparison object

template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Compare>
range<Iter2, Sent2> half_merge(range<Iter2, Sent2> const &dest, range<Iter1, Sent1> const &src1, range<Iter2, Sent2> const &src2, Compare comp)

: Merge two buffers. The first buffer is in a separate memory

Return: range with the two buffers merged

Parameters
• [in] dest: range where finish the two buffers merged
• [in] src1: first range to merge in a separate memory
• [in] src2: second range to merge, in the final part of the range where deposit the final results
• [in] comp: object for compare two elements of the type pointed by the Iter1 and Iter2

template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3, typename Sent3, typename Compare>
bool in_place_merge_uncontiguous(range<Iter1, Sent1> const &src1, range<Iter2, Sent2> const &src2, range<Iter3, Sent3> &aux, Compare comp)

: merge two non contiguous buffers src1, src2, using the range aux as auxiliary memory

Parameters
• [in] src1: first range to merge
• [in] src2: second range to merge
• [in] aux: auxiliary range used in the merge
• [in] comp: object for to compare elements

Exceptions

•

template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Compare>
range<Iter1, Sent1> in_place_merge(range<Iter1, Sent1> const &src1, range<Iter1, Sent1> const &src2, range<Iter2, Sent2> &buf, Compare comp)

: merge two contiguous buffers (src1, src2) using buf as auxiliary memory

Parameters
• [in] src1: first range to merge
• [in] src1: :second range to merge
• [in] buf: :auxiliary memory used in the merge
• [in] comp: : object for to compare elements

Exceptions
•

template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Compare>

void merge_flow (range<Iter1, Sent1> rng1, range<Iter2, Sent2> rbuf, range<Iter1, Sent1> rng2, Compare cmp)
: merge two contiguous buffers

Template Parameters
• Iter: : iterator to the elements
• compare: : object for to compare two elements pointed by Iter iterators

Parameters
• [in] first: : iterator to the first element
• [in] last: : iterator to the element after the last in the range
• [in] comp: : object for to compare elements

Exceptions
•

struct launch : public detail::policy_holder<>
    #include <launch_policy.hpp> Launch policies for hpx::async etc.

Public Functions

constexpr launch()
    Default constructor. This creates a launch policy representing all possible launch modes

constexpr launch(detail::async_policy)
    Create a launch policy representing asynchronous execution.

constexpr launch(detail::fork_policy)
    Create a launch policy representing asynchronous execution. The new thread is executed in a preferred way

constexpr launch(detail::sync_policy)
    Create a launch policy representing synchronous execution.

constexpr launch(detail::deferred_policy)
    Create a launch policy representing deferred execution.

constexpr launch(detail::apply_policy)
    Create a launch policy representing fire and forget execution.

template<typename F>
constexpr launch(detail::select_policy<F> const &p)
    Create a launch policy representing fire and forget execution.
Public Static Attributes

```cpp
const detail::async_policy async
    Predefined launch policy representing asynchronous execution.

const detail::fork_policy fork
    Predefined launch policy representing asynchronous execution. The new thread is executed in a preferred way.

const detail::sync_policy sync
    Predefined launch policy representing synchronous execution.

const detail::deferred_policy deferred
    Predefined launch policy representing deferred execution.

const detail::apply_policy apply
    Predefined launch policy representing fire and forget execution.

const detail::select_policy_generator select
    Predefined launch policy representing delayed policy selection.
```

namespace hpx

namespace hpx

Functions

```cpp
template<typename ...Ts>
tuple<future<Ts>...> split_future (future<tuple<Ts...>> &&f)
    The function `split_future` is an operator allowing to split a given future of a sequence of values (any tuple, std::pair, or std::array) into an equivalent container of futures where each future represents one of the values from the original future. In some sense this function provides the inverse operation of `when_all`.

Return  Returns an equivalent container (same container type as passed as the argument) of futures, where each future refers to the corresponding value in the input parameter. All of the returned futures become ready once the input future has become ready. If the input future is exceptional, all output futures will be exceptional as well.

Note   The following cases are special:
tuple<future<void> > split_future(future<tuple<> > && f);
array<future<void>, 1> split_future(future<array<T, 0> > && f);

Here the returned futures are directly representing the futures which were passed to the function.

**Parameters**

- \( f \): [in] A future holding an arbitrary sequence of values stored in a tuple-like container. This facility supports `hpx::tuple<>`, `std::pair<T1, T2>`, and `std::array<T, N>`

**Return** Returns a `std::vector` of futures, where each future refers to the corresponding value in the input parameter. All of the returned futures become ready once the input future has become ready. If the input future is exceptional, all output futures will be exceptional as well.

**Parameters**

- \( f \): [in] A future holding an arbitrary sequence of values stored in a `std::vector`.
- `size`: [in] The number of elements the vector will hold once the input future has become ready

**namespace hpx**

**Functions**

```cpp
template<typename InputIter>
void wait_all(InputIter first, InputIter last)
```

The function `wait_all` is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

**Note** The function `wait_all` returns after all futures have become ready. All input futures are still valid after `wait_all` returns.

**Parameters**

- `first`: The iterator pointing to the first element of a sequence of `future` or `shared_future` objects for which `wait_all` should wait.
- `last`: The iterator pointing to the last element of a sequence of `future` or `shared_future` objects for which `wait_all` should wait.

```cpp
template<typename R>
void wait_all(std::vector<future<R>> && futures)
```

The function `wait_all` is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

**Note** The function `wait_all` returns after all futures have become ready. All input futures are still valid after `wait_all` returns.

**Parameters**
• **futures**: A vector or array holding an arbitrary amount of *future* or *shared_future* objects for which *wait_all* should wait.

```cpp
template<typename R, std::size_t N>
void wait_all(std::array<future<R>, N> &&futures)
```

The function *wait_all* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

**Note** The function *wait_all* returns after all futures have become ready. All input futures are still valid after *wait_all* returns.

**Parameters**

• **futures**: A vector or array holding an arbitrary amount of *future* or *shared_future* objects for which *wait_all* should wait.

```cpp
template<typename ...T>
void wait_all(T&&... futures)
```

The function *wait_all* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

**Note** The function *wait_all* returns after all futures have become ready. All input futures are still valid after *wait_all* returns.

**Parameters**

• **futures**: An arbitrary number of *future* or *shared_future* objects, possibly holding different types for which *wait_all* should wait.

```cpp
template<typename InputIter>
InputIter wait_all_n(InputIter begin, std::size_t count)
```

The function *wait_all_n* is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

**Return** The function *wait_all_n* will return an iterator referring to the first element in the input sequence after the last processed element.

**Note** The function *wait_all_n* returns after all futures have become ready. All input futures are still valid after *wait_all_n* returns.

**Parameters**

• **begin**: The iterator pointing to the first element of a sequence of *future* or *shared_future* objects for which *wait_all_n* should wait.

• **count**: The number of elements in the sequence starting at *first*.
Functions

template<typename InputIter>
void wait_any (InputIter first, InputIter last, error_code &ec = throws)

The function wait_any is a non-deterministic choice operator. It OR-composes all future objects given and returns after one future of that list finishes execution.

Note The function wait_any returns after at least one future has become ready. All input futures are still valid after wait_any returns.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Note None of the futures in the input sequence are invalidated.

Parameters

• first: [in] The iterator pointing to the first element of a sequence of future or shared_future objects for which wait_any should wait.

• last: [in] The iterator pointing to the last element of a sequence of future or shared_future objects for which wait_any should wait.

• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

template<typename R>
void wait_any (std::vector<future<R>> &futures, error_code &ec = throws)

The function wait_any is a non-deterministic choice operator. It OR-composes all future objects given and returns after one future of that list finishes execution.

Note The function wait_any returns after at least one future has become ready. All input futures are still valid after wait_any returns.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Note None of the futures in the input sequence are invalidated.

Parameters

• futures: [in] A vector holding an arbitrary amount of future or shared_future objects for which wait_any should wait.

• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

template<typename R, std::size_t N>
void hpx::wait_any (std::array< future<R>, N > &futures, error_code &ec = throws)

The function wait_any is a non-deterministic choice operator. It OR-composes all future objects given and returns after one future of that list finishes execution.

Note The function wait_any returns after at least one future has become ready. All input futures are still valid after wait_any returns.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Note None of the futures in the input sequence are invalidated.
Parameters

- **futures**: [in] An arbitrary number of future or shared_future objects, possibly holding different types for which wait_any should wait.
- **ec**: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

```cpp
template<typename ...T>
void wait_any (error_code &ec, T&&... futures)
```

The function wait_any is a non-deterministic choice operator. It OR-composes all future objects given and returns after one future of that list finishes execution.

**Note** The function wait_any returns after at least one future has become ready. All input futures are still valid after wait_any returns.

**Note** As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

**Note** None of the futures in the input sequence are invalidated.

Parameters

- **futures**: [in] An arbitrary number of future or shared_future objects, possibly holding different types for which wait_any should wait.
- **ec**: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

```cpp
template<typename ...T>
void wait_any (T&&... futures)
```

The function wait_any is a non-deterministic choice operator. It OR-composes all future objects given and returns after one future of that list finishes execution.

**Note** The function wait_any returns after at least one future has become ready. All input futures are still valid after wait_any returns.

**Note** None of the futures in the input sequence are invalidated.

Parameters

- **futures**: [in] An arbitrary number of future or shared_future objects, possibly holding different types for which wait_any should wait.

```cpp
template<typename InputIter>
InputIter wait_any_n (InputIter first, std::size_t count, error_code &ec = throws)
```

The function wait_any_n is a non-deterministic choice operator. It OR-composes all future objects given and returns after one future of that list finishes execution.

**Note** The function wait_any_n returns after at least one future has become ready. All input futures are still valid after wait_any_n returns.

**Return** The function wait_all_n will return an iterator referring to the first element in the input sequence after the last processed element.

**Note** As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.
Note None of the futures in the input sequence are invalidated.

Parameters

• first: [in] The iterator pointing to the first element of a sequence of future or shared_future objects for which wait_any_n should wait.

• count: [in] The number of elements in the sequence starting at first.

• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

namespace hpx

Functions

template<typename F, typename Future>
void wait_each (F &&f, std::vector<Future> &&futures)
The function wait_each is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns after they finished executing. Additionally, the supplied function is called for each of the passed futures as soon as the future has become ready. wait_each returns after all futures have been become ready.

Note This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a future to be processed or a type that std::size_t is implicitly convertible to as the first parameter and the future as the second parameter. The first parameter will correspond to the index of the current future in the collection.

Parameters

• f: The function which will be called for each of the input futures once the future has become ready.

• futures: A vector holding an arbitrary amount of future or shared_future objects for which wait_each should wait.

template<typename F, typename Iterator>
void wait_each (F &&f, Iterator begin, Iterator end)
The function wait_each is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns after they finished executing. Additionally, the supplied function is called for each of the passed futures as soon as the future has become ready. wait_each returns after all futures have been become ready.

Note This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a future to be processed or a type that std::size_t is implicitly convertible to as the first parameter and the future as the second parameter. The first parameter will correspond to the index of the current future in the collection.

Parameters

• f: The function which will be called for each of the input futures once the future has become ready.

• begin: The iterator pointing to the first element of a sequence of future or shared_future objects for which wait_each should wait.
The iterator pointing to the last element of a sequence of future or shared_future objects for which wait_each should wait.

template<typename F, typename ...T>
void wait_each(F &&f, T &&...futures)
    The function wait_each is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns after they finished executing. Additionally, the supplied function is called for each of the passed futures as soon as the future has become ready. wait_each returns after all futures have been become ready.

Note This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a future to be processed or a type that std::size_t is implicitly convertible to as the first parameter and the future as the second parameter. The first parameter will correspond to the index of the current future in the collection.

Parameters

- f: The function which will be called for each of the input futures once the future has become ready.
- futures: An arbitrary number of future or shared_future objects, possibly holding different types for which wait_each should wait.

template<typename F, typename Iterator>
void wait_each_n(F &&f, Iterator begin, std::size_t count)
    The function wait_each is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing. Additionally, the supplied function is called for each of the passed futures as soon as the future has become ready.

Note This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a future to be processed or a type that std::size_t is implicitly convertible to as the first parameter and the future as the second parameter. The first parameter will correspond to the index of the current future in the collection.

Parameters

- f: The function which will be called for each of the input futures once the future has become ready.
- begin: The iterator pointing to the first element of a sequence of future or shared_future objects for which wait_each_n should wait.
- count: The number of elements in the sequence starting at first.
The function `wait_some` is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after `n` of them finished executing.

**Note** The future returned by the function `wait_some` becomes ready when at least `n` argument futures have become ready.

**Return** Returns a future holding the same list of futures as has been passed to `wait_some`.

- `future<vector<vector<future<R>>>>`: If the input cardinality is unknown at compile time and the futures are all of the same type.

**Note** Calling this version of `wait_some` where `first == last`, returns a future with an empty vector that is immediately ready. Each future and shared_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by `wait_some` will not throw an exception, but the futures held in the output collection may.

**Parameters**

- `n`: [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- `first`: [in] The iterator pointing to the first element of a sequence of `future` or `shared_future` objects for which `when_all` should wait.
- `last`: [in] The iterator pointing to the last element of a sequence of `future` or `shared_future` objects for which `when_all` should wait.
- `ec`: [in,out] This represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

The function `wait_all` returns after `n` futures have become ready. All input futures are still valid after `wait_all` returns.

**Note** Each future and shared_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by `wait_some` will not throw an exception, but the futures held in the output collection may.

**Parameters**
n: [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.

futures: [in] A vector holding an arbitrary amount of future or shared_future objects for which wait_some should wait.

e: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

Note The function wait_all returns after n futures have become ready. All input futures are still valid after wait_all returns.

Note Each future and shared_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by wait_some will not throw an exception, but the futures held in the output collection may.

Parameters

n: [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.

futures: [in] An array holding an arbitrary amount of future or shared_future objects for which wait_some should wait.

e: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.
**InputIter** `wait_some_n` (*std::size_t n, Iterator first, std::size_t count, error_code &ec = throws*)

The function `wait_some_n` is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after `n` of them finished executing.

**Note** The function `wait_all` returns after `n` futures have become ready. All input futures are still valid after `wait_all` returns.

**Return** This function returns an Iterator referring to the first element after the last processed input element.

**Note** Calling this version of `wait_some_n` where `count == 0`, returns a future with the same elements as the arguments that is immediately ready. Possibly none of the futures in that vector are ready. Each future and shared_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by `wait_some_n` will not throw an exception, but the futures held in the output collection may.

**Parameters**
- **n**: [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- **first**: [in] The iterator pointing to the first element of a sequence of future or shared_future objects for which `when_all` should wait.
- **count**: [in] The number of elements in the sequence starting at `first`.
- **ec**: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**namespace hpx**

**Functions**

```
template<typename InputIter, typename Container = vector<future<typename std::iterator_traits<InputIter>::value_type>>> future<Container<future<R>>> when_all(InputIter first, InputIter last)
```

The function `when_all` is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after they finished executing.

**Return** Returns a future holding the same list of futures as has been passed to `when_all`.

- **future<Container<future<R>>>**: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output container will be the same as given by the input iterator.

**Note** Calling this version of `when_all` where `first == last`, returns a future with an empty container that is immediately ready. Each future and shared_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by `when_all` will not throw an exception, but the futures held in the output collection may.

**Parameters**
- **first**: [in] The iterator pointing to the first element of a sequence of future or shared_future objects for which `when_all` should wait.
- **last**: [in] The iterator pointing to the last element of a sequence of future or shared_future objects for which `when_all` should wait.
template<typename Range>
future<Range> when_all(Range &&values)

The function when_all is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after they finished executing.

**Return** Returns a future holding the same list of futures as has been passed to when_all.

- future<Container<future<R>>>: If the input cardinality is unknown at compile time and the futures are all of the same type.

**Note** Calling this version of when_all where the input container is empty, returns a future with an empty container that is immediately ready. Each future and shared_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by when_all will not throw an exception, but the futures held in the output collection may.

**Parameters**
- values: [in] A range holding an arbitrary amount of future or shared_future objects for which when_all should wait.

template<typename ...T>
future<tuple<future<T>...>> when_all(T&&... futures)

The function when_all is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after they finished executing.

**Return** Returns a future holding the same list of futures as has been passed to when_all.

- future<tuple<future<T0>, future<T1>, future<T2>...>>: If inputs are fixed in number and are of heterogeneous types. The inputs can be any arbitrary number of future objects.
- future<tuple<> if when_all is called with zero arguments. The returned future will be initially ready.

**Note** Each future and shared_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by when_all will not throw an exception, but the futures held in the output collection may.

**Parameters**
- futures: [in] An arbitrary number of future or shared_future objects, possibly holding different types for which when_all should wait.

template<typename InputIter, typename Container = vector<future<typename std::iterator_traits<InputIter>::value_type>>> future<Container> when_all_n(InputIter begin, std::size_t count)

The function when_all_n is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after they finished executing.

**Return** Returns a future holding the same list of futures as has been passed to when_all_n.

- future<Container<future<R>>>: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output vector will be the same as given by the input iterator.
Note As long as \texttt{ec} is not pre-initialized to \texttt{hpx::throws} this function doesn’t throw but returns the result code using the parameter \texttt{ec}. Otherwise it throws an instance of \texttt{hpx::exception}.

Note None of the futures in the input sequence are invalidated.

**Parameters**

- \texttt{begin}: [in] The iterator pointing to the first element of a sequence of future or shared_future objects for which \texttt{wait_all_n} should wait.
- \texttt{count}: [in] The number of elements in the sequence starting at \texttt{first}.

**Exceptions**

- This function will throw errors which are encountered while setting up the requested operation only. Errors encountered while executing the operations delivering the results to be stored in the futures are reported through the futures themselves.

namespace \texttt{hpx}

**Functions**

template<typename \texttt{InputIter}, \texttt{Container} = \texttt{vector<future<typename std::iterator_traits<\texttt{InputIter}>::value_type>>> \texttt{future<when_any_result<\texttt{Container}>>> when\_any (\texttt{InputIter first}, \texttt{InputIter last})}

The function \texttt{when\_any} is a non-deterministic choice operator. It OR-composes all future objects given and returns a new future object representing the same list of futures after one future of that list finishes execution.

**Return** Returns a \texttt{when\_any\_result} holding the same list of futures as has been passed to \texttt{when\_any} and an index pointing to a ready future.

- \texttt{future<when\_any\_result<\texttt{Container}<<\texttt{future<R>>>}: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output container will be the same as given by the input iterator.

**Parameters**

- \texttt{first}: [in] The iterator pointing to the first element of a sequence of future or shared_future objects for which \texttt{when\_any} should wait.
- \texttt{last}: [in] The iterator pointing to the last element of a sequence of future or shared_future objects for which \texttt{when\_any} should wait.

template<typename \texttt{Range}> \texttt{future<when\_any\_result<\texttt{Range}>>> when\_any (\texttt{Range} &values)

The function \texttt{when\_any} is a non-deterministic choice operator. It OR-composes all future objects given and returns a new future object representing the same list of futures after one future of that list finishes execution.

**Return** Returns a \texttt{when\_any\_result} holding the same list of futures as has been passed to \texttt{when\_any} and an index pointing to a ready future.

- \texttt{future<when\_any\_result<\texttt{Container}<<\texttt{future<R>>>}: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output container will be the same as given by the input iterator.

**Parameters**
Values: [in] A range holding an arbitrary amount of futures or shared_future objects for which
when_any should wait.

```cpp
template<typename ...T>
future<when_any_result<tuple<future<T>...>>> when_any (T&&... futures)
```

The function when_any is a non-deterministic choice operator. It OR-composes all future objects given
and returns a new future object representing the same list of futures after one future of that list finishes
execution.

**Return** Returns a when_any_result holding the same list of futures as has been passed to when_any and
an index pointing to a ready future.

- future<when_any_result<tuple<future<T0>, future<T1>...>>: If inputs are fixed in number
and are of heterogeneous types. The inputs can be any arbitrary number of future objects.

- future<when_any_result<tuple<>>> if when_any is called with zero arguments. The returned
future will be initially ready.

**Parameters**

- futures: [in] An arbitrary number of future or shared_future objects, possibly holding different
types for which when_any should wait.

```cpp
template<typename InputIter, typename Container = vector<future<typename std::iterator_traits<InputIter>::value_type>>> future<when_any_result<Container>> when_any_n (InputIter first, std::size_t count)
```

The function when_any_n is a non-deterministic choice operator. It OR-composes all future objects given
and returns a new future object representing the same list of futures after one future of that list finishes
execution.

**Return** Returns a when_any_result holding the same list of futures as has been passed to when_any and
an index pointing to a ready future.

- future<when_any_result<Container<future<R>>>: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output container
will be the same as given by the input iterator.

**Note** None of the futures in the input sequence are invalidated.

**Parameters**

- first: [in] The iterator pointing to the first element of a sequence of future or shared_future
objects for which when_any_n should wait.

- count: [in] The number of elements in the sequence starting at first.

```cpp
struct when_any_result
#include <when_any.hpp> Result type for when_any, contains a sequence of futures and an index pointing
to a ready future.
```
Public Members

```
std::size_t index
The index of a future which has become ready.
```

Sequence futures
The sequence of futures as passed to `hpx::when_any`.

```
namespace hpx
```

Functions

```template<typename F, typename Future>
future< void > when_each (F &&f, std::vector<Future> &&futures)
The function `when_each` is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns a new future object representing the event of all those futures having finished executing. It also calls the supplied callback for each of the futures which becomes ready.

**Note** This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a `future` to be processed or a type that `std::size_t` is implicitly convertible to as the first parameter and the `future` as the second parameter. The first parameter will correspond to the index of the current `future` in the collection.

**Return** Returns a future representing the event of all input futures being ready.

**Parameters**

- **f**: The function which will be called for each of the input futures once the future has become ready.
- **futures**: A vector holding an arbitrary amount of `future` or `shared_future` objects for which `wait_each` should wait.
```

```template<typename F, typename Iterator>
future< Iterator > when_each (F &&f, Iterator begin, Iterator end)
The function `when_each` is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns a new future object representing the event of all those futures having finished executing. It also calls the supplied callback for each of the futures which becomes ready.

**Note** This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a `future` to be processed or a type that `std::size_t` is implicitly convertible to as the first parameter and the `future` as the second parameter. The first parameter will correspond to the index of the current `future` in the collection.

**Return** Returns a future representing the event of all input futures being ready.

**Parameters**

- **f**: The function which will be called for each of the input futures once the future has become ready.
- **begin**: The iterator pointing to the first element of a sequence of `future` or `shared_future` objects for which `wait_each` should wait.
- **end**: The iterator pointing to the last element of a sequence of `future` or `shared_future` objects for which `wait_each` should wait.
template<typename F, typename ...Ts>
future<void> when_each (F &&f, Ts&&... futures)

The function when_each is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns a new future object representing the event of all those futures having finished executing. It also calls the supplied callback for each of the futures which becomes ready.

Note This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a future to be processed or a type that std::size_t is implicitly convertible to as the first parameter and the future as the second parameter. The first parameter will correspond to the index of the current future in the collection.

Return Returns a future representing the event of all input futures being ready.

Parameters

• f: The function which will be called for each of the input futures once the future has become ready.
• futures: An arbitrary number of future or shared_future objects, possibly holding different types for which wait_each should wait.

namespace hpx

Functions

template<typename InputIter, typename Container = vector<future<typename std::iterator_traits<InputIter>::value_type>>>
future<when_some_result<Container>> when_some (std::size_t n, Iterator first, Iterator last, error_code &ec = throws)

The function when_some is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after n of them finished executing.
Note The future returned by the function when_some becomes ready when at least \( n \) argument futures have become ready.

**Return** Returns a when_some_result holding the same list of futures as has been passed to when_some and indices pointing to ready futures.

- future<when_some_result<Container<future<R>>>: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output container will be the same as given by the input iterator.

Note Calling this version of when_some where first == last, returns a future with an empty container that is immediately ready. Each future and shared_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by when_some will not throw an exception, but the futures held in the output collection may.

**Parameters**

- \( n \): [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- \( \text{first} \): [in] The iterator pointing to the first element of a sequence of future or shared_future objects for which when_all should wait.
- \( \text{last} \): [in] The iterator pointing to the last element of a sequence of future or shared_future objects for which when_all should wait.
- \( \text{ec} \): [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

```
template<typename Range>
future<when_some_result<Range>> when_some (std::size_t n, Range&& futures, error_code &ec = hpx::throws)
```

The function when_some is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after \( n \) of them finished executing.

Note The future returned by the function when_some becomes ready when at least \( n \) argument futures have become ready.

**Return** Returns a when_some_result holding the same list of futures as has been passed to when_some and indices pointing to ready futures.

- future<when_some_result<Container<future<R>>>: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output container will be the same as given by the input iterator.

Note Each future and shared_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by when_some will not throw an exception, but the futures held in the output collection may.

**Parameters**

- \( n \): [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- \( \text{futures} \): [in] A container holding an arbitrary amount of future or shared_future objects for which when_some should wait.
- \( \text{ec} \): [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.
The function when_some is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after \( n \) of them finished executing.

**Note** The future returned by the function when_some becomes ready when at least \( n \) argument futures have become ready.

**Return** Returns a when_some_result holding the same list of futures as has been passed to when_some and an index pointing to a ready future.

- future<when_some_result<tuple<future<T0>, future<T1>, ...>> if inputs are fixed in number and are of heterogeneous types. The inputs can be any arbitrary number of future objects.

- future<when_some_result<tuple<>>> if when_some is called with zero arguments. The returned future will be initially ready.

**Note** Each future and shared_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by when_some will not throw an exception, but the futures held in the output collection may.

**Parameters**

- \( n \): [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.

- \( ec \): [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

- \( futures \): [in] An arbitrary number of future or shared_future objects, possibly holding different types for which when_some should wait.
• **n**: [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.

• **futures**: [in] An arbitrary number of future or shared_future objects, possibly holding different types for which when_some should wait.

```cpp
template<typename InputIter, typename Container = vector<future<typename std::iterator_traits<InputIter>::value_type>>> when_some_n(std::size_t n, InputIter first, std::size_t count, error_code &ec = throws)
```

The function `when_some_n` is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after `n` of them finished executing.

**Note** The future returned by the function `when_some_n` becomes ready when at least `n` argument futures have become ready.

**Return** Returns a `when_some_result` holding the same list of futures as has been passed to `when_some` and indices pointing to ready futures.

• `future<when_some_result<Container<future<R>>>>`: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output container will be the same as given by the input iterator.

**Note** Calling this version of `when_some_n` where `count == 0`, returns a future with the same elements as the arguments that is immediately ready. Possibly none of the futures in that container are ready. Each future and shared_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by `when_some_n` will not throw an exception, but the futures held in the output collection may.

**Parameters**

• **n**: [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.

• **first**: [in] The iterator pointing to the first element of a sequence of future or shared_future objects for which when_all should wait.

• **count**: [in] The number of elements in the sequence starting at `first`.

• **ec**: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
template<typename Sequence>
struct when_some_result
#include <when_some.hpp> Result type for when_some, contains a sequence of futures and indices pointing to ready futures.
```

**Public Members**

```cpp
std::vector<std::size_t> indices
List of indices of futures which became ready.
```

**Sequence futures**

The sequence of futures as passed to `hpx::when_some`.

	namespace execution

struct guided_chunk_size

```
#include <guided_chunk_size.hpp>
```

Iterations are dynamically assigned to threads in blocks as threads request them until no blocks remain to be assigned. Similar to dynamic_chunk_size except that the block size decreases each time a number of loop iterations is given to a thread. The size of the initial block is proportional to number_of_iterations / number_of_cores. Subsequent blocks are proportional to number_of_iterations_remaining / number_of_cores. The optional chunk size parameter defines the minimum block size. The default chunk size is 1.
Note This executor parameters type is equivalent to OpenMP’s GUIDED scheduling directive.

Public Functions

constexpr guided_chunk_size (std::size_t min_chunk_size = 1)
Construct a guided_chunk_size executor parameters object

Parameters
• min_chunk_size: [in] The optional minimal chunk size to use as the minimal number of loop iterations to schedule together. The default minimal chunk size is 1.

namespace hpx

namespace execution

struct persistent_auto_chunk_size #include <persistent_auto_chunk_size.hpp> Loop iterations are divided into pieces and then assigned to threads. The number of loop iterations combined is determined based on measurements of how long the execution of 1% of the overall number of iterations takes. This executor parameters type makes sure that as many loop iterations are combined as necessary to run for the amount of time specified.

Public Functions

constexpr persistent_auto_chunk_size (std::uint64_t num_iters_for_timing = 0)
Construct a persistent_auto_chunk_size executor parameters object

Note Default constructed persistent_auto_chunk_size executor parameter types will use 0 microseconds as the execution time for each chunk and 80 microseconds as the minimal time for which any of the scheduled chunks should run.

persistent_auto_chunk_size (hpx::chrono::steady_duration const &time_cs, std::uint64_t num_iters_for_timing = 0)
Construct a persistent_auto_chunk_size executor parameters object

Parameters
• time_cs: The execution time for each chunk.

persistent_auto_chunk_size (hpx::chrono::steady_duration const &time_cs, hpx::chrono::steady_duration const &rel_time, std::uint64_t num_iters_for_timing = 0)
Construct a persistent_auto_chunk_size executor parameters object

Parameters
• rel_time: [in] The time duration to use as the minimum to decide how many loop iterations should be combined.
• time_cs: The execution time for each chunk.

#include <is_execution_policy.hpp>  
Extension: Detect whether given execution policy enables parallelization

1. The type `is_parallel_execution_policy` can be used to detect parallel execution policies for the purpose of excluding function signatures from otherwise ambiguous overload resolution participation.
2. If `T` is the type of a standard or implementation-defined execution policy, `is_parallel_execution_policy\langle T\rangle` shall be publicly derived from `integral_constant\langle\text{bool, true}\rangle`, otherwise from `integral_constant\langle\text{bool, false}\rangle`.
3. The behavior of a program that adds specializations for `is_parallel_execution_policy` is undefined.

```cpp
template<typename T>
struct is_sequenced_execution_policy : public \( hpx::detail::is_sequenced_execution_policy<\text{std::decay\langle T\rangle}\cdot\text{type}>\)

#include <is_execution_policy.hpp>  
Extension: Detect whether given execution policy does not enable parallelization

1. The type `is_sequenced_execution_policy` can be used to detect non-parallel execution policies for the purpose of excluding function signatures from otherwise ambiguous overload resolution participation.
2. If `T` is the type of a standard or implementation-defined execution policy, `is_sequenced_execution_policy\langle T\rangle` shall be publicly derived from `integral_constant\langle\text{bool, true}\rangle`, otherwise from `integral_constant\langle\text{bool, false}\rangle`.
3. The behavior of a program that adds specializations for `is_sequenced_execution_policy` is undefined.

executors

The contents of this module can be included with the header hpx/modules/executors.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/executors.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

```cpp
namespace hpx

namespace parallel

namespace execution

Typedefs

using current_executor = parallel::execution::thread_pool_executor

namespace this_thread

Functions

parallel::execution::current_executor get_executor(error_code &ec = throws)

Returns a reference to the executor which was used to create the current thread.

Exceptions

- If: &ec != &throws, never throws, but will set ec to an appropriate value when an error occurs. Otherwise, this function will throw an `hpx::exception` with an error code of `hpx::yield_aborted` if it is signaled with `wait_aborted`. If called outside of a HPX-thread, this function will throw an `hpx::exception` with an error code of `hpx::null_thread_id`. If this function is called while the thread-manager is not running, it will throw an `hpx::exception` with an error code of `hpx::invalid_status`.

namespace threads

Functions

parallel::execution::current_executor get_executor(thread_id_type const &id, error_code &ec = throws)

Returns a reference to the executor which was used to create the given thread.

Exceptions
If `&ec != &throws`, never throws, but will set `ec` to an appropriate value when an error occurs. Otherwise, this function will throw an `hpx::exception` with an error code of `hpx::yield_aborted` if it is signaled with `wait_aborted`. If called outside of a HPX-thread, this function will throw an `hpx::exception` with an error code of `hpx::null_thread_id`. If this function is called while the thread-manager is not running, it will throw an `hpx::exception` with an error code of `hpx::invalid_status`.

namespace hpx

namespace execution

Variables

constexpr task_policy_tag task
Default sequential execution policy object.

constexpr sequenced_policy seq
Default sequential execution policy object.

constexpr parallel_policy par
Default parallel execution policy object.

constexpr parallel_unsequenced_policy par_unseq
Default vector execution policy object.

struct parallel_policy
#include <execution_policy.hpp> The class `parallel_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm’s execution may be parallelized.

Subclassed by `hpx::execution::parallel_policy_shim< Executor, Parameters >`

Public Types

typedef parallel_executor executor_type
The type of the executor associated with this execution policy.

typedef parallel::execution::extract_executor_parameters<executor_type>::type executor_parameters_type
The type of the associated executor parameters object which is associated with this execution policy

typedef parallel_execution_tag execution_category
The category of the execution tags created by this execution policy.

Public Functions

constexpr parallel_task_policy operator() (task_policy_tag) const
Create a new `parallel_policy` referencing a chunk size.

Return The new `parallel_policy`

Parameters

- `tag`: [in] Specify that the corresponding asynchronous execution policy should be used

```cpp
template<typename Executor>
```
Create a new parallel_policy referencing an executor and a chunk size.

**Return** The new parallel_policy

**Parameters**
- `exec`: [in] The executor to use for the execution of the parallel algorithm the returned execution policy is used with

Create a new parallel_policy from the given execution parameters

**Note** Requires: is_executor_parameters<Parameters>::value is true

**Return** The new parallel_policy

**Template Parameters**
- `Parameters`: The type of the executor parameters to associate with this execution policy.

**Parameters**
- `params`: [in] The executor parameters to use for the execution of the parallel algorithm the returned execution policy is used with.

`executor_type &executor()`

Return the associated executor object.

`constexpr executor_type const &executor() const`

Return the associated executor object.

`executor_parameters_type &parameters()`

Return the associated executor parameters object.

`constexpr executor_parameters_type const &parameters() const`

Return the associated executor parameters object.

**Private Functions**

`template<typename Archive>
void serialize(Archive&, const unsigned int)`

**Private Members**

`executor_type exec_`

`executor_parameters_type params_`
Friends

```cpp
friend hpx::execution::hpx::serialization::access
```

template<typename Executor_, typename Parameters_>
struct rebind

```cpp
#include <execution_policy.hpp>
```
Rebind the type of executor used by this execution policy. The execution category of Executor shall not be weaker than that of this execution policy.

Public Types

```cpp
typedef parallel_policy_shim<Executor_, Parameters_> type
```
The type of the rebound execution policy.

```cpp
template<typename Executor, typename Parameters>
struct parallel_policy_shim: public hpx::execution::parallel_policy
#include <execution_policy.hpp>
```
The class parallel_policy_shim is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm’s execution may be parallelized.

Public Types

```cpp
typedef Executor executor_type
```
The type of the executor associated with this execution policy.

```cpp
typedef Parameters executor_parameters_type
```
The type of the associated executor parameters object which is associated with this execution policy.

```cpp
typedef hpx::traits::executor_execution_category<executor_type>::type execution_category
```
The category of the execution agents created by this execution policy.

Public Functions

```cpp
constexpr parallel_task_policy_shim<Executor, Parameters> operator() (task_policy_tag) const
```
Create a new parallel_policy referencing a chunk size.

Return The new parallel_policy

Parameters

- `tag`: [in] Specify that the corresponding asynchronous execution policy should be used

```cpp
template<typename Executor_>
parallel::execution::rebind_executor<parallel_policy_shim, Executor_, executor_parameters_type>::type on (Executor_&& exec)
const
```
Create a new parallel_policy from the given executor.

Note Requires: is_executor<Executor>::value is true

Return The new parallel_policy

Template Parameters

- `Executor`: The type of the executor to associate with this execution policy.

Parameters
• **exec**: [in] The executor to use for the execution of the parallel algorithm the returned execution policy is used with.

```cpp
template<typename ...Parameters_, typename ParametersType = typename parallel::execution::executor_policy<parallel::execution::rebind_executor<parallel_policy_shim, executor_type, ParametersType>::type with (Parameters_, params) const

Create a new `parallel_policy_shim` from the given execution parameters

**Note** Requires: is_executor_parameters<Parameters>::value is true

**Return** The new `parallel_policy_shim`

**Template Parameters**
- **Parameters**: The type of the executor parameters to associate with this execution policy.

**Parameters**
- **params**: [in] The executor parameters to use for the execution of the parallel algorithm the returned execution policy is used with.

Executor &`executor`()
Return the associated executor object.

```cpp
constexpr Executor const &executor() const
Return the associated executor object.
```

Parameters &`parameters`()
Return the associated executor parameters object.

```cpp
constexpr Parameters const &parameters() const
Return the associated executor parameters object.
```

```cpp
template<typename Executor_, typename Parameters_>
struct rebind
#include <execution_policy.hpp> Rebind the type of executor used by this execution policy. The execution category of Executor shall not be weaker than that of this execution policy

**Public Types**

```cpp
template<>
typedef parallel_policy_shim<Executor_, Parameters_> type
The type of the rebound execution policy.
```

```cpp
struct parallel_task_policy
#include <execution_policy.hpp> Extension: The class `parallel_task_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm’s execution may be parallelized.

The algorithm returns a future representing the result of the corresponding algorithm when invoked with the `parallel_policy`.

Subclassed by `hpx::execution::parallel_task_policy_shim< Executor, Parameters >`
Public Types

typedef parallel_executor executor_type
The type of the executor associated with this execution policy.

typedef parallel::execution::extract_executor_parameters<executor_type>::type executor_parameters_type
The type of the associated executor parameters object which is associated with this execution policy.

typedef parallel_execution_tag execution_category
The category of the execution agents created by this execution policy.

Public Functions

constexpr parallel_task_policy operator() (task_policy_tag) const
Create a new parallel_task_policy from itself.

   Return  The new parallel_task_policy
   Parameters
       • tag: [in] Specify that the corresponding asynchronous execution policy should be used

template<typename Executor>
parallel::execution::rebind_executor<parallel_task_policy, Executor, executor_parameters_type>::type on(Executor &&exec) const
Create a new parallel_task_policy from given executor

   Note  Requires: is_executor<Executor>::value is true
   Return  The new parallel_task_policy
   Template Parameters
       • Executor: The type of the executor to associate with this execution policy.
   Parameters
       • exec: [in] The executor to use for the execution of the parallel algorithm the returned execution policy is used with.

template<typename ...Parameters, typename ParametersType = typename parallel::execution::executor_parameters<parallel_task_policy, executor_type, ParametersType>::type with (Parameters&... params) const
Create a new parallel_policy_shim from the given execution parameters

   Note  Requires: all parameters are executor_parameters, different parameter types can’t be duplicated
   Return  The new parallel_policy_shim
   Template Parameters
       • Parameters: The type of the executor parameters to associate with this execution policy.
   Parameters
       • params: [in] The executor parameters to use for the execution of the parallel algorithm the returned execution policy is used with.

executor_type &executor ()
Return the associated executor object.
constexpr executor_type const &executor() const
    Return the associated executor object.

executor_parameters_type &parameters()
    Return the associated executor parameters object.

constexpr executor_parameters_type const &parameters() const
    Return the associated executor parameters object.

  • exec: [in] The executor to use for the execution of the parallel algorithm the returned execution policy is used with.
```

template<typename ...Parameters_, typename ParametersType = typename parallel::execution::executor_parameters::type with (Parameters_&&... params)
    parallel::execution::rebind_executor<sequenced_task_policy_shim, executor_type, ParametersType>::type with
    (Parameters_ &&... params)

Create a new sequenced_task_policy_shim from the given execution parameters

```cpp
Note  Requires: all parameters are executor_parameters, different parameter types can’t be duplicated
Return  The new sequenced_task_policy_shim
Template Parameters
  • Parameters: The type of the executor parameters to associate with this execution policy.
Parameters
  • params: [in] The executor parameters to use for the execution of the parallel algorithm the returned execution policy is used with.
```

Executor & executor ()

Return the associated executor object.

```cpp
constexpr Executor const & executor () const

Return the associated executor object.
```

Parameters &parameters ()

Return the associated executor parameters object.

```cpp
constexpr Parameters const & parameters () const

Return the associated executor parameters object.
```

```cpp
template<typename Executor_, typename Parameters_>
struct rebind

#include <execution_policy.hpp>  Rebind the type of executor used by this execution policy. The execution category of Executor shall not be weaker than that of this execution policy
```
Public Types

template<>

typedef sequenced_task_policy_shim<Executor_, Parameters_> type

The type of the rebound execution policy.

namespace parallel

namespace execution

Typedefs

typedef hpx::execution::sequenced_executor instead

namespace hpx

namespace execution

namespace experimental

class fork_join_executor

#include <fork_join_executor.hpp> An executor with fork-join (blocking) semantics.

The fork_join_executor creates on construction a set of worker threads that are kept alive for the duration of the executor. Copying the executor has reference semantics, i.e. copies of a fork_join_executor hold a reference to the worker threads of the original instance. Scheduling work through the executor concurrently from different threads is undefined behaviour.

The executor keeps a set of worker threads alive for the lifetime of the executor, meaning other work will not be executed while the executor is busy or waiting for work. The executor has a customizable delay after which it will yield to other work. Since starting and resuming the worker threads is a slow operation the executor should be reused whenever possible for multiple adjacent parallel algorithms or invocations of bulk_(a)sync_execute.

Public Types

enum loop_schedule

Type of loop schedule for use with the fork_join_executor. loop_schedule::static_ implies no work-stealing; loop_schedule::dynamic allows stealing when a worker has finished its local work.

Values:

static_

dynamic
Public Functions

`fork_join_executor` (threads::thread_priority priority = threads::thread_priority::high, threads::thread_stacksize stacksize = threads::thread_stacksize::small_, loop_schedule schedule = loop_schedule::static_, std::chrono::nanoseconds yield_delay = std::chrono::milliseconds(1))

Construct a `fork_join_executor`.

Parameters

- `priority`: The priority of the worker threads.
- `stacksize`: The stacksize of the worker threads.
- `schedule`: The loop schedule of the parallel regions.
- `yield_delay`: The time after which the executor yields to other work if it hasn’t received any new work for bulk execution.

pack_traversal

The contents of this module can be included with the header `hpx/modules/pack_traversal.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/pack_traversal.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

```cpp
namespace hpx
```

```cpp
namespace util
```

Functions

```cpp
template<typename Mapper, typename... T><unspecified> hpx::util::map_pack(Mapper &&mapper, T &&... pack)
```

Maps the pack with the given mapper.

This function tries to visit all plain elements which may be wrapped in:
- homogeneous containers (`std::vector, std::list`)
- heterogeneous containers (`hpx::tuple, std::pair, std::array`) and re-assembles the pack with the result of the mapper. Mapping from one type to a different one is supported. Elements that aren’t accepted by the mapper are routed through and preserved through the hierarchy.
// Maps all integers to floats
map_pack([](int value) {
    return float(value);
},
1, hpx::make_tuple(2, std::vector<int>{3, 4}), 5);

Return  The mapped element or in case the pack contains multiple elements, the pack is wrapped into a hpx::tuple.

Exceptions
  • std::exception: like objects which are thrown by an invocation to the mapper.

Parameters
  • mapper: A callable object, which accept an arbitrary type and maps it to another type or the same one.
  • pack: An arbitrary variadic pack which may contain any type.

namespace hpx

namespace util

Functions

template<typename Visitor, typename ...T>
auto traverse_pack_async(Visitor &&visitor, T &&...pack)
Traverses the pack with the given visitor in an asynchronous way.

This function works in the same way as traverse_pack, however, we are able to suspend and continue the traversal at later time. Thus we require a visitor callable object which provides three operator() overloads as depicted by the code sample below:

```cpp
struct my_async_visitor
{
    template <typename T>
    bool operator()(async_traverse_visit_tag, T&& element)
    {
        return true;
    }

    template <typename T, typename N>
    void operator()(async_traverse_detach_tag, T&& element, N&& next)
    {
    }

    template <typename T>
    void operator()(async_traverse_complete_tag, T&& pack)
    {
    }
};
```

See traverse_pack for a detailed description about the traversal behavior and capabilities.

Return  A hpx::intrusive_ptr that references an instance of the given visitor object.

Parameters
• **visitor**: A visitor object which provides the three `operator()` overloads that were described above. Additionally the visitor must be compatible for referencing it from a `hpx::intrusive_ptr`. The visitor should must have a virtual destructor!
• **pack**: The arbitrary parameter pack which is traversed asynchronously. Nested objects inside containers and tuple like types are traversed recursively.

```cpp
template<typename Allocator, typename Visitor, typename ...T>
auto traverse_pack_async_allocator(Allocator const &alloc, Visitor &&visitor, T&&... pack)

Traverses the pack with the given visitor in an asynchronous way.

This function works in the same way as `traverse_pack`, however, we are able to suspend and continue the traversal at later time. Thus we require a visitor callable object which provides three `operator()` overloads as depicted by the code sample below:

```cpp
struct my_async_visitor
{
  template <typename T>
  bool operator()(async_traverse_visit_tag, T&& element)
  {
    return true;
  }

  template <typename T, typename N>
  void operator()(async_traverse_detach_tag, T&& element, N&& next)
  {
  }

  template <typename T>
  void operator()(async_traverse_complete_tag, T&& pack)
  {
  }
};
```

See `traverse_pack` for a detailed description about the traversal behavior and capabilities.

**Return** A `hpx::intrusive_ptr` that references an instance of the given visitor object.

**Parameters**
• **visitor**: A visitor object which provides the three `operator()` overloads that were described above. Additionally the visitor must be compatible for referencing it from a `hpx::intrusive_ptr`. The visitor should must have a virtual destructor!
• **pack**: The arbitrary parameter pack which is traversed asynchronously. Nested objects inside containers and tuple like types are traversed recursively.
• **alloc**: Allocator instance to use to create the traversal frame.

```cpp
namespace hpx
{
  namespace util
  {
    // API definitions go here
  }
}
```

2.8. API reference
### Functions

```cpp
template<typename ...Args>
auto unwrap (Args&&... args)

A helper function for retrieving the actual result of any hpx::lcos::future like type which is wrapped in an arbitrary way.

Unwraps the given pack of arguments, so that any hpx::lcos::future object is replaced by its future result type in the argument pack:

- hpx::future<int> -> int
- hpx::future<std::vector<float>> -> std::vector<float>
- std::vector<hpx::future<float>> -> std::vector<float>

The function is capable of unwrapping hpx::lcos::future like objects that are wrapped inside any container or tuple like type, see hpx::util::map_pack() for a detailed description about which surrounding types are supported. Non hpx::lcos::future like types are permitted as arguments and passed through.
```

```cpp
// Single arguments
int i1 = hpx::util::unwrap(hpx::lcos::make_ready_future(0));

// Multiple arguments
hpx::tuple<int, int> i2 =
    hpx::util::unwrap(hpx::lcos::make_ready_future(1),
                      hpx::lcos::make_ready_future(2));
```

**Note** This function unwraps the given arguments until the first traversed nested hpx::lcos::future which corresponds to an unwrapping depth of one. See hpx::util::unwrap_n() for a function which unwraps the given arguments to a particular depth or hpx::util::unwrap_all() that unwraps all future like objects recursively which are contained in the arguments.

**Return** Depending on the count of arguments this function returns a hpx::tuple containing the unwrapped arguments if multiple arguments are given. In case the function is called with a single argument, the argument is unwrapped and returned.

**Parameters**
- `args`: the arguments that are unwrapped which may contain any arbitrary future or non future type.

**Exceptions**
- `std::exception`: like objects in case any of the given wrapped hpx::lcos::future objects were resolved through an exception. See hpx::lcos::future::get() for details.

```cpp
template<std::size_t Depth, typename ...Args>
auto unwrap_n (Args&&... args)

An alterntive version of hpx::util::unwrap(), which unwraps the given arguments to a certain depth of hpx::lcos::future like objects.
```

See unwrap for a detailed description.

**Template Parameters**
- `Depth`: The count of hpx::lcos::future like objects which are unwrapped maximally.

```cpp
template<typename ...Args>
auto unwrap_all (Args&&... args)

An alterntive version of hpx::util::unwrap(), which unwraps the given arguments recursively so that all contained hpx::lcos::future like objects are replaced by their actual value.
```

See hpx::util::unwrap() for a detailed description.
template<typename T>
auto unwrapping (T & & callable)

Returns a callable object which unwraps its arguments upon invocation using the hpx::util::unwrap() function and then passes the result to the given callable object.

```cpp
auto callable = hpx::util::unwrapping([](int left, int right) {
    return left + right;
});
int i1 = callable(hpx::lcos::make_ready_future(1),
                   hpx::lcos::make_ready_future(2));
```

See hpx::util::unwrap() for a detailed description.

**Parameters**

- `callable`: the callable object which which is called with the result of the corresponding unwrap function.

---

template<std::size_t Depth, typename T>
auto unwrapping_n (T & & callable)

Returns a callable object which unwraps its arguments upon invocation using the hpx::util::unwrap_n() function and then passes the result to the given callable object.

See hpx::util::unwrapping() for a detailed description.

---

template<typename T>
auto unwrapping_all (T & & callable)

Returns a callable object which unwraps its arguments upon invocation using the hpx::util::unwrap_all() function and then passes the result to the given callable object.

See hpx::util::unwrapping() for a detailed description.

The contents of this module can be included with the header hpx/modules/thread_pool_util.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/thread_pool_util.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

namespace hpx

namespace threads

Functions

hpx::future<void> resume_processing_unit (thread_pool_base &pool, std::size_t virt_core)

Resumes the given processing unit. When the processing unit has been resumed the returned future will be ready.

Note Can only be called from an HPX thread. Use resume_processing_unit_cb or to resume the processing unit from outside HPX. Requires that the pool has threads::policies::enable_elasticity set.

Return A future<void> which is ready when the given processing unit has been resumed.

Parameters
• virt_core: [in] The processing unit on the the pool to be resumed. The processing units are indexed starting from 0.

void resume_processing_unit_cb (thread_pool_base &pool, util::function_nonser< void > callback, std::size_t virt_core, error_code &ec = throws)

Resumes the given processing unit. Takes a callback as a parameter which will be called when the processing unit has been resumed.

Note Requires that the pool has threads::policies::enable_elasticity set.

Parameters
• callback: [in] Callback which is called when the processing unit has been suspended.
• virt_core: [in] The processing unit to resume.
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
hpx::future<void> suspend_processing_unit (thread_pool_base &pool, std::size_t virt_core)
```

Suspends the given processing unit. When the processing unit has been suspended the returned future will be ready.

**Note** Can only be called from an HPX thread. Use `suspend_processing_unit` or to suspend the processing unit from outside HPX. Requires that the pool has `threads::policies::enable_elasticity` set.

**Return** A `future<void>` which is ready when the given processing unit has been suspended.

**Parameters**
- `virt_core`: [in] The processing unit on the the pool to be suspended. The processing units are indexed starting from 0.

**Exceptions**
- `hpx::exception`: if called from outside the HPX runtime.

```cpp
void suspend_processing_unit_cb (util::function_nonser<void> callback, thread_pool_base &pool, std::size_t virt_core, error_code &ec = throws)
```

Suspends the given processing unit. Takes a callback as a parameter which will be called when the processing unit has been suspended.

**Note** Requires that the pool has `threads::policies::enable_elasticity` set.

**Parameters**
- `callback`: [in] Callback which is called when the processing unit has been suspended.
- `virt_core`: [in] The processing unit to suspend.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
hpx::future<void> resume_pool (thread_pool_base &pool)
```

Resumes the thread pool. When the all OS threads on the thread pool have been resumed the returned future will be ready.

**Note** Can only be called from an HPX thread. Use `resume_cb` or `resume_direct` to suspend the pool from outside HPX.

**Return** A `future<void>` which is ready when the thread pool has been resumed.

**Exceptions**
- `hpx::exception`: if called from outside the HPX runtime.

```cpp
void resume_pool_cb (thread_pool_base &pool, util::function_nonser<void> callback, error_code &ec = throws)
```

Resumes the thread pool. Takes a callback as a parameter which will be called when all OS threads on the thread pool have been resumed.

**Parameters**
- `callback`: [in] called when the thread pool has been resumed.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
hpx::future<void> suspend_pool (thread_pool_base &pool)
```

Suspends the thread pool. When the all OS threads on the thread pool have been suspended the returned future will be ready.
Note Can only be called from an HPX thread. Use suspend_cb or suspend_direct to suspend the pool from outside HPX. A thread pool cannot be suspended from an HPX thread running on the pool itself.

Return A future<void> which is ready when the thread pool has been suspended.

Exceptions
  • hpx::exception: if called from outside the HPX runtime.

```cpp
void suspend_pool_cb(thread_pool_base &pool, util::function_nonser<void> callback, error_code &ec) = throws
```

Suspends the thread pool. Takes a callback as a parameter which will be called when all OS threads on the thread pool have been suspended.

Note A thread pool cannot be suspended from an HPX thread running on the pool itself.

Parameters
  • callback: [in] called when the thread pool has been suspended.
  • ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

Exceptions
  • hpx::exception: if called from an HPX thread which is running on the pool itself.

timed_execution

The contents of this module can be included with the header hpx/modules/timed_execution.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/timed_execution.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

2.9 Contributing to HPX

HPX development happens on Github. The following sections are a collection of useful information related to HPX development.

2.9.1 Contributing to HPX

The main source of information to understand the process of how to contribute to HPX can be found in this document[244]. This is a living document that is constantly updated with relevant information.

2.9.2 HPX governance model

The HPX project is a meritocratic, consensus-based community project. Anyone with an interest in the project can join the community, contribute to the project design and participate in the decision making process. This document[245] describes how that participation takes place and how to set about earning merit within the project community.

2.9.3 Release procedure for HPX

Below is a step by step procedure for making an HPX release. We aim to produce two releases per year: one in March-April, and one in September-October.

This is a living document and may not be totally current or accurate. It is an attempt to capture current practices in making an HPX release. Please update it as appropriate.

One way to use this procedure is to print a copy and check off the lines as they are completed to avoid confusion.

1. Notify developers that a release is imminent.

2. Write release notes in docs/sphinx/releases/whats_new_$VERSION.rst. Keep adding merged PRs and closed issues to this until just before the release is made. Use tools/generate_pr_issue_list.sh to generate the lists. Add the new release notes to the table of contents in docs/sphinx/releases.rst.

3. Build the docs, and proof-read them. Update any documentation that may have changed, and correct any typos. Pay special attention to:
   - $HPX_SOURCE/README.rst
     - Update grant information
   - docs/sphinx/releases/whats_new_$VERSION.rst
   - docs/sphinx/about_hpx/people.rst
     - Update collaborators
     - Update grant information

4. This step does not apply to patch releases. For both APEX and libCDS:
   - Change the release branch to be the most current release tag available in the APEX/libCDS git_external section in the main CMakeLists.txt. Please contact the maintainers of the respective packages to generate a new release to synchronize with the HPX release (APEX[246], libCDS[247]).

---

244 https://github.com/STEllAR-GROUP/hpx/blob/master/.github/CONTRIBUTING.md
245 http://hpx.stellar-group.org/documents/governance/
246 http://github.com/khuck/xpress-apex
247 https://github.com/STEllAR-GROUP/libcds
5. If there have been any commits to the release branch since the last release, create a tag from the old release branch before deleting the old release branch in the next step.

6. Unprotect the release branch in the github repository settings so that it can be deleted and recreated (tick “Allow force pushes” in the release branch settings of the repository).

7. Reset the release branch to the latest stable state on master and force push to origin/release. If you are creating a patch release, branch from the release tag for which you want to create a patch release.
   
   • `git checkout -b release` (or just `checkout` in case the it exists)
   • `git reset --hard stable`
   • `git push --force origin release`

8. Protect the release branch again to disable force pushes.

9. Check out the release branch.

10. Make sure `HPX_VERSION_MAJOR/MINOR/SUBMINOR` in `CMakeLists.txt` contain the correct values. Change them if needed.

11. This step does not apply to patch releases. Remove features which have been deprecated for at least 2 releases. This involves removing build options which enable those features from the main `CMakeLists.txt` and also deleting all related code and tests from the main source tree.

   The general deprecation policy involves a three-step process we have to go through in order to introduce a breaking change:
   
   a. First release cycle: add a build option that allows for explicitly disabling any old (now deprecated) code.
   
   b. Second release cycle: turn this build option OFF by default.
   
   c. Third release cycle: completely remove the old code.

   The main `CMakeLists.txt` contains a comment indicating for which version the breaking change was introduced first. In the case of deprecated features which don’t have a replacement yet, we keep them around in case (like Vc for example).

12. Update the minimum required versions if necessary (compilers, dependencies, etc.) in `building_hpx.rst`.

13. Verify that the jenkins setup for the release branch on rostam is running and does not display any errors.

14. Repeat the following steps until satisfied with the release.

   1. Change `HPX_VERSION_TAG` in `CMakeLists.txt` to `-rcN`, where N is the current iteration of this step. Start with `-rc1`.

   2. Create a pre-release on GitHub using the script `tools/roll_release.sh`. This script automatically tag with the corresponding release number. The script requires that you have the STEllAR Group signing key.

   3. This step is not necessary for patch releases. Notify `hpx-users@stellar-group.org` and `stellar@cct.lsu.edu` of the availability of the release candidate. Ask users to test the candidate by checking out the release candidate tag.

   4. Allow at least a week for testing of the release candidate.

      • Use `git merge` when possible, and fall back to `git cherry-pick` when needed. For patch releases `git cherry-pick` is most likely your only choice if there have been significant unrelated changes on master since the previous release.

      • Go back to the first step when enough patches have been added.

      • If there are no more patches, continue to make the final release.
15. Update any occurrences of the latest stable release to refer to the version about to be released. For example, quickstart.rst contains instructions to check out the latest stable tag. Make sure that refers to the new version.

16. Add a new entry to the RPM changelog (cmake/packaging/rpm/Changelog.txt) with the new version number and a link to the corresponding changelog.

17. Change HPX_VERSION_TAG in CMakeLists.txt to an empty string.

18. Add the release date to the caption of the current “What’s New” section in the docs, and change the value of HPX_VERSION_DATE in CMakeLists.txt.

19. Create a release on GitHub using the script tools/roll_release.sh. This script automatically tag the with the corresponding release number. The script requires that you have the STE||AR Group signing key.

   - Update links on the downloads page. Link to the release on GitHub.
   - Documentation links on the docs page (link to generated documentation on GitHub Pages). Follow the style of previous releases.
   - A new blog post announcing the release, which links to downloads and the “What’s New” section in the documentation (see previous releases for examples).

21. Merge release branch into master.

22. Post-release cleanup. Create a new pull request against master with the following changes:
   1. Modify the release procedure if necessary.
   2. Change HPX_VERSION_TAG in CMakeLists.txt back to -trunk.
   3. Increment HPX_VERSION_MINOR in CMakeLists.txt.

23. Update Vcpkg (https://github.com/Microsoft/vcpkg) to pull from latest release.
   - Update version number in CONTROL
   - Update tag and SHA512 to that of the new release

   - Update version number in hpx/package.py and SHA256 to that of the new release

25. Announce the release on hpx-users@stellar-group.org, stellar@ctl.lsu.edu, allcct@ctl.lsu.edu, faculty@csc.lsu.edu, faculty@ece.lsu.edu, xpress@crest.iu.edu, the HPX Slack channel, the IRC channel, Sonia Sachs, our list of external collaborators, iso.cpp.org, reddit.com, HPC Wire, Inside HPC, Heise Online, and a CCT press release.

2.9.4 Testing HPX

To ensure correctness of HPX, we ship a large variety of unit and regression tests. The tests are driven by the CTest tool and are executed automatically by buildbot (see HPX Buildbot Website) on each commit to the HPX Github repository. In addition, it is encouraged to run the test suite manually to ensure proper operation on your target system. If a test fails for your platform, we highly recommend submitting an issue on our HPX Issues tracker with detailed information about the target system.

Running tests manually

Running the tests manually is as easy as typing `make tests && make test`. This will build all tests and run them once the tests are built successfully. After the tests have been built, you can invoke separate tests with the help of the `ctest` command. You can list all available test targets using `make help | grep tests`. Please see the CTest Documentation for further details.

Issue tracker

If you stumble over a bug or missing feature in HPX, please submit an issue to our HPX Issues page. For more information on how to submit support requests or other means of getting in contact with the developers, please see the Support Website page.

Continuous testing

In addition to manual testing, we run automated tests on various platforms. You can see the status of the current master head by visiting the HPX Buildbot Website. We also run tests on all pull requests using both CircleCI and a combination of CDash and pycicle. You can see the dashboards here: CircleCI HPX dashboard and CDash HPX dashboard.

2.9.5 Using docker for development

Although it can often be useful to set up a local development environment with system-provided or self-built dependencies, Docker provides a convenient alternative to quickly get all the dependencies needed to start development of HPX. Our testing setup on CircleCI uses a docker image to run all tests.

To get started you need to install Docker using whatever means is most convenient on your system. Once you have Docker installed, you can pull or directly run the docker image. The image is based on Debian and Clang, and can

263 https://cdash.cscs.ch/index.php?project=HPX
264 https://www.docker.com
265 https://circleci.com
266 https://www.docker.com
267 https://www.docker.com
be found on Docker Hub\textsuperscript{268}. To start a container using the HPX build environment, run:

```
docker run --interactive --tty stellargroup/build_env:latest bash
```

You are now in an environment where all the HPX build and runtime dependencies are present. You can install additional packages according to your own needs. Please see the Docker Documentation\textsuperscript{269} for more information on using Docker\textsuperscript{270}.

**Warning:** All changes made within the container are lost when the container is closed. If you want files to persist (e.g., the HPX source tree) after closing the container, you can bind directories from the host system into the container (see Docker Documentation (Bind mounts)\textsuperscript{271}).

### 2.9.6 Documentation

This documentation is built using Sphinx\textsuperscript{272}, and an automatically generated API reference using Doxygen\textsuperscript{273} and Breathe\textsuperscript{274}.

We always welcome suggestions on how to improve our documentation, as well as pull requests with corrections and additions.

#### Building documentation

Please see the documentation prerequisites section for details on what you need in order to build the HPX documentation. Enable building of the documentation by setting HPX\_WITH\_DOCUMENTATION=ON during CMake\textsuperscript{275} configuration. To build the documentation, build the docs target using your build tool. The default output format is HTML documentation. You can choose alternative output formats (single-page HTML, PDF, and man) with the HPX\_WITH\_DOCUMENTATION\_OUTPUT\_FORMATS CMake option.

**Note:** If you add new source files to the Sphinx documentation, you have to run CMake again to have the files included in the build.

#### Style guide

The documentation is written using reStructuredText. These are the conventions used for formatting the documentation:

- Use, at most, 80 characters per line.
- Top-level headings use over- and underlines with =.
- Sub-headings use only underlines with characters in decreasing level of importance: =, - and ..
- Use sentence case in headings.
- Refer to common terminology using :term:`Component`.

\textsuperscript{268} https://hub.docker.com/r/stellargroup/build_env/
\textsuperscript{269} https://docs.docker.com/
\textsuperscript{270} https://www.docker.com
\textsuperscript{271} https://docs.docker.com/storage/bind-mounts/
\textsuperscript{272} http://www.sphinx-doc.org
\textsuperscript{273} https://www.doxygen.org
\textsuperscript{274} https://breathe.readthedocs.io/en/latest
\textsuperscript{275} https://www.cmake.org
• Indent content of directives (. directive::) by three spaces.

• For C++ code samples at the end of paragraphs, use :: and indent the code sample by 4 spaces.
  – For other languages (or if you don’t want a colon at the end of the paragraph), use .. code-block::
    language and indent by three spaces as with other directives.

• Use .. list-table:: to wrap tables with a lot of text in cells.

API documentation

The source code is documented using Doxygen. If you add new API documentation either to existing or new source files, make sure that you add the documented source files to the doxygen_dependencies variable in docs/CMakeLists.txt.

2.9.7 Module structure

This section explains the structure of an HPX module.

The tool create_library_skeleton.py\(^{276}\) can be used to generate a basic skeleton. To create a library skeleton, run the tool in the libs subdirectory with the module name as an argument:

```
./create_library_skeleton <lib_name>
```

This creates a skeleton with the necessary files for an HPX module. It will not create any actual source files. The structure of this skeleton is as follows:

- `<lib_name>/`
  - README.rst
  - CMakeLists.txt
  - cmake
  - docs/
    * index.rst
  - examples/
    * CMakeLists.txt
  - include/
    * hpx/
      · `<lib_name>`
  - src/
    * CMakeLists.txt
  - tests/
    * CMakeLists.txt
    * unit/
      · CMakeLists.txt
    * regressions/

\(^{276}\) [https://github.com/STEllAR-GROUP/hpx/blob/master/libs/create_library_skeleton.py](https://github.com/STEllAR-GROUP/hpx/blob/master/libs/create_library_skeleton.py)

Chapter 2. What’s so special about HPX?
A README.rst should be always included which explains the basic purpose of the library and a link to the generated documentation.

A main CMakeLists.txt is created in the root directory of the module. By default it contains a call to add_hpx_module which takes care of most of the boilerplate required for a module. You only need to fill in the source and header files in most cases.

add_hpx_module requires a module name. Optional flags are:

Optional single-value arguments are:

- INSTALL_BINARIES: Install the resulting library.

Optional multi-value arguments are:

- SOURCES: List of source files.
- HEADERS: List of header files.
- COMPAT_HEADERS: List of compatibility header files.
- DEPENDENCIES: Libraries that this module depends on, such as other modules.
- CMAKE_SUBDIRS: List of subdirectories to add to the module.

The include directory should contain only headers that other libraries need. For each of those headers, an automatic header test to check for self containment will be generated. Private headers should be placed under the src directory. This allows for clear separation. The cmake subdirectory may include additional CMake scripts needed to generate the respective build configurations.

Compatibility headers (forwarding headers for headers whose location is changed when creating a module, if moving them from the main library) should be placed in an include_compatibility directory. This directory is not created by default.

Documentation is placed in the docs folder. A empty skeleton for the index is created, which is picked up by the main build system and will be part of the generated documentation. Each header inside the include directory will automatically be processed by Doxygen and included into the documentation. If a header should be excluded from the API reference, a comment // sphinx:undocumented needs to be added.

Tests are placed in suitable subdirectories of tests.

When in doubt, consult existing modules for examples on how to structure the module.

Finding circular dependencies

Our CI will perform a check to see if there are circular dependencies between modules. In cases where it’s not clear what is causing the circular dependency, running the cpp-dependencies tool manually can be helpful. It can give you detailed information on exactly which files are causing the circular dependency. If you do not have the cpp-dependencies tool already installed, one way of obtaining it is by using our docker image. This way you will have exactly the same environment as on the CI. See Using docker for development for details on how to use the docker image.

To produce the graph produced by CI run the following command (HPX_SOURCE is assumed to hold the path to the HPX source directory):

https://www.cmake.org

https://github.com/tomtom-international/cpp-dependencies
cpp-dependencies --dir $HPX_SOURCE/libs --graph-cycles circular_dependencies.dot

This will produce a dot file in the current directory. You can inspect this manually with a text editor. You can also convert this to an image if you have graphviz installed:

dot circular_dependencies.dot -Tsvg -o circular_dependencies.svg

This produces an svg file in the current directory which shows the circular dependencies. Note that if there are no cycles the image will be empty.

You can use cpp-dependencies to print the include paths between two modules.

cpp-dependencies --dir $HPX_SOURCE/libs --shortest <from> <to>

prints all possible paths from the module <from> to the module <to>. For example, as most modules depend on config, the following should give you a long list of paths from algorithms to config:

cpp-dependencies --dir $HPX_SOURCE/libs --shortest algorithms config

The following should report that it can’t find a path between the two modules:

cpp-dependencies --dir $HPX_SOURCE/libs --shortest config algorithms

2.10 Releases

2.10.1 HPX V1.6.0 (Feb 17, 2021)

General changes

This release continues the focus on C++20 conformance with multiple new algorithms adapted to be C++20 conformant and becoming customization point objects (CPOs). We have also added experimental support for HIP, allowing previous CUDA features to now be compiled with hipcc and run on AMD GPUs.

- The following algorithms have been adapted to be C++20 conformant: adjacent_find, includes, inplace_merge, is_heap, is_heap_until, is_partitioned, is_sorted, is_sorted_until, merge, set_difference, set_intersection, set_symmetric_difference, set_union.

- Experimental HIP support can be enabled by compiling HPX with hipcc. All CUDA functionality in HPX can now be used with HIP. The HIP functionality is for the time being exposed through the same API as the CUDA functionality, i.e. no changes are required in user code. The CUDA, and now HIP, functionality is in the hpx::cuda namespace.

- We have added partial_sort based on Francisco Tapia’s implementation.

- hpx::init and hpx::start gained new overloads taking an hpx::init_params struct in 1.5.0. All overloads not taking an hpx::init_params are now deprecated.

- We have added an experimental fork_join_executor. This executor can be used for OpenMP-style fork-join parallelism, where the latency of a parallel region is important for performance.

- The parallel_executor now uses a hierarchical spawning scheme for bulk execution, which improves data locality and performance.

- hpx::dataflow can now be used with executors that inject additional parameters into the call of the user-provided function.
We have added experimental support for properties as proposed in P2220\(^{279}\). Currently the only supported property is the scheduling hint on `parallel_executor`.

`hpx::util::annotated_function` can now be passed a dynamically generated `std::string`.

In moving functionality to new namespaces, old names have been deprecated. A deprecation warning will be issued if you are using deprecated functionality, with instructions on how to correct or ignore the warning.

We have removed all support for C and Fortran from our build system.

We have further reduced the use of Boost types within `HPX` (`boost::system::error_code` and `boost::detail::spinlock`).

We have enabled more warnings in our CI builds (unused variables and unused typedefs).

### Breaking changes

- hpxMP support has been completely removed.
- The `verbs` parcelport has been removed.
- The following compatibility options have been disabled by default: `HPX_WITH_ACTION_BASE_COMPATIBILITY`, `HPX_WITH_REGISTER_THREAD_COMPATIBILITY`, `HPX_WITH_PROMISE_ALIAS_COMPATIBILITY`, `HPX_WITH_UNSCOPED_ENUM_COMPATIBILITY`, `HPX_PROGRAM_OPTIONS_WITH_BOOST_PROGRAM_OPTIONS_COMPATIBILITY`, `HPX_WITH_EMBEDDED_THREAD_POOLS_COMPATIBILITY`, `HPX_THREAD_AWARE_TIMER_COMPATIBILITY`. Unless noted here, the above functionalities do not come with replacements. Unscoped enumerations have been replaced by scoped enumerations. Previously deprecated unscoped enumerations are disabled by `HPX_WITH_UNSCOPED_ENUM_COMPATIBILITY`. Newly deprecated unscoped enumerations have been given deprecation warnings and replaced by scoped enumerations. `hpx::promise` has been replaced with `hpx::distributed::promise`. `hpx::program_options` is a drop-in replacement for `boost::program_options`. `hpx::execution::parallel_executor` now has constructors which take a thread pool, covering the use case of `hpx::threads::executors::pool_executor`. A pool can be supplied with `hpx::resource::get_thread_pool`.

2.10.2 HPX V1.5.1 (Sep 30, 2020)

General changes

This is a patch release. It contains the following changes:

• Remove restriction on suspending runtime with multiple localities, users are now responsible for synchronizing work between localities before suspending.
• Fixes several compilation problems and warnings.
• Adds notes in the documentation explaining how to cite HPX.

Closed issues

• Issue #4971 - Parallel sort fails to compile with C++20
• Issue #4950 - Build with HPX_WITH_PARCELPORT_ACTION_COUNTERS ON fails
• Issue #4940 - Codespell report for “HPX” (on fossies.org)
• Issue #4937 - Allow suspension of runtime for multiple localities

2.10.3 HPX V1.5.0 (Sep 02, 2020)

General changes

The main focus of this release is on APIs and C++20 conformance. We have added many new C++20 features and adapted multiple algorithms to be fully C++20 conformant. As part of the modularization we have begun specifying the public API of HPX in terms of headers and functionality, and aligning it more closely to the C++ standard. All non-distributed modules are now in place, along with an experimental option to completely disable distributed features in HPX. We have also added experimental asynchronous MPI and CUDA executors. Lastly this release introduces CMake targets for depending projects, performance improvements, and many bug fixes.

- We have added the C++20 features `hpx::jthread` and `hpx::stop_token`. `hpx::condition_variable_any` now exposes new functions supporting `hpx::stop_token`.
- We have added `hpx::stable_sort` based on Francisco Tapia’s implementation.
- We have adapted existing synchronization primitives to be fully conformant C++20: `hpx::barrier`, `hpx::latch`, `hpx::counting_semaphore`, and `hpx::binary_semaphore`.
- We have started using customization point objects (CPOs) to make the corresponding algorithms fully conformant to C++20 as well as to make algorithm extension easier for the user. `all_of/any_of/hone_of`, `copy`, `count`, `destroy`, `equal`, `fill`, `find`, `for_each`, `generate`, `mismatch`, `move`, `reduce`, `transform_reduce` are using those CPOs (all in namespace `hpx`). We also have adapted their corresponding `hpx::ranges` versions to be conforming to C++20 in this release.
- We have adapted support for `co_await` to C++20, in addition to `hpx::future` it now also supports `hpx::shared_future`. We have also added allocator support for futures returned by `co_return`. It is no longer in the experimental namespace.
- We added serialization support for `std::variant` and `std::tuple`.

\(^{467}\) https://github.com/STEllAR-GROUP/hpx/pull/4939
• `result_of` and `is_callable` are now deprecated and replaced by `invoke_result` and `is_invocable` to conform to C++20.

• We continued with the modularization, making it easier for us to add the new experimental HPX_WITH_DISTRIBUTED_RUNTIME CMake option (see below). An significant amount of headers have been deprecated. We adapted the namespaces and headers we could to be closer to the standard ones (Public API). Depending code should still compile, however warnings are now generated instructing to change the include statements accordingly.

• It is now possible to have a basic CUDA support including a helper function to get a future from a CUDA stream and target handling. They are available under the `hpx::cuda::experimental` namespace and they can be enabled with the `-DHPX_WITHASYNC_CUDA=ON` CMake option.

• We added a new `hpx::mpi::experimental` namespace for getting futures from an asynchronous MPI call and a new minimal MPI executor `hpx::mpi::experimental::executor`. These can be enabled with the `-DHPX_WITHASYNC_MPI=ON` CMake option.

• A polymorphic executor has been implemented to reduce compile times as a function accepting executors can potentially be instantiated only once instead of multiple times with different executors. It accepts the function signature as a template argument. It needs to be constructed from any other executor. Please note, that the function signatures that can be scheduled using `then_execute`, `bulk_sync_execute`, `bulk_async_execute` and `bulk_then_execute` are slightly different (See the comment in PR #4514 for more details).

• The underlying executor of `block_executor` has been updated to a newer one.

• We have added a parameter to `auto_chunk_size` to control the amount of iterations to measure.

• All executor parameter hooks can now be exposed through the executor itself. This will allow to deprecate the `.with()` functionality on execution policies in the future. This is also a first step towards simplifying our executor APIs in preparation for the upcoming C++23 executors (senders/receivers).

• We have moved all of the existing APIs related to resiliency into the namespace `hpx::resiliency::experimental`. Please note this is a breaking change without backwards-compatibility option. We have converted all of those APIs to be based on customization point objects. Two new executors have been added to enable easy integration of the existing resiliency features with other facilities (like the parallel algorithms): `replay_executor` and `replicate_executor`.

• We have added performance counters type information (aggregating, monotonically increasing, average count, average timer, etc.).

• HPX threads are now re-scheduled on the same worker thread they were suspended on to avoid cache misses from moving from one thread to the other. This behavior doesn’t prevent the thread from being stolen, however.

• We have added a new configuration option `hpx::exception_verbosity` to allow to control the level of verbosity of the exceptions (3 levels available).

• `broadcast_to, broadcast_from, scatter_to and scatter_from` have been added to the collectives, modernization of `gather_here` and `gather_there` with futures taken by rvalue references. See the breaking change on `all_to_all` in the next section. None of the collectives need supporting macros anymore (e.g. specifying the data types used for a collective operation using `HPX_REGISTER_ALLGATHER` and similar is not needed anymore).

• New API functions have been added: a) to get the number of cores which are idle (`hpx::get_idle_core_count`) and b) returning a bitmask representing the currently idle cores (`hpx::get_idle_core_mask`).

• We have added an experimental option to only enable the local runtime, you can disable the distributed runtime with `HPX_WITH_DISTRIBUTED_RUNTIME=OFF`. You can also enable the local runtime by using the

468 https://github.com/STEllAR-GROUP/hpx/pull/4514
--hpx:local runtime option.

- We fixed task annotations for actions.
- The alias hpx::promise to hpx::lcos::promise is now deprecated. You can use hpx::lcos::promise directly instead. hpx::promise will refer to the local-only promise in the future.
- We have added a prepare_checkpoint API function that calculates the amount of necessary buffer space for a particular set of arguments checkpointed.
- We have added hpx::upgrade_lock and hpx::upgrade_to_unique_lock, which make hpx::shared_mutex (and similar) usable in more flexible ways.
- We have changed the CMake targets exposed to the user, it now includes HPX::hpx, HPX::wrap_main (int main as the first HPX thread of the application, see Starting the HPX runtime), HPX::plugin, HPX::component. The CMake variables HPX_INCLUDE_DIRS and HPX_LIBRARIES are deprecated and will be removed in a future release, you should now link directly to the HPX::hpx CMake target.
- A new example is demonstrating how to create and use a wrapping executor (quickstart/executor_with_thread_hooks.cpp)
- A new example is demonstrating how to disable thread stealing during the execution of parallel algorithms (quickstart/disable_thread_stealing_executor.cpp)
- We now require for our CMake build system configuration files to be formatted using cmake-format.
- We have removed more dependencies on various Boost libraries.
- We have added an experimental option enabling unity builds of HPX using the -DHPX_WITH_UNITY_BUILD=On CMake option.
- Many bug fixes.

**Breaking changes**

- HPX now requires a C++14 capable compiler. We have set the HPX C++ standard automatically to C++14 and if it needs to be set explicitly, it should be specified through the CMAKE_CXX_STANDARD setting as mandated by CMake. The HPX_WITH_CXX* variables are now deprecated and will be removed in the future.
- Building and using HPX is now supported only when using CMake V3.13 or later, Boost V1.64 or newer, and when compiling with clang V5, gcc V7, or VS2019, or later. Other compilers might still work but have not been tested thoroughly.
- We have added a hpx::init_params struct to pass parameters for HPX initialization e.g. the resource partitioner callback to initialize thread pools (Using the resource partitioner).
- The all_to_all algorithm is renamed to all_gather, and the new all_to_all algorithm is not compatible with the old one.
- We have moved all of the existing APIs related to resiliency into the namespace hpx::resiliency::experimental.

• Issue #4470\footnote{https://github.com/STEllAR-GROUP/hpx/issues/4470} - Adapt hpx::future to C++20 co\_await

2.10. Releases
• Issue #4468 - Compile error on Raspberry Pi 4
• Issue #4466 - Compile error on Windows, current stable:
• Issue #4453 - Installing HPX on fedora with dnf is not adding emake files
• Issue #4448 - New std::variant serialization broken
• Issue #4438 - Add performance counter flag is monotonically increasing
• Issue #4436 - Build problem: same code build and works with 1.4.0 but it doesn’t with 1.4.1
• Issue #4429 - Function descriptions not supported in distributed
• Issue #4423 - --hpx.ini=hpx.lock_detection=0 has no effect
• Issue #4422 - Add performance counter metadata
• Issue #4419 - Weird behavior for --hpx:print-counter-interval with large numbers
• Issue #4401 - Create module repository
• Issue #4400 - Command line options conflict related to performance counters
• Issue #4349 - --hpx:use-process-mask option throw an exception on OS X
• Issue #4345 - Move gh-pages branch out of hpx repo
• Issue #4323 - Const-correctness error in assignment operator of compute::vector
• Issue #4318 - ASIO breaks with C++2a concepts
• Issue #4317 - Application runs even if --hpx:help is specified
• Issue #4063 - Document hpxcxx compiler wrapper
• Issue #3983 - Implement the C++20 Synchronization Library
• Issue #3696 - C++11 constexpr support is now required
• Issue #3623 - Modular HPX branch and an alternative project layout
• Issue #2836 - The worst-case time complexity of parallel::sort seems to be O(N^2).

• PR #4873 - Set CUDA compute capability on rostam Jenkins builds
• PR #4872 - Force partitioned vector scan tests to run serially
• PR #4870 - Making move conforming with C++20
• PR #4869 - Making destroy and destroy_n conforming to C++20
• PR #4868 - Fix miscellaneous header problems
• PR #4867 - Add CPOs for for_each
• PR #4865 - Adapting count and count_if to be conforming to C++20
• PR #4864 - Release notes 1.5.0
• PR #4863 - Adding libcds-hpx tag to prepare for hpx1.5 release
• PR #4862 - Adding version specific deprecation options
• PR #4861 - Limiting executor improvements
• PR #4860 - Making fill and fill_n compatible with C++20
• PR #4859 - Adapting all_of, any_of, and none_of to C++20
• PR #4857 - Improve libCDS integration
• PR #4856 - Correct typos in the documentation of the hpx performance counters
• PR #4855 - Removing obsolete code
• PR #4854 - Adding test that derives component from two other components
• PR #4852 - Fix mpi_ring test in distributed mode by ensuring all ranks run hpx_main
• PR #4851 - Converting resiliency APIs to tag_invoke based CPOs
• PR #4849 - Enable use of future_overhead test when DISTRIBUTED_RUNTIME is OFF
• PR #4847 - Fixing ‘error prone’ constructs as reported by Codacy
• PR #4846 - Disable Boost.Asio concepts support
• PR #4845 - Fix PAPI counters

2.10. Releases
• PR #4843 - Remove dependency on various Boost headers
• PR #4841 - Rearrange public API headers
• PR #4840 - Fixing TSS problems during thread termination
• PR #4839 - Fix async_cuda build problems when distributed runtime is disabled
• PR #4837 - Restore compatibility for old (now deprecated) copy algorithms
• PR #4836 - Adding CPOs for hpx::reduce
• PR #4835 - Remove using util::result_of from namespace hpx
• PR #4834 - Fixing the calculation of the number of idle cores and the corresponding idle masks
• PR #4833 - Allow thread function destructors to yield
• PR #4832 - Fixing assertion in split_gids and memory leaks in 1d_stencil_7
• PR #4831 - Making sure MPI_CXX_COMPILE_FLAGS is interpreted as a sequence of options
• PR #4830 - Update documentation on using HPX::wrap_main
• PR #4827 - Update clang-newest configuration to use clang 10
• PR #4826 - Add Jenkins configuration for rostam
• PR #4825 - Move all CUDA functionality to hpx::cuda:experimental namespace
• PR #4824 - Add support for building master/release branches to Jenkins configuration
• PR #4821 - Implement customization point for hpx::copy and hpx::ranges::copy
• PR #4819 - Allow finding Boost components before finding HPX
• PR #4817 - Adding range version of stable sort
• PR #4815 - Fix a wrong #ifdef for IO/TIMER pools causing build errors
• PR #4814 - Replace hpx::function_nonser with std::function in error module
• PR #4809 - Foreach adapt
• PR #4808 - Make internal algorithms functions const

https://github.com/STEllAR-GROUP/hpx/pull/4809
https://github.com/STEllAR-GROUP/hpx/pull/4808
• PR #4807 - Add Jenkins configuration for running on Piz Daint
• PR #4806 - Update documentation links to new domain name
• PR #4805 - Applying changes that resolve time complexity issues in sort
• PR #4803 - Adding implementation of stable_sort
• PR #4802 - Fix dataraw header paths
• PR #4801 - Replace boost::shared_array<T> with std::shared_ptr<T> if supported
• PR #4799 - Fixing #include paths in compatibility headers
• PR #4798 - Include the main module header (fixes partially #4488)
• PR #4797 - Change cmake targets
• PR #4794 - Removing 128bit integer emulation
• PR #4793 - Make sure global variable is handled properly
• PR #4792 - Replace enable_if with HPX_CONCEPT_REQUIRES_ and add is_sentinel_for constraint
• PR #4790 - Move deprecation warnings from base template to template specializations for result_of etc. structs
• PR #4789 - Fix hangs during assertion handling and distributed runtime construction
• PR #4788 - Fixing inclusive transform scan algorithm to properly handle initial value
• PR #4787 - Fixing barrier test
• PR #4784 - Fixing deleter argument bindings in serialize_buffer
• PR #4783 - Add coveralls badge
• PR #4782 - Make header tests parallel again
• PR #4780 - Remove outdated comment about hpx::stop in documentation
• PR #4776 - debug print improvements
• PR #4775 - Checkpoint cleanup
• PR #4774 - Fix compilation with HPX_WITHNETWORKING=OFF
Chapter 2. What’s so special about HPX?

• PR #4767 - Remove all force linking leftovers
• PR #4765 - Fix 1d stencil index calculation
• PR #4764 - Force some tests to run serially
• PR #4764 - Update pointees in compatibility headers
• PR #4760 - Fix running and building of execution module tests on CircleCI
• PR #4759 - Storing hpx_options in global property to speed up summary report
• PR #4758 - Fix mimalloc linking on Windows
• PR #4756 - Fix compilation issues
• PR #4755 - Re-addinig API functions that were lost during merges
• PR #4751 - Revert “Create coverage reports and upload them to codecov.io”
• PR #4750 - Fixing possible race condition during termination detection
• PR #4749 - Deprecate result_of and friends
• PR #4748 - Create coverage reports and upload them to codecov.io
• PR #4747 - Changing #include for MPI parcelport
• PR #4745 - Add is_sentinel_for trait implementation and test
• PR #4743 - Fix init_globally example after runtime mode changes
• PR #4742 - Update SUPPORT.md
• PR #4741 - Fixing a warning generated for unity builds with msvc
• PR #4740 - Rename local_icos and basic_execution modules
• PR #4739 - Undeprecate a couple of hpx/modulename.hpp headers
• PR #4738 - Conditionally test schedulers in thread_stacksize_current test
• PR #4734 - Fixing a bunch of codacy warnings

https://github.com/STEllAR-GROUP/hpx/pull/4734
• PR #4733694 - Add experimental unity build option to CMake configuration
• PR #4730695 - Fixing compilation problems with unordered map
• PR #4729696 - Fix APEX build
• PR #4727697 - Fix missing runtime includes for distributed runtime
• PR #4726698 - Add more API headers
• PR #4725699 - Add more compatibility headers for deprecated module headers
• PR #4724700 - Fix 4723
• PR #4721701 - Attempt to fixing migration tests
• PR #4717702 - Make the compatibility headers macro conditional
• PR #4716703 - Add hpx/runtime.hpp and hpx/distributed/runtime.hpp API headers
• PR #4714704 - Add hpx/future.hpp header
• PR #4713705 - Remove hpx/runtime/threads_fwd.hpp and hpx/util_fwd.hpp
• PR #4711706 - Make module deprecation warnings overridable
• PR #4710707 - Add compatibility headers and other fixes after module header renaming
• PR #4708708 - Add termination handler for parallel algorithms
• PR #4707709 - Use hpx::function_nonser instead of std::function internally
• PR #4706710 - Move header file to module
• PR #4705711 - Fix incorrect behaviour of cmake-format check
• PR #4704712 - Fix resource tests
• PR #4701713 - Fix missing includes for future::then specializations
• PR #4700714 - Removing obsolete memory component
• PR #4699715 - Add short descriptions to modules missing documentation
• PR #4696716 - Rename generated modules headers

• PR #4693\textsuperscript{717} - Overhauling thread\_mapper for public consumption
• PR #4687\textsuperscript{718} - Fix thread stack size handling
• PR #4687\textsuperscript{719} - Adding all\_gather and fixing all\_to\_all
• PR #4684\textsuperscript{720} - Miscellaneous compilation fixes
• PR #4683\textsuperscript{721} - Fix HPX\_WITH\_DYNAMIC\_HPX\_MAIN=OFF
• PR #4682\textsuperscript{722} - Fix compilation of pack\_traversal\_rebind\_container.hpp
• PR #4681\textsuperscript{723} - Add missing hpx\_execution\_hpp includes for future::then
• PR #4678\textsuperscript{724} - Typeless communicator
• PR #4677\textsuperscript{725} - Forcing registry option to be accepted without checks.
• PR #4676\textsuperscript{726} - Adding scatter\_to/scatter\_from collective operations
• PR #4673\textsuperscript{727} - Fix PAPI counters compilation
• PR #4671\textsuperscript{728} - Deprecate hpx::promise alias to hpx::lcos::promise
• PR #4670\textsuperscript{729} - Explicitly instantiate get\_exception
• PR #4667\textsuperscript{730} - Add stop\_Value in Sentinel struct instead of Iterator
• PR #4666\textsuperscript{731} - Add release build on Windows to GitHub actions
• PR #4664\textsuperscript{732} - Creating itt\_notify module.
• PR #4663\textsuperscript{733} - Mpi fixes
• PR #4659\textsuperscript{734} - Making sure declarations match definitions in register\_locks implementation
• PR #4655\textsuperscript{735} - Fixing task annotations for actions
• PR #4653\textsuperscript{736} - Making sure APEX is linked into every application, if needed
• PR #4651\textsuperscript{737} - Update get\_function\_annotation\_hpp
• PR #4646\textsuperscript{738} - Runtime type
• PR #4645\textsuperscript{739} - Add a few more API headers

• PR #4644 - Fixing support for mpirun (and similar)
• PR #4643 - Fixing the fix for get_idle_core_count() API
• PR #4638 - Remove HPX_API_EXPORT missed in previous cleanup
• PR #4636 - Adding C++20 barrier
• PR #4635 - Adding C++20 latch API
• PR #4634 - Adding C++20 counting semaphore API
• PR #4633 - Unify execution parameters customization points
• PR #4632 - Adding missing bulk_sync_execute wrapper to example executor
• PR #4631 - Updates to documentation; grammar edits.
• PR #4630 - Updates to documentation; moved hyperlink
• PR #4627 - Export set_self_ptr in thread_data.hpp instead of with forward declarations where used
• PR #4623 - Clean up export macros
• PR #4621 - Trigger an error for older boost versions on power architectures
• PR #4617 - Ignore user-set compatibility header options if the module does not have compatibility headers
• PR #4616 - Fix cmake-format warning
• PR #4615 - Add handler for serializing custom exceptions
• PR #4614 - Fix error message when HPX_IGNORE_CMAKE_BUILD_TYPE_COMPATIBILITY=OFF
• PR #4613 - Make partitioner constructor private
• PR #4611 - Making auto_chunk_size execute the given function using the given executor
• PR #4610 - Making sure the thread-local lock registration data is moving to the core the suspended HPX thread is resumed on
• PR #4609 - Adding an API function that exposes the number of idle cores
• PR #4608 - Fixing moodycamel namespace
• PR #4607 - Moving winsocket initialization to core library

2.10. Releases
• PR #4606\textsuperscript{763} - Local runtime module etc.
• PR #4604\textsuperscript{764} - Add config registry module
• PR #4603\textsuperscript{765} - Deal with distributed modules in their respective CMakeLists.txt
• PR #4602\textsuperscript{766} - Small module fixes
• PR #4598\textsuperscript{767} - Making sure current executor and service executor functions are linked into the core library
• PR #4597\textsuperscript{768} - Adding broadcast_to/broadcast_from to collectives module
• PR #4596\textsuperscript{769} - Fix performance regression in block executor
• PR #4595\textsuperscript{770} - Making sure main.cpp is built as a library if HPX\_WITH\_DYNAMIC\_MAIN=OFF
• PR #4592\textsuperscript{771} - Futures module
• PR #4591\textsuperscript{772} - Adapting co\_await support for C++20
• PR #4590\textsuperscript{773} - Adding missing exception test for for\_loop()
• PR #4587\textsuperscript{774} - Move traits headers to hpx\_modulename\_traits directory
• PR #4586\textsuperscript{775} - Remove Travis CI config
• PR #4585\textsuperscript{776} - Update macOS test blacklist
• PR #4584\textsuperscript{777} - Attempting to fix missing symbols in stack trace
• PR #4583\textsuperscript{778} - Fixing bad static\_cast
• PR #4582\textsuperscript{779} - Changing download url for Windows prerequisites to circumvent bandwidth limitations
• PR #4581\textsuperscript{780} - Adding missing using placeholder::\_X
• PR #4579\textsuperscript{781} - Move get\_stack\_size\_name and related functions
• PR #4575\textsuperscript{782} - Excluding unconditional definition of class backtrace from global header
• PR #4574\textsuperscript{783} - Changing return type of hardware\_concurrency() to unsigned int
• PR #4570\textsuperscript{784} - Move tests to modules
• PR #4564\textsuperscript{785} - Reshuffle internal targets and add HPX::hpx\_no\_wrap\_main target

- PR #4563 - fix CMake option typo
- PR #4562 - Unregister lock earlier to avoid holding it while suspending
- PR #4561 - Adding test macros supporting custom output stream
- PR #4560 - Making sure hash_any::operator()() is linked into core library
- PR #4559 - Fixing compilation if HPX_WITH_THREAD_BACKTRACE_ON_SUSPENSION=On
- PR #4557 - Improve spinlock implementation to perform better in high-contention situations
- PR #4553 - Fix a runtime_ptr problem at shutdown when apex is enabled
- PR #4552 - Add configuration option for making exceptions less noisy
- PR #4551 - Clean up thread creation parameters
- PR #4549 - Test FetchContent build on GitHub actions
- PR #4548 - Fix stack size
- PR #4547 - Fix header tests
- PR #4544 - Fix a typo in sanitizer build
- PR #4541 - Add API to check if a thread pool exists
- PR #4540 - Making sure MPI support is enabled if MPI futures are used but networking is disabled
- PR #4538 - Move channel documentation examples to examples directory
- PR #4536 - Add generic allocator for execution policies
- PR #4534 - Enable compatibility headers for thread_executors module
- PR #4532 - Fixing broken url in README.rst
- PR #4531 - Update scripts
- PR #4530 - Make sure module API docs show up in correct order
- PR #4529 - Adding missing template code to module creation script
- PR #4528 - Make sure version module uses HPX’s binary dir, not the parent’s

• PR #4492 - Update copyright year in documentation
• PR #4491 - Add missing current_executor header
• PR #4490 - Update GitHub actions configs
• PR #4487 - Properly dispatch exceptions thrown from hpx_main to be rethrown from hpx::init/hpx::stop
• PR #4486 - Fixing an initialization order problem
• PR #4485 - Move miscellaneous files to their rightful modules
• PR #4484 - Clean up imported CMake target naming
• PR #4481 - Add vcpkg installation instructions
• PR #4479 - Add hints to allow to specify MIMALLOC_ROOT
• PR #4478 - Async modules
• PR #4475 - Fix rp init changes
• PR #4474 - Use #pragma once in headers
• PR #4472 - Add more descriptive error message when using x86 coroutines on non-x86 platforms
• PR #4467 - Add mimalloc find cmake script
• PR #4466 - Add thread_executors module
• PR #4464 - Include module
• PR #4462 - Merge hpx_init and hpx_wrap into one static library
• PR #4461 - Making thread_data test more realistic
• PR #4460 - Suppress MPI warnings in version.cpp
• PR #4459 - Make sure pkgconfig applications link with hpx_init
• PR #4458 - Added example demonstrating how to create and use a wrapping executor
• PR #4457 - Fixing execution of thread exit functions
• PR #4456 - Move backtrace files to debugging module
• PR #4455 - Move deadlock_detection and maintain_queue_wait_times source files into schedulers module
• PR #4450 - Fixing compilation with std::filesystem enabled
• PR #4449 - Fixing build system to actually build variant test
• PR #4447 - This fixes an obsolete #include
• PR #4446 - Resume tasks where they were suspended
• PR #4444 - Minor CUDA fixes
• PR #4443 - Add missing tests to CircleCI config
• PR #4442 - Adding a tag to all auto-generated files allowing for tools to visually distinguish those
• PR #4441 - Adding performance counter type information
• PR #4440 - Fixing MSVC build
• PR #4439 - Link HPX::plugin and component privately in hpx_setup_target
• PR #4438 - Adding a test that verifies the problem can be solved using a trait specialization
• PR #4434 - Clean up Boost dependencies and copy string algorithms to new module
• PR #4433 - Fixing compilation issues (!) if MPI parcelport is enabled
• PR #4431 - Ignore warnings about name mangling changing
• PR #4430 - Add performance_counters module
• PR #4428 - Don’t add compatibility headers to module API reference
• PR #4426 - Add currently failing tests on GitHub actions to blacklist
• PR #4425 - Clean up and correct minimum required versions
• PR #4424 - Making sure hpx.lock_detection=0 works as advertised
• PR #4421 - Making sure interval time stops underlying timer thread on termination
• PR #4417 - Adding serialization support for std::variant (if available) and std::tuple
• PR #4415 - Partially reverting changes applied by PR 4373

2.10.4 HPX V1.4.1 (Feb 12, 2020)

General changes

This is a bugfix release. It contains the following changes:

- Fix compilation issues on Windows, macOS, FreeBSD, and with gcc 10
- Install missing pdb files on Windows
- Allow running tests using an installed version of HPX
- Skip MPI finalization if HPX has not initialized MPI
- Give a hard error when attempting to use IO counters on Windows

Closed issues

- Issue #4320\(^{967}\) - HPX 1.4.0 does not compile with gcc 10
- Issue #4336\(^{968}\) - Building HPX 1.4.0 with IO Counters breaks (Windows)
- Issue #4334\(^{969}\) - HPX Debug and RelWithDebinfo builds on Windows not installing .pdb files
- Issue #4322\(^{970}\) - Undefine VT1 and VT2 after boost includes
- Issue #4314\(^{971}\) - Compile error on 1.4.0
- Issue #4307\(^{972}\) - ld: error: duplicate symbol: freebsd_environ

Closed pull requests

- PR #4376\(^{973}\) - Attempt to fix some test build errors on Windows
- PR #4357\(^{974}\) - Adding missing #includes to fix gcc V10 linker problems
- PR #4353\(^{975}\) - Skip MPI_Finalize if MPI_Init is not called from HPX
- PR #4343\(^{976}\) - Give a hard error if IO counters are enabled on non-Linux systems
- PR #4337\(^{977}\) - Installing pdb files on Windows
- PR #4335\(^{978}\) - Adding capability to buildsystem to use an installed version of HPX
- PR #4315\(^{979}\) - Forcing exported symbols from composable_guard to be linked into core library
- PR #4310\(^{980}\) - Remove environment handling from exception.cpp

2.10.5 HPX V1.4.0 (January 15, 2020)

General changes

- We have added the collectives `all_to_all` and `all_reduce`.
- We have added APIs for resiliency, which allows replication and replay for failed tasks. See the documentation for more details.
- Components can now be checkpointed.
- Performance improvements to schedulers and coroutines. A significant change is the addition of stackless coroutines. These are to be used for tasks that do not need to be suspended and can reduce overheads noticeably in applications with short tasks. A stackless coroutine can be created with the new stack size `thread_stacksize_nostack`.
- We have added an implementation of `unique_any`, which is a non-copyable version of `any`.
- The `shared_priority_queue_scheduler` has been improved. It now has lower overheads than the default scheduler in many situations. Unlike the default scheduler it fully supports NUMA scheduling hints. Enable it with the command line option `--hpx:queuing=shared-priority`. This scheduler should still be considered experimental, but its use is encouraged in real applications to help us make it production ready.
- We have added the performance counters `background-receive-duration` and `background-receive-overhead` for inspecting the time and overhead spent on receiving parcels in the background.
- Compilation time has been further improved when `HPX_WITH_NETWORKING=OFF`.
- We no longer require compiled Boost dependencies in certain configurations. This requires at least Boost 1.70, compiling on x86 with GCC 9, clang (libc++) 9, or VS2019 in C++17 mode. The dependency on Boost.Filesystem can explicitly be turned on with `HPX_FILESYSTEM_WITH_BOOST_FILESYSTEM_COMPATIBILITY=ON` (it is off by default if the standard library supports `std::filesystem`). Boost.ProgramOptions has been copied into the HPX repository. We have a compatibility layer for users who must explicitly use Boost.ProgramOptions instead of the ProgramOptions provided by HPX. To remove the dependency `HPX_PROGRAM_OPTIONS_WITH_BOOST_PROGRAM_OPTIONS_COMPATIBILITY` must be explicitly set to `OFF`. This option will be removed in a future release. We have also removed several other header-only dependencies on Boost.
- It is now possible to use the process affinity mask set by tools like `numactl` and various batch environments with the command line option `--hpx:use-process-mask`. Enabling this option implies `--hpx:ignore-batch-env`.
- It is now possible to create standalone thread pools without starting the runtime. See the `standalone_thread_pool_executor.cpp` test in the execution module for an example.
- Tasks annotated with `hpx::util::annotated_function` now have their correct name when using APEX to generate OTF2 files.
- Cloning of APEX was defective in previous releases (it required manual intervention to check out the correct tag or branch). This has been fixed.
- The option `HPX_WITH_MORE_THAN_64_THREADS` is now ignored and will be removed in a future release. The value is instead derived directly from `HPX_WITH_MAX_CPU_COUNT` option.
- We have deprecated compiling in C++11 mode. The next release will require a C++14 capable compiler.
- We have deprecated support for the Vc library. This option will be replaced with SIMD support from the standard library in a future release.
• We have significantly refactored our CMake setup. This is intended to be a non-breaking change and will allow for using HPX through CMake targets in the future.

• We have continued modularizing the HPX library. In the process we have rearranged many header files into module-specific directories. All moved headers have compatibility headers which forward from the old location to the new location, together with a deprecation warning. The compatibility headers will eventually be removed.

• We now enforce formatting with clang-format on the majority of our source files.

• We have added SPDX license tags to all files.

• Many bugfixes.

Breaking changes

• The HPX_WITH_THREAD_COMPATIBILITY option and the associated compatibility layer has been removed.

• The HPX_WITH_INCLUSIVE_SCAN_COMPATIBILITY option and the associated compatibility layer has been removed.

• The HPX_WITH_UNWRAPPED_COMPATIBILITY option and the associated compatibility layer has been removed.

HPX Documentation, master

- Issue #4182\(^{994}\) - `@HPX_CONF_PREFIX@` is the empty string
- Issue #4169\(^{995}\) - HPX won’t build with APEX
- Issue #4163\(^{996}\) - Add back `HPX_LIBRARIES` and `HPX_INCLUDE_DIRS`
- Issue #4161\(^{997}\) - It should be possible to call `find_package(HPX)` multiple times
- Issue #4155\(^{998}\) - `get_self_id()` for stackless threads returns `invalid_thread_id`
- Issue #4151\(^{999}\) - build error with MPI code
- Issue #4150\(^{1000}\) - hpx won’t build on POWER9 with clang 8
- Issue #4148\(^{1001}\) - `cacheline_data` delivers poor performance with C++17 compared to C++14
- Issue #4144\(^{1002}\) - target general in `HPX_LIBRARIES` does not exist
- Issue #4134\(^{1003}\) - CMake Error when `-DHPX_WITH_HPXMP=ON`
- Issue #4132\(^{1004}\) - parallel fill leaves elements unfilled
- Issue #4123\(^{1005}\) - PAPI performance counters are inaccessible
- Issue #4118\(^{1006}\) - `static_chunk_size` is not obeyed in scan algorithms
- Issue #4115\(^{1007}\) - dependency chaining error with APEX
- Issue #4107\(^{1008}\) - Initializing runtime without entry point function and command line arguments
- Issue #4105\(^{1009}\) - Bug in `hpx:bind=numa-balanced`
- Issue #4101\(^{1010}\) - Bound tasks
- Issue #4100\(^{1011}\) - Add SPDX identifier to all files
- Issue #4085\(^{1012}\) - `hpx_topology` library should depend on hwloc
- Issue #4067\(^{1013}\) - HPX fails to build on macOS
- Issue #4056\(^{1014}\) - Building without thread manager idle backoff fails
- Issue #4052\(^{1015}\) - Enforce `clang-format` style for modules
- Issue #4032\(^{1016}\) - Simple hello world fails to launch correctly

• PR #4200 - Making sure hpx_wrap is not passed on to linker on non-Linux systems
• PR #4198 - Fix execution_agent.cpp compilation with GCC 5
• PR #4197 - Remove deprecated options for 1.4.0 release
• PR #4196 - minor fixes for building on OSX Darwin
• PR #4195 - Use full clone on CircleCI for pushing stable tag
• PR #4193 - Add scheduling hints to hello_world_distributed
• PR #4192 - Set up CUDA in HPXConfig.cmake
• PR #4191 - Export allocators root variables
• PR #4190[108] - Don’t use constexpr in thread_data with GCC <= 6
• PR #4189[109] - Only use quick_exit if available
• PR #4188[110] - Google Season of Docs updates to documentation; writing single node hpx applications
• PR #4186[111] - correct vc to cuda in cuda cmake
• PR #4184[112] - Resetting some cached variables to make sure those are re-filled
• PR #4183[113] - Fix hpxcxx configuration
• PR #4181[114] - Rename base libraries var
• PR #4180[115] - Move header left behind earlier to plugin module
• PR #4179[116] - Moving zip_iterator and transform_iterator to iterator_support module
• PR #4178[117] - Move checkpointing support to its own module
• PR #4177[118] - Small const fix to basic_execution module
• PR #4176[119] - Add back HPX_LIBRARIES and friends to HPXConfig.cmake
• PR #4175[120] - Make Vc public and add it to HPXConfig.cmake
• PR #4173[121] - Wait for runtime to be running before returning from hpx::start
• PR #4172[122] - More protection against shutdown problems in error handling scenarios.
• PR #4171[123] - Ignore lock in condition_variable::wait
• PR #4170[124] - Adding APEX dependency to MPI parcelport
• PR #4169[125] - Adding utility include
• PR #4167[126] - Add a condition to setup the external libraries
• PR #4166[127] - Add an INTERNAL_FLAGS option to link to hpx_internal_flags
• PR #4165[128] - Forward HPX_* cmake cache variables to external projects
• PR #4164[129] - Affinity and batch environment modules
• PR #4162[130] - Handle quick exit
• PR #4160 - Using target_link_libraries for cmake versions >= 3.12
• PR #4159 - Make sure HPX_WITH_NATIVE_TLS is forwarded to dependent projects
• PR #4158 - Adding allocator imported target as a dependency of allocator module
• PR #4157 - Add hpx_memory as a dependency of parcelport plugins
• PR #4156 - Stackless coroutines now can refer to themselves (through get_self() and friends)
• PR #4154 - Added CMake policy CMP0060 for HPX applications.
• PR #4153 - add header iomanip to tests and tool
• PR #4152 - Casting MPI tag value
• PR #4149 - Add back private m_desc member variable in program_options module
• PR #4147 - Resource partitioner and threadmanager modules
• PR #4146 - Google Season of Docs updates to documentation; creating hpx projects
• PR #4145 - Adding basic support for stackless threads
• PR #4143 - Exclude test_client_1950 from all target
• PR #4142 - Add a new thread_pool_executor
• PR #4140 - Google Season of Docs updates to documentation; why hpx
• PR #4139 - Remove runtime includes from coroutines module
• PR #4138 - Forking boost::intrusive_ptr and adding it as hpx::intrusive_ptr
• PR #4137 - Fixing TSS destruction
• PR #4136 - HPX.Compute modules
• PR #4133 - Fix block_executor
• PR #4131 - Applying fixes based on reports from PVS Studio
• PR #4130 - Adding missing header to build system
• PR #4129 - Fixing compilation if HPX_WITH_DATAPAR_VC is enabled

• PR #4128\textsuperscript{1154} - Renaming moveonly\_any to unique\_any
• PR #4126\textsuperscript{1155} - Attempt to fix basic\_any constructor for gcc 7
• PR #4125\textsuperscript{1156} - Changing extra\_archive\_data implementation
• PR #4124\textsuperscript{1157} - Don’t link to Boost.System unless required
• PR #4122\textsuperscript{1158} - Add kernel launch helper utility (+saxpy demo) and merge in octotiger changes
• PR #4121\textsuperscript{1159} - Fixing migration test if networking is disabled.
• PR #4120\textsuperscript{1160} - Google Season of Docs updates to documentation; hpx build system v1
• PR #4119\textsuperscript{1161} - Making sure chunk\_size and max\_chunk are actually applied to parallel algorithms if specified
• PR #4117\textsuperscript{1162} - Make CircleCI formatting check store diff
• PR #4116\textsuperscript{1163} - Fix automatically setting C++ standard
• PR #4114\textsuperscript{1164} - Module serialization
• PR #4113\textsuperscript{1165} - Module datastructures
• PR #4111\textsuperscript{1166} - Fixing performance regression introduced earlier
• PR #4110\textsuperscript{1167} - Adding missing SPDX tags
• PR #4106\textsuperscript{1168} - Overload for start without entry point/argv.
• PR #4108\textsuperscript{1169} - Making sure C++ standard is properly detected and propagated
• PR #4106\textsuperscript{1170} - use std::round for guaranteed rounding without errors
• PR #4104\textsuperscript{1171} - Extend scheduler\_mode with new work\_stealing and task assignment modes
• PR #4103\textsuperscript{1172} - Add this to lambda capture list
• PR #4102\textsuperscript{1173} - Add spdx license and check
• PR #4099\textsuperscript{1174} - Module coroutines
• PR #4098\textsuperscript{1175} - Fix append module path in module CMakeLists template
• PR #4097\textsuperscript{1176} - Function tests

2.10. Releases
• PR #4096 - Removing return of thread_result_type from functions not needing them
• PR #4095 - Stop-gap measure until cmake overhaul is in place
• PR #4094 - Deprecate HPX_WITH_MORE_THAN_64_THREADS
• PR #4093 - Fix initialization of global_num_tasks in parallel_executor
• PR #4092 - Add support for mi-malloc
• PR #4090 - Execution context
• PR #4089 - Make counters in coroutines optional
• PR #4087 - Making hpx::util::any compatible with C++17
• PR #4084 - Making sure destination array for std::transform is properly resized
• PR #4083 - Adapting thread_queue_mc to behave even if no 128bit atomics are available
• PR #4082 - Fix compilation on GCC 5
• PR #4081 - Adding option allowing to force using Boost.FileSystem
• PR #4080 - Updating module dependencies
• PR #4079 - Add missing tests for iterator_support module
• PR #4078 - Disable parcel-layer if networking is disabled
• PR #4077 - Add missing include that causes build fails
• PR #4076 - Enable compatibility headers for functional module
• PR #4075 - Coroutines module
• PR #4073 - Use configure_file for generated files in modules
• PR #4071 - Fixing MPI detection for PMIx
• PR #4070 - Fix macOS builds
• PR #4069 - Moving more facilities to the collectives module
• PR #4068 - Adding main HPX #include directory to modules
- PR #4066 - Switching the use of \texttt{message(STATUS ".")} to \texttt{hpx_info}
- PR #4065 - Move Boost.Filesystem handling to filesystem module
- PR #4064 - Fix program_options test with older boost versions
- PR #4062 - The \texttt{cpu_features} tool fails to compile on anything but x86 architectures
- PR #4061 - Add \texttt{clang-format} checking step for modules
- PR #4060 - Making sure \texttt{HPX_IDLE_BACKOFF_TIME_MAX} is always defined (even if its unused)
- PR #4059 - Renaming module \texttt{hpx_parallel_executors} into \texttt{hpx_execution}
- PR #4058 - Do not build networking tests when networking disabled
- PR #4057 - Printing configuration summary for modules as well
- PR #4055 - Google Season of Docs updates to documentation; \texttt{hpx} build systems
- PR #4054 - Adding troubleshooting section to manual
- PR #4051 - Add more variations to \texttt{future_overhead} test
- PR #4050 - Creating plugin module
- PR #4049 - Move missing modules tests
- PR #4047 - Add boost/filesystem headers to inspect deprecated headers
- PR #4045 - Module functional
- PR #4043 - Fix preconditions and error messages for suspension functions
- PR #4041 - Pass \texttt{HPX_STANDARD} on to dependent projects via \texttt{HPXConfig.cmake}
- PR #4040 - Program options module
- PR #4039 - Moving non-serializable \texttt{any} (\texttt{any_nonser}) to datastructures module
- PR #4038 - Adding MPark's variant (V1.4.0) to \texttt{HPX}
- PR #4037 - Adding resiliency module
- PR #4036 - Add C++17 filesystem compatibility header
• PR #4035¹²²³ - Fixing support for mpirun
• PR #4028¹²²⁴ - CMake to target based directives
• PR #4027¹²²⁵ - Remove GitLab CI configuration
• PR #4026¹²²⁶ - Threading refactoring
• PR #4025¹²²⁷ - Refactoring thread queue configuration options
• PR #4024¹²²⁸ - Fix padding calculation in cache_aligned_data.hpp
• PR #4023¹²²⁹ - Fixing Codacy issues
• PR #4022¹²³⁰ - Make sure process mask option is passed to affinity_data
• PR #4021¹²³¹ - Warn about compiling in C++11 mode
• PR #4020¹²³² - Module concurrency
• PR #4019¹²³³ - Module topology
• PR #4018¹²³⁴ - Update deprecated header in thread_queue_mc.hpp
• PR #4015¹²³⁵ - Avoid overwriting artifacts
• PR #4014¹²³⁶ - Future overheads
• PR #4013¹²³⁷ - Update URL to test output conversion script
• PR #4012¹²³⁸ - Fix CUDA compilation
• PR #4011¹²³⁹ - Fixing cyclic dependencies between modules
• PR #4010¹²⁴⁰ - Ignore stable tag on CircleCI
• PR #4009¹²⁴¹ - Check circular dependencies in a circle ci step
• PR #4008¹²⁴² - Extend cache aligned data to handle tuple-like data
• PR #4007¹²⁴³ - Fixing migration for components that have actions returning a client
• PR #4006¹²⁴⁴ - Move is_value_proxy.hpp to algorithms module
• PR #4004¹²⁴⁵ - Shorten CTest timeout on CircleCI

• PR #4003\textsuperscript{1246} - Refactoring to remove (internal) dependencies
• PR #4001\textsuperscript{1247} - Exclude tests from all target
• PR #4000\textsuperscript{1248} - Module errors
• PR #3999\textsuperscript{1249} - Enable support for compatibility headers for logging module
• PR #3998\textsuperscript{1250} - Add process thread binding option
• PR #3997\textsuperscript{1251} - Export handle\_assert function
• PR #3996\textsuperscript{1252} - Attempt to solve issue where \texttt{atomic} does not support 128bit atomics
• PR #3993\textsuperscript{1253} - Make sure \texttt{\_\_LINE\_} is an unsigned
• PR #3991\textsuperscript{1254} - Fix dependencies and flags for header tests
• PR #3990\textsuperscript{1255} - Documentation tags fixes
• PR #3988\textsuperscript{1256} - Adding missing solution folder for format module test
• PR #3987\textsuperscript{1257} - Move runtime-dependent functions out of command line handling
• PR #3986\textsuperscript{1258} - Fix CMake configuration with PAPI on
• PR #3985\textsuperscript{1259} - Module timing
• PR #3984\textsuperscript{1260} - Fix default behaviour of paths in \texttt{add\_hpx\_component}
• PR #3982\textsuperscript{1261} - Parallel executors module
• PR #3981\textsuperscript{1262} - Segmented algorithms module
• PR #3980\textsuperscript{1263} - Module logging
• PR #3979\textsuperscript{1264} - Module util
• PR #3978\textsuperscript{1265} - Fix \texttt{clang-tidy} step on CircleCI
• PR #3977\textsuperscript{1266} - Fixing solution folders for moved components
• PR #3976\textsuperscript{1267} - Module format
• PR #3975\textsuperscript{1268} - Enable deprecation warnings on CircleCI

2.10. Releases
• PR #3974\textsuperscript{1269} - Fix typos in documentation
• PR #3973\textsuperscript{1270} - Fix compilation with GCC 9
• PR #3972\textsuperscript{1271} - Add condition to clone apex + use of new cmake var APEX_ROOT
• PR #3971\textsuperscript{1272} - Add testing module
• PR #3968\textsuperscript{1273} - Remove unneeded file in hardware module
• PR #3967\textsuperscript{1274} - Remove leftover PIC settings from main CMakeLists.txt
• PR #3966\textsuperscript{1275} - Add missing export option in add_hpx_module
• PR #3965\textsuperscript{1276} - Change current_function_helper back to non-constexpr
• PR #3964\textsuperscript{1277} - Fixing merge problems
• PR #3962\textsuperscript{1278} - Add a trait for std::array for unwrapping
• PR #3961\textsuperscript{1279} - Making hpx::util::tuple<Ts...> and std::tuple<Ts...> convertible
• PR #3960\textsuperscript{1280} - fix compilation with CUDA 10 and GCC 6
• PR #3959\textsuperscript{1281} - Fix C++11 incompatibility
• PR #3957\textsuperscript{1282} - Algorithms module
• PR #3956\textsuperscript{1283} - [HPX_AddModule] Fix lower name var to upper
• PR #3955\textsuperscript{1284} - Fix CMake configuration with examples off and tests on
• PR #3954\textsuperscript{1285} - Move components to separate subdirectory in root of repository
• PR #3952\textsuperscript{1286} - Update papi.cpp
• PR #3951\textsuperscript{1287} - Exclude modules header tests from all target
• PR #3950\textsuperscript{1288} - Adding all_reduce facility to collectives module
• PR #3949\textsuperscript{1289} - This adds a configuration file that will cause for stale issues to be automatically closed
• PR #3948\textsuperscript{1290} - Fixing ALPS environment
• PR #3947\textsuperscript{1291} - Add major compiler version check for building hpx as a binary package

\textsuperscript{1291}https://github.com/STEllAR-GROUP/hpx/pull/3947
• PR #3946 - [Modules] Move the location of the generated headers
• PR #3945 - Simplify tests and examples cmake
• PR #3943 - Remove example module
• PR #3942 - Add NOEXPORT option to add_hpx_{component,library}
• PR #3938 - Use https for CDash submissions
• PR #3937 - Add HPX_WITH_BUILD_BINARY_PACKAGE to the compiler check (refs #3935)
• PR #3936 - Fixing installation of binaries on windows
• PR #3934 - Add set function for sliding_semaphore max_difference
• PR #3933 - Remove cudadevrt from compile/link flags as it breaks downstream projects
• PR #3932 - Fixing 3929
• PR #3931 - Adding all_to_all
• PR #3930 - Add test demonstrating the use of broadcast with component actions
• PR #3928 - fixed number of tasks and number of threads for heterogeneous slurm environments
• PR #3927 - Moving Cache module’s tests into separate solution folder
• PR #3926 - Move unit tests to cache module
• PR #3925 - Move version check to config module
• PR #3924 - Add schedule hint executor parameters
• PR #3923 - Allow aligning objects bigger than the cache line size
• PR #3922 - Add Windows builds with Travis CI
• PR #3921 - Add ccls cache directory to gitignore
• PR #3920 - Fix git_external fetching of tags
• PR #3905 - Correct rostambod url. Fix typo in doc
• PR #3904 - Fix bug in context_base.hpp

2.10. Releases
• PR #3903 - Adding new performance counters
• PR #3902 - Add add_hpx_module function
• PR #3901 - Factoring out container remapping into a separate trait
• PR #3900 - Making sure errors during command line processing are properly reported and will not cause assertions
• PR #3899 - Remove old compatibility bases from make_action
• PR #3898 - Make parameter size be of type size_t
• PR #3897 - Making sure all tests are disabled if HPX_WITH_TESTS=OFF
• PR #3895 - Add documentation for annotated_function
• PR #3894 - Working around VS2019 problem with make_action
• PR #3892 - Avoid MSVC compatibility warning in internal allocator
• PR #3891 - Removal of the default intel config include
• PR #3888 - Fix async_customization dataflow example and Clarify what’s being tested
• PR #3887 - Add Doxygen documentation
• PR #3882 - Minor docs fixes
• PR #3880 - Updating APEX version tag
• PR #3878 - Making sure symbols are properly exported from modules (needed for Windows/MacOS)
• PR #3877 - Documentation
• PR #3876 - Module hardware
• PR #3875 - Converted typedefs in actions submodule to using directives
• PR #3874 - Allow one to suppress target keywords in hpx_setup_target for backwards compatibility
• PR #3873 - Add scripts to create releases and generate lists of PRs and issues
• PR #3872 - Fix latest HTML docs location
• PR #3870 - Module cache
• PR #3869 - Post 1.3.0 version bumps
• PR #3868 - Replace the macro HPX_ASSERT by HPX_TEST in tests
• PR #3845 - Assertion module
• PR #3839 - Make tuple serialization non-intrusive
• PR #3832 - Config module
• PR #3799 - Remove compat namespace and its contents
• PR #3701 - MoodyCamel lockfree
• PR #3496 - Disabling MPI’s (deprecated) C++ interface
• PR #3192 - Move type info into hpx::debug namespace and add print helper functions
• PR #3159 - Support Checkpointing Components

2.10.6 HPX V1.3.0 (May 23, 2019)

General changes

• Performance improvements: the schedulers have significantly reduced overheads from removing false sharing and the parallel executor has been updated to create fewer futures.
• HPX now defaults to not turning on networking when running on one locality. This means that you can run multiple instances on the same system without adding command line options.
• Multiple issues reported by Clang sanitizers have been fixed.
• We have added (back) single-page HTML documentation and PDF documentation.
• We have started modularizing the HPX library. This is useful both for developers and users. In the long term users will be able to consume only parts of the HPX libraries if they do not require all the functionality that HPX currently provides.
• We have added an implementation of function_ref.
• The barrier and latch classes have gained a few additional member functions.
Breaking changes

• Executable and library targets are now created without the _exe and _lib suffix respectively. For example, the target 1d_stencil_1_exe is now simply called 1d_stencil_1.

• We have removed the following deprecated functionality: queue, scoped_unlock, and support for input iterators in algorithms.

• We have turned off the compatibility layer for unwrapped by default. The functionality will be removed in the next release. The option can still be turned on using the CMake option HPX_WITH_UNWRAPPED_SUPPORT. Likewise, inclusive_scan compatibility overloads have been turned off by default. They can still be turned on with HPX_WITH_INCLUSIVE_SCAN_COMPATIBILITY.

• The minimum compiler and dependency versions have been updated. We now support GCC from version 5 onwards, Clang from version 4 onwards, and Boost from version 1.61.0 onwards.

• The headers for preprocessor macros have moved as a result of the functionality being moved to a separate module. The old headers are deprecated and will be removed in a future version of HPX. You can turn off the warnings by setting HPX_PREPROCESSOR_WITH_DEPRECATED_WARNINGS=OFF or turn off the compatibility headers completely with HPX_PREPROCESSOR_WITH_COMPATIBILITY_HEADERS=OFF.

Closed issues

• Issue #3863 shouldn’t “-faligned-new” be a usage requirement?
• Issue #3841 Build error with msvc 19 caused by SFINAE and C++17
• Issue #3836 master branch does not build with idle rate counters enabled
• Issue #3819 Add debug suffix to modules built in debug mode
• Issue #3817 HPX_INCLUDE_DIRS contains non-existent directory
• Issue #3810 Source groups are not created for files in modules
• Issue #3805 HPX won’t compile with -DHPX_WITH_APEX=TRUE
• Issue #3792 Barrier Hangs When Locality Zero not included
• Issue #3778 Replace throw() with noexcept
• Issue #3763 configurable sort limit per task
• Issue #3758 dataflow doesn’t convert future<future<T>> to future<T>
• Issue #3757 When compiling undefined reference to hpx::hpx_check_version_1_2 HPX V1.2.1, Ubuntu 18.04.01 Server Edition
• Issue #3753 --hpx:list-counters=full crashes
- Issue #3746 - Detection of MPI with pmix
- Issue #3744 - Separate spinlock from same cacheline as internal data for all LCOs
- Issue #3743 - hpxcxx’s shebang doesn’t specify the python version
- Issue #3738 - Unable to debug parcelport on a single node
- Issue #3735 - Latest master: Can’t compile in MSVC
- Issue #3731 - `util::bound` seems broken on Clang with older libstdc++
- Issue #3724 - Allow to pre-set command line options through environment
- Issue #3723 - examples/resource_partitioner build issue on master branch / ubuntu 18
- Issue #3721 - faced a building error
- Issue #3720 - Hello World example fails to link
- Issue #3719 - pkg-config produces invalid output: `-l-pthread`
- Issue #3718 - Please make the python executable configurable through cmake
- Issue #3717 - interested to contribute to the organisation
- Issue #3699 - Remove ‘HPX runtime’ executable
- Issue #3698 - Ignore all locks while handling asserts
- Issue #3689 - Incorrect and inconsistent website structure http://stellar.cct.lsu.edu/downloads/
- Issue #3681 - Broken links on http://stellar.cct.lsu.edu/2015/05/hpx-archives-now-on-gmane/
- Issue #3676 - HPX master built from source, cmake fails to link main.cpp example in docs
- Issue #3673 - HPX build fails with `std::atomic` missing error
- Issue #3670 - Generate PDF again from documentation (with Sphinx)
- Issue #3643 - Warnings when compiling HPX 1.2.1 with gcc 9
- Issue #3641 - Trouble with using ranges-v3 and `hpx::parallel::reduce`
- Issue #3639 - `util::unwrapping` does not work well with member functions
• Issue #3634 - The build fails if `shared_future<>::then` is called with a thread executor
• Issue #3622 - VTune Amplifier 2019 not working with `use_itt_notify=1`
• Issue #3616 - HPX Fails to Build with CUDA 10
• Issue #3612 - False sharing of scheduling counters
• Issue #3609 - `executor_parameters` timeout with gcc <= 7 and Debug mode
• Issue #3601 - Misleading error message on power pc for rdtsc and rdtscp
• Issue #3598 - Build of some examples fails when using Vc
• Issue #3594 - Error: The number of OS threads requested (20) does not match the number of threads to bind (12): HPX(bad_parameter)
• Issue #3592 - Undefined Reference Error
• Issue #3589 - `include` could not find load file: HPX_Utils.cmake
• Issue #3587 - HPX won’t compile on POWER8 with Clang 7
• Issue #3583 - Fedora and openSUSE instructions missing on “Distribution Packages” page
• Issue #3578 - Build error when configuring with `HPX_HAVE_ALGORITHM_INPUT_ITERATOR_SUPPORT=ON`
• Issue #3575 - Merge openSUSE reproducible patch
• Issue #3570 - Update HPX to work with the latest VC version
• Issue #3567 - Build succeed and make failed for `hpx:cout`
• Issue #3565 - Polymorphic simple component destructor not getting called
• Issue #3559 - 1.2.0 is missing from download page
• Issue #3554 - Clang 6.0 warning of hiding overloaded virtual function
• Issue #3510 - Build on ppc64 fails
• Issue #3482 - Improve error message when `HPX_WITH_MAX_CPU_COUNT` is too low for given system
• Issue #3453 - Two HPX applications can’t run at the same time.
• Issue #3452 - Scaling issue on the change to 2 NUMA domains

- **Issue #3442** - HPX set_difference, set_intersection failure cases
- **Issue #3437** - Ensure parent_task pointer when child task is created and child/parent are on same locality
- **Issue #3255** - Suspension with lock for --hpx:list-component-types
- **Issue #3034** - Use C++17 structured bindings for serialization
- **Issue #2999** - Change thread scheduling use of size_t for thread indexing

**Closed pull requests**

- **PR #3865** - adds hpx_target_compile_option_if_available
- **PR #3864** - Helper functions that are useful in numa binding and testing of allocator
- **PR #3862** - Temporary fix to local_dataflow_boost_small_vector test
- **PR #3860** - Add cache line padding to intermediate results in for loop reduction
- **PR #3859** - Remove HPX_TLL_PUBLIC and HPX_TLL_PRIVATE from CMake files
- **PR #3858** - Add compile flags and definitions to modules
- **PR #3851** - update hpxmp release tag to v0.2.0
- **PR #3849** - Correct BOOST_ROOT variable name in quick start guide
- **PR #3847** - Fix attach_debugger configuration option
- **PR #3846** - Add tests for libs header tests
- **PR #3844** - Fixing source_groups in preprocessor module to properly handle compatibility headers
- **PR #3843** - This fixes the launch_process/launched_process pair of tests
- **PR #3842** - Fix macro call with ITTNOTIFY enabled
- **PR #3840** - Fixing SLURM environment parsing
- **PR #3837** - Fixing misplaced #endif
- **PR #3835** - make all latch members protected for consistency
- **PR #3834** - Disable transpose_block_numa example on CircleCI
• PR #3833 - make latch `counter_` protected for deriving latch in hpxmp
• PR #3831 - Fix CircleCI config for modules
• PR #3830 - minor fix: option HPX_WITH_TEST was not working correctly
• PR #3828 - Avoid for binaries that depend on HPX to directly link against internal modules
• PR #3827 - Adding shortcut for `hpx::get_ptr<>{sync, id}` for a local, non-migratable objects
• PR #3826 - Fix and update modules documentation
• PR #3825 - Updating default APEX version to 2.1.3 with HPX
• PR #3823 - Fix pkgconfig libs handling
• PR #3822 - Change includes in `hpx_wrap.cpp` to more specific includes
• PR #3821 - Disable barrier_3792 test when networking is disabled
• PR #3820 - Assorted CMake fixes
• PR #3815 - Removing left-over debug output
• PR #3814 - Allow setting default scheduler mode via the configuration database
• PR #3813 - Make the deprecation warnings issued by the old pp headers optional
• PR #3812 - Windows requires to handle symlinks to directories differently from those linking files
• PR #3811 - Clean up PP module and library skeleton
• PR #3806 - Moving include path configuration to before APEX
• PR #3804 - Fix latch
• PR #3803 - Update hpxcxx to look at lib64 and use python3
• PR #3802 - Numa binding allocator
• PR #3801 - Remove duplicated includes
• PR #3800 - Attempt to fix Posix context switching after lazy init changes
• PR #3798 - `count` and `count_if` accepts different iterator types

1438 Chapter 2. What’s so special about HPX?
• PR #3734 Limiting executor
• PR #3732 More constrained bound constructors
• PR #3730 Attempt to fix deadlocks during component loading
• PR #3729 Add latch member function `count_up` and reset, requested by hpxMP
• PR #3728 Send even empty buffers on `hpx::endl` and `hpx::flush`
• PR #3727 Adding example demonstrating how to customize the memory management for a component
• PR #3726 Adding support for passing command line options through the `HPX_COMMANDLINE_OPTIONS` environment variable
• PR #3721 Document known broken OpenMPI builds
• PR #3716 Add barrier reset function, requested by hpxMP for reusing barrier
• PR #3715 More work on functions and vtables
• PR #3714 Generate single-page HTML, PDF, manpage from documentation
• PR #3713 Updating default APEX version to 2.1.2
• PR #3712 Update release procedure
• PR #3710 Fix the C++11 build, after #3704
• PR #3709 Move some component_registry functionality to source file
• PR #3708 Ignore all locks while handling assertions
• PR #3707 Remove obsolete hpx runtime executable
• PR #3705 Fix and simplify `make_ready_future` overload sets
• PR #3704 Reduce use of binders
• PR #3703 Ini
• PR #3702 Fixing CUDA compiler errors
• PR #3700 Added `barrier::increment` function to increase total number of thread
• PR #3697 One more attempt to fix migration...

2.10.7 \textit{HPX V1.2.1} (Feb 19, 2019)

General changes

This is a bugfix release. It contains the following changes:

• Fix compilation on ARM, s390x and 32-bit architectures.
• Fix a critical bug in the future implementation.
• Fix several problems in the CMake configuration which affects external projects.
• Add support for Boost 1.69.0.

Closed issues

2.10.8 \textit{HPX V1.2.0} (Nov 12, 2018)

General changes

Here are some of the main highlights and changes for this release:

- Thanks to the work of our Google Summer of Code student, Nikunj Gupta, we now have a new implementation of \texttt{hpx\_main.hpp} on supported platforms (Linux, BSD and MacOS). This is intended to be a less fragile drop-in replacement for the old implementation relying on preprocessor macros. The new implementation does not require changes if you are using the \texttt{CMake} or \texttt{pkg-config}. The old behaviour can be restored by setting \texttt{HPX\_WITH\_DYNAMIC\_HPX\_MAIN=OFF} during \texttt{CMake} configuration. The implementation on Windows is unchanged.

- We have added functionality to allow passing scheduling hints to our schedulers. These will allow us to create executors that for example target a specific NUMA domain or allow for \textit{HPX} threads to be pinned to a particular worker thread.

- We have significantly improved the performance of our futures implementation by making the shared state atomic.

\textit{Note:}

1642 https://www.cmake.org
1643 https://www.cmake.org
• We have replaced Boostbook by Sphinx for our documentation. This means the documentation is easier to navigate with built-in search and table of contents. We have also added a quick start section and restructured the documentation to be easier to follow for new users.

• We have added a new option to the \texttt{--hpx:threads} command line option. It is now possible to use cores to tell HPX to only use one worker thread per core, unlike the existing option \texttt{all} which uses one worker thread per processing unit (processing unit can be a hyperthread if hyperthreads are available). The default value of \texttt{--hpx:threads} has also been changed to cores as this leads to better performance in most cases.

• All command line options can now be passed alongside configuration options when initializing HPX. This means that some options that were previously only available on the command line can now set as configuration options.

• HPXMP is a portable, scalable, and flexible application programming interface using the OpenMP specification that supports multi-platform shared memory multiprocessing programming in C and C++. HPXMP can be enabled within HPX by setting \texttt{DHPX\_WITH\_HPXMP=ON} during CMake configuration.

• Two new performance counters were added for measuring the time spent doing background work. \texttt{/threads/time/background-work-duration} returns the time spent doing background on a given thread or locality, while \texttt{/threads/time/background-overhead} returns the fraction of time spent doing background work with respect to the overall time spent running the scheduler. The new performance counters are disabled by default and can be turned on by setting \texttt{HPX\_WITH\_BACKGROUND\_THREAD\_COUNTERS=ON} during CMake configuration.

• The idling behaviour of HPX has been tweaked to allow for faster idling. This is useful in interactive applications where the HPX worker threads may not have work all the time. This behaviour can be tweaked and turned off as before with \texttt{HPX\_WITH\_THREAD\_MANAGER\_IDLE\_BACKOFF=OFF} during CMake configuration.

• It is now possible to register callback functions for HPX worker thread events. Callbacks can be registered for starting and stopping worker threads, and for when errors occur.

\section*{Breaking changes}

• The implementation of \texttt{hpx\_main.hpp} has changed. If you are using custom Makefiles you will need to make changes. Please see the documentation on \textit{using Makefiles} for more details.

• The default value of \texttt{--hpx:threads} has changed from \texttt{all} to \texttt{cores}. The new option \texttt{cores} only starts one worker thread per core.

• We have dropped support for Boost 1.56 and 1.57. The minimal version of Boost we now test is 1.58.

• Our \texttt{boost::format}-based formatting implementation has been revised and replaced with a custom implementation. This changes the formatting syntax and requires changes if you are relying on \texttt{hpx::util::format} or \texttt{hpx::util::format_to}. The pull request for this change contains more information: PR \#3266.

• The following deprecated options have now been completely removed: \texttt{HPX\_WITH\_ASYNC\_FUNCTION\_COMPATIBILITY}, \texttt{HPX\_WITH\_LOCAL\_DATAFLOW}, \texttt{HPX\_WITH\_GENERIC\_EXECUTION\_POLICY}, \texttt{HPX\_WITH\_BOOST\_CHRONO\_COMPATIBILITY}, \texttt{HPX\_WITH\_EXECUTOR\_COMPATIBILITY}, \texttt{HPX\_WITH\_EXECUTION\_POLICY\_COMPATIBILITY}, and \texttt{HPX\_WITH\_TRANSFORM\_REDUCE\_COMPATIBILITY}.

• PR #3516 - Drop usage of deprecated facilities removed in C++17
• PR #3515 - Remove remaining uses of Boost.TypeTraits
• PR #3513 - Fixing a CMake problem when trying to use libfabric
• PR #3508 - Remove memory_block component
• PR #3507 - Propagating the MPI compile definitions to all relevant targets
• PR #3503 - Update documentation colors and logo
• PR #3502 - Fix bogus `throws` bindings in scheduled_thread_pool_impl
• PR #3501 - Split parallel::remove_if tests to avoid OOM on CircleCI
• PR #3500 - Support NONAMEPREFIX in add_hpx_library()
• PR #3497 - Note that cuda support requires cmake 3.9
• PR #3495 - Fixing dataflow
• PR #3493 - Remove deprecated options for 1.2.0 part 2
• PR #3492 - Add CUDA_LINK_LIBRARIES_KEYWORd to allow PRIVATE keyword in linkage t...
• PR #3491 - Changing Base docker image
• PR #3490 - Don’t create tasks immediately with hpx::apply
• PR #3489 - Remove deprecated options for 1.2.0
• PR #3488 - Revert “Use BUILD_INTERFACE generator expression to fix cmake flag exports”
• PR #3487 - Revert “Fixing type attribute warning for transfer_action”
• PR #3485 - Use BUILD_INTERFACE generator expression to fix cmake flag exports
• PR #3483 - Fixing type attribute warning for transfer_action
• PR #3481 - Remove unused variables
• PR #3480 - Towards a more lightweight transfer action
• PR #3479 - Fix FLAGS - Use correct version of target_compile_options
• PR #3478 - Making sure the application’s exit code is properly propagated back to the OS
• PR #3476 - Don’t print docker credentials as part of the environment.
• PR #3473 - Fixing invalid cmake code if no jemalloc prefix was given
• PR #3472 - Attempting to work around recent clang test compilation failures
• PR #3471 - Enable jemalloc on windows
• PR #3470 - Updates readme
• PR #3468 - Avoid hang if there is an exception thrown during startup
• PR #3467 - Add compiler specific fallback attributes if C++17 attribute is not available
• PR #3466 - Bugfix : fix compilation with llvm-7.0
• PR #3465 - This patch adds various optimizations extracted from the thread_local_allocator work
• PR #3464 - Check for forked repos in CircleCI docker push step
• PR #3463 - CMake : create the parent directory before symlinking
• PR #3459 - Remove unused/incomplete functionality from util/logging
• PR #3458 - Fix a problem with scope of CMAKE_CXX_FLAGS and hpx_add_compile_flag
• PR #3457 - Fixing more size_t -> int16_t (and similar) warnings
• PR #3456 - Add #ifdefs to topology.cpp to support old hwloc versions again
• PR #3454 - Fixing warnings related to silent conversion of size_t -> int16_t
• PR #3451 - Add examples as unit tests
• PR #3450 - Constexpr-ifying bind and other functional facilities
• PR #3446 - Fix some thread suspension timeouts
• PR #3445 - Fix various warnings
• PR #3443 - Only enable service pool config options if pools are enabled
• PR #3441 - Fix missing closing brackets in documentation

2.10. Releases
• PR #3439 - Use correct MPI CXX libraries for MPI parcelport
• PR #3436 - Add projection function to find_* (and fix very bad bug)
• PR #3435 - Fixing 1205
• PR #3434 - Fix threads cores
• PR #3433 - Add Heise Online to release announcement list
• PR #3432 - Don’t track task dependencies for distributed runs
• PR #3431 - Circle CI setting changes for hpxMP
• PR #3430 - Fix unused params warning
• PR #3429 - One thread per core
• PR #3428 - This suppresses a deprecation warning that is being issued by MSVC 19.15.26726
• PR #3427 - Fixes #3426
• PR #3425 - Use source cache and workspace between job steps on CircleCI
• PR #3421 - Add CDash timing output to future overhead test (for graphs)
• PR #3420 - Add guided_pool_executor
• PR #3419 - Fix typo in CircleCI config
• PR #3418 - Add sphinx documentation
• PR #3415 - Scheduler NUMA hint and shared priority scheduler
• PR #3414 - Adding step to synchronize the APEX release
• PR #3413 - Fixing multiple defines of APEX_HAVE_HPX
• PR #3412 - Fixes linking with libhpx_wrap error with BSD and Windows based systems
• PR #3410 - Fix typo in CMakeLists.txt
• PR #3409 - Fix brackets and indentation in existing_performance_counters.qbk
• PR #3407 - Fix unused param and extra ; warnings emitted by gcc 8.x
• PR #3406 - Adding thread local allocator and use it for future shared states
• PR #3405 - Adding DHPX_HAVE_THREAD_LOCAL_STORAGE=ON to builds
• PR #3404 - fixing multiple definition of main() in linux
• PR #3402 - Allow debug option to be enabled only for Linux systems with dynamic main on
• PR #3401 - Fix cuda_future_helper.h when compiling with C++11
• PR #3400 - Fix floating point exception scheduler_base idle backoff
• PR #3398 - Atomic future state
• PR #3397 - Fixing code for older gcc versions
• PR #3396 - Allowing to register thread event functions (start/stop/error)
• PR #3394 - Fix small mistake in primary_namespace_server.cpp
• PR #3393 - Explicitly instantiate configured schedulers
• PR #3392 - Add performance counters background overhead and background work duration
• PR #3391 - Adapt integration of HPXMP to latest build system changes
• PR #3390 - Make AGAS measurements optional
• PR #3389 - Fix deadlock during shutdown
• PR #3388 - Add several functionalities allowing to optimize synchronous action invocation
• PR #3387 - Add cmake option to opt out of fail-compile tests
• PR #3386 - Adding support for boost::container::small_vector to dataflow
• PR #3385 - Adds Debug option for hpx initializing from main
• PR #3384 - This hopefully fixes two tests that occasionally fail
• PR #3383 - Making sure thread local storage is enable for hpxMP
• PR #3382 - Fix usage of HPX_CAPTURE together with default value capture [=]
• PR #3381 - Replace undefined instantiations of uniform_int_distribution
• PR #3380\(^{1807}\) - Add missing semicolons to uses of HPX_COMPILER_FENCE
• PR #3379\(^{1808}\) - Fixing #3378
• PR #3377\(^{1809}\) - Adding build system support to integrate hpxmp into hpx at the user’s machine
• PR #3375\(^{1810}\) - Replacing wrapper for _libc_start_main with main
• PR #3374\(^{1811}\) - Adds hpx_wrap to HPX_LINK_LIBRARIES which links only when specified.
• PR #3373\(^{1812}\) - Forcing cache settings in HPXConfig.cmake to guarantee updated values
• PR #3372\(^{1813}\) - Fix some more c++11 build problems
• PR #3371\(^{1814}\) - Adds HPX_LINKER_FLAGS to HPX applications without editing their source codes
• PR #3370\(^{1815}\) - util::format: add type_specifier<> specializations for %!s(MISSING) and %!l(MISSING)s
• PR #3369\(^{1816}\) - Adding configuration option to allow explicit disable of the new hpx_main feature on Linux
• PR #3368\(^{1817}\) - Updates doc with recent hpx_wrap implementation
• PR #3367\(^{1818}\) - Adds Mac OS implementation to hpx_main.hpp
• PR #3365\(^{1819}\) - Fix order of hpx libs in HPX_CONFIG_LIBRARIES.
• PR #3363\(^{1820}\) - Apex fixing null wrapper
• PR #3361\(^{1821}\) - Making sure all parcels get destroyed on an HPX thread (TCP pp)
• PR #3359\(^{1822}\) - Feature/improveerrorforcompiler
• PR #3357\(^{1823}\) - Static/dynamic executable implementation
• PR #3355\(^{1824}\) - Reverting changes introduced by #3283 as those make applications hang
• PR #3354\(^{1825}\) - Add external dependencies to HPX_LIBRARY_DIR
• PR #3353\(^{1826}\) - Fix libfabric tcp
• PR #3351\(^{1827}\) - Move obsolete header to tests directory.
• PR #3350\(^{1828}\) - Renaming two functions to avoid problem described in #3285
• PR #3349\(^{1829}\) - Make idle backoff exponential with maximum sleep time

1454 Chapter 2. What’s so special about HPX?
• PR #3347 - Replace `simple_component*` with `component*` in the Documentation

• PR #3346 - Fix CMakeLists.txt example in quick start

• PR #3345 - Fix automatic setting of `HPX_MORE_THAN_64_THREADS`

• PR #3344 - Reduce amount of information printed for unknown command line options

• PR #3343 - Safeguard HPX against destruction in global contexts

• PR #3341 - Allowing for all command line options to be used as configuration settings

• PR #3340 - Always convert inspect results to JUnit XML

• PR #3336 - Only run docker push on master on CircleCI

• PR #3335 - Update description of `hpx.os_threads` config parameter.

• PR #3334 - Making sure early logging settings don’t get mixed with others

• PR #3333 - Update CMake links and versions in documentation

• PR #3332 - Add notes on target suffixes to CMake documentation

• PR #3331 - Add quickstart section to documentation

• PR #3330 - Rename `resource_partitioner` test to avoid conflicts with pseudodependencies

• PR #3328 - Making sure object is pinned while executing actions, even if action returns a future

• PR #3327 - Add missing `std::forward` to `tuple.hpp`

• PR #3326 - Make sure logging is up and running while modules are being discovered.

• PR #3324 - Replace C++14 overload of `std::equal` with C++11 code.

• PR #3323 - Fix a missing apex thread data (wrapper) initialization

• PR #3320 - Adding support for `-std=c++2a` (define `HPX_WITH_CXX2A=On`)

• PR #3319 - Replacing C++14 feature with equivalent C++11 code

• PR #3317 - Fix compilation with VS 15.7.1 and `/std:c++latest`

• PR #3316 - Fix includes for 1d_stencil_*_omp examples

1852 - https://github.com/STEllAR-GROUP/hpx/pull/3316

2.10. Releases
• PR #3314 - Remove some unused parameter warnings
• PR #3313 - Fix pu-step and pu-offset command line options
• PR #3312 - Add conversion of inspect reports to JUnit XML
• PR #3311 - Fix escaping of closing braces in format specification syntax
• PR #3310 - Don’t overwrite user settings with defaults in registration database
• PR #3309 - Fixing potential stack overflow for dataflow
• PR #3308 - This updates the .clang-format configuration file to utilize newer features
• PR #3306 - Marking migratable objects in their gid to allow not handling migration in AGAS
• PR #3305 - Add proper exception handling to run_as_hpx_thread
• PR #3303 - Changed std::rand to a better inbuilt PRNG Generator
• PR #3302 - All non-migratable (simple) components now encode their lva and component type in their gid
• PR #3301 - Add nullptr_t overloads to resource partitioner
• PR #3298 - Apex task wrapper memory bug
• PR #3295 - Fix mistakes after merge of CircleCI config
• PR #3294 - Fix partitioned vector include in partitioned_vector_find tests
• PR #3293 - Adding emplace support to promise and make_ready_future
• PR #3292 - Add new cuda kernel synchronization with hpx::future demo
• PR #3291 - Fixes #3290
• PR #3289 - Fixing Docker image creation
• PR #3288 - Avoid allocating shared state for wait_all
• PR #3287 - Fixing /scheduler/utilization/instantaneous performance counter
• PR #3286 - dataflow() and future::then() use sync policy where possible
• PR #3284 - Background thread can use relaxed atomics to manipulate thread state
• PR #3283\(^{1876}\) - Do not unwrap ready future
• PR #3282\(^{1877}\) - Fix virtual method override warnings in static schedulers
• PR #3281\(^{1878}\) - Disable set_area_membind_nodeset for OSX
• PR #3279\(^{1879}\) - Add two variations to the future_overhead benchmark
• PR #3278\(^{1880}\) - Fix circleci workspace
• PR #3277\(^{1881}\) - Support external plugins
• PR #3276\(^{1882}\) - Fix missing parenthesis in hello_compute.cu.
• PR #3274\(^{1883}\) - Reinit counters synchronously in reinit_counters test
• PR #3273\(^{1884}\) - Splitting tests to avoid compiler OOM
• PR #3271\(^{1885}\) - Remove leftover code from context_generic_context.hpp
• PR #3269\(^{1886}\) - Fix bulk_construct with count = 0
• PR #3268\(^{1887}\) - Replace constexpr with HPX_CXX14_CONSTEXPR and HPX_CONSTEXPR
• PR #3266\(^{1888}\) - Replace boost::format with custom sprintf-based implementation
• PR #3265\(^{1889}\) - Split parallel tests on CircleCI
• PR #3262\(^{1890}\) - Making sure documentation correctly links to source files
• PR #3261\(^{1891}\) - Apex refactoring fix rebind
• PR #3260\(^{1892}\) - Isolate performance counter parser into a separate TU
• PR #3256\(^{1893}\) - Post 1.1.0 version bumps
• PR #3254\(^{1894}\) - Adding trait for actions allowing to make runtime decision on whether to execute it directly
• PR #3253\(^{1895}\) - Bump minimal supported Boost to 1.58.0
• PR #3251\(^{1896}\) - Adds new feature: changing interval used in interval_timer (issue 3244)
• PR #3239\(^{1897}\) - Changing std::rand() to a better inbuilt PRNG generator.
• PR #3234\(^{1898}\) - Disable background thread when networking is off

• PR #3232 - Clean up suspension tests
• PR #3230 - Add optional scheduler mode parameter to create_thread_pool function
• PR #3228 - Allow suspension also on static schedulers
• PR #3163 - libfabric parcelport w/o HPX_PARCELPORT_LIBFABRIC_ENDPOINT_RDM
• PR #3036 - Switching to CircleCI 2.0

2.10.9 HPX V1.1.0 (Mar 24, 2018)

General changes

Here are some of the main highlights and changes for this release (in no particular order):

• We have changed the way HPX manages the processing units on a node. We do not longer implicitly bind all available cores to a single thread pool. The user has now full control over what processing units are bound to what thread pool, each with a separate scheduler. It is now also possible to create your own scheduler implementation and control what processing units this scheduler should use. We added the hpx::resource::partitioner that manages all available processing units and assigns resources to the used thread pools. Thread pools can be now be suspended/resumed independently. This functionality helps in running HPX concurrently to code that is directly relying on OpenMP and/or MPI.

• We have continued to implement various parallel algorithms. HPX now almost completely implements all of the parallel algorithms as specified by the C++17 Standard. We have also continued to implement these algorithms for the distributed use case (for segmented data structures, such as hpx::partitioned_vector).

• Added a compatibility layer for std::thread, std::mutex, and std::condition_variable allowing for the code to use those facilities where available and to fall back to the corresponding Boost facilities otherwise. The CMake configuration option -DHPX_WITH_THREAD_COMPATIBILITY=On can be used to force using the Boost equivalents.

• The parameter sequence for the hpx::parallel::transform_inclusive_scan overload taking one iterator range has changed (again) to match the changes this algorithm has undergone while being moved to C++17. The old overloads can be still enabled at configure time by passing -DHPX_WITH_TRANSFORM_REDUCE_COMPATIBILITY=On to CMake.

• The parameter sequence for the hpx::parallel::inclusive_scan overload taking one iterator range has changed to match the changes this algorithm has undergone while being moved to C++17. The old overloads can be still enabled at configure time by passing -DHPX_WITH_INCLUSIVE_SCAN_COMPATIBILITY=On to CMake.

• Added a helper facility hpx::local_new which is equivalent to hpx::new except that it creates components locally only. As a consequence, the used component constructor may accept non-serializable argument types and/or non-const references or pointers.

• Removed the (broken) component type hpx::lcos::queue<T>. The old type is still available at configure time by passing -DHPX_WITH_QUEUE_COMPATIBILITY=On to CMake.

1902 https://github.com/STEllAR-GROUP/hpx/pull/3163
1903 https://github.com/STEllAR-GROUP/hpx/pull/3036
1904 https://openmp.org/wp/
1905 https://en.wikipedia.org/wiki/Message_Passing_Interface
1906 http://www.open-std.org/jtc1/sc22/wg21
1907 https://www.cmake.org
1908 https://www.cmake.org
• The parallel algorithms adopted for C++17 restrict the iterator categories usable with those to at least forward iterators. Our implementation of the parallel algorithms was supporting input iterators (and output iterators) as well by simply falling back to sequential execution. We have now made our implementations conforming by requiring at least forward iterators. In order to enable the old behavior use the compatibility option -DHPX_WITH_ALGORITHM_INPUT_ITERATOR_SUPPORT=On on the CMake\textsuperscript{1909} command line.

• We have added the functionalities allowing for LCOs being implemented using (simple) components. Before LCOs had to always be implemented using managed components.

• User defined components don’t have to be default-constructible anymore. Return types from actions don’t have to be default-constructible anymore either. Our serialization layer now in general supports non-default-constructible types.

• We have added a new launch policy `hpx::launch::lazy` that allows one to defer the decision on what launch policy to use to the point of execution. This policy is initialized with a function (object) that – when invoked – is expected to produce the desired launch policy.

### Breaking changes

• We have dropped support for the gcc compiler version V4.8. The minimal gcc version we now test on is gcc V4.9. The minimally required version of CMake\textsuperscript{1910} is now V3.3.2.

• We have dropped support for the Visual Studio 2013 compiler version. The minimal Visual Studio version we now test on is Visual Studio 2015.5.

• We have dropped support for the Boost V1.51-V1.54. The minimal version of Boost we now test is Boost V1.55.

• We have dropped support for the `hpx::util::unwrapped` API. `hpx::util::unwrapped` will stay functional to some degree, until it finally gets removed in a later version of HPX. The functional usage of `hpx::util::unwrapped` should be changed to the new `hpx::util::unwrapping` function whereas the immediate usage should be replaced to `hpx::util::unwrap`.

• The performance counter names referring to properties as exposed by the threading subsystem have changes as those now additionally have to specify the thread-pool. See the corresponding documentation for more details.

• The overloads of `hpx::async` that invoke an action do not perform implicit unwrapping of the returned future anymore in case the invoked function does return a future in the first place. In this case `hpx::async` now returns a `hpx::future<future<T>>` making its behavior conforming to its local counterpart.

• We have replaced the use of `boost::exception_ptr` in our APIs with the equivalent `std::exception_ptr`. Please change your codes accordingly. No compatibility settings are provided.

• We have removed the compatibility settings for `HPX_WITH_COLOCATED_BACKWARDS_COMPATIBILITY` and `HPX_WITH_COMPONENT_GET_GID_COMPATIBILITY` as their life-cycle has reached its end.

• We have removed the experimental thread schedulers `hierarchy_scheduler`, `periodic_priority_scheduler` and `throttling_scheduler` in an effort to clean up and consolidate our thread schedulers.

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release.

- PR #3250¹⁹¹¹ - Apex refactoring with guids
- PR #3249¹⁹¹² - Updating People.qbk
- PR #3246¹⁹¹³ - Assorted fixes for CUDA
- PR #3245¹⁹¹⁴ - Apex refactoring with guids
- PR #3242¹⁹¹⁵ - Modify task counting in thread_queue.hpp
- PR #3240¹⁹¹⁶ - Fixed typos
- PR #3238¹⁹¹⁷ - Readding accidentally removed std::abort
- PR #3237¹⁹¹⁸ - Adding Pipeline example
- PR #3236¹⁹¹⁹ - Fixing memory_block
- PR #3233¹⁹²⁰ - Make schedule_thread take suspended threads into account
- Issue #3226¹⁹²¹ - memory_block is breaking, signaling SIGSEGV on a thread on creation and freeing
- PR #3225¹⁹²² - Applying quick fix for hwloc-2.0
- Issue #3224¹⁹²³ - HPX counters crashing the application
- PR #3223¹⁹²⁴ - Fix returns when setting config entries
- Issue #3222¹⁹²⁵ - Errors linking libhpx.so
- Issue #3221¹⁹²⁶ - HPX on Mac OS X with HWLoc 2.0.0 fails to run
- PR #3216¹⁹²⁷ - Reorder a variadic array to satisfy VS 2017 15.6
- PR #3214¹⁹²⁸ - Changed prerequisites.qbk to avoid confusion while building boost
- PR #3213¹⁹²⁹ - Relax locks for thread suspension to avoid holding locks when yielding
- PR #3212¹⁹³⁰ - Fix check in sequenced_executor test
- PR #3211¹⁹³¹ - Use preinit_array to set argc/argv in init_globally example

• PR #3210\(^{1932}\)  - Adapted parallel::{search | search_n} for Ranges TS (see #1668)
• PR #3209\(^{1933}\)  - Fix locking problems during shutdown
• Issue #3208\(^{1934}\) - init_globally throwing a run-time error
• PR #3206\(^{1935}\) - Addition of new arithmetic performance counter “Count”
• PR #3205\(^{1936}\) - Fixing return type calculation for bulk_then_execute
• PR #3204\(^{1937}\) - Changing std::rand() to a better inbuilt PRNG generator
• PR #3203\(^{1938}\) - Resolving problems during shutdown for VS2015
• PR #3202\(^{1939}\) - Making sure resource partitioner is not accessed if its not valid
• PR #3201\(^{1940}\) - Fixing optional::swap
• Issue #3200\(^{1941}\) - hpx::util::optional fails
• PR #3199\(^{1942}\) - Fix sliding_semaphore test
• PR #3198\(^{1943}\) - Set pre_main status before launching run_helper
• PR #3197\(^{1944}\) - Update README.rst
• PR #3194\(^{1945}\) - parallel::{fill|fill_n} updated for Ranges TS
• PR #3193\(^{1946}\) - Updating Runtime.cpp by adding correct description of Performance counters during register
• PR #3191\(^{1947}\) - Fix sliding_semaphore_2338 test
• PR #3190\(^{1948}\) - Topology improvements
• PR #3189\(^{1949}\) - Deleting one include of median from BOOST library to arithmetics_counter file
• PR #3188\(^{1950}\) - Optionally disable printing of diagnostics during terminate
• PR #3187\(^{1951}\) - Suppressing cmake warning issued by cmake > V3.11
• PR #3185\(^{1952}\) - Remove unused scoped_unlock, unlock_guard_try
• PR #3184\(^{1953}\) - Fix nqueen example
• PR #3183\(^{1954}\) - Add runtime start/stop, resume/suspend and OpenMP benchmarks

2.10. Releases
• Issue #3182 - bulk_then_execute has unexpected return type/does not compile
• Issue #3181 - hwloc 2.0 breaks topo class and cannot be used
• Issue #3180 - Schedulers that don’t support suspend/resume are unusable
• PR #3179 - Various minor changes to support FLeCSI
• PR #3178 - Fix #3124
• PR #3177 - Removed allgather
• PR #3176 - Fixed Documentation for “using_hpx_pkgconfig”
• PR #3174 - Add hpx::iostreams::ostream overload to format_to
• PR #3172 - Fix lifo queue backend
• PR #3171 - adding the missing unset() function to cpu_mask() for case of more than 64 threads
• PR #3170 - Add cmake flag -DHPX_WITH_FAULT_TOLERANCE=ON (OFF by default)
• PR #3169 - Adapted parallel::{count|count_if} for Ranges TS (see #1668)
• PR #3168 - Changing used namespace for seq execution policy
• Issue #3167 - Update GSoC projects
• Issue #3166 - Application (Octotiger) gets stuck on hpx::finalize when only using one thread
• Issue #3165 - Compilation of parallel algorithms with HPX_WITH_DATAPAR is broken
• PR #3164 - Fixing component migration
• PR #3162 - regex_from_pattern: escape regex special characters to avoid misinterpretation
• Issue #3161 - Building HPX with hwloc 2.0.0 fails
• PR #3160 - Fixing the handling of quoted command line arguments.
• PR #3158 - Fixing a race with timed suspension (second attempt)
• PR #3157 - Revert “Fixing a race with timed suspension”
• PR #3156 - Fixing serialization of classes with incompatible serialize signature

• PR #3154¹⁹⁷⁸ - More refactorings based on clang-tidy reports
• PR #3153¹⁹⁷⁹ - Fixing a race with timed suspension
• PR #3152¹⁹⁸⁰ - Documentation for runtime suspension
• PR #3151¹⁹⁸¹ - Use small_vector only from boost version 1.59 onwards
• PR #3150¹⁹⁸² - Avoiding more stack overflows
• PR #3148¹⁹⁸³ - Refactoring component_base and base_action/transfer_base_action
• PR #3147¹⁹⁸⁴ - Move yield_while out of detail namespace and into own file
• PR #3145¹⁹⁸⁵ - Remove a leftover of the cxx11 std array cleanup
• PR #3144¹⁹⁸⁶ - Minor changes to how actions are executed
• PR #3143¹⁹⁸⁷ - Fix stack overhead
• PR #3142¹⁹⁸⁸ - Fix typo in config.hpp
• PR #3141¹⁹⁸⁹ - Fixing small_vector compatibility with older boost version
• PR #3140¹⁹⁹⁰ - is_heap_text fix
• Issue #3139¹⁹⁹¹ - Error in is_heap_tests.hpp
• PR #3138¹⁹⁹² - Partially reverting #3126
• PR #3137¹⁹⁹³ - Suspend speedup
• PR #3136¹⁹⁹⁴ - Revert “Fixing #2325”
• PR #3135¹⁹⁹⁵ - Improving destruction of threads
• Issue #3134¹⁹⁹⁶ - HPX_SERIALIZATION_SPLIT_FREE does not stop compiler from looking for serialize() method
• PR #3133¹⁹⁹⁷ - Make hwloc compulsory
• PR #3132¹⁹⁹⁸ - Update CXX14 constexpr feature test
• PR #3131¹⁹⁹⁹ - Fixing #2325
• PR #3130²⁰⁰⁰ - Avoid completion handler allocation

- PR #3110<sup>2020</sup> - Suspend thread pool
- PR #3109<sup>2021</sup> - Fixing thread scheduling when yielding a thread id
- PR #3108<sup>2022</sup> - Revert “Suspend thread pool”
- PR #3107<sup>2023</sup> - Remove UB from thread::id relational operators

---

• PR #3106\textsuperscript{2024} - Add cmake test for std::decay_t to fix cuda build
• PR #3105\textsuperscript{2025} - Fixing refcount for async traversal frame
• PR #3104\textsuperscript{2026} - Local execution of direct actions is now actually performed directly
• PR #3103\textsuperscript{2027} - Adding support for generic counter\_raw\_values performance counter type
• Issue #3102\textsuperscript{2028} - Introduce generic performance counter type returning an array of values
• PR #3101\textsuperscript{2029} - Revert “Adapting stack overhead limit for gcc 4.9”
• PR #3100\textsuperscript{2030} - Fix #3068 (condition\_variable deadlock)
• PR #3099\textsuperscript{2031} - Fixing lock held during suspension in papi counter component
• PR #3098\textsuperscript{2032} - Unbreak broadcast\_wait\_for\_2822 test
• PR #3097\textsuperscript{2033} - Adapting stack overhead limit for gcc 4.9
• PR #3096\textsuperscript{2034} - Fix detection of cxx11\_std\_atomic
• PR #3095\textsuperscript{2035} - Add ciso646 header to get _LIBCPP\_VERSION for testing inplace merge
• PR #3094\textsuperscript{2036} - Relax atomic operations on performance counter values
• PR #3093\textsuperscript{2037} - Short-circuit all\_of\/any\_of\/none\_of instantiations
• PR #3092\textsuperscript{2038} - Take advantage of C++14 lambda capture initialization syntax, where possible
• PR #3091\textsuperscript{2039} - Remove more references to Boost from logging code
• PR #3090\textsuperscript{2040} - Unify use of yield/yield\_k
• PR #3089\textsuperscript{2041} - Fix a strange thing in parallel::detail\::handle\_exception. (Fix #2834.)
• Issue #3088\textsuperscript{2042} - A strange thing in parallel\::sort.
• PR #3087\textsuperscript{2043} - Fixing assertion in default\_distribution\_policy
• PR #3086\textsuperscript{2044} - Implement parallel\::remove and parallel\::remove\_if
• PR #3085\textsuperscript{2045} - Addressing breaking changes in Boost V1.66
• PR #3084\textsuperscript{2046} - Ignore build warnings round 2

• PR #3083 - Fix typo HPX_WITH_MM_PREFECTH
• PR #3081 - Pre-decay template arguments early
• PR #3080 - Suspend thread pool
• PR #3079 - Ignore build warnings
• PR #3078 - Don’t test inplace_merge with libc++
• PR #3076 - Fixing 3075: Part 1
• PR #3074 - Fix more build warnings
• PR #3073 - Suspend thread cleanup
• PR #3072 - Change existing symbol_namespace::iterate to return all data instead of invoking a callback
• PR #3071 - Fixing pack_traversal_async test
• PR #3070 - Fix dynamic_counters_loaded_1508 test by adding dependency to memory_component
• PR #3069 - Fix scheduling loop exit
• Issue #3068 - hpx::lcos::condition_variable could be suspect to deadlocks
• PR #3067 - #ifdef out random_shuffle deprecated in later c++
• PR #3066 - Make coalescing test depend on coalescing library to ensure it gets built
• PR #3065 - Workaround for minimal_timed_async_executor_test compilation failures, attempts to copy a deferred call (in unevaluated context)
• PR #3064 - Fixing wrong condition in wrapper_heap
• PR #3062 - Fix exception handling for execution::seq
• PR #3061 - Adapt MSVC C++ mode handling to VS15.5
• PR #3060 - Fix compiler problem in MSVC release mode
• PR #3059 - Fixing #2931
• Issue #3058 - minimal_timed_async_executor_test_exe fails to compile on master (d6f505c)
• PR #3057 - Fix stable_merge_2964 compilation problems

https://github.com/STEllAR-GROUP/hpx/pull/3057
- **PR #3056** - Fix some build warnings caused by unused variables/unnecessary tests
- **PR #3055** - Update documentation for running tests
- **Issue #3054** - Assertion failure when using bulk hpx::new in asynchronous mode
- **PR #3052** - Do not bind test running to cmake test build rule
- **PR #3051** - Fix HPX-Qt interaction in Qt example.
- **Issue #3048** - nqueen example fails occasionally
- **PR #3047** - Fixing #3044
- **PR #3046** - Add OS thread suspension
- **PR #3042** - PyCicle - first attempt at a build tool for checking PR’s
- **PR #3041** - Fix a problem about asynchronous execution of parallel::merge and parallel::partition.
- **PR #3040** - Fix a mistake about exception handling in asynchronous execution of scan_partitioner.
- **PR #3039** - Consistently use executors to schedule work
- **PR #3038** - Fixing local direct function execution and lambda actions perfect forwarding
- **PR #3035** - Make parallel unit test names match build target/folder names
- **PR #3033** - Fix setting of default build type
- **Issue #3032** - Fix partitioner arg copy found in #2982
- **Issue #3031** - Errors linking libhpx.so due to missing references (master branch, commit 6679a8882)
- **PR #3030** - Revert “implement executor then interface with && forwarding reference”
- **PR #3029** - Run CI inspect checks before building
- **PR #3028** - Added range version of parallel::move
- **Issue #3027** - Implement all scheduling APIs in terms of executors
- **PR #3026** - implement executor then interface with && forwarding reference
- **PR #3025** - Fix typo uninitialized to uninitialized

• PR #3024 - Inspect fixes
• PR #3023 - P0356 Simplified partial function application
• PR #3023 - Master fixes
• PR #3021 - Segfault fix
• PR #3020 - Disable command-line aliasing for applications that use user_main
• PR #3019 - Adding enable_elasticity option to pool configuration
• PR #3018 - Fix stack overflow detection configuration in header files
• PR #3017 - Speed up local action execution
• PR #3016 - Unify stack-overflow detection options, remove reference to libsigsegv
• PR #3015 - Speeding up accessing the resource partitioner and the topology info
• Issue #3014 - HPX does not compile on POWER8 with gcc 5.4
• Issue #3013 - hello_world occasionally prints multiple lines from a single OS-thread
• PR #3012 - Silence warning about casting away qualifiers in itt_notify.hpp
• PR #3011 - Fix cpuset leak in hwloc_topology_info.cpp
• PR #3010 - Remove useless decay_copy
• PR #3009 - Fixing 2996
• PR #3008 - Remove unused internal function
• PR #3007 - Fixing wrapper_heap alignment problems
• Issue #3006 - hwloc memory leak
• PR #3004 - Silence C4251 (needs to have dll-interface) for future_data_void
• Issue #3003 - Suspension of runtime
• PR #3001 - Attempting to avoid data races in async_traversal while evaluating dataflow()
• PR #3000 - Adding hpx::util::optional as a first step to replace experimental::optional

2114 https://github.com/STEllAR-GROUP/hpx/pull/3001
2115 https://github.com/STEllAR-GROUP/hpx/pull/3000
• PR #2998
  - Cleanup up and Fixing component creation and deletion
• Issue #2996
  - Build fails with HPX_WITH_HWLOC=OFF
• PR #2995
  - Push more future_data functionality to source file
• PR #2994
  - WIP: Fix throttle test
• PR #2993
  - Making sure –hpx:help does not throw for required (but missing) arguments
• PR #2992
  - Adding non-blocking (on destruction) service executors
• Issue #2991
  - run_as_os_thread locks up
• Issue #2990
  - --help will not work until all required options are provided
• PR #2989
  - Improve error messages caused by misuse of dataflow
• PR #2988
  - Improve error messages caused by misuse of .then
• Issue #2987
  - stack overflow detection producing false positives
• PR #2986
  - Deduplicate non-dependent thread_info logging types
• PR #2985
  - Adapted parallel::{all_of|any_of|none_of} for Ranges TS (see #1668)
• PR #2984
  - Refactor one_size_heap code to simplify code
• PR #2983
  - Fixing local_new_component
• PR #2982
  - Clang tidy
• PR #2981
  - Simplify allocator rebinding in pack traversal
• PR #2979
  - Fixing integer overflows
• PR #2978
  - Implement parallel::inplace_merge
• Issue #2977
  - Make hwloc compulsory instead of optional
• PR #2976
  - Making sure client_base instance that registered the component does not unregister it when being destructed
• PR #2975
  - Change version of pulled APEX to master
• PR #2974
  - Fix domain not being freed at the end of scheduling loop

2138 https://github.com/STEllAR-GROUP/hpx/pull/2974

2.10. Releases
• PR #2973  - Fix small typos
  • PR #2972  - Adding uintstd.h header
  • PR #2971  - Fall back to creating local components using local_new
  • PR #2970  - Improve is_tuple_like trait
  • PR #2960  - Fix HPX_WITH_MORE_THAN_64_THREADS default value
  • PR #2968  - Cleaning up dataflow overload set
  • PR #2967  - Make parallel::merge is stable. (Fix #2964.)
  • PR #2966  - Fixing a couple of held locks during exception handling
  • PR #2965  - Adding missing #include
  • Issue #2964  - parallel merge is not stable
  • PR #2962  - Making sure any function object passed to dataflow is released after being invoked
  • PR #2961  - Partially reverting #2891
  • Issue #2959  - Program terminates during error handling
  • Issue #2958  - HPX_PLAIN_ACTION breaks due to missing include
  • PR #2957  - Fixing errors generated by mixing different attribute syntaxes
  • Issue #2956  - Mixing attribute syntaxes leads to compiler errors
  • Issue #2955  - Fix OS-Thread throttling
  • PR #2953  - Making sure any hpx.os_threads=N supplied through a --hpx::config file is taken into account
  • PR #2952  - Removing wrong call to cleanup_terminated_locked
  • PR #2951  - Revert “Make sure the function vtables are initialized before use”
  • PR #2950  - Fix a namespace compilation error when some schedulers are disabled
  • Issue #2949  - master branch giving lockups on shutdown

Chapter 2. What’s so special about HPX?
• Issue #2947
  - hpx.ini is not used correctly at initialization
• PR #2946
  - Adding explicit feature test for thread_local
• PR #2945
  - Make sure the function vtables are initialized before use
• PR #2944
  - Attempting to solve affinity problems on CircleCI
• PR #2943
  - Changing channel actions to be direct
• PR #2942
  - Adding split_future for std::vector
• PR #2941
  - Add a feature test to test for CXX11 override
• Issue #2940
  - Add split_future for future<vector<T>>
• PR #2940
  - Making error reporting during problems with setting affinity masks more verbose
• PR #2938
  - Fix this various executors
• PR #2937
  - Fix some typos in documentation
• PR #2934
  - Remove the need for “complete” SFINAE checks
• PR #2933
  - Making sure parallel::for_loop is executed in parallel if requested
• PR #2932
  - Classify chunk_size_iterator to input iterator tag. (Fix #2866)
• Issue #2931
  - –hpx:help triggers unusual error with clang build
• PR #2930
  - Add #include files needed to set _POSIX_VERSION for debug check
• PR #2929
  - Fix a couple of deprecated c++ features
• PR #2928
  - Fixing execution parameters
• Issue #2927
  - CMake warning: … cycle in constraint graph
• PR #2926
  - Default pool rename
• Issue #2925
  - Default pool cannot be renamed
• Issue #2924
  - hpx:attach-debugger=startup does not work any more
• PR #2923
  - Alloc membind

2.10. Releases
• PR #2922\textsuperscript{2185} - This fixes CircleCI errors when running with --hpx:bind=none
• PR #2921\textsuperscript{2186} - Custom pool executor was missing priority and stacksize options
• PR #2920\textsuperscript{2187} - Adding test to trigger problem reported in #2916
• PR #2919\textsuperscript{2188} - Make sure the resource\_partitioner is properly destructed on hpx::finalize
• Issue #2918\textsuperscript{2189} - hpx::init calls wrong (first) callback when called multiple times
• PR #2917\textsuperscript{2190} - Adding util::checkpoint
• Issue #2916\textsuperscript{2191} - Weird runtime failures when using a channel and chained continuations
• PR #2915\textsuperscript{2192} - Introduce executor parameters customization points
• Issue #2914\textsuperscript{2193} - Task assignment to current Pool has unintended consequences
• PR #2913\textsuperscript{2194} - Fix rp hang
• PR #2912\textsuperscript{2195} - Update contributors
• PR #2911\textsuperscript{2196} - Fixing CUDA problems
• PR #2910\textsuperscript{2197} - Improve error reporting for process component on POSIX systems
• PR #2909\textsuperscript{2198} - Fix typo in include path
• PR #2908\textsuperscript{2199} - Use proper container according to iterator tag in benchmarks of parallel algorithms
• PR #2907\textsuperscript{2200} - Optionally force-delete remaining channel items on close
• PR #2906\textsuperscript{2201} - Making sure generated performance counter names are correct
• Issue #2905\textsuperscript{2202} - collecting idle-rate performance counters on multiple localities produces an error
• Issue #2904\textsuperscript{2203} - build broken for Intel 17 compilers
• PR #2903\textsuperscript{2204} - Documentation Updates-- Adding New People
• PR #2902\textsuperscript{2205} - Fixing service\_executor
• PR #2901\textsuperscript{2206} - Fixing partitioned\_vector creation
• PR #2900\textsuperscript{2207} - Add numa-balanced mode to hpx::bind, spread cores over numa domains

\textsuperscript{2207}https://github.com/STEllAR-GROUP/hpx/pull/2900
• Issue #2899 - hpx::bind does not have a mode that balances cores over numa domains
• PR #2898 - Adding missing #include and missing guard for optional code section
• PR #2897 - Removing dependency on Boost.ICL
• Issue #2896 - Debug build fails without -fpermissive with GCC 7.1 and Boost 1.65
• PR #2895 - Fixing SLURM environment parsing
• PR #2894 - Fix incorrect handling of compile definition with value 0
• Issue #2893 - Disabling schedulers causes build errors
• PR #2892 - added list serializer
• PR #2891 - Resource Partitioner Fixes
• Issue #2890 - Destroying a non-empty channel causes an assertion failure
• PR #2889 - Add check for libatomic
• PR #2888 - Fix compilation problems if HPX_WITH_ITT_NOTIFY=ON
• PR #2887 - Adapt broadcast() to non-unwrapping async<Action>
• PR #2886 - Replace Boost.Random with C++11 <random>
• Issue #2885 - regression in broadcast?
• Issue #2884 - linking -latomic is not portable
• PR #2883 - Explicitly set -pthread flag if available
• PR #2882 - Wrap boost::format uses
• Issue #2881 - hpx not compiling with HPX_WITH_ITTNOTIFY=On
• Issue #2880 - hpx::bind scatter/balanced give wrong pu masks
• PR #2878 - Fix incorrect pool usage masks setup in RP/thread manager
• PR #2877 - Require std::array by default
• PR #2875 - Deprecate use of BOOST_ASSERT

2.10. Releases
• PR #2874\(^{2231}\) - Changed serialization of boost.variant to use variadic templates
• Issue #2873\(^{2232}\) - building with parcelport_mpi fails on cori
• PR #2871\(^{2233}\) - Adding missing support for throttling scheduler
• PR #2870\(^{2234}\) - Disambiguate use of base_lco_with_value macros with channel
• Issue #2869\(^{2235}\) - Difficulty compiling `HPX_REGISTER_CHANNEL_DECLARATION(double)`
• PR #2868\(^{2236}\) - Removing unneeded assert
• PR #2867\(^{2237}\) - Implement parallel::unique
• Issue #2866\(^{2238}\) - The chunk_size_iterator violates multipass guarantee
• PR #2865\(^{2239}\) - Only use sched_getcpu on linux machines
• PR #2864\(^{2240}\) - Create redistribution archive for successful builds
• PR #2863\(^{2241}\) - Replace casts/assignments with hard-coded memcpy operations
• Issue #2862\(^{2242}\) - sched_getcpu not available on MacOS
• PR #2861\(^{2243}\) - Fixing unmatched header defines and recursive inclusion of threadmanager
• Issue #2860\(^{2244}\) - Master program fails with assertion ‘type == data_type_address’ failed: HPX(assertion_failure)
• Issue #2852\(^{2245}\) - Support for ARM64
• PR #2858\(^{2246}\) - Fix misplaced #if #endif’s that cause build failure without THREAD_CUMULATIVE_COUNTS
• PR #2857\(^{2247}\) - Fix some listing in documentation
• PR #2856\(^{2248}\) - Fixing component handling for lcos
• PR #2855\(^{2249}\) - Add documentation for coarrays
• PR #2854\(^{2250}\) - Support ARM64 in timestamps
• PR #2853\(^{2251}\) - Update Table 17. Non-modifying Parallel Algorithms in Documentation
• PR #2851\(^{2252}\) - Allowing for non-default-constructible component types

• PR #2850\(^{2253}\) - Enable returning future<\(R\)> from actions where \(R\) is not default-constructible
• PR #2849\(^{2254}\) - Unify serialization of non-default-constructable types
• Issue #2848\(^{2255}\) - Components have to be default constructible
• Issue #2847\(^{2256}\) - Returning a future<\(R\)> where \(R\) is not default-constructable broken
• Issue #2846\(^{2257}\) - Unify serialization of non-default-constructible types
• PR #2845\(^{2258}\) - Add Visual Studio 2015 to the tested toolchains in Appveyor
• Issue #2844\(^{2259}\) - Change the appveyor build to use the minimal required MSVC version
• Issue #2843\(^{2260}\) - multi node hello_world hangs
• PR #2842\(^{2261}\) - Correcting Spelling mistake in docs
• PR #2841\(^{2262}\) - Fix usage of std::aligned_storage
• PR #2840\(^{2263}\) - Remove constexpr from a void function
• Issue #2839\(^{2264}\) - memcpy buffer overflow: load_construct_data() and std::complex members
• Issue #2835\(^{2265}\) - constexpr functions with void return type break compilation with CUDA 8.0
• Issue #2834\(^{2266}\) - One suspicion in parallel::detail::handle_exception
• PR #2833\(^{2267}\) - Implement parallel::merge
• PR #2832\(^{2268}\) - Fix a strange thing in parallel::util::detail::handle_local_exceptions. (Fix #2818)
• PR #2830\(^{2269}\) - Break the debugger when a test failed
• Issue #2831\(^{2270}\) - parallel/executors/execution_fwd.hpp causes compilation failure in C++11 mode.
• PR #2829\(^{2271}\) - Implement an API for asynchronous pack traversal
• PR #2828\(^{2272}\) - Split unit test builds on CircleCI to avoid timeouts
• Issue #2827\(^{2273}\) - failure to compile hello_world example with -Werror
• PR #2824\(^{2274}\) - Making sure promises are marked as started when used as continuations
• PR #2823\(^{2275}\) - Add documentation for partitioned_vector_view

- Issue #2822 - Yet another issue with wait_for similar to #2796
- PR #2821 - Fix bugs and improve that about HPX_HAVE_CXX11_AUTO_RETURN_VALUE of CMake
- PR #2820 - Support C++11 in benchmark codes of parallel::partition and parallel::partition_copy
- PR #2819 - Fix compile errors in unit test of container version of parallel::partition
- Issue #2818 - A strange thing in parallel::util::detail::handle_local_exceptions
- Issue #2815 - HPX fails to compile with HPX_WITH_CUDA=ON and the new CUDA 9.0 RC
- Issue #2814 - Using ‘gmakeN’ after ‘cmake’ produces error in src/CMakeFiles/hpx.dir/runtime/agas/addressing_service.cpp.o
- PR #2813 - Properly support [[noreturn]] attribute if available
- Issue #2812 - Compilation fails with gcc 7.1.1
- PR #2811 - Adding hpx::launch::lazy and support for async, dataflow, and future::then
- PR #2810 - Add option allowing to disable deprecation warning
- PR #2809 - Disable throttling scheduler if HWLOC is not found/used
- PR #2808 - Fix compile errors on some environments of parallel::partition
- Issue #2807 - Difficulty building with HPX_WITH_HWLOC=Off
- PR #2806 - Partitioned vector
- PR #2805 - Serializing collections with non-default constructible data
- PR #2802 - Fix FreeBSD 11
- Issue #2801 - Rate limiting techniques in io_service
- Issue #2800 - New Launch Policy: async_if
- PR #2799 - Fix a unit test failure on GCC in tuple_cat
- PR #2798 - bump minimum required cmake to 3.0 in test
- PR #2797 - Making sure future::wait_for et.al. work properly for action results
- Issue #2796 - wait_for does always in “deferred” state for calls on remote localities

- Issue #2795 - Serialization of types without default constructor
- PR #2794 - Fixing test for partitioned_vector iteration
- PR #2792 - Implemented segmented find and its variations for partitioned vector
- PR #2791 - Circumvent scary warning about placement new
- PR #2790 - Fix OSX build
- PR #2789 - Resource partitioner
- PR #2788 - Adapt parallel::is_heap and parallel::is_heap_until to Ranges TS
- PR #2787 - Unwrap hotfixes
- PR #2786 - Update CMake Minimum Version to 3.3.2 (refs #2565)
- Issue #2785 - Issues with masks and cpuset
- PR #2784 - Error with reduce and transform reduce fixed
- PR #2783 - StackOverflow integration with libsigsegv
- PR #2782 - Replace boost::atomic with std::atomic (where possible)
- PR #2781 - Check for and optionally use [[deprecated]] attribute
- PR #2780 - Adding empty (but non-trivial) destructor to circumvent warnings
- PR #2779 - Exception info tweaks
- PR #2778 - Implement parallel::partition
- PR #2777 - Improve error handling in gather_here/gather_there
- PR #2776 - Fix a bug in compiler version check
- PR #2775 - Fix compilation when HPX_WITH_LOGGING is OFF
- PR #2774 - Removing dependency on Boost.Date_Time
- PR #2773 - Add sync_images() method to spmd_block class
- PR #2772 - Adding documentation for PAPI counters

• PR #2771 - Removing boost preprocessor dependency
• PR #2770 - Adding test, fixing deadlock in config registry
• PR #2769 - Remove some other warnings and errors detected by clang 5.0
• Issue #2768 - Is there iterator tag for HPX?
• PR #2767 - Improvements to continuation annotation
• PR #2765 - gcc split stack support for HPX threads #620
• PR #2764 - Fix some uses of begin/end, remove unnecessary includes
• PR #2763 - Bump minimal Boost version to 1.55.0
• PR #2762 - hpx::partitioned_vector serializer
• PR #2761 - Adding configuration summary to cmake output and --hpx:info
• PR #2760 - Removing 1d_hydro example as it is broken
• PR #2758 - Remove various warnings detected by clang 5.0
• Issue #2757 - In case of a “raw thread” is needed per core for implementing parallel algorithm, what is good practice in HPX?
• PR #2756 - Allowing for LCOs to be simple components
• PR #2755 - Removing make_index_pack_unrolled
• PR #2754 - Implement parallel::unique_copy
• PR #2753 - Fixing detection of [[fallthrough]] attribute
• PR #2752 - New thread priority names
• PR #2751 - Replace boost::exception with proposed exception_info
• PR #2750 - Replace boost::iterator_range
• PR #2749 - Fixing hdf5 examples
• Issue #2748 - HPX fails to build with enabled hdf5 examples
• Issue #2747 - Inherited task priorities break certain DAG optimizations

• Issue #2722 - channel register_as() failing on compilation
• PR #2721 - Mind map
• PR #2720 - reorder forward declarations to get rid of C++14-only auto return types
• PR #2719 - Add documentation for partitioned_vector and add features in pack.hpp
• Issue #2718 - Some forward declarations in execution_fwd.hpp aren’t C++11-compatible
• PR #2717 - Config support for fallback attribute
• PR #2716 - Implement parallel::partition_copy
• PR #2715 - initial import of icu string serializer
• PR #2714 - initial import of valarray serializer
• PR #2713 - Remove slashes before CMAKE_FILES_DIRECTORY variables
• PR #2712 - Fixing wait for 1751
• PR #2711 - Adjust code for minimal supported GCC having being bumped to 4.9
• PR #2710 - Adding code of conduct
• PR #2709 - Fixing UB in destroy tests
• PR #2708 - Add inline to prevent multiple definition issue
• Issue #2707 - Multiple defined symbols for task_block.hpp in VS2015
• PR #2706 - Adding .clang-format file
• PR #2704 - Add a synchronous mapping API
• Issue #2703 - Request: Add the .clang-format file to the repository
• Issue #2702 - STEllAR-GROUP/Vc slower than VCv1 possibly due to wrong instructions generated
• Issue #2701 - Datapar with STEllAR-GROUP/Vc requires obscure flag
• Issue #2700 - Naming inconsistency in parallel algorithms
• Issue #2699 - Iterator requirements are different from standard in parallel copy_if.
• PR #2698 - Properly releasing parcelport write handlers
• Issue #2697 - Compile error in addressing_service.cpp
• Issue #2696 - Building and using HPX statically: undefined references from runtime_support_server.cpp
• Issue #2695 - Executor changes cause compilation failures
• PR #2694 - Refining C++ language mode detection for MSVC
• PR #2693 - P0443 r2
• PR #2692 - Partially reverting changes to parcel_await
• Issue #2689 - HPX build fails when HPX_WITH_CUDA is enabled
• PR #2688 - Make Cuda Clang builds pass
• PR #2687 - Add an is_tuple_like trait for sequenceable type detection
• PR #2686 - Allowing throttling scheduler to be used without idle backoff
• PR #2685 - Add support of std::array to hpx::util::tuple_size and tuple_element
• PR #2684 - Adding new statistics performance counters
• PR #2683 - Replace boost::exception_ptr with std::exception_ptr
• Issue #2682 - HPX does not compile with HPX_WITH_THREAD_MANAGER_IDLE_BACKOFF=OFF
• PR #2681 - Attempt to fix problem in managed_component_base
• PR #2680 - Fix bad size during archive creation
• Issue #2679 - Mismatch between size of archive and container
• Issue #2678 - In parallel algorithm, other tasks are executed to the end even if an exception occurs in any task.
• PR #2677 - Adding include check for std::addressof
• PR #2676 - Adding parallel::destroy and destroy_n
• PR #2675 - Making sure statistics counters work as expected
• PR #2674 - Turning assertions into exceptions

2.10. Releases
• PR #2673 - Inhibit direct conversion from future<future<T>> -> future<void>
• PR #2672 - C++17 invoke forms
• PR #2671 - Adding uninitialized_value_construct and uninitialized_value_construct_n
• PR #2670 - Integrate spmd multidimensional views for partitioned_vectors
• PR #2669 - Adding uninitialized_default_construct and uninitialized_default_construct_n
• PR #2668 - Fixing documentation index
• Issue #2667 - Ambiguity of nested hpx::future<void>’s
• Issue #2666 - Statistics Performance counter is not working
• PR #2664 - Adding uninitialized_move and uninitialized_move_n
• Issue #2663 - Seg fault in managed_component::get_base_gid, possibly cause by util::reinitializable_static
• Issue #2662 - Crash in managed_component::get_base_gid due to problem with util::reinitializable_static
• PR #2661 - Hide the detail namespace in doxygen per default
• PR #2660 - Add documentation to hpx::util::unwrapped and hpx::util::unwrapped2
• PR #2659 - Improve integration with vcpkg
• PR #2658 - Unify access_data trait for use in both, serialization and de-serialization
• PR #2657 - Removing hpx::ics::queue<T>
• PR #2656 - Reduce MAX_TERMINATED_THREADS default, improve memory use on manycore cpus
• PR #2655 - Maintenance for emulate-deleted macros
• PR #2654 - Implement parallel is_heap and is_heap_until
• PR #2653 - Drop support for VS2013
• PR #2652 - This patch makes sure that all parcels in a batch are properly handled
• PR #2649 - Update docs (Table 18) - move transform to end
• Issue #2647 - hpx::parcelset::detail::parcel_data::has_continuation_is uninitialized
• Issue #2644 - Some .vcxproj in the HPX.sln fail to build
• Issue #2641 - hpx::lcos::queue should be deprecated
• PR #2640 - A new throttling policy with public APIs to suspend/resume
• PR #2639 - Fix a tiny typo in tutorial.
• Issue #2638 - Invalid return type ‘void’ of constexpr function
• PR #2636 - Add and use HPX_MSVC_WARNING_PRAGMA for #pragma warning
• PR #2633 - Distributed define_spmd_block
• PR #2632 - Making sure container serialization uses size-compatible types
• PR #2631 - Add lcos::local::one_element_channel
• PR #2629 - Move unordered_map out of parcelport into hpx/concurrent
• PR #2628 - Making sure that shutdown does not hang
• PR #2627 - Fix serialization
• PR #2626 - Generate cmake_variables.qbk and cmake_toolchains.qbk outside of the source tree
• PR #2625 - Supporting -std=c++17 flag
• PR #2624 - Fixing a small cmake typo
• PR #2622 - Update CMake minimum required version to 3.0.2 (closes #2621)
• Issue #2621 - Compiling hpx master fails with /usr/bin/ld: final link failed: Bad value
• PR #2620 - Remove warnings due to some captured variables
• PR #2619 - LF multiple parcels
• PR #2618 - Some fixes to libfabric that didn’t get caught before the merge
• PR #2617 - Adding hpx::local_new
• PR #2616 - Documentation: Extract all entities in order to autolink functions correctly
• Issue #2615 - Documentation: Linking functions is broken

• Issue #1400 - hpx::util::unwrapped doesn’t work with non-future types
• Issue #1205 - TSS is broken
• Issue #1126 - vector<future<T>> does not work gracefully with dataflow, when_all and unwrapped
• Issue #1056 - Thread manager cleanup
• Issue #863 - Futures should not require a default constructor
• Issue #856 - Allow runtimemode_connect to be used with security enabled
• Issue #726 - Valgrind
• Issue #701 - Add RCR performance counter component
• Issue #528 - Add support for known failures and warning count/comparisons to hpx_run_tests.py

2.10.10 HPX V1.0.0 (Apr 24, 2017)

General changes

Here are some of the main highlights and changes for this release (in no particular order):

• Added the facility hpx::split_future which allows one to convert a future<tuple<Ts...>> into a tuple<future<Ts>...>. This functionality is not available when compiling HPX with VS2012.

• Added a new type of performance counter which allows one to return a list of values for each invocation. We also added a first counter of this type which collects a histogram of the times between parcels being created.

• Added new LCOs: hpx::lcos::channel and hpx::lcos::local::channel which are very similar to the well known channel constructs used in the Go language.

• Added new performance counters reporting the amount of data handled by the networking layer on a action-by-action basis (please see PR #2289 for more details).

• Added a new facility hpx::lcos::barrier, replacing the equally named older one. The new facility has a slightly changed API and is much more efficient. Most notable, the new facility exposes a (global) function hpx::lcos::barrier::synchronize() which represents a global barrier across all localities.
• We have started to add support for vectorization to our parallel algorithm implementations. This support depends on using an external library, currently either Vc Library or boost_simd. Please see Issue #2333 for a list of currently supported algorithms. This is an experimental feature and its implementation and/or API might change in the future. Please see this blog-post for more information.

• The parameter sequence for the hpx::parallel::transform_reduce overload taking one iterator range has changed to match the changes this algorithm has undergone while being moved to C++17. The old overload can be still enabled at configure time by specifying -DHPX_WITH_TRANSFORM_REDUCE_COMPATIBILITY=On to CMake.

• The algorithm hpx::parallel::inner_product has been renamed to hpx::parallel::transform_reduce to match the changes this algorithm has undergone while being moved to C++17. The old inner_product names can be still enabled at configure time by specifying -DHPX_WITH_TRANSFORM_REDUCE_COMPATIBILITY=On to CMake.

• Added versions of hpx::get_ptr taking client side representations for component instances as their parameter (instead of a global id).

• Added the helper utility hpx::performance_counters::performance_counter_set helping to encapsulate a set of performance counters to be managed concurrently.

• All execution policies and related classes have been renamed to be consistent with the naming changes applied for C++17. All policies now live in the namespace hpx::parallel::execution. The old names can be still enabled at configure time by specifying -DHPX_WITH_EXECUTION_POLICY_COMPATIBILITY=On to CMake.

• The thread scheduling subsystem has undergone a major refactoring which results in significant performance improvements. We have also improved the performance of creating hpx::future and of various facilities handling those.

• We have consolidated all of the code in HPX.Compute related to the integration of CUDA. hpx::partitioned_vector has been enabled to be usable with hpx::compute::vector which allows one to place the partitions on one or more GPU devices.

• Added new performance counters exposing various internals of the thread scheduling subsystem, such as the current idle- and busy-loop counters and instantaneous scheduler utilization.

• Extended and improved the use of the ITTNotify hooks allowing to collect performance counter data and function annotation information from within the Intel Amplifier tool.

Breaking changes

• We have dropped support for the gcc compiler versions V4.6 and 4.7. The minimal gcc version we now test on is gcc V4.8.

• We have removed (default) support for boost::chrono in interfaces, uses of it have been replaced with std::chrono. This facility can be still enabled at configure time by specifying -DHPX_WITH_BOOST_CHRONO_COMPATIBILITY=On to CMake.

• The parameter sequence for the hpx::parallel::transform_reduce overload taking one iterator range has changed to match the changes this algorithm has undergone while being moved to C++17.

• The algorithm hpx::parallel::inner_product has been renamed to hpx::parallel::transform_reduce to match the changes this algorithm has undergone while being moved to C++17.

---

2521 https://github.com/STEllAR-GROUP/hpx/issues/2333
• the build options `HPX_WITH_COLOCATED_BACKWARDS_COMPATIBILITY` and `HPX_WITH_COMPONENT_GET_GID_COMPATIBILITY` are now disabled by default. Please change your code still depending on the deprecated interfaces.

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release.

- PR #2596\(^{2523}\) - Adding apex data
- PR #2595\(^{2524}\) - Remove obsolete file
- Issue #2594\(^{2525}\) - FindOpenCL.cmake mismatch with the official cmake module
- PR #2592\(^{2526}\) - First attempt to introduce spmd_block in hpx
- Issue #2591\(^{2527}\) - Feature request: continuation (then) which does not require the callable object to take a future<R> as parameter
- PR #2588\(^{2528}\) - Daint fixes
- PR #2587\(^{2529}\) - Fixing transfer_(continuation)_action::schedule
- PR #2585\(^{2530}\) - Work around MSVC having an ICE when compiling with -Ob2
- PR #2582\(^{2531}\) - changing 7zip command to 7za in roll_release.sh
- PR #2582\(^{2532}\) - First attempt to introduce spmd_block in hpx
- PR #2581\(^{2533}\) - Enable annotated function for parallel algorithms
- PR #2580\(^{2534}\) - First attempt to introduce spmd_block in hpx
- PR #2579\(^{2535}\) - Make thread NICE level setting an option
- PR #2578\(^{2536}\) - Implementing enqueue instead of busy wait when no sender is available
- PR #2577\(^{2537}\) - Retrieve -std=c++11 consistent nvcc flag
- PR #2576\(^{2538}\) - Add missing dependencies of cuda based tests
- PR #2575\(^{2539}\) - Remove warnings due to some captured variables
- PR #2573\(^{2540}\) - Attempt to resolve resolve_locality
- PR #2572\(^{2541}\) - Adding APEX hooks to background thread

• PR #2541 - avoid recompiles when enabling/disabling examples
• PR #2540 - Fixing usage of target_link_libraries()
• PR #2539 - fix RPATH behaviour
• Issue #2538 - HPX_WITH_CUDA corrupts compilation flags
• PR #2537 - Add output of a Bazel Skylark extension for paths and compile options
• PR #2536 - Add counter exposing total available memory to Windows as well
• PR #2535 - Remove obsolete support for security
• Issue #2534 - Remove command line option --hpx:run-agas-server
• PR #2533 - Pre-cache locality endpoints during bootstrap
• PR #2532 - Fixing handling of GIDs during serialization preprocessing
• PR #2531 - Amend uses of the term “functor”
• PR #2529 - added counter for reading available memory
• PR #2527 - Facilities to create actions from lambdas
• PR #2526 - Updated docs: HPX_WITH_EXAMPLES
• PR #2525 - Remove warnings related to unused captured variables
• Issue #2524 - CMAKE failed because it is missing: TCMALLOC_LIBRARY TCMALLOC_INCLUDE_DIR
• PR #2523 - Fixing compose_cb stack overflow
• PR #2522 - Instead of unlocking, ignore the lock while creating the message handler
• PR #2521 - Create LPROGRESS_ logging macro to simplify progress tracking and timings
• PR #2520 - Intel 17 support
• PR #2519 - Fix components example
• PR #2518 - Fixing parcel scheduling
• Issue #2517 - Race condition during Parcel Coalescing Handler creation
• Issue #2516 - HPX locks up when using at least 256 localities
• Issue #2515 - error: Install cannot find “/lib/hpx/libparcel_coalescing.so.0.9.99” but I can see that file
• PR #2514 - Making sure that all continuations of a shared future are invoked in order
• PR #2513 - Fixing locks held during suspension
• PR #2512 - MPI Parcelport improvements and fixes related to the background work changes
• PR #2511 - Fixing bit-wise (zero-copy) serialization
• Issue #2509 - Linking errors in hwloc_topology
• PR #2508 - Added documentation for debugging with core files
• PR #2506 - Fixing background work invocations
• PR #2505 - Fix tuple serialization
• Issue #2504 - Ensure continuations are called in the order they have been attached
• PR #2503 - Adding serialization support for Vc v2 (datapar)
• PR #2502 - Resolve various, minor compiler warnings
• PR #2501 - Some other fixes around cuda examples
• Issue #2500 - nvcc / cuda clang issue due to a missing -DHPX_WITH_CUDA flag
• PR #2499 - Adding support for std::array to wait_all and friends
• PR #2498 - Execute background work as HPX thread
• PR #2497 - Fixing configuration options for spinlock-deadlock detection
• PR #2496 - Accounting for different compilers in CrayKNL toolchain file
• PR #2494 - Adding component base class which ties a component instance to a given executor
• PR #2493 - Enable controlling amount of pending threads which must be available to allow thread stealing
• PR #2492 - Adding new command line option –hpx:print-counter-reset

• PR #2491 - Resolve ambiguities when compiling with APEX
• PR #2490 - Resuming threads waiting on future with higher priority
• Issue #2489 - nvcc issue because -std=c++11 appears twice
• PR #2488 - Adding performance counters exposing the internal idle and busy-loop counters
• PR #2487 - Allowing for plain suspend to reschedule thread right away
• PR #2486 - Only flag HPX code for CUDA if HPX_WITH_CUDA is set
• PR #2485 - Making thread-queue parameters runtime-configurable
• PR #2484 - Added atomic counter for parcel-destinations
• PR #2483 - Added priority-queue lifo scheduler
• PR #2482 - Changing scheduler to steal only if more than a minimal number of tasks are available
• PR #2481 - Extending command line option –hpx:print-counter-destination to support value 'none'
• PR #2479 - Added option to disable signal handler
• PR #2480 - Making sure the sine performance counter module gets loaded only for the corresponding example
• Issue #2477 - Breaking at a throw statement
• PR #2476 - Annotated function
• PR #2475 - Ensure that using %osthread% during logging will not throw for non-hpx threads
• PR #2474 - Remove now superficial non_direct actions from base_lco and friends
• PR #2473 - Refining support for ITTNotify
• PR #2472 - Some fixes around hpx compute
• Issue #2470 - redefinition of boost::detail::spinlock
• Issue #2469 - Dataflow performance issue
• PR #2468 - Perf docs update
• PR #2466 - Guarantee to execute remote direct actions on HPX-thread

Chapter 2. What’s so special about HPX?
• PR #2465 - Improve demo: Async copy and fixed device handling
• PR #2464 - Adding performance counter exposing instantaneous scheduler utilization
• PR #2463 - Downcast to future<void>
• PR #2462 - Fixed usage of ITT-Notify API with Intel Amplifier
• PR #2461 - Cublas demo
• PR #2460 - Fixing thread bindings
• PR #2459 - Make -std=c++11 nvcc flag consistent for in-build and installed versions
• Issue #2457 - Segmentation fault when registering a partitioned vector
• PR #2452 - Properly releasing global barrier for unhandled exceptions
• PR #2451 - Fixing long shutdown times
• PR #2450 - Attempting to fix initialization errors on newer platforms (Boost V1.63)
• PR #2449 - Replace BOOST_COMPILER_FENCE with an HPX version
• PR #2448 - This fixes a possible race in the migration code
• PR #2445 - Fixing dataflow et.al. for futures or future-ranges wrapped into ref()
• PR #2444 - Fix segfaults
• PR #2443 - Issue 2442
• Issue #2442 - Mismatch between #if/#endif and namespace scope brackets in this_thread_executers.hpp
• Issue #2441 - undeclared identifier BOOST_COMPILER_FENCE
• PR #2440 - Knl build
• PR #2438 - Datapar backend
• PR #2437 - Adapt algorithm parameter sequence changes from C++17
• PR #2436 - Adapt execution policy name changes from C++17
• Issue #2435 - Trunk broken, undefined reference to hpx::thread::interrupt(hpx::thread::id, bool)

[PR #2465](https://github.com/STEllAR-GROUP/hpx/pull/2465)
[PR #2464](https://github.com/STEllAR-GROUP/hpx/pull/2464)
[PR #2463](https://github.com/STEllAR-GROUP/hpx/pull/2463)
[PR #2462](https://github.com/STEllAR-GROUP/hpx/pull/2462)
[PR #2461](https://github.com/STEllAR-GROUP/hpx/pull/2461)
[PR #2460](https://github.com/STEllAR-GROUP/hpx/pull/2460)
[PR #2459](https://github.com/STEllAR-GROUP/hpx/pull/2459)
[Issue #2457](https://github.com/STEllAR-GROUP/hpx/issues/2457)
[Issue #2442](https://github.com/STEllAR-GROUP/hpx/issues/2442)
[Issue #2441](https://github.com/STEllAR-GROUP/hpx/issues/2441)
[PR #2440](https://github.com/STEllAR-GROUP/hpx/pull/2440)
[PR #2438](https://github.com/STEllAR-GROUP/hpx/pull/2438)
[PR #2437](https://github.com/STEllAR-GROUP/hpx/pull/2437)
[PR #2436](https://github.com/STEllAR-GROUP/hpx/pull/2436)
[Issue #2435](https://github.com/STEllAR-GROUP/hpx/issues/2435)
• PR #2434 - More fixes to resource manager
• PR #2433 - Added versions of `hpx::get_ptr` taking client side representations
• PR #2432 - Warning fixes
• PR #2431 - Adding facility representing set of performance counters
• PR #2430 - Fix parallel_executor thread spawning
• PR #2429 - Fix attribute warning for gcc
• Issue #2427 - Seg fault running octo-tiger with latest HPX commit
• Issue #2426 - Bug in 9592f5c0bc29806fceb073e7f35b6ca7e027edcb causes immediate crash in Octo-tiger
• PR #2425 - Fix nvcc errors due to constexpr specifier
• Issue #2424 - Async action on component present on hpx::find_here is executing synchronously
• PR #2423 - Fix nvcc errors due to constexpr specifier
• PR #2422 - Implementing hpx::this_thread thread data functions
• PR #2421 - Adding benchmark for wait_all
• Issue #2420 - Returning object of a component client from another component action fails
• PR #2419 - Infiniband parcelport
• Issue #2418 - gcc + nvcc fails to compile code that uses partitioned_vector
• PR #2417 - Fixing context switching
• PR #2416 - Adding fixes and workarounds to allow compilation with nvcc/msvc (VS2015up3)
• PR #2415 - Fix errors coming from hpx compute examples
• PR #2414 - Fixing msvc12
• PR #2413 - Enable cuda/nvcc or cuda/clang when using add_hpx_executable()
• PR #2412 - Fix issue in HPX_SetupTarget.cmake when cuda is used
• PR #2411 - This fixes the core compilation issues with MSVC12
• Issue #2410 - undefined reference to opal_hwloc191_hwloc......
• PR #2409 - Fixing locking for channel and receive_buffer
• PR #2407 - Solving #2402 and #2403
• PR #2406 - Improve guards
• PR #2405 - Enable parallel::for_each for iterators returning proxy types
• PR #2404 - Forward the explicitly given result_type in the hpx invoke
• Issue #2403 - datapar_execution + zip iterator: lambda arguments aren’t references
• Issue #2402 - datapar algorithm instantiated with wrong type #2402
• PR #2401 - Added support for imported libraries to HPX_Libraries.cmake
• PR #2400 - Use CMake policy CMP0060
• Issue #2399 - Error trying to push back vector of futures to vector
• PR #2398 - Allow config #defines to be written out to custom config/defines.hpp
• Issue #2397 - CMake generated config defines can cause tedious rebuilds category
• Issue #2396 - BOOST_ROOT paths are not used at link time
• PR #2395 - Fix target_link_libraries() issue when HPX Cuda is enabled
• Issue #2394 - Template compilation error using HPX_WITH_DATAPAR_LIBFLATARRAY
• PR #2393 - Fixing lock registration for recursive mutex
• PR #2392 - Add keywords in target_link_libraries in hpx_setup_target
• PR #2391 - Clang goroutines
• Issue #2390 - Adapt execution policy name changes from C++17
• PR #2389 - Chunk allocator and pool are not used and are obsolete
• PR #2388 - Adding functionalities to datapar needed by octotiger
• PR #2387 - Fixing race condition for early parcels

• Issue #2386 - Lock registration broken for recursive_mutex
• PR #2385 - Datapar zip iterator
• PR #2384 - Fixing race condition in for_loop_reduction
• PR #2383 - Continuations
• PR #2382 - add LibFlatArray-based backend for datapar
• PR #2381 - remove unused typedef to get rid of compiler warnings
• PR #2380 - Tau cleanup
• PR #2379 - Can send immediate
• PR #2378 - Renaming copy_helper/copy_n_helper/move_helper/move_n_helper
• Issue #2376 - Boost trunk’s spinlock initializer fails to compile
• PR #2375 - Add support for minimal thread local data
• PR #2374 - Adding API functions set_config_entry_callback
• PR #2373 - Add a simple utility for debugging that gives suspended task backtraces
• PR #2372 - Barrier Fixes
• Issue #2370 - Can’t wait on a wrapped future
• PR #2369 - Fixing stable_partition
• PR #2368 - Fixing find_prefixes for Windows platforms
• PR #2366 - Testing for experimental/optional only in C++14 mode
• PR #2364 - Adding set_config_entry
• PR #2363 - Fix papi
• PR #2362 - Adding missing macros for new non-direct actions
• PR #2361 - Improve cmake output to help debug compiler incompatibility check
• PR #2360 - Fixing race condition in condition_variable
• PR #2359 - Fixing shutdown when parcels are still in flight
• Issue #2357 - failed to insert console_print_action into typename_to_id_t registry
• PR #2356 - Fixing return type of get_iterator_tuple
• PR #2355 - Fixing compilation against Boost 1.62
• PR #2354 - Adding serialization for mask_type if CPU_COUNT > 64
• PR #2353 - Adding hooks to tie in APEX into the parcel layer
• Issue #2352 - Compile errors when using intel 17 beta (for KNL) on edison
• PR #2351 - Fix function vtable get_function_address implementation
• Issue #2350 - Build failure - master branch (4de09f5) with Intel Compiler v17
• PR #2349 - Enabling zero-copy serialization support for std::vector<>  
• PR #2348 - Adding test to verify #2334 is fixed
• PR #2347 - Bug fixes for hpx.compute and hpx::lcos::channel
• PR #2346 - Removing cmake “find” files that are in the APEX cmake Modules
• PR #2345 - Implemented parallel::stable_partition
• PR #2344 - Making hpx::lcos::channel usable with basename registration
• PR #2343 - Fix a couple of examples that failed to compile after recent api changes
• Issue #2342 - Enabling APEX causes link errors
• PR #2341 - Removing cmake “find” files that are in the APEX cmake Modules
• PR #2340 - Implemented all existing datapar algorithms using Boost.SIMD
• PR #2339 - Fixing 2338
• PR #2338 - Possible race in sliding semaphore
• PR #2337 - Adjust osu_latency test to measure window_size parcels in flight at once
• PR #2336 - Allowing remote direct actions to be executed without spawning a task
- PR #2335 - Making sure multiple components are properly initialized from arguments
- Issue #2334 - Cannot construct component with large vector on a remote locality
- PR #2332 - Fixing hpx::lcos::local::barrier
- PR #2331 - Updating APEX support to include OTF2
- PR #2330 - Support for data-parallelism for parallel algorithms
- Issue #2329 - Coordinate settings in cmake
- PR #2328 - fix LibGeoDecomp builds with HPX + GCC 5.3.0 + CUDA 8RC
- PR #2326 - Making scan_partitioner work (for now)
- Issue #2323 - Constructing a vector of components only correctly initializes the first component
- PR #2322 - Fix problems that bubbled up after merging #2278
- PR #2321 - Scalable barrier
- PR #2320 - Std flag fixes
- Issue #2319 - -std=c++14 and -std=c++1y with Intel can’t build recent Boost builds due to insufficient C++14 support; don’t enable these flags by default for Intel
- PR #2318 - Improve handling of --hpx:bind=<bind-spec>
- PR #2317 - Making sure command line warnings are printed once only
- PR #2316 - Fixing command line handling for default bind mode
- PR #2315 - Set id_retrieved if set_id is present
- Issue #2314 - Warning for requested/allocated thread discrepancy is printed twice
- Issue #2313 - --hpx:print-bind doesn’t work with --hpx:pu-step
- Issue #2312 - --hpx:bind range specifier restrictions are overly restrictive
- Issue #2311 - hpx_0.9.99 out of project build fails
- PR #2310 - Simplify function registration
- PR #2309 - Spelling and grammar revisions in documentation (and some code)
• PR #2306 - Correct minor typo in the documentation
• PR #2303 - Cleaning up and fixing parcel coalescing
• PR #2304 - Inspect checks for stream related includes
• PR #2303 - Add functionality allowing to enumerate threads of given state
• PR #2301 - Algorithm overloads fix for VS2013
• PR #2300 - Use <cstdint>, add inspect checks
• PR #2299 - Replace boost::[c]ref with std::[c]ref, add inspect checks
• PR #2297 - Fixing compilation with no hw_loc
• PR #2296 - Hpx compute
• PR #2295 - Making sure for_loop(execution::par, 0, N, ... ) is actually executed in parallel
• PR #2294 - Throwing exceptions if the runtime is not up and running
• PR #2293 - Removing unused parcel port code
• PR #2292 - Refactor function vtables
• PR #2291 - Fixing 2286
• PR #2290 - Simplify algorithm overloads
• PR #2289 - Adding performance counters reporting parcel related data on a per-action basis
• Issue #2288 - Remove dormant parcelports
• Issue #2286 - adjustments to parcel handling to support parcelports that do not need a connection cache
• PR #2285 - Add CMake option to disable package export
• PR #2283 - Add more inspect checks for use of deprecated components
• Issue #2282 - Arithmetic exception in executor static chunker
• Issue #2281 - For loop doesn’t parallelize
• PR #2280 - Fixing 2277: build failure with PAPI

• PR #2279\textsuperscript{2795} - Child vs parent stealing
• Issue #2277\textsuperscript{2796} - master branch build failure (53c5b4f) with papi
• PR #2276\textsuperscript{2797} - Compile time launch policies
• PR #2275\textsuperscript{2798} - Replace boost::chrono with std::chrono in interfaces
• PR #2274\textsuperscript{2799} - Replace most uses of Boost.Assign with initializer list
• PR #2273\textsuperscript{2800} - Fixed typos
• PR #2272\textsuperscript{2801} - Inspect checks
• PR #2270\textsuperscript{2802} - Adding test verifying -lhpx.os_threads=all
• PR #2269\textsuperscript{2803} - Added inspect check for now obsolete boost type traits
• PR #2268\textsuperscript{2804} - Moving more code into source files
• Issue #2267\textsuperscript{2805} - Add inspect support to deprecate Boost.TypeTraits
• PR #2265\textsuperscript{2806} - Adding channel LCO
• PR #2264\textsuperscript{2807} - Make support for std::ref mandatory
• PR #2263\textsuperscript{2808} - Constrain tuple_member forwarding constructor
• Issue #2262\textsuperscript{2809} - Test hpx.os_threads=all
• Issue #2261\textsuperscript{2810} - OS X: Error: no matching constructor for initialization of 'hpx::lcos::local::condition_variable_any'
• Issue #2260\textsuperscript{2811} - Make support for std::ref mandatory
• PR #2259\textsuperscript{2812} - Remove most of Boost.MPL, Boost.EnableIf and Boost.TypeTraits
• PR #2258\textsuperscript{2813} - Fixing #2256
• PR #2257\textsuperscript{2814} - Fixing launch process
• Issue #2256\textsuperscript{2815} - Actions are not registered if not invoked
• PR #2255\textsuperscript{2816} - Coalescing histogram
• PR #2254\textsuperscript{2817} - Silence explicit initialization in copy-constructor warnings
• PR #2253 - Drop support for GCC 4.6 and 4.7
• PR #2252 - Prepare V1.0
• PR #2251 - Convert to 0.9.99
• PR #2249 - Adding iterator_facade and iterator_adaptor
• Issue #2248 - Need a feature to yield to a new task immediately
• PR #2246 - Adding split_future
• PR #2245 - Add an example for handing over a component instance to a dynamically launched locality
• Issue #2243 - Add example demonstrating AGAS symbolic name registration
• Issue #2242 - pkgconfig test broken on CentOS 7 / Boost 1.61
• Issue #2241 - Compilation error for partitioned vector in hpx_compute branch
• PR #2240 - Fixing termination detection on one locality
• Issue #2239 - Create a new facility lcos::split_all
• Issue #2236 - hpx::cout vs. std::cout
• PR #2232 - Implement local-only primary namespace service
• Issue #2147 - would like to know how much data is being routed by particular actions
• Issue #2109 - Warning while compiling hpx
• Issue #1973 - Setting INTERFACE_COMPILE_OPTIONS for hpx_init in CMake taints Fortran_FLAGS
• Issue #1864 - run_guarded using bound function ignores reference
• Issue #1754 - Running with TCP parcelport causes immediate crash or freeze
• Issue #1655 - Enable zip_iterator to be used with Boost traversal iterator categories
• Issue #1591 - Optimize AGAS for shared memory only operation
• Issue #1401 - Need an efficient infiniband parcelport
• Issue #1125 - Fix the IPC parcelport
• Issue #839 - Refactor ibverbs and shmep parcelport
• Issue #702 - Add instrumentation of parcel layer
• Issue #668 - Implement ispc task interface
• Issue #533 - Thread queue/deque internal parameters should be runtime configurable
• Issue #475 - Create a means of combining performance counters into querysets

2.10.11 HPX V0.9.99 (Jul 15, 2016)

General changes

As the version number of this release hints, we consider this release to be a preview for the upcoming HPX V1.0. All of the functionalities we set out to implement for V1.0 are in place; all of the features we wanted to have exposed are ready. We are very happy with the stability and performance of HPX and we would like to present this release to the community in order for us to gather broad feedback before releasing V1.0. We still expect for some minor details to change, but on the whole this release represents what we would like to have in a V1.0.

Overall, since the last release we have had almost 1600 commits while closing almost 400 tickets. These numbers reflect the incredible development activity we have seen over the last couple of months. We would like to express a big ‘Thank you!’ to all contributors and those who helped to make this release happen.

The most notable addition in terms of new functionality available with this release is the full implementation of object migration (i.e. the ability to transparently move HPX components to a different compute node). Additionally, this release of HPX cleans up many minor issues and some API inconsistencies.

Here are some of the main highlights and changes for this release (in no particular order):

• We have fixed a couple of issues in AGAS and the parcel layer which have caused hangs, segmentation faults at exit, and a slowdown of applications over time. Fixing those has significantly increased the overall stability and performance of distributed runs.

• We have started to add parallel algorithm overloads based on the C++ Extensions for Ranges (N4560) proposal. This also includes the addition of projections to the existing algorithms. Please see Issue #1668 for a list of algorithms which have been adapted to N4560.

• We have implemented index-based parallel for-loops based on a corresponding standardization proposal (P0075R1). Please see Issue #2016 for a list of available algorithms.

• We have added implementations for more parallel algorithms as proposed for the upcoming C++ 17 Standard. See Issue #1141 for an overview of which algorithms are available by now.

• We have started to implement a new prototypical functionality with HPX.Compute which uniformly exposes some of the higher level APIs to heterogeneous architectures (currently CUDA). This functionality is an early preview and should not be considered stable. It may change considerably in the future.

• We have pervasively added (optional) executor arguments to all API functions which schedule new work. Executors are now used throughout the code base as the main means of executing tasks.

https://github.com/STEllAR-GROUP/hpx/issues/475
https://github.com/STEllAR-GROUP/hpx/issues/1668
https://github.com/STEllAR-GROUP/hpx/issues/2016
https://github.com/STEllAR-GROUP/hpx/issues/1141
• Added `hpx::make_future<R>(future<T> &&)` allowing to convert a future of any type T into a future of any other type R, either based on default conversion rules of the embedded types or using a given explicit conversion function.

• We finally finished the implementation of transparent migration of components to another locality. It is now possible to trigger a migration operation without ‘stopping the world’ for the object to migrate. **HPX** will make sure that no work is being performed on an object before it is migrated and that all subsequently scheduled work for the migrated object will be transparently forwarded to the new locality. Please note that the global id of the migrated object does not change, thus the application will not have to be changed in any way to support this new functionality. Please note that this feature is currently considered experimental. See Issue #559 and PR #1966 for more details.

• The `hpx::dataflow` facility is now usable with actions. Similarly to `hpx::async`, actions can be specified as an explicit template argument (`hpx::dataflow<Action>(target, ...)`) or as the first argument (`hpx::dataflow(Action(), target, ...)`). We have also enabled the use of distribution policies as the target for dataflow invocations. Please see Issue #1265 and PR #1912 for more information.

• Adding overloads of `gather_here` and `gather_there` to accept the plain values of the data to gather (in addition to the existing overloads expecting futures).

• We have cleaned up and refactored large parts of the code base. This helped reducing compile and link times of **HPX** itself and also of applications depending on it. We have further decreased the dependency of **HPX** on the Boost libraries by replacing part of those with facilities available from the standard libraries.

• Wherever possible we have removed dependencies of our API on Boost by replacing those with the equivalent facility from the C++11 standard library.

• We have added new performance counters for parcel coalescing, file-IO, the AGAS cache, and overall scheduler time. Resetting performance counters has been overhauled and fixed.

• We have introduced a generic client type `hpx::components::client<>` and added support for using it with `hpx::async`. This removes the necessity to implement specific client types for every component type without losing type safety. This deemphasizes the need for using the low level `hpx::id_type` for referencing (possibly remote) component instances. The plan is to deprecate the direct use of `hpx::id_type` in user code in the future.

• We have added a special iterator which supports automatic prefetching of one or more arrays for speeding up loop-like code (see `hpx::parallel::util::make_prefetcher_context()`).

• We have extended the interfaces exposed from executors (as proposed by N4406) to accept an arbitrary number of arguments.

### Breaking changes

• In order to move the dataflow facility to namespace `hpx` we added a definition of `hpx::dataflow` which might create ambiguities in existing codes. The previous definition of this facility (`hpx::lcos::local::dataflow`) has been deprecated and is available only if the constant `-DHPX_WITH_LOCAL_DATAFLOW_COMPATIBILITY=On` to **CMake** is defined at configuration time. Please explicitly qualify all uses of the dataflow facility if you enable this compatibility setting and encounter ambiguities.

---

2852 [https://github.com/STEllAR-GROUP/hpx/issues/559](https://github.com/STEllAR-GROUP/hpx/issues/559)
2853 [https://github.com/STEllAR-GROUP/hpx/pull/1966](https://github.com/STEllAR-GROUP/hpx/pull/1966)
2854 [https://github.com/STEllAR-GROUP/hpx/issues/1265](https://github.com/STEllAR-GROUP/hpx/issues/1265)
2855 [https://github.com/STEllAR-GROUP/hpx/pull/1912](https://github.com/STEllAR-GROUP/hpx/pull/1912)
2857 [https://www.cmake.org](https://www.cmake.org)
• The adaptation of the C++ Extensions for Ranges (N4560) proposal imposes some breaking changes related to the return types of some of the parallel algorithms. Please see Issue #1668 for a list of algorithms which have already been adapted.

• The facility `hpx::lcos::make_future_void()` has been replaced by `hpx::make_future<void>()`.

• We have removed support for Intel V13 and gcc 4.4.x.

• We have removed (default) support for the generic `hpx::parallel::execution_policy` because it was removed from the Parallelism TS (_cpp11_n4104_) while it was being added to the upcoming C++17 Standard. This facility can be still enabled at configure time by specifying `-DHPX_WITH_GENERIC_EXECUTION_POLICY=On` to CMake.

• Uses of `boost::shared_ptr` and related facilities have been replaced with `std::shared_ptr` and friends. Uses of `boost::unique_lock`, `boost::lock_guard` etc. have also been replaced by the equivalent (and equally named) tools available from the C++11 standard library.

• Facilities that used to expect an explicit `boost::unique_lock` now take an `std::unique_lock`. Additionally, `condition_variable` no longer aliases `condition_variable_any`; its interface now only works with `std::unique_lock<local::mutex>`.

• Uses of `boost::function`, `boost::bind`, `boost::tuple` have been replaced by the corresponding facilities in HPX (`hpx::util::function`, `hpx::util::bind`, and `hpx::util::tuple`, respectively).

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release.

• PR #2250 - change default chunker of parallel executor to static one
• PR #2247 - HPX on ppc64le
• PR #2244 - Fixing MSVC problems
• PR #2238 - Fixing small typos
• PR #2237 - Fixing small typos
• PR #2234 - Fix broken add test macro when extra args are passed in
• PR #2231 - Fixing possible race during future awaiting in serialization
• PR #2230 - Fix stream nvcc
• PR #2229 - Fixed run_as_hpx_thread
• PR #2228 - On prefetching_test branch : adding prefetching_iterator and related tests used for prefetching containers within lambda functions

2.10. Releases
• Issue #2103 - Build error with octotiger and hpx commit e657426d
• PR #2102 - Combining thread data storage
• PR #2101 - Added repartition version of 1d stencil that uses any performance counter
• PR #2100 - Drop obsolete TR1 result_of protocol
• PR #2099 - Replace uses of boost::bind with util::bind
• PR #2098 - Deprecated inspect checks
• PR #2097 - Reduce by key, extends #1141
• PR #2096 - Moving local cache from external to hpx/util
• PR #2095 - Bump minimum required Boost to 1.50.0
• PR #2094 - Add include checks for several Boost utilities
• Issue #2093 - ../local_cache.hpp(89): error #303: explicit type is missing (“int” assumed)
• PR #2091 - Fix for Raspberry pi build
• PR #2090 - Fix storage size for util::function<>
• PR #2089 - Fix #2088
• Issue #2088 - More verbose output from cmake configuration
• PR #2087 - Making sure init_globally always executes hpx_main
• Issue #2086 - Race condition with recent HPX
• PR #2085 - Adding #include checker
• PR #2084 - Replace boost lock types with standard library ones
• PR #2083 - Simplify packaged task
• PR #2082 - Updating APEX version for testing
• PR #2081 - Cleanup exception headers
• PR #2080 - Make call_once variadic

• Issue #20793008 - With GNU C++, line 85 of hpx/config/version.hpp causes link failure when linking application
• Issue #20783009 - Simple test fails with _GLIBCXX_DEBUG defined
• PR #20773010 - Instantiate board in nqueen client
• PR #20763011 - Moving coalescing registration to TUs
• PR #20753012 - Fixed some documentation typos
• PR #20743013 - Adding flush-mode to message handler flush
• PR #20733014 - Fixing performance regression introduced lately
• PR #20723015 - Refactor local::condition_variable
• PR #20713016 - Timer based on boost::asio::deadline_timer
• PR #20703017 - Refactor tuple based functionality
• PR #20693018 - Fixed typos
• Issue #20683019 - Seg fault with octotiger
• PR #20673020 - Algorithm cleanup
• PR #20663021 - Split credit fixes
• PR #20653022 - Rename HPX_MOVABLE_BUT_NOT_COPYABLE to HPX_MOVABLE_ONLY
• PR #20643023 - Fixed some typos in docs
• PR #20633024 - Adding example demonstrating template components
• Issue #20623025 - Support component templates
• PR #20613026 - Replace some uses of lexical_cast<string> with C++11 std::to_string
• PR #20603027 - Replace uses of boost::noncopyable with HPX_NON_COPYABLE
• PR #20593028 - Adding missing for_loop algorithms
• PR #20583029 - Move several definitions to more appropriate headers
• PR #20573030 - Simplify assert_owns_lock and ignore_while_checking

• PR #2056 - Replacing std::result_of with util::result_of
• PR #2055 - Fix process launching/connecting back
• PR #2054 - Add a forwarding coroutine header
• PR #2053 - Replace uses of boost::unordered_map with std::unordered_map
• PR #2052 - Rewrite tuple unwrap
• PR #2050 - Replace uses of BOOST_SCOPED_ENUM with C++11 scoped enums
• PR #2049 - Attempt to narrow down split_credit problem
• PR #2048 - Fixing gcc startup hangs
• PR #2047 - Fixing when_xxx and wait_xxx for MSVC12
• PR #2046 - adding persistent_auto_chunk_size and related tests for for_each
• PR #2045 - Fixing HPX_HAVE_THREAD_BACKTRACE_DEPTH build time configuration
• PR #2044 - Adding missing service executor types
• PR #2043 - Removing ambiguous definitions for is_future_range and future_range_traits
• PR #2042 - Clarify that HPX builds can use (much) more than 2GB per process
• PR #2041 - Changing future_iterator_traits to support pointers
• Issue #2040 - Improve documentation memory usage warning?
• PR #2039 - Coroutine cleanup
• PR #2038 - Fix cmake policy CMP0042 warning MACOSX_RPATH
• PR #2037 - Avoid redundant specialization of [unique_]function_nonser
• PR #2036 - nvcc dies with an internal error upon pushing/popping warnings inside templates
• Issue #2035 - Use a less restrictive iterator definition in hpx::lcos::detail::future_iterator_traits
• PR #2034 - Fixing compilation error with thread queue wait time performance counter
• Issue #2033 - Compilation error when compiling with thread queue waittime performance counter

• Issue #2032 - Ambiguous template instantiation for is_future_range and future_range_traits.
• PR #2031 - Don’t restart timer on every incoming parcel
• PR #2030 - Unify handling of execution policies in parallel algorithms
• PR #2029 - Make pkg-config .pc files use .dylib on OSX
• PR #2028 - Adding process component
• PR #2027 - Making check for compiler compatibility independent on compiler path
• PR #2025 - Fixing inspect tool
• PR #2024 - Intel13 removal
• PR #2023 - Fix errors related to older boost versions and parameter pack expansions in lambdas
• Issue #2022 - gmake fail: “No rule to make target /usr/lib46/libboost_context-mt.so”
• PR #2021 - Added Sudoku example
• Issue #2020 - Make errors related to init_globally.cpp example while building HPX out of the box
• PR #2019 - Fixed some compilation and cmake errors encountered in nqueen example
• PR #2018 - For loop algorithms
• PR #2017 - Non-recursive at_index implementation
• Issue #2016 - Add index-based for-loops
• Issue #2015 - Change default bind-mode to balanced
• PR #2014 - Fixed dataflow if invoked action returns a future
• PR #2013 - Fixing compilation issues with external example
• PR #2012 - Added Sierpinski Triangle example
• Issue #2011 - Compilation error while running sample hello_world_component code
• PR #2010 - Segmented move implemented for hpx::vector
• Issue #2009 - pkg-config order incorrect on 14.04 / GCC 4.8

• Issue #2008 - Compilation error in dataflow of action returning a future
• PR #2007 - Adding new performance counter exposing overall scheduler time
• PR #2006 - Function includes
• PR #2005 - Adding an example demonstrating how to initialize HPX from a global object
• PR #2004 - Fixing 2000
• PR #2003 - Adding generation parameter to gather to enable using it more than once
• PR #2002 - Turn on position independent code to solve link problem with hpx_init
• Issue #2001 - Gathering more than once segfaults
• Issue #2000 - Undefined reference to hpx::assertion_failed
• Issue #1999 - Seg fault in hpx::lcos::base_lco_with_value<>::set_value_nonvirt() when running octo-tiger
• PR #1998 - Detect unknown command line options
• PR #1997 - Extending thread description
• PR #1996 - Adding natvis files to solution (MSVC only)
• Issue #1995 - Command line handling does not produce error
• PR #1994 - Possible missing include in test_utils.hpp
• PR #1993 - Add missing LANGUAGES tag to a hpx_add_compile_flag_if_available() call in CMakeLists.txt
• PR #1992 - Fixing shared_executor_test
• PR #1991 - Making sure the winsock library is properly initialized
• PR #1990 - Fixing bind_test placeholder ambiguity coming from boost-1.60
• PR #1989 - Performance tuning
• PR #1987 - Make configurable size of internal storage in util::function
• PR #1986 - AGAS Refactoring+1753 Cache mods
• PR #1985 - Adding missing task_block::run() overload taking an executor

2.10. Releases
• PR #1911 - Adding first batch of container algorithms
• PR #1910 - Keep cmake_module_path
• PR #1909 - Fix mpirun with pbs
• PR #1908 - Changing parallel::sort to return the last iterator as proposed by N4560
• PR #1907 - Adding a minimum version for Open MPI
• PR #1906 - Updates to the Release Procedure
• PR #1905 - Fixing #1903
• PR #1904 - Making sure std containers are cleared before serialization loads data
• Issue #1903 - When running octotiger, I get: assertion '(*new_gids_)[gid].size() == 1' failed: HPX(assertion_failure)
• Issue #1902 - Immediate crash when running hpx/octetiger with _GLIBCXX_DEBUG defined.
• PR #1901 - Making non-serializable classes non-serializable
• Issue #1900 - Two possible issues with std::list serialization
• PR #1899 - Fixing a problem with credit splitting as revealed by #1898
• Issue #1898 - Accessing component from locality where it was not created segfaults
• PR #1897 - Changing parallel::sort to return the last iterator as proposed by N4560
• Issue #1896 - version 1.0?
• Issue #1895 - Warning comment on numa_allocator is not very clear
• PR #1894 - Add support for compilers that have thread_local
• PR #1893 - Fixing 1890
• PR #1892 - Adds typed future::_type for executor_traits
• PR #1891 - Fix wording in certain parallel algorithm docs
• Issue #1890 - Invoking papi counters give segfault
• PR #1889 - Fixing problems as reported by clang-check
• PR #1888\textsuperscript{3192} - WIP parallel is_heap
• PR #1887\textsuperscript{3193} - Fixed resetting performance counters related to idle-rate, etc
• Issue #1886\textsuperscript{3194} - Run hpx with qsub does not work
• PR #1885\textsuperscript{3195} - Warning cleaning pass
• PR #1884\textsuperscript{3196} - Add missing parallel algorithm header
• PR #1883\textsuperscript{3197} - Add feature test for thread_local on Clang for TLS
• PR #1882\textsuperscript{3198} - Fix some redundant qualifiers
• Issue #1881\textsuperscript{3199} - Unable to compile Octotiger using HPX and Intel MPI on SuperMIC
• Issue #1880\textsuperscript{3200} - clang with libc++ on Linux needs TLS case
• PR #1879\textsuperscript{3201} - Doc fixes for #1868
• PR #1878\textsuperscript{3202} - Simplify functions
• PR #1877\textsuperscript{3203} - Removing most usage of Boost.Config
• PR #1876\textsuperscript{3204} - Add missing parallel algorithms to algorithm.hpp
• PR #1875\textsuperscript{3205} - Simplify callables
• PR #1874\textsuperscript{3206} - Address long standing FIXME on using std::unique_ptr with incomplete types
• PR #1873\textsuperscript{3207} - Fixing 1871
• PR #1872\textsuperscript{3208} - Making sure PBS environment uses specified node list even if no PBS_NODEFILE env is available
• Issue #1871\textsuperscript{3209} - Fortran checks should be optional
• PR #1870\textsuperscript{3210} - Touch local::mutex
• PR #1869\textsuperscript{3211} - Documentation refactoring based off #1868
• PR #1867\textsuperscript{3212} - Embrace static_assert
• PR #1866\textsuperscript{3213} - Fix #1803 with documentation refactoring
• PR #1865\textsuperscript{3214} - Setting OUTPUT_NAME as target properties

2.10.12 HPX V0.9.11 (Nov 11, 2015)

Our main focus for this release was the design and development of a coherent set of higher-level APIs exposing various types of parallelism to the application programmer. We introduced the concepts of an executor, which can be used to customize the where and when of execution of tasks in the context of parallelizing codes. We extended all APIs related to managing parallel tasks to support executors which gives the user the choice of either using one of the predefined executor types or to provide its own, possibly application specific, executor. We paid very close attention to align all of these changes with the existing C++ Standards documents or with the ongoing proposals for standardization.

This release is the first after our change to a new development policy. We switched all development to be strictly performed on branches only, all direct commits to our main branch (master) are prohibited. Any change has to go through a peer review before it will be merged to master. As a result the overall stability of our code base has significantly increased, the development process itself has been simplified. This change manifests itself in a large number of pull-requests which have been merged (please see below for a full list of closed issues and pull-requests).
All in all for this release, we closed almost 100 issues and merged over 290 pull-requests. There have been over 1600 commits to the master branch since the last release.

**General changes**

- We are moving into the direction of unifying managed and simple components. As such, the classes `hpx::components::component` and `hpx::components::component_base` have been added which currently just forward to the currently existing simple component facilities. The examples have been converted to only use those two classes.
- Added integration with the CircleCI\(^\text{3254}\) hosted continuous integration service. This gives us constant and immediate feedback on the health of our master branch.
- The compiler configuration subsystem in the build system has been reimplemented. Instead of using Boost.Config we now use our own lightweight set of cmake scripts to determine the available language and library features supported by the used compiler.
- The API for creating instances of components has been consolidated. All component instances should be created using the `hpx::new_` only. It allows one to instantiate both, single component instances and multiple component instances. The placement of the created components can be controlled by special distribution policies. Please see the corresponding documentation outlining the use of `hpx::new_`.
- Introduced four new distribution policies which can be used with many API functions which traditionally expected to be used with a locality id. The new distribution policies are:
  - `hpx::components::default_distribution_policy` which tries to place multiple component instances as evenly as possible.
  - `hpx::components::colocating_distribution_policy` which will refer to the locality where a given component instance is currently placed.
  - `hpx::components::binpacking_distribution_policy` which will place multiple component instances as evenly as possible based on any performance counter.
  - `hpx::components::target_distribution_policy` which allows one to represent a given locality in the context of a distribution policy.
- The new distribution policies can now be also used with `hpx::async`. This change also deprecates `hpx::async_colocated(id, ...)` which now is replaced by a distribution policy: `hpx::async(hpx::colocated(id), ...)`. The `hpx::vector` and `hpx::unordered_map` data structures can now be used with the new distribution policies as well.
- The parallel facility `hpx::parallel::task_region` has been renamed to `hpx::parallel::task_block` based on the changes in the corresponding standardization proposal N4411\(^\text{3255}\).
- Added extensions to the parallel facility `hpx::parallel::task_block` allowing to combine a task_block with an execution policy. This implies a minor breaking change as the `hpx::parallel::task_block` is now a template.
- Added new LCOs: `hpx::lcos::latch` and `hpx::lcos::local::latch` which semantically conform to the proposed `std::latch` (see \(^\text{N4399}\)^{3256}).
- Added performance counters exposing data related to data transferred by input/output (filesystem) operations (thanks to Maciej Brodowicz).

\(^{3254}\) https://circleci.com/gh/STEllAR-GROUP/hpx
\(^{3255}\) http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2015/n4411.pdf
\(^{3256}\) http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2015/n4399.html
• Added performance counters allowing to track the number of action invocations (local and remote invocations).

• Added new command line options –hpx:print-counter-at and –hpx:reset-counters.

• The hpx::vector component has been renamed to hpx::partitioned_vector to make it explicit that the underlying memory is not contiguous.

• Introduced a completely new and uniform higher-level parallelism API which is based on executors. All existing parallelism APIs have been adapted to this. We have added a large number of different executor types, such as a numa-aware executor, a this-thread executor, etc.

• Added support for the MingW toolchain on Windows (thanks to Eric Lemanissier).

• HPX now includes support for APEX, (Autonomic Performance Environment for eXascale). APEX is an instrumentation and software adaptation library that provides an interface to TAU profiling / tracing as well as runtime adaptation of HPX applications through policy definitions. For more information and documentation, please see https://github.com/khuck/xpress-apex. To enable APEX at configuration time, specify -DHPX_WITH_APEX=On. To also include support for TAU profiling, specify -DHPX_WITH_TAU=On and specify the -DTAU_ROOT, -DTAU_ARCH and -DTAU_OPTIONS cmake parameters.

• We have implemented many more of the Using parallel algorithms. Please see Issue #11413257 for the list of all available parallel algorithms (thanks to Daniel Bourgeois and John Biddiscombe for contributing their work).

Breaking changes

• We are moving into the direction of unifying managed and simple components. In order to stop exposing the old facilities, all examples have been converted to use the new classes. The breaking change in this release is that performance counters are now a hpx::components::component_base instead of hpx::components::managed_component_base.

• We removed the support for stackless threads. It turned out that there was no performance benefit when using stackless threads. As such, we decided to clean up our codebase. This feature was not documented.

• The CMake project name has changed from ‘hpx’ to ‘HPX’ for consistency and compatibility with naming conventions and other CMake projects. Generated config files go into <prefix>/lib/cmake/HPX and not <prefix>/lib/cmake/hpx.

• The macro HPX_REGISTER_MINIMAL_COMPONENT_FACTORY has been deprecated. Please use HPX_REGISTER_COMPONENT instead. The old macro will be removed in the next release.

• The obsolete distributing_factory and binpacking_factory components have been removed. The corresponding functionality is now provided by the hpx::new_ API function in conjunction with the hpx::default_layout and hpx::binpacking distribution policies (hpx::components::default_distribution_policy and hpx::components::binpacking_distribution_policy)

• The API function hpx::new_colocated has been deprecated. Please use the consolidated API hpx::new_ in conjunction with the new hpx::colocated distribution policy (hpx::components::colocating_distribution_policy) instead. The old API function will still be available for at least one release of HPX if the configuration variable HPX_WITH_COLOCATED_BACKWARDS_COMPATIBILITY is enabled.

• The API function hpx::async_colocated has been deprecated. Please use the consolidated API hpx::async in conjunction with the new hpx::colocated distribution policy (hpx::components::colocating_distribution_policy) instead. The old API function will still be available for at least one release of HPX if the configuration variable HPX_WITH_COLOCATED_BACKWARDS_COMPATIBILITY is enabled.

3257 https://github.com/STEllAR-GROUP/hpx/issues/1141
• The obsolete remote_object component has been removed.

• Replaced the use of Boost.Serialization with our own solution. While the new version is mostly compatible with Boost.Serialization, this change requires some minor code modifications in user code. For more information, please see the corresponding announcement on the hpx-users@stellar.cct.lsu.edu mailing list.

• The names used by cmake to influence various configuration options have been unified. The new naming scheme relies on all configuration constants to start with HPX_WITH..., while the preprocessor constant which is used at build time starts with HPX_HAVE.... For instance, the former cmake command line
-DHPX_MALLOC=... now has to be specified a -DHPX_WITH_MALLOC=... and will cause the preprocessor constant HPX_HAVE_MALLOC to be defined. The actual name of the constant (i.e. MALLOC) has not changed. Please see the corresponding documentation for more details (CMake variables used to configure HPX).

• The get_gid() functions exposed by the component base classes
  hpx::components::server::simple_component_base, hpx::components::server::managed_component_base, and hpx::components::server::fixed_component_base have been replaced by two new functions: get_unmanaged_id() and get_id(). To enable the old function name for backwards compatibility, use the cmake configuration option HPX_WITH_COMPONENT_GET_GID_COMPATIBILITY=On.

• All functions which were named get_gid() but were returning hpx::id_type have been renamed to get_id(). To enable the old function names for backwards compatibility, use the cmake configuration option HPX_WITH_COMPONENT_GET_GID_COMPATIBILITY=On.

**Bug fixes (closed tickets)**

Here is a list of the important tickets we closed for this release.

• PR #1855 - Completely removing external/endian
• PR #1854 - Don’t pollute CMAKE_CXX_FLAGS through find_package()
• PR #1853 - Updating CMake configuration to get correct version of TAU library
• PR #1852 - Fixing Performance Problems with MPI Parcelport
• PR #1851 - Fixing hpx_add_link_flag() and hpx_remove_link_flag()
• PR #1850 - Fixing 1836, adding parallel::sort
• PR #1849 - Fixing configuration for use of more than 64 cores
• PR #1848 - Change default APEX version for release
• PR #1847 - Fix client_base::then on release
• PR #1846 - Removing broken lcos::local::channel from release
• PR #1845 - Adding example demonstrating a possible safe-object implementation to release

Chapter 2. What’s so special about HPX?

- PR #1765[^3339] - Restricting thread_data to creating only with intrusive_pointers
- PR #1764[^3340] - Fixing 1763
- Issue #1763[^3341] - UB in thread_data::operator delete
- PR #1762[^3342] - Making sure all serialization registries/factories are unique
- PR #1761[^3343] - Fixed #1751: hpx::future::wait_for fails a simple test
- PR #1758[^3344] - Fixing #1757
- Issue #1757[^3345] - pinning not correct using –hpx:bind
- Issue #1756[^3346] - compilation error with MinGW
- PR #1755[^3347] - Making output serialization const-correct
- Issue #1753[^3348] - HPX performance degrades with time since execution begins
- Issue #1752[^3349] - Error in AGAS
- Issue #1751[^3350] - hpx::future::wait_for fails a simple test
- PR #1750[^3351] - Removing hpx_fwd.hpp includes
- PR #1749[^3352] - Simplify result_of and friends
- PR #1747[^3353] - Removed superfluous code from message_buffer.hpp
- PR #1746[^3354] - Tuple dependencies
- Issue #1745[^3355] - Broken when_some which takes iterators
- PR #1744[^3356] - Refining archive interface
- PR #1743[^3357] - Fixing when_all when only a single future is passed
- PR #1742[^3358] - Config includes
- PR #1741[^3359] - Os executors
- Issue #1740[^3360] - hpx::promise has some problems
- PR #1739[^3361] - Parallel composition with generic containers

- Issue #1738 - After building program and successfully linking to a version of hpx DHPX_DIR seems to be ignored
- Issue #1737 - Uptime problems
- PR #1736 - added convenience c-tor and begin()/end() to serialize_buffer
- PR #1735 - Config includes
- PR #1734 - Fixed #1688: Add timer counters for tfunc_total and exec_total
- Issue #1733 - Add unit test for hpx/lcos/local/receive_buffer.hpp
- PR #1732 - Renaming get_os_thread_count
- PR #1731 - Basename registration
- Issue #1730 - Use after move of thread_init_data
- PR #1729 - Rewriting channel based on new gate component
- PR #1728 - Fixing #1722
- PR #1727 - Fixing compile problems with apply_colocated
- PR #1726 - Apex integration
- PR #1725 - fixed test timeouts
- PR #1724 - Renaming vector
- Issue #1723 - Drop support for intel compilers and gcc 4.4. based standard libs
- Issue #1722 - Add support for detecting non-ready futures before serialization
- PR #1721 - Unifying parallel executors, initializing from launch policy
- PR #1720 - dropped superfluous typedef
- Issue #1718 - Windows 10 x64, VS 2015 - Unknown CMake command “add_hpx_pseudo_target”.
- PR #1717 - Timed executor traits for thread-executors
- PR #1716 - serialization of arrays didn’t work with non-pod types. fixed
- PR #1715 - List serialization

• PR #1714 - changing misspellings
• PR #1713 - Fixed distribution policy executors
• PR #1712 - Moving library detection to be executed after feature tests
• PR #1711 - Simplify parcel
• PR #1710 - Compile only tests
• PR #1709 - Implemented timed executors
• PR #1708 - Implement parallel::executor_traits for thread-executors
• PR #1707 - Various fixes to threads::executors to make custom schedulers work
• PR #1706 - Command line option --hpx:cores does not work as expected
• Issue #1705 - command line option --hpx:cores does not work as expected
• PR #1704 - vector deserialization is speeded up a little
• PR #1703 - Fixing shared_mutes
• Issue #1702 - Shared_mutex does not compile with no_mutex cond_var
• PR #1701 - Add distribution_policy_executor
• PR #1700 - Executor parameters
• PR #1699 - Readers writer lock
• PR #1698 - Remove leftovers
• PR #1697 - Fixing held locks
• PR #1696 - Modified Scan Partitioner for Algorithms
• PR #1695 - This thread executors
• PR #1694 - Fixed #1688: Add timer counters for tfunc_total and exec_total
• PR #1693 - Fix #1691: is_executor template specification fails for inherited executors
• PR #1692 - Fixed #1662: Possible exception source in coalescing_message_handler
• Issue #1691 - is_executor template specification fails for inherited executors
• PR #1690 - added macro for non-intrusive serialization of classes without a default c-tor
• PR #1689 - Replace value_or_error with custom storage, unify future_data state
• Issue #1688 - Add timer counters for tfunc_total and exec_total
• PR #1687 - Fixed interval timer
• PR #1686 - Fixing cmake warnings about not existing pseudo target dependencies
• PR #1685 - Converting partitioners to use bulk async execute
• PR #1683 - Adds a tool for inspect that checks for character limits
• PR #1682 - Change project name to (uppercase) HPX
• PR #1681 - Counter shortnames
• PR #1680 - Extended Non-intrusive Serialization to Ease Usage for Library Developers
• PR #1679 - Working on 1544: More executor changes
• PR #1678 - Transpose fixes
• PR #1677 - Improve Boost compatibility check
• PR #1676 - 1d stencil fix
• Issue #1675 - hpx project name is not HPX
• PR #1674 - Fixing the MPI parcelport
• PR #1673 - added move semantics to map/vector deserialization
• PR #1672 - Vs2015 await
• PR #1671 - Adapt transform for #1668
• PR #1670 - Started to work on #1668
• PR #1669 - Add this_thread_executors
• Issue #1667 - Apple build instructions in docs are out of date

2.10. Releases
• PR #1666\textsuperscript{3431} - Apex integration
• PR #1665\textsuperscript{3432} - Fixes an error with the whitespace check that showed the incorrect location of the error
• Issue #1664\textsuperscript{3433} - Inspect tool found incorrect endline whitespace
• PR #1663\textsuperscript{3434} - Improve use of locks
• Issue #1662\textsuperscript{3435} - Possible exception source in coalescing_message_handler
• PR #1661\textsuperscript{3436} - Added support for 128bit number serialization
• PR #1660\textsuperscript{3437} - Serialization 128bits
• PR #1659\textsuperscript{3438} - Implemented inner_product and adjacent_diff algos
• PR #1658\textsuperscript{3439} - Add serialization for std::set (as there is for std::vector and std::map)
• PR #1657\textsuperscript{3440} - Use of shared_ptr in io_service_pool changed to unique_ptr
• Issue #1656\textsuperscript{3441} - 1d_stencil codes all have wrong factor
• PR #1654\textsuperscript{3442} - When using runtime_mode_connect, find the correct localhost public ip address
• PR #1653\textsuperscript{3443} - Fixing 1617
• PR #1652\textsuperscript{3444} - Remove traits::action_may_require_id_splitting
• PR #1651\textsuperscript{3445} - Fixed performance counters related to AGAS cache timings
• PR #1650\textsuperscript{3446} - Remove leftovers of traits::type_size
• PR #1649\textsuperscript{3447} - Shorten target names on Windows to shorten used path names
• PR #1648\textsuperscript{3448} - Fixing problems introduced by merging #1623 for older compilers
• PR #1647\textsuperscript{3449} - Simplify running automatic builds on Windows
• Issue #1646\textsuperscript{3450} - Cache insert and update performance counters are broken
• Issue #1644\textsuperscript{3451} - Remove leftovers of traits::type_size
• Issue #1643\textsuperscript{3452} - Remove traits::action_may_require_id_splitting
• PR #1642\textsuperscript{3453} - Adds spell checker to the inspect tool for qbk and doxygen comments

Chapter 2. What's so special about HPX?
• PR #1640 - First step towards fixing 688
• PR #1639 - Re-apply remaining changes from limit_dataflow_recursion branch
• PR #1638 - This fixes possible deadlock in the test ignore_while_locked_1485
• PR #1637 - Fixing hpx::wait_all() invoked with two vector<future<T>>
• PR #1636 - Partially re-apply changes from limit_dataflow_recursion branch
• PR #1635 - Adding missing test for #1572
• PR #1634 - Revert “Limit recursion-depth in dataflow to a configurable constant”
• PR #1633 - Add command line option to ignore batch environment
• PR #1631 - hpx::lcos::queue exhibits strange behavior
• PR #1630 - Fixed endline_whitespace_check.cpp to detect lines with only whitespace
• Issue #1629 - Inspect trailing whitespace checker problem
• PR #1628 - Removed meaningless const qualifiers. Minor icpc fix.
• PR #1627 - Fixing the queue LCO and add example demonstrating its use
• PR #1626 - Deprecating get_gid(), add get_id() and get_unmanaged_id()
• PR #1625 - Allowing to specify whether to send credits along with message
• Issue #1624 - Lifetime issue
• Issue #1623 - hpx::wait_all() invoked with two vector<future<T>> fails
• PR #1622 - Executor partitioners
• PR #1621 - Clean up coroutines implementation
• Issue #1620 - Revert #1535
• PR #1619 - Fix result type calculation for hpx::make_continuation
• PR #1618 - Fixing RDTSC on Xeon/Phi
• Issue #1617 - hpx cmake not working when run as a subproject
• Issue #1616\textsuperscript{3477} - cmake problem resulting in RDTSC not working correctly for Xeon Phi creates very strange results for duration counters

• Issue #1615\textsuperscript{3478} - hpx::make\_continuation requires input and output to be the same

• PR #1614\textsuperscript{3479} - Fixed remove copy test

• Issue #1613\textsuperscript{3480} - Dataflow causes stack overflow

• PR #1612\textsuperscript{3481} - Modified foreach partitioner to use bulk execute

• PR #1611\textsuperscript{3482} - Limit recursion-depth in dataflow to a configurable constant

• PR #1610\textsuperscript{3483} - Increase timeout for CircleCI

• PR #1609\textsuperscript{3484} - Refactoring thread manager, mainly extracting thread pool

• PR #1608\textsuperscript{3485} - Fixed running multiple localities without localities parameter

• PR #1607\textsuperscript{3486} - More algorithm fixes to adjacentfind

• Issue #1606\textsuperscript{3487} - Running without localities parameter binds to bogus port range

• Issue #1605\textsuperscript{3488} - Too many serializations

• PR #1604\textsuperscript{3489} - Changes the HPX image into a hyperlink

• PR #1601\textsuperscript{3490} - Fixing problems with remove\_copy algorithm tests

• PR #1600\textsuperscript{3491} - Actions with ids cleanup

• PR #1599\textsuperscript{3492} - Duplicate binding of global ids should fail

• PR #1598\textsuperscript{3493} - Fixing array access

• PR #1597\textsuperscript{3494} - Improved the reliability of connecting/disconnecting localities

• Issue #1596\textsuperscript{3495} - Duplicate id binding should fail

• PR #1595\textsuperscript{3496} - Fixing more cmake config constants

• PR #1594\textsuperscript{3497} - Fixing preprocessor constant used to enable C++11 chrono

• PR #1593\textsuperscript{3498} - Adding operator() for hpx::launch

• Issue #1592\textsuperscript{3499} - Error (typo) in the docs

\textsuperscript{3499} https://github.com/STEllAR-GROUP/hpx/issues/1592
• Issue #1590  - CMake fails when CMAKE_BINARY_DIR contains '+'.
• Issue #1589  - Disconnecting a locality results in segfault using heartbeat example
• PR #1588  - Fix doc string for config option HPX_WITH_EXAMPLES
• PR #1586  - Fixing 1493
• PR #1583  - Additional Check for Inspect Tool to detect Endline Whitespace
• Issue #1584  - Clean up coroutines implementation
• PR #1583  - Adding a check for end line whitespace
• PR #1582  - Attempt to fix assert firing after scheduling loop was exited
• PR #1581  - Fixed adjacentfind_binary test
• PR #1580  - Prevent some of the internal cmake lists from growing indefinitely
• PR #1579  - Removing type_size trait, replacing it with special archive type
• Issue #1578  - Remove demangle_helper
• PR #1577  - Get ptr problems
• Issue #1576  - Refactor async, dataflow, and future::then
• PR #1575  - Fixing tests for parallel rotate
• PR #1574  - Cleaning up schedulers
• PR #1573  - Fixing thread pool executor
• PR #1572  - Fixing number of configured localities
• PR #1571  - Reimplement decay
• PR #1570  - Refactoring async, apply, and dataflow APIs
• PR #1569  - Changed range for mach-o library lookup
• PR #1568  - Mark decltype support as required
• PR #1567  - Removed const from algorithms
• Issue #1566 - CMAKE Configuration Test Failures for clang 3.5 on debian
• PR #1565 - Dylib support
• PR #1564 - Converted partitioners and some algorithms to use executors
• PR #1563 - Fix several #includes for Boost.Preprocessor
• PR #1562 - Adding configuration option disabling/enabling all message handlers
• PR #1561 - Removed all occurrences of boost::move replacing it with std::move
• Issue #1560 - Leftover HPX_REGISTER_ACTION_DECLARATION_2
• PR #1559 - Revisit async/apply SFINAЕ conditions
• PR #1558 - Removing type_size trait, replacing it with special archive type
• PR #1557 - Executor algorithms
• PR #1555 - Remove the necessity to specify archive flags on the receiving end
• PR #1554 - Removing obsolete Boost.Serialization macros
• PR #1553 - Properly fix HPX_DEFINE_*_ACTION macros
• PR #1552 - Fixed algorithms relying on copy_if implementation
• PR #1551 - Pxfs - Modifying FindOrangeFS.cmake based on OrangeFS 2.9.X
• Issue #1550 - Passing plain identifier inside HPX_DEFINE_PLAIN_ACTION_1
• PR #1549 - Fixing intel14/libstdc++4.4
• PR #1548 - Moving raw_ptr to detail namespace
• PR #1547 - Adding support for executors to future.then
• PR #1546 - Executor traits result types
• PR #1545 - Integrate executors with dataflow
• PR #1544 - Fix potential zero-copy for primarynamespace::bulk_service_async et.al.
• PR #1543 - Merging HPX0.9.10 into pxfs branch
• PR #1541 - Removed stale cmake tests, unused since the great cmake refactoring
• PR #1540 - Fix idle-rate on platforms without TSC
• PR #1539 - Reporting situation if zero-copy-serialization was performed by a parcel generated from a plain apply/async
• PR #1538 - Changed return type of bulk executors and added test
• Issue #1537 - Incorrect cpuid config tests
• PR #1536 - Changed return type of bulk executors and added test
• PR #1535 - Make sure promise::get_gid() can be called more than once
• PR #1534 - Fixed async_callback with bound callback
• PR #1533 - Updated the link in the documentation to a publically-accessible URL
• PR #1532 - Make sure sync primitives are not copyable nor movable
• PR #1531 - Fix unwrapped issue with future ranges of void type
• PR #1530 - Serialization complex
• Issue #1529 - Unwrapped issue with future<void>
• Issue #1527 - HPX does not build with Boost 1.58.0
• PR #1526 - Added support for boost.multi_array serialization
• PR #1525 - Properly handle deferred futures, fixes #1506
• PR #1524 - Making sure invalid action argument types generate clear error message
• Issue #1522 - Need serialization support for boost multi array
• Issue #1521 - Remote async and zero-copy serialization optimizations don’t play well together
• PR #1520 - Fixing UB while registering polymorphic classes for serialization
• PR #1519 - Making detail::condition_variable safe to use
• PR #1518 - Fix when_some bug missing indices in its result
• Issue #1517 - Typo may affect CMake build system tests

2.10. Releases
• PR #1516 - Fixing Posix context
• PR #1515 - Fixing Posix context
• PR #1514 - Correct problems with loading dynamic components
• PR #1513 - Fixing intel glibc4 4
• Issue #1508 - memory and papi counters do not work
• Issue #1507 - Unrecognized Command Line Option Error causing exit status 0
• Issue #1506 - Properly handle deferred futures
• PR #1505 - Adding #include - would not compile without this
• Issue #1502 - boost::filesystem::exists throws unexpected exception
• Issue #1501 - hwloc configuration options are wrong for MIC
• PR #1504 - Making sure boost::filesystem::exists() does not throw
• PR #1500 - Exit application on --hpx:version/-v and --hpx:info
• PR #1498 - Extended task block
• PR #1497 - Unique ptr serialization
• PR #1496 - Unique ptr serialization (closed)
• PR #1495 - Switching circleci build type to debug
• Issue #1494 - --hpx:version/-v does not exit after printing version information
• Issue #1493 - add an hpx_ prefix to libraries and components to avoid name conflicts
• Issue #1492 - Define and ensure limitations for arguments to async/apply
• PR #1489 - Enable idle rate counter on demand
• PR #1488 - Made sure detail::condition_variable can be safely destroyed
• PR #1487 - Introduced default (main) template implementation for ignore_while_checking
• PR #1486 - Add HPX inspect tool

Chapter 2. What’s so special about HPX?
- Issue #1485 - `ignore_while_locked` doesn’t support all Lockable types
- PR #1484 - Docker image generation
- PR #1483 - Move external endian library into HPX
- PR #1482 - Actions with integer type ids
- Issue #1481 - Sync primitives safe destruction
- Issue #1480 - Move external/boost/endian into hpx/util
- Issue #1478 - Boost inspect violations
- PR #1479 - Adds serialization for arrays; some further/minor fixes
- PR #1477 - Fixing problems with the Intel compiler using a GCC 4.4 std library
- PR #1476 - Adding `hpx::lcos::latch` and `hpx::lcos::local::latch`
- Issue #1475 - Boost inspect violations
- PR #1473 - Fixing action move tests
- Issue #1471 - Sync primitives should not be movable
- PR #1470 - Removing `hpx::util::polymorphic_factory`
- PR #1468 - Fixed container creation
- Issue #1467 - HPX application fail during finalization
- Issue #1466 - HPX doesn’t pick up Torque’s nodefile on SuperMIC
- Issue #1464 - HPX option for pre and post bootstrap performance counters
- PR #1463 - Replacing `async_colocated(id, ...)` with `async(colocated(id), ...)`
- PR #1462 - Consolidated task_region with N4411
- PR #1461 - Consolidate inconsistent CMake option names
- Issue #1460 - Which malloc is actually used? or at least which one is HPX built with
- Issue #1459 - Make cmake configure step fail explicitly if compiler version is not supported

© 2019 STEllAR-GROUP

2.10. Releases
• Issue #1458 - Update parallel::task_region with N4411
• PR #1456 - Consolidating new_<>()
• Issue #1455 - Replace async_colocated(id, ...) with async(colocated(id), ...)
• PR #1454 - Removed harmful std::moves from return statements
• PR #1453 - Use range-based for-loop instead of Boost.Foreach
• PR #1452 - C++ feature tests
• PR #1451 - When serializing, pass archive flags to traits::get_type_size
• Issue #1450 - traits::get_type_size needs archive flags to enable zero_copy optimizations
• Issue #1449 - “couldn’t create performance counter” - AGAS
• Issue #1448 - Replace distributing factories with new_<T[]>({...})
• PR #1447 - Removing obsolete remote_object component
• PR #1446 - Hpx serialization
• PR #1445 - Replacing travis with circleci
• PR #1444 - Always stripping HPX command line arguments before executing start function
• PR #1443 - Adding –hpx:bind=none to disable thread affinities
• Issue #1442 - Libraries get linked in multiple times, RPATH is not properly set
• PR #1441 - Removed superfluous typedefs
• Issue #1439 - hpx::init() should strip HPX-related flags from argv
• Issue #1438 - Add strong scaling option to htxs
• PR #1437 - Adding async_cb, async_continue_cb, and async_colocated_cb
• PR #1436 - Added missing install rule, removed some dead CMake code
• PR #1435 - Add GitExternal and SubProject cmake scripts from eyescale/cmake repo
• Issue #1432 - Add command line flag to disable thread pinning

- PR #1431
  - Fix #1423
- Issue #1430
  - Inconsistent CMake option names
- Issue #1429
  - Configure setting HPX_HAVE_PARCELPORT_MPI is ignored
- PR #1428
  - Fixes #1419 (closed)
- PR #1427
  - Adding stencil_iterator and transform_iterator
- PR #1426
  - Fixes #1419
- PR #1425
  - During serialization memory allocation should honour allocator chunk size
- Issue #1424
  - chunk allocation during serialization does not use memory pool/allocator chunk size
- Issue #1423
  - Remove HPX_STD_UNIQUE_PTR
- Issue #1422
  - hpx:threads=all allocates too many os threads
- PR #1420
  - added .travis.yml
- Issue #1419
  - Unify enums: hpx::runtime::state and hpx::state
- PR #1416
  - Adding travis builder
- Issue #1414
  - Correct directory for dispatch_gcc46.hpp iteration
- Issue #1410
  - Set operation algorithms
- Issue #1389
  - Parallel algorithms relying on scan partitioner break for small number of elements
- Issue #1325
  - Exceptions thrown during parcel handling are not handled correctly
- Issue #1315
  - Errors while running performance tests
- Issue #1309
  - hpx::vector partitions are not easily extendable by applications
- PR #1300
  - Added serialization/de-serialization to examples.tuplespace
- Issue #1251
  - hpx::threads::get_thread_count doesn’t consider pending threads
- Issue #1008
  - Decrease in application performance overtime; occasional spikes of major slowdown
- Issue #1001
  - Zero copy serialization raises assert
2.10.13 HPX V0.9.10 (Mar 24, 2015)

General changes

This is the 12th official release of HPX. It coincides with the 7th anniversary of the first commit to our source code repository. Since then, we have seen over 12300 commits amounting to more than 220000 lines of C++ code.

The major focus of this release was to improve the reliability of large scale runs. We believe to have achieved this goal as we now can reliably run HPX applications on up to ~24k cores. We have also showed that HPX can be used with success for symmetric runs (applications using both, host cores and Intel Xeon/Phi coprocessors). This is a huge step forward in terms of the usability of HPX. The main focus of this work involved isolating the causes of the segmentation faults at start up and shut down. Many of these issues were discovered to be the result of the suspension of threads which hold locks.

A very important improvement introduced with this release is the refactoring of the code representing our parcel-port implementation. Parcel-ports can now be implemented by 3rd parties as independent plugins which are dynamically loaded at runtime (static linking of parcel-ports is also supported). This refactoring also includes a massive improvement of the performance of our existing parcel-ports. We were able to significantly reduce the networking latencies and to improve the available networking bandwidth. Please note that in this release we disabled the ibverbs and ipc parcel ports as those have not been ported to the new plugin system yet (see Issue #839).

Another corner stone of this release is our work towards a complete implementation of __cpp11_n4104__ (Working Draft, Technical Specification for C++ Extensions for Parallelism). This document defines a set of parallel algorithms to be added to the C++ standard library. We now have implemented about 75% of all specified parallel algorithms (see [link hpx.manual.parallel.parallel_algorithms Parallel Algorithms] for more details). We also implemented some extensions to __cpp11_n4104__ allowing to invoke all of the algorithms asynchronously.

This release adds a first implementation of hpx::vector which is a distributed data structure closely aligned to the functionality of std::vector. The difference is that hpx::vector stores the data in partitions where the partitions can be distributed over different localities. We started to work on allowing to use the parallel algorithms with hpx::vector. At this point we have implemented only a few of the parallel algorithms to support distributed data structures (like hpx::vector) for testing purposes (see Issue #1338 for a documentation of our progress).

Breaking changes

With this release we put a lot of effort into changing the code base to be more compatible to C++11. These changes have caused the following issues for backward compatibility:

- Move to Variadics- All of the API now uses variadic templates. However, this change required to modify the argument sequence for some of the exiting API functions (hpx::async_continue, hpx::apply_continue, hpx::when_each, hpx::wait_each, synchronous invocation of actions).

- Changes to Macros- We also removed the macros HPX_STD_FUNCTION and HPX_STD_TUPLE. This shouldn’t affect any user code as we replaced HPX_STD_FUNCTION with hpx::util::function_nonser which was the default expansion used for this macro. All HPX API functions which expect a hpx::util::function_nonser (or a hpx::util::unique_function_nonser) can now be transparently called with a compatible

---

3661 https://github.com/STEllAR-GROUP/hpx/issues/721
3662 https://github.com/STEllAR-GROUP/hpx/issues/524
3663 https://github.com/STEllAR-GROUP/hpx/issues/839
3664 https://github.com/STEllAR-GROUP/hpx/issues/1338
\texttt{std::function} instead. Similarly, \texttt{HPX_STD_TUPLE} was replaced by its default expansion as well:\n\texttt{hpx::util::tuple}.

- Changes to \texttt{hpx::unique_future} - \texttt{hpx::unique_future}, which was deprecated in the previous release for \texttt{hpx::future} is now completely removed from \texttt{HPX}. This completes the transition to a completely standards conforming implementation of \texttt{hpx::future}.

- Changes to Supported Compilers. Finally, in order to utilize more C++11 semantics, we have officially dropped support for GCC 4.4 and MSVC 2012. Please see our \textit{Prerequisites} page for more details.

**Bug fixes (closed tickets)**

Here is a list of the important tickets we closed for this release.

- Issue #1402\textsuperscript{3665} - Internal shared_future serialization copies
- Issue #1399\textsuperscript{3666} - Build takes unusually long time...
- Issue #1398\textsuperscript{3667} - Tests using the scan partitioner are broken on at least gcc 4.7 and intel compiler
- Issue #1397\textsuperscript{3668} - Completely remove \texttt{hpx::unique_future}
- Issue #1396\textsuperscript{3669} - Parallel scan algorithms with different initial values
- Issue #1395\textsuperscript{3670} - Race Condition - \texttt{1d_stencil_8} - SuperMIC
- Issue #1394\textsuperscript{3671} - “suspending thread while at least one lock is being held” - \texttt{1d_stencil_8} - SuperMIC
- Issue #1393\textsuperscript{3672} - \texttt{SEGFALOFT} in \texttt{1d_stencil_8} on SuperMIC
- Issue #1392\textsuperscript{3673} - Fixing #1168
- Issue #1391\textsuperscript{3674} - Parallel Algorithms for scan partitioner for small number of elements
- Issue #1387\textsuperscript{3675} - Failure with more than 4 localities
- Issue #1386\textsuperscript{3676} - Dispatching unhandled exceptions to outer user code
- Issue #1385\textsuperscript{3677} - Adding Copy algorithms, fixing \texttt{parallel::copy_if}
- Issue #1384\textsuperscript{3678} - Fixing 1325
- Issue #1383\textsuperscript{3679} - Fixed #504: Refactor Dataflow LCO to work with futures, this removes the dataflow component as it is obsolete
- Issue #1382\textsuperscript{3680} - \texttt{is_sorted}, \texttt{is_sorted_until} and \texttt{is_partitioned} algorithms
- Issue #1381\textsuperscript{3681} - fix for CMake versions prior to 3.1

  - N4071 Search/Search_n finished, minor changes
• Issue #1316
  - Add config option to make -lpx.run_hpx_main!=1 the default
• Issue #1314
  - Variadic support for async and apply
• Issue #1313
  - Adjust when_any/some to the latest proposed interfaces
• Issue #1312
  - Fixing #857: hpx::naming::locality leaks parcelport specific information into the public interface
• Issue #1311
  - Distributed get’er/set’er_values for distributed vector
• Issue #1310 - Crashing in hpx::parcelset::policies::mpi::connection_handler::handle_messages() on Super-MIC
• Issue #1308 - Unable to execute an application with –hpx:threads
• Issue #1307 - merge_graph linking issue
• Issue #1306 - First batch of variadic templates support
• Issue #1305 - Create a compiler wrapper
• Issue #1304 - Provide a compiler wrapper for hpx
• Issue #1303 - Drop support for GCC44
• Issue #1302 - Fixing #1297
• Issue #1301 - Compilation error when tried to use boost range iterators with wait_all
• Issue #1298 - Distributed vector
• Issue #1297 - Unable to invoke component actions recursively
• Issue #1294 - HDF5 build error
• Issue #1275 - The parcelport implementation is non-optimal
• Issue #1267 - Added classes and unit tests for local_file, orangefs_file and pxfs_file
• Issue #1264 - Error “assertion ‘!m_fun’ failed” randomly occurs when using TCP
• Issue #1254 - thread binding seems to not work properly
• Issue #1220 - parallel::copy_if is broken
• Issue #1217 - Find a better way of fixing the issue patched by #1216
• Issue #1168 - Starting HPX on Cray machines using aprun isn’t working correctly
• Issue #1085 - Replace startup and shutdown barriers with broadcasts
• Issue #981 - With SLURM, –hpx:threads=8 should not be necessary
• Issue #857 - hpx::naming::locality leaks parcelport specific information into the public interface
• Issue #850 - “flush” not documented

• Issue #763\(^{3773}\) - Create buildbot instance that uses std::bind as HPX_STD_BIND
• Issue #680\(^{3774}\) - Convert parcel ports into a plugin system
• Issue #582\(^{3775}\) - Make exception thrown from HPX threads available from hpx::init
• Issue #504\(^{3776}\) - Refactor Dataflow LCO to work with futures
• Issue #196\(^{3777}\) - Don’t store copies of the locality network metadata in the gva table

2.10.14 HPX V0.9.9 (Oct 31, 2014, codename Spooky)

General changes

We have had over 1500 commits since the last release and we have closed over 200 tickets (bugs, feature requests, pull requests, etc.). These are by far the largest numbers of commits and resolved issues for any of the HPX releases so far. We are especially happy about the large number of people who contributed for the first time to HPX.

• We completed the transition from the older (non-conforming) implementation of hpx::future to the new and fully conforming version by removing the old code and by renaming the type hpx::unique_future to hpx::future. In order to maintain backwards compatibility with existing code which uses the type hpx::unique_future we support the configuration variable HPX_UNIQUE_FUTURE_ALIAS. If this variable is set to ON while running cmake it will additionally define a template alias for this type.

• We rewrote and significantly changed our build system. Please have a look at the new (now generated) documentation here: HPX build system. Please revisit your build scripts to adapt to the changes. The most notable changes are:
  
  – HPX_NO_INSTALL is no longer necessary.
  
  – For external builds, you need to set HPX_DIR instead of HPX_ROOT as described here: Using HPX with CMake-based projects.
  
  – IDEs that support multiple configurations (Visual Studio and XCode) can now be used as intended. that means no build dir.
  
  – Building HPX statically (without dynamic libraries) is now supported (-DHPX_STATIC_LINKING=On).
  
  – Please note that many variables used to configure the build process have been renamed to unify the naming conventions (see the section CMake variables used to configure HPX for more information).
  
  – This also fixes a long list of issues, for more information see Issue #1204\(^{3778}\).

• We started to implement various proposals to the C++ Standardization committee related to parallelism and concurrency, most notably N4409\(^{3779}\) (Working Draft, Technical Specification for C++ Extensions for Parallelism), N4411\(^{3780}\) (Task Region Rev. 3), and N4313\(^{3781}\) (Working Draft, Technical Specification for C++ Extensions for Concurrency).

\(^{3775}\) https://github.com/STEllAR-GROUP/hpx/issues/582
\(^{3776}\) https://github.com/STEllAR-GROUP/hpx/issues/504
\(^{3777}\) https://github.com/STEllAR-GROUP/hpx/issues/196
\(^{3778}\) https://github.com/STEllAR-GROUP/hpx/issues/1204
\(^{3779}\) http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2015/n4409.pdf
\(^{3780}\) http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2015/n4411.pdf
\(^{3781}\) http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2014/n4313.html
• We completely remodeled our automatic build system to run builds and unit tests on various systems and compilers. This allows us to find most bugs right as they were introduced and helps to maintain a high level of quality and compatibility. The newest build logs can be found at HPX Buildbot Website.

**Bug fixes (closed tickets)**

Here is a list of the important tickets we closed for this release.

• Issue #1296 - Rename make_error_future to make_exceptional_future, adjust to N4123
• Issue #1295 - building issue
• Issue #1293 - Transpose example
• Issue #1292 - Wrong abs() function used in example
• Issue #1291 - non-synchronized shift operators have been removed
• Issue #1290 - RDTSCP is defined as true for Xeon Phi build
• Issue #1289 - Fixing 1288
• Issue #1288 - Add new performance counters
• Issue #1287 - Hierarchy scheduler broken performance counters
• Issue #1286 - Algorithm cleanup
• Issue #1285 - Broken Links in Documentation
• Issue #1284 - Uninitialized copy
• Issue #1283 - missing boost::scoped_ptr includes
• Issue #1282 - Update documentation of build options for schedulers
• Issue #1281 - reset idle rate counter
• Issue #1280 - Bug when executing on Intel MIC
• Issue #1279 - Add improved when_all/wait_all
• Issue #1278 - Implement improved when_all/wait_all
• Issue #1277 - feature request: get access to argc argv and variables_map

3801 https://github.com/STEllAR-GROUP/hpx/issues/1277
• Issue #1276 - Remove merging map
• Issue #1274 - Weird (wrong) string code in papi.cpp
• Issue #1273 - Sequential task execution policy
• Issue #1272 - Avoid CMake name clash for Boost.Thread library
• Issue #1271 - Updates on HPX Test Units
• Issue #1270 - hpx/util/safe_lexical_cast.hpp is added
• Issue #1269 - Added default value for “LIB” cmake variable
• Issue #1268 - Memory Counters not working
• Issue #1266 - FindHPX.cmake is not installed
• Issue #1263 - apply_remote test takes too long
• Issue #1262 - Chrono cleanup
• Issue #1261 - Need make install for papi counters and this builds all the examples
• Issue #1260 - Documentation of Stencil example claims
• Issue #1259 - Avoid double-linking Boost on Windows
• Issue #1257 - Adding additional parameter to create_thread
• Issue #1256 - added buildbot changes to release notes
• Issue #1255 - Cannot build MiniGhost
• Issue #1253 - hpx::thread defects
• Issue #1252 - HPX_PREFIX is too fragile
• Issue #1250 - switch_to_fiber_emulation does not work properly
• Issue #1249 - Documentation is generated under Release folder
• Issue #1248 - Fix usage of hpx::generic_coroutine_context and get tests passing on powerpc
• Issue #1247 - Dynamic linking error

1550 Chapter 2. What’s so special about HPX?
• Issue #1246 - Make cpuid.cpp C++11 compliant
• Issue #1245 - HPX fails on startup (setting thread affinity mask)
• Issue #1244 - HPX_WITH_RDTSC configure test fails, but should succeed
• Issue #1243 - CTest dashboard info for CSCS CDash drop location
• Issue #1242 - Mac fixes
• Issue #1241 - Failure in Distributed with Boost 1.56
• Issue #1240 - fix a race condition in examples.diskperf
• Issue #1239 - fix wait_each in examples.diskperf
• Issue #1238 - Fixed #1237: hpx::util::portable_binary_iarchive failed
• Issue #1237 - hpx::util::portable_binary_iarchive faileds
• Issue #1235 - Fixing clang warnings and errors
• Issue #1234 - TCP runs fail: Transport endpoint is not connected
• Issue #1233 - Making sure the correct number of threads is registered with AGAS
• Issue #1232 - Fixing race in wait_XXX
• Issue #1231 - Parallel minmax
• Issue #1230 - Distributed run of 1d_stencil_8 uses less threads than spec. & sometimes gives errors
• Issue #1229 - Unstable number of threads
• Issue #1228 - HPX link error (cmake / MPI)
• Issue #1226 - Warning about struct/class thread_counters
• Issue #1225 - Adding parallel::replace etc
• Issue #1224 - Extending dataflow to pass through non-future arguments
• Issue #1223 - Remaining find algorithms implemented, N4071
• Issue #1222 - Merging all the changes

2.10. Releases 1551
- Issue #1221 - No error output when using mpirun with hpx
- Issue #1219 - Adding new AGAS cache performance counters
- Issue #1216 - Fixing using futures (clients) as arguments to actions
- Issue #1215 - Error compiling simple component
- Issue #1214 - Stencil docs
- Issue #1213 - Using more than a few dozen MPI processes on SuperMike results in a seg fault before getting to hpx_main
- Issue #1212 - Parallel rotate
- Issue #1211 - Direct actions cause the future's shared_state to be leaked
- Issue #1210 - Refactored local::promise to be standard conformant
- Issue #1209 - Improve command line handling
- Issue #1208 - Adding parallel::reverse and parallel::reverse_copy
- Issue #1207 - Add copy_backward and move_backward
- Issue #1206 - N4071 additional algorithms implemented
- Issue #1204 - Cmake simplification and various other minor changes
- Issue #1203 - Implementing new launch policy for (local) async: hpx::launch::fork.
- Issue #1202 - Failed assertion in connection_cache.hpp
- Issue #1201 - pkg-config doesn’t add mpi link directories
- Issue #1200 - Error when querying time performance counters
- Issue #1199 - Library path is now configurable (again)
- Issue #1198 - Error when querying performance counters
- Issue #1197 - Tests fail with intel compiler
- Issue #1196 - Silence several warnings
- Issue #1195 - Rephrase initializers to work with VC++ 2012

https://github.com/STEllAR-GROUP/hpx/issues/1196
https://github.com/STEllAR-GROUP/hpx/issues/1195
- Issue #1194 Simplify parallel algorithms
- Issue #1193 Adding parallel::equal
- Issue #1192 HPX(out_of_memory) on including <hpx/hpx.hpp>
- Issue #1191 Fixing #1189
- Issue #1190 Chrono cleanup
- Issue #1189 Deadlock .. somewhere? (probably serialization)
- Issue #1188 Removed future::get_status()
- Issue #1186 Fixed FindOpenCL to find current AMD APP SDK
- Issue #1184 Tweaking future unwrapping
- Issue #1183 Extended parallel::reduce
- Issue #1182 future::unwrap hangs for launch::deferred
- Issue #1181 Adding all_of, any_of, and none_of and corresponding documentation
- Issue #1180 hpx::cout defect
- Issue #1179 hpx::async does not work for member function pointers when called on types with self-defined unary operator*
- Issue #1178 Implemented variadic hpx::util::zip_iterator
- Issue #1177 MPI parcelport defect
- Issue #1176 HPX_DEFINE_COMPONENT_CONST_ACTION_TPL does not have a 2-argument version
- Issue #1175 Create util::zip_iterator working with util::tuple<>
- Issue #1174 Error Building HPX on linux, root_certificate_authority.cpp
- Issue #1173 hpx::cout output lost
- Issue #1172 HPX build error with Clang 3.4.2
- Issue #1171 CMAKE_INSTALL_PREFIX ignored
- Issue #1170 Close hpx_benchmarks repository on Github

https://github.com/STEllAR-GROUP/hpx/issues/1170
• Issue #1169 - Buildbot emails have syntax error in url
• Issue #1167 - Merge partial implementation of standards proposal N3960
• Issue #1166 - Fixed several compiler warnings
• Issue #1165 - cmake warns: “tests.regressions.actions” does not exist
• Issue #1164 - Want my own serialization of hpx::future
• Issue #1162 - Segfault in hello_world example
• Issue #1161 - Use HPX_ASSERT to aid the compiler
• Issue #1160 - Do not put -DNDEBUG into hpx_application.pc
• Issue #1159 - Support Clang 3.4.2
• Issue #1158 - Fixed #1157: Rename when_n/wait_n, add when_xxx_n/wait_xxx_n
• Issue #1157 - Rename when_n/wait_n, add when_xxx_n/wait_xxx_n
• Issue #1156 - Force inlining fails
• Issue #1155 - changed header of printout to be compatible with python csv module
• Issue #1154 - Fixing iostreams
• Issue #1153 - Standard manipulators (like std::endl) do not work with hpx::ostream
• Issue #1152 - Functions revamp
• Issue #1151 - Suppressing cmake 3.0 policy warning for CMP0026
• Issue #1150 - Client Serialization error
• Issue #1149 - Segfault on Stampede
• Issue #1148 - Refactoring mini-ghost
• Issue #1147 - N3960 copy_if and copy_n implemented and tested
• Issue #1146 - Stencil print
• Issue #1145 - N3960 hpx::parallel::copy implemented and tested

https://github.com/STEllAR-GROUP/hpx/issues/1145
• Issue #1144 - OpenMP examples 1d_stencil do not build
• Issue #1143 - 1d_stencil OpenMP examples do not build
• Issue #1142 - Cannot build HPX with gcc 4.6 on OS X
• Issue #1140 - Fix OpenMP lookup, enable usage of config tests in external CMake projects.
• Issue #1139 - hpx/hpx/config/compiler_specific.hpp
• Issue #1138 - clean up pkg-config files
• Issue #1137 - Improvements to create binary packages
• Issue #1136 - HPX_GCC_VERSION not defined on all compilers
• Issue #1135 - Avoiding collision between winsock2.h and windows.h
• Issue #1134 - Making sure, that hpx::finalize can be called from any locality
• Issue #1133 - 1d stencil examples
• Issue #1131 - Refactor unique_function implementation
• Issue #1130 - Unique function
• Issue #1129 - Some fixes to the Build system on OS X
• Issue #1128 - Action future args
• Issue #1127 - Executor causes segmentation fault
• Issue #1124 - Adding new API functions: register_id_with_basename, unregister_id_with_basename, find_ids_from_basename; adding test
• Issue #1123 - Reduce nesting of try-catch construct in encode_parcel?
• Issue #1122 - Client base fixes
• Issue #1121 - Update hpxrun.py.in
• Issue #1120 - HTTS2 tests compile errors on v110 (VS2012)
• Issue #1119 - Remove references to boost::atomic in accumulator example
• Issue #1118 - Only build test thread_pool_executor_1114_test if HPX_LOCAL_SCHEDULER is set

Chapter 2. What’s so special about HPX?
• Issue #1094 - Syntax error for -DHPX UNIQUE FUTURE_ALIAS in master
• Issue #1093 - Syntax error for -DHPX UNIQUE FUTURE_ALIAS
• Issue #1092 - Rename unique_future<> back to future<>
• Issue #1091 - Inconsistent error message
• Issue #1090 - On windows 8.1 the examples crashed if using more than one os thread
• Issue #1089 - Components should be allowed to have their own executor
• Issue #1088 - Add possibility to select a network interface for the ibverbs parcelport
• Issue #1087 - ibverbs and ipc parcelport uses zero copy optimization
• Issue #1083 - Make shell examples copyable in docs
• Issue #1082 - Implement proper termination detection during shutdown
• Issue #1081 - Implement thread_specific_ptr for hpx::threads
• Issue #1072 - make install not working properly
• Issue #1070 - Complete quoting for parameters of some CMake commands
• Issue #1059 - Fix more unused variable warnings
• Issue #1051 - Implement when_each
• Issue #973 - Would like option to report hwloc bindings
• Issue #970 - Bad flags for Fortran compiler
• Issue #941 - Create a proper user level context switching class for BG/Q
• Issue #935 - Build error with gcc 4.6 and Boost 1.54.0 on hpx trunk and 0.9.6
• Issue #934 - Want to build HPX without dynamic libraries
• Issue #927 - Make hpx/lcos/reduce.hpp accept futures of id_type
• Issue #926 - All unit tests that are run with more than one thread with CTest/hpx_run_test should configure hpx.os_threads
• Issue #925 - regression_dataflow_791 needs to be brought in line with HPX standards

https://github.com/STEllAR-GROUP/hpx/issues/926
https://github.com/STEllAR-GROUP/hpx/issues/925
• Issue #899 - Fix race conditions in regression tests
• Issue #879 - Hung test leads to cascading test failure; make tests should support the MPI parcelport
• Issue #865 - future<T> and friends shall work for movable only Ts
• Issue #847 - Dynamic libraries are not installed on OS X
• Issue #816 - First Program tutorial pull request
• Issue #799 - Wrap lexical_cast to avoid exceptions
• Issue #720 - Broken configuration when using cmake on Ubuntu
• Issue #622 - --hpx:hpx and --hpx:debug-hpx-log is nonsensical
• Issue #525 - Extend barrier LCO test to run in distributed
• Issue #515 - Multi-destination version of hpx::apply is broken
• Issue #509 - Push Boost.Atomic changes upstream
• Issue #503 - Running HPX applications on Windows should not require setting %PATH%
• Issue #461 - Add a compilation sanity test
• Issue #456 - hpx_run_tests.py should log output from tests that timeout
• Issue #454 - Investigate threadmanager performance
• Issue #345 - Add more versatile environmental/cmake variable support to hpx_find_* CMake macros
• Issue #209 - Support multiple configurations in generated build files
• Issue #190 - hpx::cout should be a std::ostream
• Issue #189 - iostreams component should use startup/shutdown functions
• Issue #183 - Use Boost.ICL for correctness in AGAS
• Issue #44 - Implement real futures

2.10.15 HPX V0.9.8 (Mar 24, 2014)

We have had over 800 commits since the last release and we have closed over 65 tickets (bugs, feature requests, etc.). With the changes below, HPX is once again leading the charge of a whole new era of computation. By intrinsically breaking down and synchronizing the work to be done, HPX insures that application developers will no longer have to fret about where a segment of code executes. That allows coders to focus their time and energy to understanding the data dependencies of their algorithms and thereby the core obstacles to an efficient code. Here are some of the advantages of using HPX:

- HPX is solidly rooted in a sophisticated theoretical execution model – ParalleX
- HPX exposes an API fully conforming to the C++11 and the draft C++14 standards, extended and applied to distributed computing. Everything programmers know about the concurrency primitives of the standard C++ library is still valid in the context of HPX.
- It provides a competitive, high performance implementation of modern, future-proof ideas which gives an smooth migration path from today’s mainstream techniques
- There is no need for the programmer to worry about lower level parallelization paradigms like threads or message passing; no need to understand pthreads, MPI, OpenMP, or Windows threads, etc.
- There is no need to think about different types of parallelism such as tasks, pipelines, or fork-join, task or data parallelism.
- The same source of your program compiles and runs on Linux, BlueGene/Q, Mac OS X, Windows, and Android.
- The same code runs on shared memory multi-core systems and supercomputers, on handheld devices and Intel® Xeon Phi™ accelerators, or a heterogeneous mix of those.

General changes

- A major API breaking change for this release was introduced by implementing `hpx::future` and `hpx::shared_future` fully in conformance with the C++11 Standard. While `hpx::shared_future` is new and will not create any compatibility problems, we revised the interface and implementation of the existing `hpx::future`. For more details please see the mailing list archive.

To avoid any incompatibilities for existing code we named the type which implements the `std::future` interface as `hpx::unique_future`. For the next release this will be renamed to `hpx::future`, making it full conforming to C++11 Standard.

- A large part of the code base of HPX has been refactored and partially re-implemented. The main changes were related to
  - The threading subsystem: these changes significantly reduce the amount of overheads caused by the schedulers, improve the modularity of the code base, and extend the variety of available scheduling algorithms.
  - The parcel subsystem: these changes improve the performance of the HPX networking layer, modularize the structure of the parcelports, and simplify the creation of new parcelports for other underlying networking libraries.
  - The API subsystem: these changes improved the conformance of the API to C++11 Standard, extend and unify the available API functionality, and decrease the overheads created by various elements of the API.
  - The robustness of the component loading subsystem has been improved significantly, allowing to more portably and more reliably register the components needed by an application as startup. This additionally speeds up general application initialization.

---

4007 http://www.open-std.org/jtc1/sc22/wg21
4008 http://mail.cct.lsu.edu/pipermail/hpx-users/2014-January/000141.html
4009 http://www.open-std.org/jtc1/sc22/wg21
• We added new API functionality like `hpx::migrate` and `hpx::copy_component` which are the basic building blocks necessary for implementing higher level abstractions for system-wide load balancing, runtime-adaptive resource management, and object-oriented checkpointing and state-management.

• We removed the use of C++11 move emulation (using Boost.Move), replacing it with C++11 rvalue references. This is the first step towards using more and more native C++11 facilities which we plan to introduce in the future.

• We improved the reference counting scheme used by HPX which helps managing distributed objects and memory. This improves the overall stability of HPX and further simplifies writing real world applications.

• The minimal Boost version required to use HPX is now V1.49.0.

• This release coincides with the first release of HPXPI (V0.1.0), the first implementation of the XPI specification.

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release.

• Issue #1086 - Expose internal boost::shared_array to allow user management of array lifetime
• Issue #1083 - Make shell examples copyable in docs
• Issue #1080 - /threads{locality#*/total}/count/cumulative broken
• Issue #1079 - Build problems on OS X
• Issue #1078 - Improve robustness of component loading
• Issue #1077 - Fix a missing enum definition for 'take' mode
• Issue #1076 - Merge Jb master
• Issue #1075 - Unknown CMake command “add_hpx_pseudo_target”
• Issue #1074 - Implement `apply_continue_callback` and `apply_colocated_callback`
• Issue #1073 - The new `apply_colocated` and `async_colocated` functions lead to automatic registered functions
• Issue #1071 - Remove `deferred_packaged_task`
• Issue #1069 - `serialize_buffer` with allocator fails at destruction
• Issue #1068 - Coroutines include and forward declarations missing
• Issue #1067 - Add allocator support to `util::serialize_buffer`

4023 https://github.com/STEllAR-GROUP/hpx/issues/1068
4024 https://github.com/STEllAR-GROUP/hpx/issues/1067
• Issue #1066 - Allow for MPI_Init being called before HPX launches
• Issue #1065 - AGAS cache isn’t used/populated on worker localities
• Issue #1064 - Reorder includes to ensure ws2 includes early
• Issue #1063 - Add hpx::runtime::suspend and hpx::runtime::resume
• Issue #1062 - Fix async_continue to properly handle return types
• Issue #1061 - Implement async_colocated and apply_colocated
• Issue #1060 - Implement minimal component migration
• Issue #1058 - Remove HPX_UTIL_TUPLE from code base
• Issue #1057 - Add performance counters for threading subsystem
• Issue #1055 - Thread allocation uses two memory pools
• Issue #1053 - Work stealing flawed
• Issue #1052 - Fix a number of warnings
• Issue #1049 - Fixes for TLS on OSX and more reliable test running
• Issue #1048 - Fixing after 588 hang
• Issue #1047 - Use port ‘0’ for networking when using one locality
• Issue #1046 - composable_guard test is broken when having more than one thread
• Issue #1045 - Security missing headers
• Issue #1044 - Native TLS on FreeBSD via __thread
• Issue #1043 - async et.al. compute the wrong result type
• Issue #1042 - async et.al. implicitly unwrap reference_wrappers
• Issue #1041 - Remove redundant costly Kleene stars from regex searches
• Issue #1040 - CMake script regex match patterns has unnecessary kleenes
• Issue #1039 - Remove use of Boost.Move and replace with std::move and real rvalue refs
• Issue #1038 - Bump minimal required Boost to 1.49.0
• Issue #1037 - Implicit unwrapping of futures in async broken
• Issue #1036 - Scheduler hangs when user code attempts to “block” OS-threads
• Issue #1035 - Idle-rate counter always reports 100% idle rate
• Issue #1034 - Symbolic name registration causes application hangs
• Issue #1033 - Application options read in from an options file generate an error message
• Issue #1032 - hpx::id_type local reference counting is wrong
• Issue #1031 - Negative entry in reference count table
• Issue #1030 - Implement condition_variable
• Issue #1029 - Deadlock in thread scheduling subsystem
• Issue #1028 - HPX-thread cumulative count performance counters report incorrect value
• Issue #1027 - Expose hpx::thread_interrupted error code as a separate exception type
• Issue #1026 - Exceptions thrown in asynchronous calls can be lost if the value of the future is never queried
• Issue #1025 - future::wait_for/wait_until do not remove callback
• Issue #1024 - Remove dependence to boost assert and create hpx assert
• Issue #1023 - Segfaults with tmalloc
• Issue #1022 - prerequisites link in readme is broken
• Issue #1020 - HPX Deadlock on external synchronization
• Issue #1019 - Convert using BOOST_ASSERT to HPX_ASSERT
• Issue #1018 - compiling bug with gcc 4.8.1
• Issue #1017 - Possible crash in io_pool executor
• Issue #1016 - Crash at startup
• Issue #1014 - Implement Increment/Decrement Merging

• Issue #1013 - Add more logging channels to enable greater control over logging granularity
• Issue #1012 - --hpx:debug-hpx-log and --hpx:debug-agas-log lead to non-thread safe writes
• Issue #1011 - After installation, running applications from the build/staging directory no longer works
• Issue #1010 - Mergeable decrement requests are not being merged
• Issue #1009 - --hpx:list-symbolic-names crashes
• Issue #1007 - Components are not properly destroyed
• Issue #1006 - Segfault/hang in set_data
• Issue #1005 - Performance counter naming issue
• Issue #982 - Race condition during startup
• Issue #912 - OS X: component type not found in map
• Issue #663 - Create a buildbot slave based on Clang 3.2/OSX
• Issue #636 - Expose this_locality::apply<act>(p1, p2); for local execution
• Issue #197 - Add --console=address option for PBS runs
• Issue #175 - Asynchronous AGAS API

2.10.16 HPX V0.9.7 (Nov 13, 2013)

We have had over 1000 commits since the last release and we have closed over 180 tickets (bugs, feature requests, etc.).

General changes

• Ported HPX to BlueGene/Q
• Improved HPX support for Xeon/Phi accelerators
• Reimplemented hpx::bind, hpx::tuple, and hpx::function for better performance and better compliance with the C++11 Standard. Added hpx::mem_fn.
• Reworked hpx::when_all and hpx::when_any for better compliance with the ongoing C++ standardization effort, added heterogeneous version for those functions. Added hpx::when_any_swapped.
• Added hpx::copy as a precursor for a migrate functionality
• Added hpx::get_ptr allowing to directly access the memory underlying a given component

4084 https://github.com/STEllAR-GROUP/hpx/issues/175
HPX Documentation, master

- Added the `hpx::lcos::broadcast`, `hpx::lcos::reduce`, and `hpx::lcos::fold` collective operations
- Added `hpx::get_locality_name` allowing to retrieve the name of any of the localities for the application.
- Added support for more flexible thread affinity control from the HPX command line, such as new modes for `--hpx:bind` (balanced, scattered, compact), improved default settings when running multiple localities on the same node.
- Added experimental executors for simpler thread pooling and scheduling. This API may change in the future as it will stay aligned with the ongoing C++ standardization efforts.
- Massively improved the performance of the HPX serialization code. Added partial support for zero copy serialization of array and bitwise-copyable types.
- General performance improvements of the code related to threads and futures.

**Bug fixes (closed tickets)**

Here is a list of the important tickets we closed for this release.

- **Issue #1005** 4085 - Allow one to disable array optimizations and zero copy optimizations for each parcelport
- **Issue #1004** 4086 - Generate new HPX logo image for the docs
- **Issue #1002** 4087 - If MPI parcelport is not available, running HPX under mpirun should fail
- **Issue #1001** 4088 - Zero copy serialization raises assert
- **Issue #1000** 4089 - Can’t connect to a HPX application running with the MPI parcelport from a non MPI parcelport locality
- **Issue #999** 4090 - Optimize `hpx::when_n`
- **Issue #998** 4091 - Fixed const-correctness
- **Issue #997** 4092 - Making `serialize_buffer::data()` type save
- **Issue #996** 4093 - Memory leak in `hpx::lcos::promise`
- **Issue #995** 4094 - Race while registering pre-shutdown functions
- **Issue #994** 4095 - thread_rescheduling regression test does not compile

• Issue #988 - multiple_init test is failing
• Issue #986 - Can’t call a function called “init” from “main” when using <hpx/hpx_main.hpp>
• Issue #984 - Reference counting tests are failing
• Issue #983 - thread_suspension_executor test fails
• Issue #980 - Terminating HPX threads don’t leave stack in virgin state
• Issue #979 - Static scheduler not in documents
• Issue #978 - Preprocessing limits are broken
• Issue #977 - Make tests.regressions.lcos.future_hang_on_get shorter
• Issue #976 - Wrong library order in pkgconfig
• Issue #975 - Please reopen #963
• Issue #974 - Option pu-offset ignored in fixing_588 branch
• Issue #972 - Cannot use MKL with HPX
• Issue #969 - Non-existent INI files requested on the command line via --hpx:config do not cause warnings or errors.
• Issue #968 - Cannot build examples in fixing_588 branch
• Issue #967 - Command line description of --hpx:queuing seems wrong
• Issue #966 - --hpx:print-bind physical core numbers are wrong
• Issue #965 - Deadlock when building in Release mode
• Issue #963 - Not all worker threads are working
• Issue #962 - Problem with SLURM integration
• Issue #961 - --hpx:print-bind outputs incorrect information
• Issue #960 - Fix cut and paste error in documentation of get_thread_priority
• Issue #959 - Change link to boost.atomic in documentation to point to boost.org
• Issue #958 - Undefined reference to intrusive_ptr_release
• Issue #957 - Make tuple standard compliant
• Issue #956 - Segfault with a3382fb
• Issue #955 - --hpx:node and --hpx:nodefiles do not work with foreign nodes
• Issue #954 - Make order of arguments for hpx::async and hpx::broadcast consistent
• Issue #953 - Cannot use MKL with HPX
• Issue #952 - register_[pre_]shutdown_function never throw
• Issue #951 - Assert when number of threads is greater than hardware concurrency
• Issue #948 - HPX_HAVE_GENERIC_CONTEXT_COROUTINES conflicts with HPX_HAVE_FIBER_BASED_COROUTINES
• Issue #947 - Need MPI_THREAD_MULTIPLE for backward compatibility
• Issue #946 - HPX does not call MPI_Finalize
• Issue #945 - Segfault with hpx::lcos::broadcast
• Issue #944 - OS X: assertion pu_offset_ < hardware_concurrency failed
• Issue #943 - #include <hpx/hpx_main.hpp> does not work
• Issue #942 - Make the BG/Q work with -O3
• Issue #940 - Use separator when concatenating locality name
• Issue #939 - Refactor MPI parcelport to use MPI_Wait instead of multiple MPI_Test calls
• Issue #938 - Want to officially access client_base::gid_
• Issue #937 - client_base::gid_ should be private``
• Issue #936 - Want doxygen-like source code index
• Issue #935 - Build error with gcc 4.6 and Boost 1.54.0 on hpx trunk and 0.9.6
• Issue #933 - Cannot build HPX with Boost 1.54.0
• Issue #932 - Components are destructed too early
• Issue #931 - Make HPX work on BG/Q

• Issue #930 - make git-docs is broken
• Issue #929 - Generating index in docs broken
• Issue #928 - Optimize hpx::util::static_ for C++11 compilers supporting magic statics
• Issue #924 - Make kill_process_tree (in process.py) more robust on Mac OSX
• Issue #923 - Correct BLAS and RNPL cmake tests
• Issue #922 - Cannot link against BLAS
• Issue #921 - Implement hpx::mem_fn
• Issue #920 - Output locality with --hpx:print-bind
• Issue #919 - Correct grammar; simplify boolean expressions
• Issue #918 - Link to hello_world.cpp is broken
• Issue #917 - adapt cmake file to new boostbook version
• Issue #916 - fix problem building documentation with xsltproc >= 1.1.27
• Issue #915 - Add another TBBMalloc library search path
• Issue #914 - Build problem with Intel compiler on Stampede (TACC)
• Issue #913 - fix error messages in fibonacci examples
• Issue #911 - Update OS X build instructions
• Issue #910 - Want like to specify MPL_ROOT instead of compiler wrapper script
• Issue #909 - Warning about void* arithmetic
• Issue #908 - Buildbot for MIC is broken
• Issue #906 - Can’t use --hpx:bind=balanced with multiple MPI processes
• Issue #905 - --hpx:bind documentation should describe full grammar
• Issue #904 - Add hpx::lcos::fold and hpx::lcos::inverse_fold collective operation
• Issue #903 - Add hpx::when_any_swapped()
• Issue #902 Add `hpx::lcos::reduce` collective operation
• Issue #901 Web documentation is not searchable
• Issue #900 Web documentation for trunk has no index
• Issue #898 Some tests fail with GCC 4.8.1 and MPI parcel port
• Issue #897 HWLOC causes failures on Mac
• Issue #896 pu_offset leads to startup error
• Issue #895 `hpx::get_locality_name` not defined
• Issue #894 Race condition at shutdown
• Issue #893 `--hpx:print-bind` switches std::cout to hexadecimal mode
• Issue #892 `hwloc_topology_load` can be expensive – don’t call multiple times
• Issue #891 The documentation for `get_locality_name` is wrong
• Issue #890 `--hpx:print-bind` should not exit
• Issue #889 `--hpx:debug-hpx-log=FILE` does not work
• Issue #888 MPI parcelport does not exit cleanly for `--hpx:print-bind`
• Issue #887 Choose thread affinities more cleverly
• Issue #886 Logging documentation is confusing
• Issue #885 Two threads are slower than one
• Issue #884 is_callable failing with member pointers in C++11
• Issue #883 Need help with is_callable_test
• Issue #882 `tests.regressions.lcos.future_hang_on_get` does not terminate
• Issue #881 `tests/regressions/block_matrix/matrix.hh` won’t compile with GCC 4.8.1
• Issue #880 HPX does not work on OS X
• Issue #878 `future::unwrap` triggers assertion

• Issue #846 - Update hpx_external_example
• Issue #845 - Issues with having both debug and release modules in the same directory
• Issue #844 - Create configuration header
• Issue #843 - Tests should use CTest
• Issue #842 - Remove buffer_pool from MPI parcelport
• Issue #841 - Add possibility to broadcast an index with hpx::lcos::broadcast
• Issue #838 - Simplify util::tuple
• Issue #837 - Adopt boost::tuple tests for util::tuple
• Issue #836 - Adopt boost::function tests for util::function
• Issue #835 - Tuple interface missing pieces
• Issue #833 - Partially preprocessing files not working
• Issue #832 - Native papi counters do not work with wild cards
• Issue #831 - Arithmetics counter fails if only one parameter is given
• Issue #830 - Convert hpx::util::function to use new scheme for serializing its base pointer
• Issue #829 - Consistently use decay<T> instead of remove_const<remove_reference<T>>
• Issue #828 - Update future implementation to N3721 and N3722
• Issue #827 - Enable MPI parcelport for bootstrapping whenever application was started using mpirun
• Issue #826 - Support command line option --hpx:print-bind even if --hpx::bind was not used
• Issue #825 - Memory counters give segfault when attempting to use thread wild cards or numbers only total works
• Issue #824 - Enable lambda functions to be used with hpx::async/hpx::apply
• Issue #823 - Using a hashing filter
• Issue #822 - Silence unused variable warning
• Issue #821 - Detect if a function object is callable with given arguments
• Issue #820 - Allow wildcards to be used for performance counter names
• Issue #819 - Make the AGAS symbolic name registry distributed
• Issue #818 - Add future::then() overload taking an executor
• Issue #817 - Fixed typo
• Issue #815 - Create an lco that is performing an efficient broadcast of actions
• Issue #814 - Papi counters cannot specify thread##* to get the counts for all threads
• Issue #813 - Scoped unlock
• Issue #811 - simple_central_tuplespace_client run error
• Issue #810 - ostream error when << any objects
• Issue #809 - Optimize parcel serialization
• Issue #808 - HPX applications throw exception when executed from the build directory
• Issue #807 - Create performance counters exposing overall AGAS statistics
• Issue #795 - Create timed make_ready_future
• Issue #794 - Create heterogeneous when_all/when_any/etc.
• Issue #721 - Make HPX usable for Xeon Phi
• Issue #694 - CMakue should complain if you attempt to build an example without its dependencies
• Issue #692 - SLURM support broken
• Issue #683 - python/hpx/process.py imports epoll on all platforms
• Issue #619 - Automate the doc building process
• Issue #600 - GTC performance broken
• Issue #577 - Allow for zero copy serialization/networking
• Issue #551 - Change executable names to have debug postfix in Debug builds
• Issue #544 - Write a custom .lib file on Windows pulling in hpx_init and hpx.dll, phase out hpx_init

HPX Documentation, master

- Issue #534\(^{4260}\) - hpx::init should take functions by std::function and should accept all forms of hpx_main
- Issue #508\(^{4261}\) - FindPackage fails to set FOO_LIBRARY_DIR
- Issue #506\(^{4262}\) - Add cmake support to generate ini files for external applications
- Issue #470\(^{4263}\) - Changing build-type after configure does not update boost library names
- Issue #453\(^{4264}\) - Document hpx_run_tests.py
- Issue #445\(^{4265}\) - Significant performance mismatch between MPI and HPX in SMP for allgather example
- Issue #443\(^{4266}\) - Make docs viewable from build directory
- Issue #421\(^{4267}\) - Support multiple HPX instances per node in a batch environment like PBS or SLURM
- Issue #316\(^{4268}\) - Add message size limitation
- Issue #249\(^{4269}\) - Clean up locking code in big boot barrier
- Issue #136\(^{4270}\) - Persistent CMake variables need to be marked as cache variables

2.10.17 HPX V0.9.6 (Jul 30, 2013)

We have had over 1200 commits since the last release and we have closed roughly 140 tickets (bugs, feature requests, etc.).

General changes

The major new features in this release are:

- We further consolidated the API exposed by HPX. We aligned our APIs as much as possible with the existing C++11 Standard\(^{4271}\) and related proposals to the C++ standardization committee (such as N3632\(^{4272}\) and N3857\(^{4273}\)).
- We implemented a first version of a distributed AGAS service which essentially eliminates all explicit AGAS network traffic.
- We created a native ibverbs parcelport allowing to take advantage of the superior latency and bandwidth characteristics of Infiniband networks.
- We successfully ported HPX to the Xeon Phi platform.
- Support for the SLURM scheduling system was implemented.
- Major efforts have been dedicated to improving the performance counter framework, numerous new counters were implemented and new APIs were added.

\(^{4273}\) http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2014/n3857.pdf
• We added a modular parcel compression system allowing to improve bandwidth utilization (by reducing the overall size of the transferred data).

• We added a modular parcel coalescing system allowing to combine several parcels into larger messages. This reduces latencies introduced by the communication layer.

• Added an experimental executors API allowing to use different scheduling policies for different parts of the code. This API has been modelled after the Standards proposal N3562\textsuperscript{4274}. This API is bound to change in the future, though.

• Added minimal security support for localities which is enforced on the parcelport level. This support is preliminary and experimental and might change in the future.

• We created a parcelport using low level MPI functions. This is in support of legacy applications which are to be gradually ported and to support platforms where MPI is the only available portable networking layer.

• We added a preliminary and experimental implementation of a tuple-space object which exposes an interface similar to such systems described in the literature (see for instance The Linda Coordination Language\textsuperscript{4275}).

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release. This is again a very long list of newly implemented features and fixed issues.

• Issue #806\textsuperscript{4276} - make (all) in examples folder does nothing
• Issue #805\textsuperscript{4277} - Adding the introduction and fixing DOCBOOK dependencies for Windows use
• Issue #804\textsuperscript{4278} - Add stackless (non-suspendable) thread type
• Issue #803\textsuperscript{4279} - Create proper serialization support functions for util::tuple
• Issue #800\textsuperscript{4280} - Add possibility to disable array optimizations during serialization
• Issue #798\textsuperscript{4281} - HPX\_LIMIT does not work for local dataflow
• Issue #797\textsuperscript{4282} - Create a parcelport which uses MPI
• Issue #796\textsuperscript{4283} - Problem with Large Numbers of Threads
• Issue #793\textsuperscript{4284} - Changing dataflow test case to hang consistently
• Issue #792\textsuperscript{4285} - CMake Error
• Issue #791\textsuperscript{4286} - Problems with local::dataflow
• Issue #790\textsuperscript{4287} - wait\_for() doesn’t compile
• Issue #789\textsuperscript{4288} - HPX with Intel compiler segfaults

\textsuperscript{4288}https://github.com/STEllAR-GROUP/hpx/issues/789
• Issue #788 - Intel compiler support
• Issue #787 - Fixed SFINAEd specializations
• Issue #786 - Memory issues during benchmarking.
• Issue #785 - Create an API allowing to register external threads with HPX
• Issue #784 - util::plugin is throwing an error when a symbol is not found
• Issue #783 - How does hpx::bind work?
• Issue #782 - Added quotes around STRING REPLACE potentially empty arguments
• Issue #781 - Make sure no exceptions propagate into the thread manager
• Issue #780 - Allow arithmetics performance counters to expand its parameters
• Issue #779 - Test case for 778
• Issue #778 - Swapping futures segfaults
• Issue #777 - hpx::lcos::details::when_xxx don’t restore completion handlers
• Issue #776 - Compiler chokes on dataflow overload with launch policy
• Issue #775 - Runtime error with local dataflow (copying futures?)
• Issue #774 - Using local dataflow without explicit namespace
• Issue #773 - Local dataflow with unwrap: functor operators need to be const
• Issue #772 - Allow (remote) actions to return a future
• Issue #771 - Setting HPX_LIMIT gives huge boost MPL errors
• Issue #770 - Add launch policy to (local) dataflow
• Issue #769 - Make compile time configuration information available
• Issue #768 - Const correctness problem in local dataflow
• Issue #767 - Add launch policies to async
• Issue #766 - Mark data structures for optimized (array based) serialization

• Issue #765 - Align `hpx::any` with N3508: Any Library Proposal (Revision 2)
• Issue #764 - Align `hpx::future` with newest N3558: A Standardized Representation of Asynchronous Operations
• Issue #762 - added a human readable output for the ping pong example
• Issue #761 - Ambiguous typename when constructing derived component
• Issue #760 - Simple components can not be derived
• Issue #759 - make install doesn’t give a complete install
• Issue #758 - Stack overflow when using `locking_hook<>`
• Issue #757 - copy paste error; unsupported function overloading
• Issue #756 - GTCX runtime issue in Gordon
• Issue #755 - Papi counters don’t work with reset and evaluate API’s
• Issue #753 - cmake bugfix and improved component action docs
• Issue #752 - hpx simple component docs
• Issue #750 - Add `hpx::util::any`
• Issue #749 - Thread phase counter is not reset
• Issue #748 - Memory performance counter are not registered
• Issue #747 - Create performance counters exposing arithmetic operations
• Issue #745 - `apply_callback` needs to invoke callback when applied locally
• Issue #744 - CMake fixes
• Issue #743 - Problem Building github version of HPX
• Issue #742 - Remove `HPX_STD_BIND`
• Issue #741 - assertion `px != 0` failed: HPX(assertion_failure) for low numbers of OS threads
• Issue #739 - Performance counters do not count to the end of the program or evaluation
• Issue #738 - Dedicated AGAS server runs don’t work; console ignores -a option.

2.10. Releases
• Issue #682 - Add performance counters exposing number of stolen threads
• Issue #681 - Add apply_continue for asynchronous chaining of actions
• Issue #679 - Remove obsolete async_callback API functions
• Issue #678 - Add new API for setting/triggering LCOs
• Issue #677 - Add async_continue for true continuation style actions
• Issue #676 - Buildbot for gcc 4.4 broken
• Issue #675 - Partial preprocessing broken
• Issue #674 - HPX segfaults when built with gcc 4.7
• Issue #673 - use_guard_pages has inconsistent preprocessor guards
• Issue #672 - External build breaks if library path has spaces
• Issue #671 - release tarballs are tarbombs
• Issue #670 - CMake won’t find Boost headers in layout=versioned install
• Issue #669 - Links in docs to source files broken if not installed
• Issue #667 - Not reading ini file properly
• Issue #664 - Adapt new meanings of ‘const’ and ‘mutable’
• Issue #661 - Implement BTL Parcel port
• Issue #655 - Make HPX work with the “decltype” result_of
• Issue #647 - documentation for specifying the number of high priority threads
  --hpx:high-priority-threads
• Issue #643 - Error parsing host file
• Issue #642 - HWLoc issue with TAU
• Issue #639 - Logging potentially suspends a running thread
• Issue #634 - Improve error reporting from parcel layer
• Issue #627 - Add tests for async and apply overloads that accept regular C++ functions

General changes

This release is continuing along the lines of code and API consolidation, and overall usability improvements. We dedicated much attention to performance and we were able to significantly improve the threading and networking subsystems.

We successfully ported HPX to the Android platform. HPX applications now not only can run on mobile devices, but we support heterogeneous applications running across architecture boundaries. At the Supercomputing Conference 2012 we demonstrated connecting Android tablets to simulations running on a Linux cluster. The Android tablet was used to query performance counters from the Linux simulation and to steer its parameters.

We successfully ported HPX to Mac OSX (using the Clang compiler). Thanks to Pyry Jahkola for contributing the corresponding patches. Please see the section How to install HPX on OS X (Mac) for more details.

We made a special effort to make HPX usable in highly concurrent use cases. Many of the HPX API functions which possibly take longer than 100 microseconds to execute now can be invoked asynchronously. We added uniform
support for composing futures which simplifies to write asynchronous code. HPX actions (function objects encapsu-
ating possibly concurrent remote function invocations) are now well integrated with all other API facilities such like

hpx::bind.

All of the API has been aligned as much as possible with established paradigms. HPX now mirrors many of the
facilities as defined in the C++11 Standard, such as hpx::thread, hpx::function, hpx::future, etc.

A lot of work has been put into improving the documentation. Many of the API functions are documented now,
concepts are explained in detail, and examples are better described than before. The new documentation index enables
finding information with lesser effort.

This is the first release of HPX we perform after the move to Github. This step has enabled a wider participation
from the community and further encourages us in our decision to release HPX as a true open source library (HPX is
licensed under the very liberal Boost Software License).

**Bug fixes (closed tickets)**

Here is a list of the important tickets we closed for this release. This is by far the longest list of newly implemented
features and fixed issues for any of HPX releases so far.

- **Issue #666** - Segfault on calling hpx::finalize twice
- **Issue #665** - Adding declaration num_of_cores
- **Issue #662** - pkgconfig is building wrong
- **Issue #660** - Need uninterrupt function
- **Issue #659** - Move our logging library into a different namespace
- **Issue #658** - Dynamic performance counter types are broken
- **Issue #657** - HPX v0.9.5 (RC1) hello_world example segfaulting
- **Issue #656** - Define the affinity of parcel-pool, io-pool, and timer-pool threads
- **Issue #654** - Integrate the Boost auto_index tool with documentation
- **Issue #653** - Make HPX build on OS X + Clang + libc++
- **Issue #651** - Add fine-grained control for thread pinning
- **Issue #650** - Command line no error message when using -hpx:(anything)
- **Issue #645** - Command line aliases don’t work in [teletype] @file `c++`
- **Issue #644** - Terminated threads are not always properly cleaned up
• Issue #640 4432 - future_data<T>::set_on_completed_used without locks
• Issue #638 4433 - hpx build with intel compilers fails on linux
• Issue #637 4434 - --copy-dt-needed-entries breaks with gold
• Issue #635 4435 - Boost V1.53 will add Boost.Lockfree and Boost.Atomic
• Issue #633 4436 - Re-add examples to final 0.9.5 release
• Issue #632 4437 - Example thread_aware_timer is broken
• Issue #631 4438 - FFT application throws error in parcellayer
• Issue #630 4439 - Event synchronization example is broken
• Issue #629 4440 - Waiting on futures hangs
• Issue #628 4441 - Add an HPX_ALWAYS_ASSERT macro
• Issue #625 4442 - Port coroutines context switch benchmark
• Issue #621 4443 - New INI section for stack sizes
• Issue #618 4444 - pkg_config support does not work with a HPX debug build
• Issue #617 4445 - hpx/external/logging/boost/logging/detail/cache_before_init.hpp:139:67: error: ‘get_thread_id’ was not declared in this scope
• Issue #616 4446 - Change wait_xxx not to use locking
• Issue #615 4447 - Revert visibility ‘fix’ (fb0b6b8245dad1127b0c25ebaf9386b3945cca9)
• Issue #614 4448 - Fix Dataflow linker error
• Issue #613 4449 - find_here should throw an exception on failure
• Issue #612 4450 - Thread phase doesn’t show up in debug mode
• Issue #611 4451 - Make stack guard pages configurable at runtime (initialization time)
• Issue #610 4452 - Co-Locate Components
• Issue #609 4453 - future_overhead
• Issue #608 4454 - --hpx:list-counter-infos problem

4453 https://github.com/STEllAR-GROUP/hpx/issues/609
4454 https://github.com/STEllAR-GROUP/hpx/issues/608
• Issue #607 - Update Boost.Context based backend for coroutines
• Issue #606 - 1d_wave_equation is not working
• Issue #605 - Any C++ function that has serializable arguments and a serializable return type should be remotable
• Issue #604 - Connecting localities isn’t working anymore
• Issue #603 - Do not verify any ini entries read from a file
• Issue #602 - Rename argument_size to type_size/ added implementation to get parcel size
• Issue #599 - Enable locality specific command line options
• Issue #598 - Need an API that accesses the performance counter reporting the system uptime
• Issue #597 - compiling on ranger
• Issue #595 - I need a place to store data in a thread self pointer
• Issue #594 - 32/64 interoperability
• Issue #593 - Warn if logging is disabled at compile time but requested at runtime
• Issue #592 - Add optional argument value to --hpx:list-counters and --hpx:list-counter-infos
• Issue #591 - Allow for wildcards in performance counter names specified with --hpx:print-counter
• Issue #590 - Local promise semantic differences
• Issue #589 - Create API to query performance counter names
• Issue #587 - Add get_num_localities and get_num_threads to AGAS API
• Issue #586 - Adjust local AGAS cache size based on number of localities
• Issue #585 - Error while using counters in HPX
• Issue #584 - counting argument size of actions, initial pass.
• Issue #581 - Remove RemoteResult template parameter for future<>
• Issue #580 - Add possibility to hook into actions
- Issue #578 - Use angle brackets in HPX error dumps
- Issue #576 - Exception incorrectly thrown when --help is used
- Issue #575 - HPX(bad_component_type) with gcc 4.7.2 and boost 1.51
- Issue #574 - --hpx:connect command line parameter not working correctly
- Issue #571 - hpx::wait() (callback version) should pass the future to the callback function
- Issue #570 - hpx::wait should operate on boost::arrays and std::lists
- Issue #569 - Add a logging sink for Android
- Issue #568 - 2-argument version of HPX_DEFINE_COMPONENT_ACTION
- Issue #567 - Connecting to a running HPX application works only once
- Issue #565 - HPX doesn’t shutdown properly
- Issue #564 - Partial preprocessing of new component creation interface
- Issue #563 - Add hpx::start/hpx::stop to avoid blocking main thread
- Issue #562 - All command line arguments swallowed by hpx
- Issue #561 - Boost.Tuple is not move aware
- Issue #558 - boost::shared_ptr<> style semantics/syntax for client classes
- Issue #556 - Creation of partially preprocessed headers should be enabled for Boost newer than V1.50
- Issue #555 - BOOST_FORCEINLINE does not name a type
- Issue #554 - Possible race condition in thread get_id()
- Issue #552 - Move enable client_base
- Issue #550 - Add stack size category ‘huge’
- Issue #549 - ShenEOS run seg-faults on single or distributed runs
- Issue #545 - AUTOGLOB broken for add_hpx_component
- Issue #542 - FindHPX_HDF5 still searches multiple times
• Issue #541 - Quotes around application name in hpx::init
• Issue #539 - Race condition occurring with new lightweight threads
• Issue #535 - hpx_run_tests.py exits with no error code when tests are missing
• Issue #530 - Thread description in logs
• Issue #523 - Make thread objects more lightweight
• Issue #521 - hpx::error_code is not usable for lightweight error handling
• Issue #520 - Add full user environment to HPX logs
• Issue #519 - Build succeeds, running fails
• Issue #517 - Add a guard page to linux coroutine stacks
• Issue #516 - hpx::thread::detach suspends while holding locks, leads to hang in debug
• Issue #514 - Preprocessed headers for <hpx/apply.hpp> don’t compile
• Issue #513 - Buildbot configuration problem
• Issue #512 - Implement action based stack size customization
• Issue #511 - Move action priority into a separate type trait
• Issue #510 - trunk broken
• Issue #507 - no matching function for call to boost::scoped_ptr<hpx::threads::topology>::scoped_ptr(hpx::threads::linux_topology*)
• Issue #505 - undefined_symbol regression test currently failing
• Issue #502 - Adding OpenCL and OCLM support to HPX for Windows and Linux
• Issue #501 - find_package(HPX) sets cmake output variables
• Issue #500 - wait_any/wait_all are badly named
• Issue #499 - Add support for disabling pbs support in pbs runs
• Issue #498 - Error during no-cache runs
• Issue #496 - Add partial preprocessing support to cmake

• Issue #495 - Support HPX modules exporting startup/shutdown functions only
• Issue #494 - Allow modules to specify when to run startup/shutdown functions
• Issue #493 - Avoid constructing a string in make_success_code
• Issue #492 - Performance counter creation is no longer synchronized at startup
• Issue #491 - Performance counter creation is no longer synchronized at startup
• Issue #490 - Sheneos on_completed_bulk seg fault in distributed
• Issue #489 - compiling issue with g++44
• Issue #488 - Adding OpenCL and OCLM support to HPX for the MSVC platform
• Issue #487 - FindHPX.cmake problems
• Issue #485 - Change distributing_factory and binpacking_factory to use bulk creation
• Issue #484 - Change HPX_DONT_USE_PREPROCESSED_FILES to HPX_USE_PREPROCESSED_FILES
• Issue #483 - Memory counter for Windows
• Issue #479 - strange errors appear when requesting performance counters on multiple nodes
• Issue #477 - Create (global) timer for multi-threaded measurements
• Issue #472 - Add partial preprocessing using Wave
• Issue #471 - Segfault stack traces don’t show up in release
• Issue #468 - External projects need to link with internal components
• Issue #462 - Startup/shutdown functions are called more than once
• Issue #458 - Consolidate hpx::util::high_resolution_timer and hpx::util::high_resolution_clock
• Issue #455 - index out of bounds in allgather_and_gate on 4 cores or more
• Issue #448 - Make HPX compile with clang
• Issue #447 - ‘make tests’ should execute tests on local installation
• Issue #446 - Remove SVN-related code from the codebase

• Issue #171 - Add an INI option to turn off deadlock detection independently of logging
• Issue #170 - OSHL internal counters are incorrect
• Issue #103 - Better diagnostics for multiple component/action registrations under the same name
• Issue #48 - Support for Darwin (Xcode + Clang)
• Issue #21 - Build fails with GCC 4.6

2.10.19 HPX V0.9.0 (Jul 5, 2012)

We have had roughly 800 commits since the last release and we have closed approximately 80 tickets (bugs, feature requests, etc.).

General changes

• Significant improvements made to the usability of HPX in large-scale, distributed environments.
• Renamed hpx::lcos::packaged_task to hpx::lcos::packaged_action to reflect the semantic differences to a packaged_task as defined by the C++11 Standard.
• HPX now exposes hpx::thread which is compliant to the C++11 std::thread type except that it (purely locally) represents an HPX thread. This new type does not expose any of the remote capabilities of the underlying HPX-thread implementation.
• The type hpx::lcos::future is now compliant to the C++11 std::future<> type. This type can be used to synchronize both, local and remote operations. In both cases the control flow will ‘return’ to the future in order to trigger any continuation.
• The types hpx::lcos::local::promise and hpx::lcos::local::packaged_task are now compliant to the C++11 std::promise<> and std::packaged_task<> types. These can be used to create a future representing local work only. Use the types hpx::lcos::promise and hpx::lcos::packaged_action to wrap any (possibly remote) action into a future.
• hpx::thread and hpx::lcos::future are now cancelable.
• Added support for sequential and logic composition of hpx::lcos::futures. The member function hpx::lcos::future::when permits futures to be sequentially composed. The helper functions hpx::wait_all, hpx::wait_any, and hpx::wait_n can be used to wait for more than one future at a time.
• HPX now exposes hpx::apply and hpx::async as the preferred way of creating (or invoking) any deferred work. These functions are usable with various types of functions, function objects, and actions and provide a uniform way to spawn deferred tasks.
• HPX now utilizes hpx::util::bind to (partially) bind local functions and function objects, and also actions. Remote bound actions can have placeholders as well.
• HPX continuations are now fully polymorphic. The class hpx::actions::forwarding_continuation is an example of how the user can write is own types of continuations. It can be used to execute any function as an continuation of a particular action.

https://github.com/STEllAR-GROUP/hpx/issues/171
https://github.com/STEllAR-GROUP/hpx/issues/170
https://github.com/STEllAR-GROUP/hpx/issues/103
https://github.com/STEllAR-GROUP/hpx/issues/48
https://github.com/STEllAR-GROUP/hpx/issues/21
http://www.open-std.org/jtc1/sc22/wg21
• Reworked the action invocation API to be fully conformant to normal functions. Actions can now be invoked using `hpx::apply`, `hpx::async`, or using the `operator()` implemented on actions. Actions themselves can now be cheaply instantiated as they do not have any members anymore.

• Reworked the lazy action invocation API. Actions can now be directly bound using `hpx::util::bind` by passing an action instance as the first argument.

• A minimal HPX program now looks like this:

```cpp
#include <hpx/hpx_init.hpp>

int hpx_main()
{
    return hpx::finalize();
}

int main()
{
    return hpx::init();
}
```

This removes the immediate dependency on the Boost.Program Options\(^{4575}\) library.

**Note:** This minimal version of an HPX program does not support any of the default command line arguments (such as --help, or command line options related to PBS). It is suggested to always pass `argc` and `argv` to HPX as shown in the example below.

• In order to support those, but still not to depend on Boost.Program Options\(^{4576}\), the minimal program can be written as:

```cpp
#include <hpx/hpx_init.hpp>

// The arguments for hpx_main can be left off, which very similar to the
// behavior of `main()` as defined by C++.
int hpx_main(int argc, char* argv[])
{
    return hpx::finalize();
}

int main(int argc, char* argv[])
{
    return hpx::init(argc, argv);
}
```

• Added performance counters exposing the number of component instances which are alive on a given locality.

• Added performance counters exposing then number of messages sent and received, the number of parcels sent and received, the number of bytes sent and received, the overall time required to send and receive data, and the overall time required to serialize and deserialize the data.

• Added a new component: `hpx::components::binpacking_factory` which is equivalent to the existing `hpx::components::distributing_factory` component, except that it equalizes the overall population of the components to create. It exposes two factory methods, one based on the number of existing instances of the component type to create, and one based on an arbitrary performance counter which will be queried for all relevant localities.

\(^{4575}\)https://www.boost.org/doc/html/program_options.html

\(^{4576}\)https://www.boost.org/doc/html/program_options.html
• Added API functions allowing to access elements of the diagnostic information embedded in the given exception: `hpx::get_locality_id`, `hpx::get_host_name`, `hpx::get_process_id`, `hpx::get_function_name`, `hpx::get_file_name`, `hpx::get_line_number`, `hpx::get_os_thread`, `hpx::get_thread_id`, and `hpx::get_thread_description`.

### Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release:

- **Issue #71**[^71] - GIDs that are not serialized via `handle_gid<>` should raise an exception
- **Issue #105**[^105] - Allow for `hpx::util::functions` to be registered in the AGAS symbolic namespace
- **Issue #107**[^107] - Nasty threadmanger race condition (reproducible in sheneos_test)
- **Issue #108**[^108] - Add millisecond resolution to HPX logs on Linux
- **Issue #110**[^110] - Shutdown hang in distributed with release build
- **Issue #116**[^116] - Don’t use TSS for the applier and runtime pointers
- **Issue #162**[^162] - Move local synchronous execution shortcut from `hpx::function` to the applier
- **Issue #172**[^172] - Cache sources in CMake and check if they change manually
- **Issue #178**[^178] - Add an INI option to turn off ranged-based AGAS caching
- **Issue #187**[^187] - Support for disabling performance counter deployment
- **Issue #202**[^202] - Support for sending performance counter data to a specific file
- **Issue #218**[^218] - Boost.coroutines allows different stack sizes, but stack pool is unaware of this
- **Issue #231**[^231] - Implement movable `boost::bind`
- **Issue #232**[^232] - Implement movable `boost::function`
- **Issue #236**[^236] - Allow binding `hpx::util::function` to actions
- **Issue #239**[^239] - Replace `hpx::function` with `hpx::util::function`
- **Issue #240**[^240] - Can’t specify `RemoteResult` with lcos::async
- **Issue #242**[^242] - REGISTER_TEMPLATE support for plain actions
- **Issue #243**[^243] - `handle_gid<>` support for `hpx::util::function`[^71] 4577 https://github.com/STEllAR-GROUP/hpx/issues/71

• Issue #245\(^{4596}\) - *c_cache code throws an exception if the queried GID is not in the local cache
• Issue #246\(^{4597}\) - Undefined references in dataflow/adaptive1d example
• Issue #252\(^{4598}\) - Problems configuring sheneos with CMake
• Issue #254\(^{4599}\) - Lifetime of components doesn’t end when client goes out of scope
• Issue #259\(^{4600}\) - CMak does not detect that MSVC10 has lambdas
• Issue #260\(^{4601}\) - io_service_pool segfault
• Issue #261\(^{4602}\) - Late parcel executed outside of pxthread
• Issue #263\(^{4603}\) - Cannot select allocator with CMake
• Issue #264\(^{4604}\) - Fix allocator select
• Issue #267\(^{4605}\) - Runtime error for hello_world
• Issue #269\(^{4606}\) - pthread_affinity_np test fails to compile
• Issue #270\(^{4607}\) - Compiler noise due to -Wcast-qual
• Issue #275\(^{4608}\) - Problem with configuration tests/include paths on Gentoo
• Issue #325\(^{4609}\) - Sheneos is 200-400 times slower than the fortran equivalent
• Issue #331\(^{4610}\) - *hpx::init and hpx_main() should not depend on program_options
• Issue #333\(^{4611}\) - Add doxygen support to CMake for doc toolchain
• Issue #340\(^{4612}\) - Performance counters for parcels
• Issue #346\(^{4613}\) - Component loading error when running hello_world in distributed on MSVC2010
• Issue #362\(^{4614}\) - Missing initializer error
• Issue #363\(^{4615}\) - Parcel port serialization error
• Issue #366\(^{4616}\) - Parcel buffering leads to types incompatible exception
• Issue #368\(^{4617}\) - Scalable alternative to rand() needed for HPX
• Issue #369\(^{4618}\) - IB over IP is substantially slower than just using standard TCP/IP

2.10.20  HPX V0.8.1 (Apr 21, 2012)

This is a point release including important bug fixes for HPX V0.8.0 (Mar 23, 2012).

General changes

- HPX does not need to be installed anymore to be functional.

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this point release:

- **Issue #295** - Don’t require install path to be known at compile time.
- **Issue #371** - Add hpx iostreams to standard build.
- **Issue #384** - Fix compilation with GCC 4.7.
- **Issue #390** - Remove keep_factory_alive startup call from ShenEOS; add shutdown call to H5close.
- **Issue #393** - Thread affinity control is broken.

Bug fixes (commits)

Here is a list of the important commits included in this point release:

- **r7642** - External: Fix backtrace memory violation.
- **r7775** - Components: Fix symbol visibility bug with component startup providers. This prevents one components providers from overriding another components.
- **r7778** - Components: Fix startup/shutdown provider shadowing issues.

2.10.21  HPX V0.8.0 (Mar 23, 2012)

We have had roughly 1000 commits since the last release and we have closed approximately 70 tickets (bugs, feature requests, etc.).

General changes

- Improved PBS support, allowing for arbitrary naming schemes of node-hostnames.
- Finished verification of the reference counting framework.
- Implemented decrement merging logic to optimize the distributed reference counting system.
- Restructured the LCO framework. Renamed hpx::lcos::eager_future<> and hpx::lcos::lazy_future<> into hpx::lcos::packaged_task and hpx::lcos::deferred_packaged_task. Split hpx::lcos::promise into hpx::lcos::packaged_task and hpx::lcos::future. Added ‘local’ futures (in namespace hpx::lcos::local).

[4639] https://github.com/STEllAR-GROUP/hpx/issues/295
[4640] https://github.com/STEllAR-GROUP/hpx/issues/371
[4641] https://github.com/STEllAR-GROUP/hpx/issues/384
[4642] https://github.com/STEllAR-GROUP/hpx/issues/390
[4643] https://github.com/STEllAR-GROUP/hpx/issues/393

Chapter 2. What’s so special about HPX?
• Improved the general performance of local and remote action invocations. This (under certain circumstances) drastically reduces the number of copies created for each of the parameters and return values.

• Reworked the performance counter framework. Performance counters are now created only when needed, which reduces the overall resource requirements. The new framework allows for much more flexible creation and management of performance counters. The new sine example application demonstrates some of the capabilities of the new infrastructure.

• Added a buildbot-based continuous build system which gives instant, automated feedback on each commit to SVN.

• Added more automated tests to verify proper functioning of HPX.

• Started to create documentation for HPX and its API.

• Added documentation toolchain to the build system.

• Added dataflow LCO.

• Changed default HPX command line options to have hpx: prefix. For instance, the former option --threads is now --hpx:threads. This has been done to make ambiguities with possible application specific command line options as unlikely as possible. See the section HPX Command Line Options for a full list of available options.

• Added the possibility to define command line aliases. The former short (one-letter) command line options have been predefined as aliases for backwards compatibility. See the section HPX Command Line Options for a detailed description of command line option aliasing.

• Network connections are now cached based on the connected host. The number of simultaneous connections to a particular host is now limited. Parcels are buffered and bundled if all connections are in use.

• Added more refined thread affinity control. This is based on the external library Portable Hardware Locality (HWLOC).

• Improved support for Windows builds with CMake.

• Added support for components to register their own command line options.

• Added the possibility to register custom startup/shutdown functions for any component. These functions are guaranteed to be executed by an HPX thread.

• Added two new experimental thread schedulers: hierarchy_scheduler and periodic_priority_scheduler. These can be activated by using the command line options --hpx:queuing=hierarchy or --hpx:queuing=periodic.

Example applications

• Graph500 performance benchmark\(^{4644}\) (thanks to Matthew Anderson for contributing this application).

• GTC (Gyrokinetic Toroidal Code)\(^{4645}\): a skeleton for particle in cell type codes.

• Random Memory Access: an example demonstrating random memory accesses in a large array

• ShenEOS example\(^{4646}\), demonstrating partitioning of large read-only data structures and exposing an interpolation API.

• Sine performance counter demo.

• Accumulator examples demonstrating how to write and use HPX components.

\(^{4644}\) http://www.graph500.org/
\(^{4645}\) http://www.nersc.gov/research-and-development/benchmarking-and-workload-characterization/nersc-6-benchmarks/gtc/
\(^{4646}\) http://stellarcollapse.org/equationofstate
• Quickstart examples (like hello_world, fibonacci, quicksort, factorial, etc.) demonstrating simple HPX concepts which introduce some of the concepts in HPX.
• Load balancing and work stealing demos.

API changes

• Moved all local LCOs into a separate namespace hpx::lcos::local (for instance, hpx::lcos::local_mutex is now hpx::lcos::local::mutex).
• Replaced hpx::actions::function with hpx::util::function. Cleaned up related code.
• Removed hpx::traits::handle_gid and moved handling of global reference counts into the corresponding serialization code.
• Changed terminology: prefix is now called locality_id, renamed the corresponding API functions (such as hpx::get_prefix, which is now called hpx::get_locality_id).
• Adding hpx::find_remote_localities, and hpx::get_num_localities.
• Changed performance counter naming scheme to make it more bash friendly. The new performance counter naming scheme is now /object{parentname#parentindex/instance#index}/counter#parameters
• Added hpx::get_worker_thread_num replacing hpx::threadmanager_base::get_thread_num.
• Renamed hpx::get_num_os_threads to hpx::get_os_threads_count.
• Added hpx::threads::get_thread_count.
• Restructured the Futures sub-system, renaming types in accordance with the terminology used by the C++11 ISO standard.

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release:

• Issue #31^{4647} - Specialize handle_gid<> for examples and tests
• Issue #72^{4648} - Fix AGAS reference counting
• Issue #104^{4649} - heartbeat throws an exception when decrefing the performance counter it’s watching
• Issue #111^{4650} - throttle causes an exception on the target application
• Issue #142^{4651} - One failed component loading causes an unrelated component to fail
• Issue #165^{4652} - Remote exception propagation bug in AGAS reference counting test
• Issue #186^{4653} - Test credit exhaustion/splitting (e.g. prepare_gid and symbol NS)
• Issue #188^{4654} - Implement remaining AGAS reference counting test cases

---

^{4653} https://github.com/STEllAR-GROUP/hpx/issues/186
^{4654} https://github.com/STEllAR-GROUP/hpx/issues/188
• Issue #258\textsuperscript{4655} - No type checking of GIDs in stubs classes
• Issue #271\textsuperscript{4656} - Seg fault/shared pointer assertion in distributed code
• Issue #281\textsuperscript{4657} - CMake options need descriptive text
• Issue #283\textsuperscript{4658} - AGAS caching broken (gva_cache needs to be rewritten with ICL)
• Issue #285\textsuperscript{4659} - HPX\_INSTALL root directory not the same as CMAKE\_INSTALL\_PREFIX
• Issue #286\textsuperscript{4660} - New segfault in dataflow applications
• Issue #289\textsuperscript{4661} - Exceptions should only be logged if not handled
• Issue #290\textsuperscript{4662} - c++11 tests failure
• Issue #293\textsuperscript{4663} - Build target for component libraries
• Issue #296\textsuperscript{4664} - Compilation error with Boost V1.49rc1
• Issue #298\textsuperscript{4665} - Illegal instructions on termination
• Issue #299\textsuperscript{4666} - gravity aborts with multiple threads
• Issue #301\textsuperscript{4667} - Build error with Boost trunk
• Issue #303\textsuperscript{4668} - Logging assertion failure in distributed runs
• Issue #304\textsuperscript{4669} - Exception ‘what’ strings are lost when exceptions from decode_parcel are reported
• Issue #306\textsuperscript{4670} - Performance counter user interface issues
• Issue #307\textsuperscript{4671} - Logging exception in distributed runs
• Issue #308\textsuperscript{4672} - Logging deadlocks in distributed
• Issue #309\textsuperscript{4673} - Reference counting test failures and exceptions
• Issue #311\textsuperscript{4674} - Merge AGAS remote\_interface with the runtime\_support object
• Issue #314\textsuperscript{4675} - Object tracking for id\_types
• Issue #315\textsuperscript{4676} - Remove handle\_gid and handle credit splitting in id\_type serialization
• Issue #320\textsuperscript{4677} - applier::get\_locality\_id() should return an error value (or throw an exception)

\textsuperscript{4677} https://github.com/STEllAR-GROUP/hpx/issues/320
• Issue #321 - Optimization for id_types which are never split should be restored
• Issue #322 - Command line processing ignored with Boost 1.47.0
• Issue #323 - Credit exhaustion causes object to stay alive
• Issue #324 - Duplicate exception messages
• Issue #326 - Integrate Quickbook with CMake
• Issue #329 - --help and --version should still work
• Issue #330 - Create pkg-config files
• Issue #337 - Improve usability of performance counter timestamps
• Issue #338 - Non-std exceptions deriving from std::exceptions in tfunc may be sliced
• Issue #339 - Decrease the number of send_pending_parcel threads
• Issue #343 - Dynamically setting the stack size doesn’t work
• Issue #351 - ‘make install’ does not update documents
• Issue #353 - Disable FIXMEs in the docs by default; add a doc developer CMake option to enable FIXMEs
• Issue #355 - ‘make’ doesn’t do anything after correct configuration
• Issue #356 - Don’t use hpx::util::static_ in topology code
• Issue #359 - Infinite recursion in hpx::tuple serialization
• Issue #361 - Add compile time option to disable logging completely
• Issue #364 - Installation seriously broken in r7443

2.10.22 HPX V0.7.0 (Dec 12, 2011)

We have had roughly 1000 commits since the last release and we have closed approximately 120 tickets (bugs, feature requests, etc.).
General changes

- Completely removed code related to deprecated AGAS V1, started to work on AGAS V2.1.
- Started to clean up and streamline the exposed APIs (see ‘API changes’ below for more details).
- Revamped and unified performance counter framework, added a lot of new performance counter instances for monitoring of a diverse set of internal HPX parameters (queue lengths, access statistics, etc.).
- Improved general error handling and logging support.
- Fixed several race conditions, improved overall stability, decreased memory footprint, improved overall performance (major optimizations include native TLS support and ranged-based AGAS caching).
- Added support for running HPX applications with PBS.
- Many updates to the build system, added support for gcc 4.5.x and 4.6.x, added C++11 support.
- Many updates to default command line options.
- Added many tests, set up buildbot for continuous integration testing.
- Better shutdown handling of distributed applications.

Example applications

- quickstart/factorial and quickstart/fibonacci, future-recursive parallel algorithms.
- quickstart/hello_world, distributed hello world example.
- quickstart/rma, simple remote memory access example
- quickstart/quicksort, parallel quicksort implementation.
- gtc, gyrokinetic torodial code.
- bfs, breadth-first-search, example code for a graph application.
- sheneos, partitioning of large data sets.
- accumulator, simple component example.
- balancing/os_thread_num, balancing/px_thread_phase, examples demonstrating load balancing and work stealing.

API changes

- Added `hpx::find_all_localities`.
- Added `hpx::terminate` for non-graceful termination of applications.
- Added `hpx::lcos::async` functions for simpler asynchronous programming.
- Added new AGAS interface for handling of symbolic namespace (`hpx::agas::*`).
- Renamed `hpx::components::wait` to `hpx::lcos::wait`.
- Renamed `hpx::lcos::future_value` to `hpx::lcos::promise`.
- Renamed `hpx::lcos::recursive_mutex` to `hpx::lcos::local_recursive_mutex`, `hpx::lcos::mutex` to `hpx::lcos::local_mutex`
- Removed support for Boost versions older than V1.38, recommended Boost version is now V1.47 and newer.
- Removed `hpx::process` (this will be replaced by a real process implementation in the future).
• Removed non-functional LCO code (`hpx::lcos::dataflow`, `hpx::lcos::thunk`, `hpx::lcos::dataflow_variable`).
• Removed deprecated `hpx::naming::full_address`.

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release:

• Issue #284696 - Integrate Windows/Linux CMake code for HPX core
• Issue #324697 - hpx::cout() should be hpx::cout
• Issue #334698 - AGAS V2 legacy client does not properly handle error_code
• Issue #604699 - AGAS: allow for registrerid to optionally take ownership of the gid
• Issue #624700 - adaptive1d compilation failure in Fusion
• Issue #644701 - Parcel subsystem doesn’t resolve domain names
• Issue #834702 - No error handling if no console is available
• Issue #844703 - No error handling if a hosted locality is treated as the bootstrap server
• Issue #904704 - Add general commandline option -N
• Issue #914705 - Add possibility to read command line arguments from file
• Issue #924706 - Always log exceptions/errors to the log file
• Issue #934707 - Log the command line/program name
• Issue #954708 - Support for distributed launches
• Issue #974709 - Attempt to create a bad component type in AMR examples
• Issue #1004710 - factorial and factorial_get examples trigger AGAS component type assertions
• Issue #1014711 - Segfault when hpx::process::here() is called in fibonacci2
• Issue #1024712 - unknown_component_address in int_object_semaphore_client
• Issue #1144713 - marduk raises assertion with default parameters
• Issue #1154714 - Logging messages for SMP runs (on the console) shouldn’t be buffered

4713 https://github.com/STEllAR-GROUP/hpx/issues/114
4714 https://github.com/STEllAR-GROUP/hpx/issues/115
• Issue #119 - marduk linking strategy breaks other applications
• Issue #121 - pbsdsh problem
• Issue #123 - marduk, dataflow and adaptive1d fail to build
• Issue #124 - Lower default preprocessing arity
• Issue #125 - Move hpx::detail::diagnostic_information out of the detail namespace
• Issue #126 - Test definitions for AGAS reference counting
• Issue #128 - Add averaging performance counter
• Issue #129 - Error with endian.hpp while building adaptive1d
• Issue #130 - Bad initialization of performance counters
• Issue #131 - Add global startup/shutdown functions to component modules
• Issue #132 - Avoid using auto_ptr
• Issue #133 - On Windows hpx.dll doesn’t get installed
• Issue #134 - HPX_LIBRARY does not reflect real library name (on Windows)
• Issue #135 - Add detection of unique_ptr to build system
• Issue #137 - Add command line option allowing to repeatedly evaluate performance counters
• Issue #139 - Logging is broken
• Issue #140 - CMake problem on windows
• Issue #141 - Move all non-component libraries into $PREFIX/lib/hpx
• Issue #143 - adaptive1d throws an exception with the default command line options
• Issue #146 - Early exception handling is broken
• Issue #147 - Sheneos doesn’t link on Linux
• Issue #149 - sheneos_test hangs
• Issue #154 - Compilation fails for r5661

2.11 Citing HPX

Please cite HPX whenever you use it for publications. Use our paper in The Journal of Open Source Software as the main citation for HPX: 4772. Use the Zenodo entry for referring to the latest version of HPX: 4773. Entries for citing specific versions of HPX can also be found at 4774.

2.12 HPX users

A list of institutions and projects using HPX can be found on the HPX Users4775 page.

2.13 About HPX

2.13.1 History

The development of High Performance ParalleX (HPX) began in 2007. At that time, Hartmut Kaiser became interested in the work done by the ParalleX group at the Center for Computation and Technology (CCT)4776, a multi-disciplinary research institute at Louisiana State University (LSU)4777. The ParalleX group was working to develop a new and
experimental execution model for future high performance computing architectures. This model was christened ParalleX. The first implementations of ParalleX were crude, and many of those designs had to be discarded entirely. However, over time the team learned quite a bit about how to design a parallel, distributed runtime system which implements the concepts of ParalleX.

From the very beginning, this endeavour has been a group effort. In addition to a handful of interested researchers, there have always been graduate and undergraduate students participating in the discussions, design, and implementation of HPX. In 2011 we decided to formalize our collective research efforts by creating the STE||AR group (Systems Technology, Emergent Parallelism, and Algorithm Research). Over time, the team grew to include researchers around the country and the world. In 2014, the STE||AR Group was reorganized to become the international community it is today. This consortium of researchers aims to develop stable, sustainable, and scalable tools which will enable application developers to exploit the parallelism latent in the machines of today and tomorrow. Our goal of the HPX project is to create a high quality, freely available, open source implementation of ParalleX concepts for conventional and future systems by building a modular and standards conforming runtime system for SMP and distributed application environments. The API exposed by HPX is conformant to the interfaces defined by the C++11/14 ISO standard and adheres to the programming guidelines used by the Boost collection of C++ libraries. We steer the development of HPX with real world applications and aim to provide a smooth migration path for domain scientists.

To learn more about STE||AR and ParalleX, see People and Why HPX?

2.13.2 People

The STE||AR Group (pronounced as stellar) stands for “Systems Technology, Emergent Parallelism, and Algorithm Research”. We are an international group of faculty, researchers, and students working at various institutions around the world. The goal of the STE||AR Group is to promote the development of scalable parallel applications by providing a community for ideas, a framework for collaboration, and a platform for communicating these concepts to the broader community.

Our work is focused on building technologies for scalable parallel applications. HPX, our general purpose C++ runtime system for parallel and distributed applications, is no exception. We use HPX for a broad range of scientific applications, helping scientists and developers to write code which scales better and shows better performance compared to more conventional programming models such as MPI.

HPX is based on ParalleX which is a new (and still experimental) parallel execution model aiming to overcome the limitations imposed by the current hardware and the techniques we use to write applications today. Our group focuses on two types of applications - those requiring excellent strong scaling, allowing for a dramatic reduction of execution time for fixed workloads and those needing highest level of sustained performance through massive parallelism. These applications are presently unable (through conventional practices) to effectively exploit a relatively small number of cores in a multi-core system. By extension, these application will not be able to exploit high-end exascale computing systems which are likely to employ hundreds of millions of such cores by the end of this decade.

Critical bottlenecks to the effective use of new generation high performance computing (HPC) systems include:

- **Starvation:** due to lack of usable application parallelism and means of managing it,
- **Overhead:** reduction to permit strong scalability, improve efficiency, and enable dynamic resource management,
- **Latency:** from remote access across system or to local memories,
- **Contention:** due to multicore chip I/O pins, memory banks, and system interconnects.
The ParalleX model has been devised to address these challenges by enabling a new computing dynamic through the application of message-driven computation in a global address space context with lightweight synchronization. The work on HPX is centered around implementing the concepts as defined by the ParalleX model. HPX is currently targeted at conventional machines, such as classical Linux based Beowulf clusters and SMP nodes.

We fully understand that the success of HPX (and ParalleX) is very much the result of the work of many people. To see a list of who is contributing see our tables below.

Acknowledgements

Thanks also to the following people who contributed directly or indirectly to the project through discussions, pull requests, documentation patches, etc.

- Brice Goglin, for reporting and helping fix issues related to the integration of hwloc in HPX.
- Giannis Gonidelis, for his work on the ranges adaptation during the Google Summer of Code 2020.
- Auriane Reverdell (Swiss National Supercomputing Centre\footnote{https://www.cscs.ch}), for her tireless work on refactoring our CMake setup and modularizing HPX.
- Christopher Hinz, for his work on refactoring our CMake setup.
- Weile Wei, for fixing HPX builds with CUDA on Summit.
- Severin Strobl, for fixing our CMake setup related to linking and adding new entry points to the HPX runtime.
- Rebecca Stobaugh, for her major documentation review and contributions during and after the 2019 Google Season of Documentation.
- Jan Melech, for adding automatic serialization of simple structs.
- Austin McCartney, for adding concept emulation of the Ranges TS bidirectional and random access iterator concepts.
- Marco Diers, reporting and fixing issues related PMIx.
- Maximilian Bremer, for reporting multiple issues and extending the component migration tests.
- Piotr Mikolajczyk, for his improvements and fixes to the set and count algorithms.
- Grant Rostig, for reporting several deficiencies on our web pages.
- Jakub Golinowski, for implementing an HPX backend for OpenCV and in the process improving documentation and reporting issues.
- Mikael Simberg (Swiss National Supercomputing Centre\footnote{https://www.cscs.ch}), for his tireless help cleaning up and maintaining HPX.
- Tianyi Zhang, for his work on HPXMP.
- Shahrzad Shirzad, for her contributions related to Phylanx.
- Christopher Ogle, for his contributions to the parallel algorithms.
- Surya Priy, for his work with statistic performance counters.
- Anushi Maheshwari, for her work on random number generation.
- Bruno Pitrus, for his work with parallel algorithms.
- Nikunj Gupta, for rewriting the implementation of \texttt{hpx\_main.hpp} and for his fixes for tests.
- Christopher Taylor, for his interest in HPX and the fixes he provided.
- Shoshana Jakobovits, for her work on the resource partitioner.
- Denis Blank, who re-wrote our unwrapped function to accept plain values arbitrary containers, and properly deal with nested futures.
- Ajai V. George, who implemented several of the parallel algorithms.
- Taeguk Kwon, who worked on implementing parallel algorithms as well as adapting the parallel algorithms to the Ranges TS.
• Zach Byerly (Louisiana State University (LSU)\textsuperscript{4823}), who in his work developing applications on top of HPX opened tickets and contributed to the HPX examples.

• Daniel Estermann, for his work porting HPX to the Raspberry Pi.

• Alireza Kheirkhahan (Louisiana State University (LSU)\textsuperscript{4824}), who built and administered our local cluster as well as his work in distributed IO.

• Abhimanyu Rawat, who worked on stack overflow detection.

• David Pfander, who improved signal handling in HPX, provided his optimization expertise, and worked on incorporating the Vc vectorization into HPX.

• Denis Demidov, who contributed his insights with VexCL.

• Khalid Hasanov, who contributed changes which allowed to run HPX on 64Bit power-.pc architectures.

• Zahra Khatami (Louisiana State University (LSU)\textsuperscript{4825}), who contributed the prefetching iterators and the persistent auto chunking executor parameters implementation.

• Marcin Copik, who worked on implementing GPU support for C++AMP and HCC. He also worked on implementing a HCC backend for HPX.Compute.

• Minh-Khanh Do, who contributed the implementation of several segmented algorithms.

• Bibek Wagle (Louisiana State University (LSU)\textsuperscript{4826}), who worked on fixing and analyzing the performance of the parcel coalescing plugin in HPX.

• Lukas Troska, who reported several problems and contributed various test cases allowing to reproduce the corresponding issues.

• Andreas Schaefer, who worked on integrating his library (LibGeoDecomp\textsuperscript{4827}) with HPX. He reported various problems and submitted several patches to fix issues allowing for a better integration with LibGeoDecomp\textsuperscript{4828}.

• Satyaki Upadhyay, who contributed several examples to HPX.

• Brandon Cordes, who contributed several improvements to the inspect tool.

• Harris Brakmic, who contributed an extensive build system description for building HPX with Visual Studio.

• Parsa Amini (Louisiana State University (LSU)\textsuperscript{4829}), who refactored and simplified the implementation of AGAS in HPX and who works on its implementation and optimization.

• Luis Martinez de Bartolome who implemented a build system extension for HPX integrating it with the Conan\textsuperscript{4830} C/C++ package manager.

• Vinay C Amatya (Louisiana State University (LSU)\textsuperscript{4831}), who contributed to the documentation and provided some of the HPX examples.

• Kevin Huck and Nick Chaimov (University of Oregon\textsuperscript{4832}), who contributed the integration of APEX (Autonomic Performance Environment for eXascale) with HPX.

• Francisco Jose Tapia, who helped with implementing the parallel sort algorithm for HPX.

• Patrick Diehl, who worked on implementing CUDA support for our companion library targeting GPGPUs (HPXCL).

• Eric Lemanisier contributed fixes to allow compilation using the MingW toolchain.

• Nidhi Makhijani who helped cleaning up some enum consistencies in HPX and contributed to the resource manager used in the thread scheduling subsystem. She also worked on HPX in the context of the Google Summer of Code 2015.

• Larry Xiao, Devang Bacharwar, Marcin Copik, and Konstantin Kronfeldner who worked on HPX in the context of the Google Summer of Code program 2015.

• Daniel Bourgeois (Center for Computation and Technology (CCT)) who contributed to HPX the implementation of several parallel algorithms (as proposed by N4313).

• Anuj Sharma and Christopher Bross (Department of Computer Science 3 - Computer Architecture), who worked on HPX in the context of the Google Summer of Code program 2014.

• Martin Stumpf (Department of Computer Science 3 - Computer Architecture), who rebuilt our contiguous testing infrastructure (see the HPX Buildbot Website). Martin is also working on HPXCL (mainly all work related to OpenCL) and implementing an HPX backend for POCL, a portable computing language solution based on OpenCL.

• Grant Mercer (University of Nevada, Las Vegas), who helped creating many of the parallel algorithms (as proposed by N4313).

• Damond Howard (Louisiana State University (LSU)), who works on HPXCL (mainly all work related to CUDA).

• Christoph Junghans (Los Alamos National Lab), who helped making our buildsystem more portable.

• Antoine Tran Tan (Laboratoire de Recherche en Informatique, Paris), who worked on integrating HPX as a backend for NT2. He also contributed an implementation of an API similar to Fortran co-arrays on top of HPX.

• John Biddiscombe (Swiss National Supercomputing Centre), who helped with the BlueGene/Q port of HPX, implemented the parallel sort algorithm, and made several other contributions.

• Erik Schnetter (Perimeter Institute for Theoretical Physics), who greatly helped to make HPX more robust by submitting a large amount of problem reports, feature requests, and made several direct contributions.

• Mathias Gaunard (Metascale), who contributed several patches to reduce compile time warnings generated while compiling HPX.

• Andreas Buhr, who helped with improving our documentation, especially by suggesting some fixes for inconsistencies.
• Patricia Grubel (New Mexico State University[^4851]), who contributed the description of the different HPX thread scheduler policies and is working on the performance analysis of our thread scheduling subsystem.

• Lars Viklund, whose wit, passion for testing, and love of odd architectures has been an amazing contribution to our team. He has also contributed platform specific patches for FreeBSD and MSVC12.

• Agustin Berge, who contributed patches fixing some very nasty hidden template meta-programming issues. He rewrote large parts of the API elements ensuring strict conformance with C++11/14.

• Anton Bikineev for contributing changes to make using `boost::lexical_cast` safer, he also contributed a thread safety fix to the iostreams module. He also contributed a complete rewrite of the serialization infrastructure replacing Boost.Serialization inside HPX.

• Pyry Jahkola, who contributed the Mac OS build system and build documentation on how to build HPX using Clang and libc++.

• Mario Mulansky, who created an HPX backend for his Boost.Odeint library, and who submitted several test cases allowing us to reproduce and fix problems in HPX.

• Rekha Raj, who contributed changes to the description of the Windows build instructions.

• Jeremy Kemp how worked on an HPX OpenMP backend and added regression tests.

• Alex Nagelberg for his work on implementing a C wrapper API for HPX.

• Chen Guo, helvihartmann, Nicholas Pezolano, and John West who added and improved examples in HPX.

• Joseph Kleinhenz, Markus Elfring, Kirill Kropivyansky, Alexander Neundorf, Bryant Lam, and Alex Hirsch who improved our CMake.

• Tapasweni Pathak, Praveen Velliengiri, Jean-Loup Tastet, Michael Levine, Aalekh Nigam, HadrienG2, Prayag Verma, Islada, Alex Myczko, and Avyav Kumar who improved the documentation.

• Jayesh Badwaik, J. F. Bastien, Christoph Garth, Christopher Hinz, Brandon Kohn, Mario Lang, Maikel Nadolski, pierrele, hendrx, Dekken, woodmeister123, xaguilar, Andrew Kemp, Dylan Stark, Matthew Anderson, Jeremy Wilke, Jiazheng Yuan, CyberDrudge, david8dixon, Maxwell Reeser, Raffaele Solca, Marco Ippolito, Jules Penuchot, Weile Wei, Severin Strobl, Kor de Jong, albestro, Jeff Trull, Yuri Victorovich, and Gregor Daiß who contributed to the general improvement of HPX.
