WHAT IS HPX?

HPX is a C++ Standard Library for Concurrency and Parallelism. It implements all of the corresponding facilities as defined by the C++ Standard. Additionally, in HPX we implement functionalities proposed as part of the ongoing C++ standardization process. We also extend the C++ Standard APIs to the distributed case. HPX is developed by the STE||AR group (see People).

The goal of HPX is to create a high quality, freely available, open source implementation of a new programming model for conventional systems, such as classic Linux based Beowulf clusters or multi-socket highly parallel SMP nodes. At the same time, we want to have a very modular and well designed runtime system architecture which would allow us to port our implementation onto new computer system architectures. We want to use real-world applications to drive the development of the runtime system, coining out required functionalities and converging onto a stable API which will provide a smooth migration path for developers.

The API exposed by HPX is not only modeled after the interfaces defined by the C++11/14/17/20 ISO standard. It also adheres to the programming guidelines used by the Boost collection of C++ libraries. We aim to improve the scalability of today’s applications and to expose new levels of parallelism which are necessary to take advantage of the exascale systems of the future.
WHAT’S SO SPECIAL ABOUT HPX?

- HPX exposes a uniform, standards-oriented API for ease of programming parallel and distributed applications.
- It enables programmers to write fully asynchronous code using hundreds of millions of threads.
- HPX provides unified syntax and semantics for local and remote operations.
- HPX makes concurrency manageable with dataflow and future based synchronization.
- It implements a rich set of runtime services supporting a broad range of use cases.
- HPX exposes a uniform, flexible, and extendable performance counter framework which can enable runtime adaptivity.
- It is designed to solve problems conventionally considered to be scaling-impaired.
- HPX has been designed and developed for systems of any scale, from hand-held devices to very large scale systems.
- It is the first fully functional implementation of the ParalleX execution model.
- HPX is published under a liberal open-source license and has an open, active, and thriving developer community.

2.1 Why HPX?

Current advances in high performance computing (HPC) continue to suffer from the issues plaguing parallel computation. These issues include, but are not limited to, ease of programming, inability to handle dynamically changing workloads, scalability, and efficient utilization of system resources. Emerging technological trends such as multi-core processors further highlight limitations of existing parallel computation models. To mitigate the aforementioned problems, it is necessary to rethink the approach to parallelization models. ParalleX contains mechanisms such as multi-threading, parcels, global name space support, percolation and local control objects (LCO). By design, ParalleX overcomes limitations of current models of parallelism by alleviating contention, latency, overhead and starvation. With ParalleX, it is further possible to increase performance by at least an order of magnitude on challenging parallel algorithms, e.g., dynamic directed graph algorithms and adaptive mesh refinement methods for astrophysics. An additional benefit of ParalleX is fine-grained control of power usage, enabling reductions in power consumption.
2.1.1 ParalleX—a new execution model for future architectures

ParalleX is a new parallel execution model that offers an alternative to the conventional computation models, such as message passing. ParalleX distinguishes itself by:

- Split-phase transaction model
- Message-driven
- Distributed shared memory (not cache coherent)
- Multi-threaded
- Futures synchronization
- Local Control Objects (LCOs)
- Synchronization for anonymous producer-consumer scenarios
- Percolation (pre-staging of task data)

The ParalleX model is intrinsically latency hiding, delivering an abundance of variable-grained parallelism within a hierarchical namespace environment. The goal of this innovative strategy is to enable future systems delivering very high efficiency, increased scalability and ease of programming. ParalleX can contribute to significant improvements in the design of all levels of computing systems and their usage from application algorithms and their programming languages to system architecture and hardware design together with their supporting compilers and operating system software.

2.1.2 What is HPX?

High Performance ParalleX (HPX) is the first runtime system implementation of the ParalleX execution model. The HPX runtime software package is a modular, feature-complete, and performance-oriented representation of the ParalleX execution model targeted at conventional parallel computing architectures, such as SMP nodes and commodity clusters. It is academically developed and freely available under an open source license. We provide HPX to the community for experimentation and application to achieve high efficiency and scalability for dynamic adaptive and irregular computational problems. HPX is a C++ library that supports a set of critical mechanisms for dynamic adaptive resource management and lightweight task scheduling within the context of a global address space. It is solidly based on many years of experience in writing highly parallel applications for HPC systems.

The two-decade success of the communicating sequential processes (CSP) execution model and its message passing interface (MPI) programming model have been seriously eroded by challenges of power, processor core complexity, multi-core sockets, and heterogeneous structures of GPUs. Both efficiency and scalability for some current (strong scaled) applications and future Exascale applications demand new techniques to expose new sources of algorithm parallelism and exploit unused resources through adaptive use of runtime information.

The ParalleX execution model replaces CSP to provide a new computing paradigm embodying the governing principles for organizing and conducting highly efficient scalable computations greatly exceeding the capabilities of today's problems. HPX is the first practical, reliable, and performance-oriented runtime system incorporating the principal concepts of the ParalleX model publicly provided in open source release form.

HPX is designed by the STEllAR\(^5\) Group (Systems Technology, Emergent Parallelism, and Algorithm Research) at Louisiana State University (LSU)\(^6\)’s Center for Computation and Technology (CCT)\(^7\) to enable developers to exploit the full processing power of many-core systems with an unprecedented degree of parallelism. STEllAR\(^8\) is a research group focusing on system software solutions and scientific application development for hybrid and many-core hardware architectures.

### 2.1.3 What makes our systems slow?

Estimates say that we currently run our computers at well below 100% efficiency. The theoretical peak performance (usually measured in FLOPS\(^10\)—floating point operations per second) is much higher than any practical peak performance reached by any application. This is particularly true for highly parallel hardware. The more hardware parallelism we provide to an application, the better the application must scale in order to efficiently use all the resources of the machine. Roughly speaking, we distinguish two forms of scalability: strong scaling (see Amdahl’s Law\(^11\)) and weak scaling (see Gustafson’s Law\(^12\)). Strong scaling is defined as how the solution time varies with the number of processors for a fixed total problem size. It gives an estimate of how much faster we can solve a particular problem by throwing more resources at it. Weak scaling is defined as how the solution time varies with the number of processors for a fixed problem size per processor. In other words, it defines how much more data can we process by using more hardware resources.

In order to utilize as much hardware parallelism as possible an application must exhibit excellent strong and weak scaling characteristics, which requires a high percentage of work executed in parallel, i.e., using multiple threads of execution. Optimally, if you execute an application on a hardware resource with N processors it either runs N times faster or it can handle N times more data. Both cases imply 100% of the work is executed on all available processors in parallel. However, this is just a theoretical limit. Unfortunately, there are more things that limit scalability, mostly inherent to the hardware architectures and the programming models we use. We break these limitations into four fundamental factors that make our systems SLOW:

- *Starvation* occurs when there is insufficient concurrent work available to maintain high utilization of all resources.
- *Latencies* are imposed by the time-distance delay intrinsic to accessing remote resources and services.
- *Overhead* is work required for the management of parallel actions and resources on the critical execution path, which is not necessary in a sequential variant.
- *Waiting for contention resolution* is the delay due to the lack of availability of oversubscribed shared resources.

Each of those four factors manifests itself in multiple and different ways; each of the hardware architectures and programming models expose specific forms. However, the interesting part is that all of them are limiting the scalability of applications no matter what part of the hardware jungle we look at. Hand-holds, PCs, supercomputers, or the cloud, all suffer from the reign of the 4 horsemen: Starvation, Latency, Overhead, and Contention. This realization is very important as it allows us to derive the criteria for solutions to the scalability problem from first principles, and it allows us to focus our analysis on very concrete patterns and measurable metrics. Moreover, any derived results will be applicable to a wide variety of targets.

### 2.1.4 Technology demands new response

Today’s computer systems are designed based on the initial ideas of John von Neumann\(^13\), as published back in 1945, and later extended by the Harvard architecture\(^14\). These ideas form the foundation, the execution model, of computer systems we use currently. However, a new response is required in the light of the demands created by today’s technology.

So, what are the overarching objectives for designing systems allowing for applications to scale as they should? In our opinion, the main objectives are:

• Performance: as previously mentioned, scalability and efficiency are the main criteria people are interested in.

• Fault tolerance: the low expected mean time between failures (MTBF\(^{15}\)) of future systems requires embracing faults, not trying to avoid them.

• Power: minimizing energy consumption is a must as it is one of the major cost factors today, and will continue to rise in the future.

• Generality: any system should be usable for a broad set of use cases.

• Programmability: for programmer this is a very important objective, ensuring long term platform stability and portability.

What needs to be done to meet those objectives, to make applications scale better on tomorrow’s architectures? Well, the answer is almost obvious: we need to devise a new execution model—a set of governing principles for the holistic design of future systems—targeted at minimizing the effect of the outlined SLOW factors. Everything we create for future systems, every design decision we make, every criteria we apply, have to be validated against this single, uniform metric. This includes changes in the hardware architecture we prevalently use today, and it certainly involves new ways of writing software, starting from the operating system, runtime system, compilers, and at the application level. However, the key point is that all those layers have to be co-designed; they are interdependent and cannot be seen as separate facets. The systems we have today have been evolving for over 50 years now. All layers function in a certain way, relying on the other layers to do so. But we do not have the time to wait another 50 years for a new coherent system to evolve. The new paradigms are needed now—therefore, co-design is the key.

2.1.5 Governing principles applied while developing HPX

As it turn out, we do not have to start from scratch. Not everything has to be invented and designed anew. Many of the ideas needed to combat the 4 horsemen already exist, many for more than 30 years. All it takes is to gather them into a coherent approach. We’ll highlight some of the derived principles we think to be crucial for defeating SLOW. Some of those are focused on high-performance computing, others are more general.

2.1.6 Focus on latency hiding instead of latency avoidance

It is impossible to design a system exposing zero latencies. In an effort to come as close as possible to this goal many optimizations are mainly targeted towards minimizing latencies. Examples for this can be seen everywhere, such as low latency network technologies like InfiniBand\(^{16}\), caching memory hierarchies in all modern processors, the constant optimization of existing MPI\(^{17}\) implementations to reduce related latencies, or the data transfer latencies intrinsic to the way we use GPGPUs\(^{18}\) today. It is important to note that existing latencies are often tightly related to some resource having to wait for the operation to be completed. At the same time it would be perfectly fine to do some other, unrelated work in the meantime, allowing the system to hide the latencies by filling the idle-time with useful work. Modern systems already employ similar techniques (pipelined instruction execution in the processor cores, asynchronous input/output operations, and many more). What we propose is to go beyond anything we know today and to make latency hiding an intrinsic concept of the operation of the whole system stack.

\(^{15}\) http://en.wikipedia.org/wiki/Mean_time_between_failures

\(^{16}\) http://en.wikipedia.org/wiki/InfiniBand

\(^{17}\) https://en.wikipedia.org/wiki/Message_Passing_Interface

\(^{18}\) http://en.wikipedia.org/wiki/GPGPU
2.1.7 Embrace fine-grained parallelism instead of heavyweight threads

If we plan to hide latencies even for very short operations, such as fetching the contents of a memory cell from main memory (if it is not already cached), we need to have very lightweight threads with extremely short context switching times, optimally executable within one cycle. Granted, for mainstream architectures, this is not possible today (even if we already have special machines supporting this mode of operation, such as the Cray XMT\(^{19}\)). For conventional systems, however, the smaller the overhead of a context switch and the finer the granularity of the threading system, the better will be the overall system utilization and its efficiency. For today’s architectures we already see a flurry of libraries providing exactly this type of functionality: non-pre-emptive, task-queue based parallelization solutions, such as Intel Threading Building Blocks (TBB)\(^{20}\), Microsoft Parallel Patterns Library (PPL)\(^{21}\), Cilk++\(^{22}\), and many others. The possibility to suspend a current task if some preconditions for its execution are not met (such as waiting for I/O or the result of a different task), seamlessly switching to any other task which can continue, and to reschedule the initial task after the required result has been calculated, which makes the implementation of latency hiding almost trivial.

2.1.8 Rediscover constraint-based synchronization to replace global barriers

The code we write today is riddled with implicit (and explicit) global barriers. By “global barriers,” we mean the synchronization of the control flow between several (very often all) threads (when using OpenMP\(^{23}\)) or processes (MPI\(^{24}\)). For instance, an implicit global barrier is inserted after each loop parallelized using OpenMP as the system synchronizes the threads used to execute the different iterations in parallel. In MPI each of the communication steps imposes an explicit barrier onto the execution flow as (often all) nodes have to be synchronized. Each of those barriers is like the eye of a needle the overall execution is forced to be squeezed through. Even minimal fluctuations in the execution times of the parallel threads (jobs) causes them to wait. Additionally, it is often only one of the executing threads that performs the actual reduce operation, which further impedes parallelism. A closer analysis of a couple of key algorithms used in science applications reveals that these global barriers are not always necessary. In many cases it is sufficient to synchronize a small subset of the threads. Any operation should proceed whenever the preconditions for its execution are met, and only those. Usually there is no need to wait for iterations of a loop to finish before you can continue calculating other things; all you need is to complete the iterations that produce the required results for the next operation. Good bye global barriers, hello constraint based synchronization! People have been trying to build this type of computing (and even computers) since the 1970s. The theory behind what they did is based on ideas around static and dynamic dataflow. There are certain attempts today to get back to those ideas and to incorporate them with modern architectures. For instance, a lot of work is being done in the area of constructing dataflow-oriented execution trees. Our results show that employing dataflow techniques in combination with the other ideas, as outlined herein, considerably improves scalability for many problems.

2.1.9 Adaptive locality control instead of static data distribution

While this principle seems to be a given for single desktop or laptop computers (the operating system is your friend), it is everything but ubiquitous on modern supercomputers, which are usually built from a large number of separate nodes (i.e., Beowulf clusters), tightly interconnected by a high-bandwidth, low-latency network. Today’s prevalent programming model for those is MPI, which does not directly help with proper data distribution, leaving it to the programmer to decompose the data to all of the nodes the application is running on. There are a couple of specialized languages and programming environments based on PGAS\(^{27}\) (Partitioned Global Address Space) designed to over-

---

\(^{19}\) http://en.wikipedia.org/wiki/Cray_XMT

\(^{20}\) https://www.threadingbuildingblocks.org/

\(^{22}\) https://software.intel.com/en-us/articles/intel-cilk-plus/

\(^{23}\) https://openmp.org/wp/

\(^{24}\) https://en.wikipedia.org/wiki/Message_Passing_Interface

\(^{25}\) https://openmp.org/wp/

\(^{26}\) https://en.wikipedia.org/wiki/Message_Passing_Interface

\(^{27}\) https://www.pgas.org/
come this limitation, such as Chapel\textsuperscript{28}, X10\textsuperscript{29}, UPC\textsuperscript{30}, or Fortress\textsuperscript{31}. However, all systems based on PGAS rely on static data distribution. This works fine as long as this static data distribution does not result in heterogeneous workload distributions or other resource utilization imbalances. In a distributed system these imbalances can be mitigated by migrating part of the application data to different localities (nodes). The only framework supporting (limited) migration today is Charm++\textsuperscript{32}. The first attempts towards solving related problem go back decades as well, a good example is the Linda coordination language\textsuperscript{33}. Nevertheless, none of the other mentioned systems support data migration today, which forces the users to either rely on static data distribution and live with the related performance hits or to implement everything themselves, which is very tedious and difficult. We believe that the only viable way to flexibly support dynamic and adaptive locality control is to provide a global, uniform address space to the applications, even on distributed systems.

### 2.1.10 Prefer moving work to the data over moving data to the work

For the best performance it seems obvious to minimize the amount of bytes transferred from one part of the system to another. This is true on all levels. At the lowest level we try to take advantage of processor memory caches, thus, minimizing memory latencies. Similarly, we try to amortize the data transfer time to and from GPGPUs\textsuperscript{34} as much as possible. At high levels we try to minimize data transfer between different nodes of a cluster or between different virtual machines on the cloud. Our experience (well, it’s almost common wisdom) shows that the amount of bytes necessary to encode a certain operation is very often much smaller than the amount of bytes encoding the data the operation is performed upon. Nevertheless, we still often transfer the data to a particular place where we execute the operation just to bring the data back to where it came from afterwards. As an example let’s look at the way we usually write our applications for clusters using MPI. This programming model is all about data transfer between nodes. MPI is the prevalent programming model for clusters, and it is fairly straightforward to understand and to use. Therefore, we often write applications in a way that accommodates this model, centered around data transfer. These applications usually work well for smaller problem sizes and for regular data structures. The larger the amount of data we have to churn and the more irregular the problem domain becomes, the worse the overall machine utilization and the (strong) scaling characteristics become. While it is not impossible to implement more dynamic, data driven, and asynchronous applications using MPI, it is somewhat difficult to do so. At the same time, if we look at applications that prefer to execute the code close to the locality where the data was placed, i.e., utilizing active messages (for instance based on Charm++\textsuperscript{35}), we see better asynchrony, simpler application codes, and improved scaling.

### 2.1.11 Favor message driven computation over message passing

Today’s prevalently used programming model on parallel (multi-node) systems is MPI. It is based on message passing, as the name implies, which means that the receiver has to be aware of a message about to come in. Both codes, the sender and the receiver, have to synchronize in order to perform the communication step. Even the newer, asynchronous interfaces require explicitly coding the algorithms around the required communication scheme. As a result, everything but the most trivial MPI applications spends a considerable amount of time waiting for incoming messages, thus, causing starvation and latencies to impede full resource utilization. The more complex and more dynamic the data structures and algorithms become, the larger the adverse effects. The community discovered message-driven and data-driven methods of implementing algorithms a long time ago, and systems such as Charm++\textsuperscript{36} have already integrated active messages demonstrating the validity of the concept. Message-driven computation allows for sending messages without requiring the receiver to actively wait for them. Any incoming message is handled asynchronously and triggers

\textsuperscript{32} https://charm.cs.uiuc.edu/

\textsuperscript{33} http://en.wikipedia.org/wiki/Linda_(coordination_language)

\textsuperscript{34} http://en.wikipedia.org/wiki/GPGPU

\textsuperscript{35} https://charm.cs.uiuc.edu/

\textsuperscript{36} https://charm.cs.uiuc.edu/
the encoded action by passing along arguments and—possibly—continuations. HPX combines this scheme with work-queue based scheduling as described above, which allows the system to almost completely overlap any communication with useful work, thereby minimizing latencies.

2.2 Quick start

This section is intended to get you to the point of running a basic HPX program as quickly as possible. To that end we skip many details but instead give you hints and links to more details along the way.

We assume that you are on a Unix system with access to reasonably recent packages. You should have cmake and make available for the build system (pkg-config is also supported, see Using HPX with pkg-config).

2.2.1 Getting HPX

Download a tarball of the latest release from HPX Downloads and unpack it or clone the repository directly using git:

```bash
git clone https://github.com/STEllAR-GROUP/hpx.git
```

It is also recommended that you check out the latest stable tag:

```bash
git checkout 1.6.0
```

2.2.2 HPX dependencies

The minimum dependencies needed to use HPX are Boost and Portable Hardware Locality (HWLOC). If these are not available through your system package manager, see Installing Boost and Installing Hwloc for instructions on how to build them yourself. In addition to Boost and Portable Hardware Locality (HWLOC), it is recommended that you don’t use the system allocator, but instead use either tcmalloc from google-perftools (default) or jemalloc for better performance. If you would like to try HPX without a custom allocator at this point, you can configure HPX to use the system allocator in the next step.

A full list of required and optional dependencies, including recommended versions, is available at Prerequisites.

2.2.3 Building HPX

Once you have the source code and the dependencies, set up a separate build directory and configure the project. Assuming all your dependencies are in paths known to CMake, the following gets you started:

```bash
# In the HPX source directory
mkdir build && cd build
cmake -DCMAKE_INSTALL_PREFIX=/install/path ..
make install
```

---

37 https://hpx.stellar-group.org/downloads/
38 https://www.boost.org/
39 https://www.open-mpi.org/projects/hwloc/
40 https://code.google.com/p/gperftools
41 http://jemalloc.net
This will build the core HPX libraries and examples, and install them to your chosen location. If you want to install HPX to system folders, simply leave out the CMAKE_INSTALL_PREFIX option. This may take a while. To speed up the process, launch more jobs by passing the \(-jN\) option to make.

**Tip:** Do not set only \(-j\) (i.e. \(-j\) without an explicit number of jobs) unless you have a lot of memory available on your machine.

**Tip:** If you want to change CMake variables for your build, it is usually a good idea to start with a clean build directory to avoid configuration problems. It is especially important that you use a clean build directory when changing between Release and Debug modes.

If your dependencies are in custom locations, you may need to tell CMake where to find them by passing one or more of the following options to CMake:

```
-DBOOST_ROOT=/path/to/boost
-DHWLOC_ROOT=/path/to/hwloc
-DTCMALLOC_ROOT=/path/to/tcmalloc
-DJEMALLOC_ROOT=/path/to/jemalloc
```

If you want to try HPX without using a custom allocator pass \(-DHPX\_WITH\_MALLOC=system\) to CMake.

**Important:** If you are building HPX for a system with more than 64 processing units, you must change the CMake variables HPX\_WITH\_MORE\_THAN\_64\_THREADS (to On) and HPX\_WITH\_MAX\_CPU\_COUNT (to a value at least as big as the number of (virtual) cores on your system).

To build the tests, run make tests. To run the tests, run either make test or use ctest for more control over which tests to run. You can run single tests for example with ctest --output-on-failure -R tests. unit.parallel.algorithms.for_loop or a whole group of tests with ctest --output-on-failure -R tests.unit.

If you did not run make install earlier, do so now or build the hello_world_1 example by running:

```
make hello_world_1
```

HPX executables end up in the bin directory in your build directory. You can now run hello_world_1 and should see the following output:

```
./bin/hello_world_1
Hello World!
```

You’ve just run an example which prints Hello World! from the HPX runtime. The source for the example is in examples/quickstart/hello_world_1.cpp. The hello_world_distributed example (also available in the examples/quickstart directory) is a distributed hello world program, which is described in Remote execution with actions: Hello world. It provides a gentle introduction to the distributed aspects of HPX.

**Tip:** Most build targets in HPX have two names: a simple name and a hierarchical name corresponding to what type of example or test the target is. If you are developing HPX it is often helpful to run make help to get a list of available targets. For example, make help | grep hello_world outputs the following:

```
... examples.quickstart.hello_world_2
... hello_world_2
```

(continues on next page)
It is also possible to build, for instance, all quickstart examples using `make examples.quickstart`.

### 2.2.4 Installing and building HPX via vcpkg

You can download and install HPX using the vcpkg <https://github.com/Microsoft/vcpkg> dependency manager:

```bash
git clone https://github.com/Microsoft/vcpkg.git
cd vcpkg
./bootstrap-vcpkg.sh
./vcpkg integrate install
vcpkg install hpx
```

The HPX port in vcpkg is kept up to date by Microsoft team members and community contributors. If the version is out of date, please create an issue or pull request <https://github.com/Microsoft/vcpkg> on the vcpkg repository.

### 2.2.5 Hello, World!

The following `CMakeLists.txt` is a minimal example of what you need in order to build an executable using CMake and HPX:

```cmake
cmake_minimum_required(VERSION 3.17)
project(my_hpx_project CXX)
find_package(HPX REQUIRED)
add_executable(my_hpx_program main.cpp)
target_link_libraries(my_hpx_program HPX::hpx HPX::wrap_main HPX::iostreams_component)
```

**Note:** You will most likely have more than one `main.cpp` file in your project. See the section on Using HPX with CMake-based projects for more details on how to use `add_hpx_executable`.

**Note:** HPX::wrap_main is required if you are implicitly using `main()` as the runtime entry point. See Re-use the `main()` function as the main HPX entry point for more information.

**Note:** HPX::iostreams_component is optional for a minimal project but lets us use the HPX equivalent of `std::cout`, i.e., the HPX The HPX I/O-streams component functionality in our application.

Create a new project directory and a `CMakeLists.txt` with the contents above. Also create a `main.cpp` with the contents below.

```c
// Including 'hpx/hpx_main.hpp' instead of the usual 'hpx/hpx_init.hpp' enables
// to use the plain C-main below as the direct main HPX entry point.
#include <hpx/hpx_main.hpp>
#include <hpx/iostream.hpp>
```

(continues on next page)
int main()
{
    // Say hello to the world!
    std::cout << "Hello World!\n" << std::flush;
    return 0;
}

Then, in your project directory run the following:

```
mkdir build && cd build
cmake -DCMAKE_PREFIX_PATH=/path/to/hpx/installation ..
make all
./my_hpx_program
```

The program looks almost like a regular C++ hello world with the exception of the two includes and `hpx::cout`. When you include `hpx_main.hpp` some things will be done behind the scenes to make sure that `main` actually gets launched on the `HPX` runtime. So while it looks almost the same you can now use futures, async, parallel algorithms and more which make use of the `HPX` runtime with lightweight threads. `hpx::cout` is a replacement for `std::cout` to make sure printing never blocks a lightweight thread. You can read more about `hpx::cout` in *The HPX I/O-streams component*. If you rebuild and run your program now, you should see the familiar `Hello World!`:

```
./my_hpx_program
Hello World!
```

**Note:** You do not have to let `HPX` take over your main function like in the example. You can instead keep your normal main function, and define a separate `hpx_main` function which acts as the entry point to the `HPX` runtime. In that case you start the `HPX` runtime explicitly by calling `hpx::init`:

```cpp
#include <hpx/hpx_init.hpp>
#include <hpx/iostream.hpp>

int hpx_main(int, char**)
{
    // Say hello to the world!
    hpx::cout << "Hello World!\n" << hpx::flush;
    return hpx::finalize();
}

int main(int argc, char* argv[])
{
    return hpx::init(argc, argv);
}
```
You can also use `hpx::start` and `hpx::stop` for a non-blocking alternative, or use `hpx::resume` and `hpx::suspend` if you need to combine HPX with other runtimes.

See *Starting the HPX runtime* for more details on how to initialize and run the HPX runtime.

---

**Caution:** When including `hpx_main.hpp` the user-defined `main` gets renamed and the real `main` function is defined by HPX. This means that the user-defined `main` must include a return statement, unlike the real `main`. If you do not include the return statement, you may end up with confusing compile time errors mentioning `user_main` or even runtime errors.

### 2.2.6 Writing task-based applications

So far we haven’t done anything that can’t be done using the C++ standard library. In this section we will give a short overview of what you can do with HPX on a single node. The essence is to avoid global synchronization and break up your application into small, composable tasks whose dependencies control the flow of your application. Remember, however, that HPX allows you to write distributed applications similarly to how you would write applications for a single node (see *Why HPX?* and *Writing distributed HPX applications*).

If you are already familiar with `async` and `futures` from the C++ standard library, the same functionality is available in HPX.

The following terminology is essential when talking about task-based C++ programs:

- **lightweight thread**: Essential for good performance with task-based programs. Lightweight refers to smaller stacks and faster context switching compared to OS threads. Smaller overheads allow the program to be broken up into smaller tasks, which in turns helps the runtime fully utilize all processing units.

- **async**: The most basic way of launching tasks asynchronously. Returns a `future<T>`.

- **future<T>**: Represents a value of type `T` that will be ready in the future. The value can be retrieved with `get` (blocking) and one can check if the value is ready with `is_ready` (non-blocking).

- **shared_future<T>**: Same as `future<T>` but can be copied (similar to `std::unique_ptr` vs `std::shared_ptr`).

- **continuation**: A function that is to be run after a previous task has run (represented by a future). `then` is a method of `future<T>` that takes a function to run next. Used to build up dataflow DAGs (directed acyclic graphs). `shared_futures` help you split up nodes in the DAG and functions like `when_all` help you join nodes in the DAG.

The following example is a collection of the most commonly used functionality in HPX:

```cpp
#include <hpx/hpx_main.hpp>
#include <hpx/include/lcos.hpp>
#include <hpx/include/parallel_generate.hpp>
#include <hpx/include/parallel_sort.hpp>
#include <hpx/iostream.hpp>

#include <random>
#include <vector>

void final_task(
    hpx::future<hpx::tuple<hpx::future<double>, hpx::future<void>>>)
{
    hpx::cout << "in final_task" << hpx::endl;
}
```

(continues on next page)
// Avoid ABI incompatibilities between C++11/C++17 as std::rand has exception
// specification in libstdc++.

int rand_wrapper()
{
    return std::rand();
}

int main(int, char**)
{
    // A function can be launched asynchronously. The program will not block
    // here until the result is available.
    hpx::future<int> f = hpx::async([]() { return 42; });
    hpx::cout << "Just launched a task!" << hpx::endl;

    // Use get to retrieve the value from the future. This will block this task
    // until the future is ready, but the HPX runtime will schedule other tasks
    // if there are tasks available.
    hpx::cout << "f contains " << f.get() << hpx::endl;

    // Let's launch another task.
    hpx::future<double> g = hpx::async([]() { return 3.14; });

    // Tasks can be chained using the then method. The continuation takes the
    // future as an argument.
    hpx::future<double> result = g.then([](hpx::future<double>&& gg) {
        // This function will be called once g is ready. gg is g moved
        // into the continuation.
        return gg.get() * 42.0 * 42.0;
    });

    // You can check if a future is ready with the is_ready method.
    hpx::cout << "Result is ready? " << result.is_ready() << hpx::endl;

    // You can launch other work in the meantime. Let's sort a vector.
    std::vector<int> v(1000000);

    // We fill the vector synchronously and sequentially.
    hpx::generate(hpx::execution::seq, std::begin(v), std::end(v),
                  &rand_wrapper);

    // We can launch the sort in parallel and asynchronously.
    hpx::future<void> done_sorting = hpx::parallel::sort(
        hpx::execution::par,
        std::begin(v), std::end(v));

    // We launch the final task when the vector has been sorted and result is
    // ready using when_all.
    auto all = hpx::when_all(result, done_sorting).then(&final_task);

    // We can wait for all to be ready.
    all.wait();

    // all must be ready at this point because we waited for it to be ready.
    hpx::cout << (all.is_ready() ? "all is ready!" : "all is not ready...")
               << hpx::endl;
}(continues on previous page)
Try copying the contents to your main.cpp file and look at the output. It can be a good idea to go through the program step by step with a debugger. You can also try changing the types or adding new arguments to functions to make sure you can get the types to match. The type of the then method can be especially tricky to get right (the continuation needs to take the future as an argument).

Note: HPX programs accept command line arguments. The most important one is --hpx:threads=N to set the number of OS threads used by HPX. HPX uses one thread per core by default. Play around with the example above and see what difference the number of threads makes on the sort function. See Launching and configuring HPX applications for more details on how and what options you can pass to HPX.

Tip: The example above used the construction hpx::when_all(...).then(...). For convenience and performance it is a good idea to replace uses of hpx::when_all(...).then(...) with dataflow. See Dataflow: Interest calculator for more details on dataflow.

Tip: If possible, try to use the provided parallel algorithms instead of writing your own implementation. This can save you time and the resulting program is often faster.

## 2.2.7 Next steps

If you haven’t done so already, reading the Terminology section will help you get familiar with the terms used in HPX.

The Examples section contains small, self-contained walkthroughs of example HPX programs. The Local to remote: 1D stencil example is a thorough, realistic example starting from a single node implementation and going stepwise to a distributed implementation.

The Manual contains detailed information on writing, building and running HPX applications.

## 2.3 Terminology

This section gives definitions for some of the terms used throughout the HPX documentation and source code.

**Locality** A locality in HPX describes a synchronous domain of execution, or the domain of bounded upper response time. This normally is just a single node in a cluster or a NUMA domain in a SMP machine.

**Active Global Address Space**

AGAS HPX incorporates a global address space. Any executing thread can access any object within the domain of the parallel application with the caveat that it must have appropriate access privileges. The model does not assume that global addresses are cache coherent; all loads and stores will deal directly with the site of the target object. All global addresses within a Synchronous Domain are assumed to be cache coherent for those processor cores that incorporate transparent caches. The Active Global Address Space used by HPX differs from research PGAS models. Partitioned Global Address Space is passive in their means of address

---

42 https://www.pgas.org/
translation. Copy semantics, distributed compound operations, and affinity relationships are some of the global functionality supported by AGAS.

Process The concept of the “process” in HPX is extended beyond that of either sequential execution or communicating sequential processes. While the notion of process suggests action (as do “function” or “subroutine”) it has a further responsibility of context, that is, the logical container of program state. It is this aspect of operation that process is employed in HPX. Furthermore, referring to “parallel processes” in HPX designates the presence of parallelism within the context of a given process, as well as the coarse grained parallelism achieved through concurrency of multiple processes of an executing user job. HPX processes provide a hierarchical name space within the framework of the active global address space and support multiple means of internal state access from external sources.

Parcel The Parcel is a component in HPX that communicates data, invokes an action at a distance, and distributes flow-control through the migration of continuations. Parcels bridge the gap of asynchrony between synchronous domains while maintaining symmetry of semantics between local and global execution. Parcels enable message-driven computation and may be seen as a form of “active messages”. Other important forms of message-driven computation predating active messages include dataflow tokens\(^{43}\), the J-machine’s\(^{44}\) support for remote method instantiation, and at the coarse grained variations of Unix remote procedure calls, among others. This enables work to be moved to the data as well as performing the more common action of bringing data to the work. A parcel can cause actions to occur remotely and asynchronously, among which are the creation of threads at different system nodes or synchronous domains.

Local Control Object

Lightweight Control Object

LCO A local control object (sometimes called a lightweight control object) is a general term for the synchronization mechanisms used in HPX. Any object implementing a certain concept can be seen as an LCO. This concepts encapsulates the ability to be triggered by one or more events which when taking the object into a predefined state will cause a thread to be executed. This could either create a new thread or resume an existing thread.

The LCO is a family of synchronization functions potentially representing many classes of synchronization constructs, each with many possible variations and multiple instances. The LCO is sufficiently general that it can subsume the functionality of conventional synchronization primitives such as spinlocks, mutexes, semaphores, and global barriers. However due to the rich concept an LCO can represent powerful synchronization and control functionality not widely employed, such as dataflow and futures (among others), which open up enormous opportunities for rich diversity of distributed control and operation.

See Using LCOs for more details on how to use LCOs in HPX.

Action An action is a function that can be invoked remotely. In HPX a plain function can be made into an action using a macro. See Applying actions for details on how to use actions in HPX.

Component A component is a C++ object which can be accessed remotely. A component can also contain member functions which can be invoked remotely. These are referred to as component actions. See Writing components for details on how to use components in HPX.

2.4 Examples

The following sections analyze some examples to help you get familiar with the HPX style of programming. We start off with simple examples that utilize basic HPX elements and then begin to expose the reader to the more complex and powerful HPX concepts.

2.4.1 Asynchronous execution with hpx::async: Fibonacci

The Fibonacci sequence is a sequence of numbers starting with 0 and 1 where every subsequent number is the sum of the previous two numbers. In this example, we will use HPX to calculate the value of the n-th element of the Fibonacci sequence. In order to compute this problem in parallel, we will use a facility known as a future.

As shown in the Fig. ?? below, a future encapsulates a delayed computation. It acts as a proxy for a result initially not known, most of the time because the computation of the result has not completed yet. The future synchronizes the access of this value by optionally suspending any HPX-threads requesting the result until the value is available. When a future is created, it spawns a new HPX-thread (either remotely with a parcel or locally by placing it into the thread queue) which, when run, will execute the function associated with the future. The arguments of the function are bound when the future is created.

![Fig. 2.1: Schematic of a future execution.](image)

Once the function has finished executing, a write operation is performed on the future. The write operation marks the future as completed, and optionally stores data returned by the function. When the result of the delayed computation is needed, a read operation is performed on the future. If the future’s function hasn’t completed when a read operation is performed on it, the reader HPX-thread is suspended until the future is ready. The future facility allows HPX to schedule work early in a program so that when the function value is needed it will already be calculated and available. We use this property in our Fibonacci example below to enable its parallel execution.
Setup

The source code for this example can be found here: fibonacci_local.cpp.

To compile this program, go to your HPX build directory (see HPX build system for information on configuring and building HPX) and enter:

```
make examples.quickstart.fibonacci_local
```

To run the program type:

```
./bin/fibonacci_local
```

This should print (time should be approximate):

```
fibonacci(10) == 55
elapsed time: 0.002430 [s]
```

This run used the default settings, which calculate the tenth element of the Fibonacci sequence. To declare which Fibonacci value you want to calculate, use the --n-value option. Additionally you can use the --hpx:threads option to declare how many OS-threads you wish to use when running the program. For instance, running:

```
./bin/fibonacci --n-value 20 --hpx:threads 4
```

Will yield:

```
fibonacci(20) == 6765
elapsed time: 0.062854 [s]
```

Walkthrough

Now that you have compiled and run the code, let’s look at how the code works. Since this code is written in C++, we will begin with the main() function. Here you can see that in HPX, main() is only used to initialize the runtime system. It is important to note that application-specific command line options are defined here. HPX uses Boost.Program Options\(^{45}\) for command line processing. You can see that our programs --n-value option is set by calling the add_options() method on an instance of hpx::program_options::options_description. The default value of the variable is set to 10. This is why when we ran the program for the first time without using the --n-value option the program returned the 10th value of the Fibonacci sequence. The constructor argument of the description is the text that appears when a user uses the --hpx:help option to see what command line options are available. HPX_APPLICATION_STRING is a macro that expands to a string constant containing the name of the HPX application currently being compiled.

In HPX main() is used to initialize the runtime system and pass the command line arguments to the program. If you wish to add command line options to your program you would add them here using the instance of the Boost class options_description, and invoking the public member function .add_options() (see Boost Documentation\(^{46}\) for more details). hpx::init calls hpx_main() after setting up HPX, which is where the logic of our program is encoded.

```
int main(int argc, char* argv[])
{
    // Configure application-specific options
    hpx::program_options::options_description desc_commandline(
        "Usage: " HPX_APPLICATION_STRING " [options]"");
```

---

\(^{45}\) [https://www.boost.org/doc/html/program_options.html](https://www.boost.org/doc/html/program_options.html)

\(^{46}\) [https://www.boost.org/doc/](https://www.boost.org/doc/)
desc_commandline.add_options()("n-value",
    hpx::program_options::value<std::uint64_t>()->default_value(10),
    "n value for the Fibonacci function");

// Initialize and run HPX
hpx::init_params init_args;
init_args.desc_cmdline = desc_commandline;

return hpx::init(argc, argv, init_args);
}

The `hpx::init` function in `main()` starts the runtime system, and invokes `hpx_main()` as the first HPX-thread. Below we can see that the basic program is simple. The command line option `--n-value` is read in, a timer (`hpx::chrono::high_resolution_timer`) is set up to record the time it takes to do the computation, the `fibonacci` function is invoked synchronously, and the answer is printed out.

```cpp
int hpx_main(hpx::program_options::variables_map& vm)
{
    // extract command line argument, i.e. fib(N)
    std::uint64_t n = vm["n-value"].as<std::uint64_t>();

    // Keep track of the time required to execute.
    hpx::chrono::high_resolution_timer t;
    std::uint64_t r = fibonacci(n);

    char const* fmt = "fibonacci({1}) == {2}\n
    elapsed time: {3} [s]\n"
    hpx::util::format_to(std::cout, fmt, n, r, t.elapsed());

    return hpx::finalize();   // Handles HPX shutdown
}
```

The `fibonacci` function itself is synchronous as the work done inside is asynchronous. To understand what is happening we have to look inside the `fibonacci` function:

```cpp
std::uint64_t fibonacci(std::uint64_t n)
{
    if (n < 2)
        return n;

    // Invoking the Fibonacci algorithm twice is inefficient.
    // However, we intentionally demonstrate it this way to create some
    // heavy workload.
    hpx::future<std::uint64_t> n1 = hpx::async(fibonacci, n - 1);
    hpx::future<std::uint64_t> n2 = hpx::async(fibonacci, n - 2);

    return n1.get() + n2.get();  // wait for the Futures to return their values
}
```

This block of code looks similar to regular C++ code. First, if \( n < 2 \), meaning \( n \) is 0 or 1, then we return 0 or 1 (recall the first element of the Fibonacci sequence is 0 and the second is 1). If \( n \) is larger than 1 we spawn two new tasks whose results are contained in \( n1 \) and \( n2 \). This is done using `hpx::async` which
takes as arguments a function (function pointer, object or lambda) and the arguments to the function. Instead of returning a std::uint64_t like fibonacci does, hpx::async returns a future of a std::uint64_t, i.e. hpx::future<std::uint64_t>. Each of these futures represents an asynchronous, recursive call to fibonacci. After we’ve created the futures, we wait for both of them to finish computing, we add them together, and return that value as our result. We get the values from the futures using the get method. The recursive call tree will continue until n is equal to 0 or 1, at which point the value can be returned because it is implicitly known. When this termination condition is reached, the futures can then be added up, producing the n-th value of the Fibonacci sequence.

Note that calling get potentially blocks the calling HPX-thread, and lets other HPX-threads run in the meantime. There are, however, more efficient ways of doing this. examples/quickstart/fibonacci_futures.cpp contains many more variations of locally computing the Fibonacci numbers, where each method makes different tradeoffs in where asynchrony and parallelism is applied. To get started, however, the method above is sufficient and optimizations can be applied once you are more familiar with HPX. The example Dataflow: Interest calculator presents dataflow, which is a way to more efficiently chain together multiple tasks.

2.4.2 Asynchronous execution with hpx::async and actions: Fibonacci

This example extends the previous example by introducing actions: functions that can be run remotely. In this example, however, we will still only run the action locally. The mechanism to execute actions stays the same: hpx::async. Later examples will demonstrate running actions on remote localities (e.g. Remote execution with actions: Hello world).

Setup

The source code for this example can be found here: fibonacci.cpp.

To compile this program, go to your HPX build directory (see HPX build system for information on configuring and building HPX) and enter:

```
make examples.quickstart.fibonacci
```

To run the program type:

```
./bin/fibonacci
```

This should print (time should be approximate):

```
fibonacci(10) == 55
elapsed time: 0.00186288 [s]
```

This run used the default settings, which calculate the tenth element of the Fibonacci sequence. To declare which Fibonacci value you want to calculate, use the --n-value option. Additionally you can use the --hpx:threads option to declare how many OS-threads you wish to use when running the program. For instance, running:

```
./bin/fibonacci --n-value 20 --hpx:threads 4
```

Will yield:

```
fibonacci(20) == 6765
elapsed time: 0.233827 [s]
```
### Walkthrough

The code needed to initialize the HPX runtime is the same as in the previous example:

```cpp
int main(int argc, char* argv[]) {
    // Configure application-specific options
    hpx::program_options::options_description desc_commandline("Usage: " HPX_APPLICATION_STRING " [options]");
    desc_commandline.add_options()
        ("n-value",
         hpx::program_options::value<std::uint64_t>()->default_value(10),
         "n value for the Fibonacci function")
        ;

    // Initialize and run HPX
    hpx::init_params init_args;
    init_args.desc_cmdline = desc_commandline;
    return hpx::init(argc, argv, init_args);
}
```

The `hpx::init` function in `main()` starts the runtime system, and invokes `hpx_main()` as the first HPX-thread. The command line option `--n-value` is read in, a timer (`hpx::chrono::high_resolution_timer`) is set up to record the time it takes to do the computation, the `fibonacci_action` is invoked synchronously, and the answer is printed out.

```cpp
int hpx_main(hpx::program_options::variables_map& vm) {
    // extract command line argument, i.e. fib(N)
    std::uint64_t n = vm["n-value"].as<std::uint64_t>();

    { // Keep track of the time required to execute.
        hpx::chrono::high_resolution_timer t;
        // Wait for fib() to return the value
        fibonacci_action fib;
        std::uint64_t r = fib(hpx::find_here(), n);

        char const* fmt = "fibonacci({1}) == {2}
                             elapsed time: {3} [s]
";
        hpx::util::format_to(std::cout, fmt, n, r, t.elapsed());
    }
    return hpx::finalize(); // Handles HPX shutdown
}
```

Upon a closer look we see that we’ve created a `std::uint64_t` to store the result of invoking our `fibonacci_action fib`. This `action` will launch synchronously (as the work done inside of the `action` will be asynchronous itself) and return the result of the Fibonacci sequence. But wait, what is an `action`? And what is this `fibonacci_action`? For starters, an `action` is a wrapper for a function. By wrapping functions, HPX can send packets of work to different processing units. These vehicles allow users to calculate work now, later, or on certain nodes. The first argument to our `action` is the location where the `action` should be run. In this case, we just want to run the `action` on the machine that we are currently on, so we use `hpx::find_here`. To further understand this we turn to the code to find where `fibonacci_action` was defined:
A plain action is the most basic form of action. Plain actions wrap simple global functions which are not associated with any particular object (we will discuss other types of actions in Components and actions: Accumulator). In this block of code the function fibonacci() is declared. After the declaration, the function is wrapped in an action in the declaration HPX_PLAIN_ACTION. This function takes two arguments: the name of the function that is to be wrapped and the name of the action that you are creating.

This picture should now start making sense. The function fibonacci() is wrapped in an action fibonacci_action, which was run synchronously but created asynchronous work, then returns a std::uint64_t representing the result of the function fibonacci(). Now, let’s look at the function fibonacci():

```cpp
std::uint64_t fibonacci(std::uint64_t n)
{
    if (n < 2)
        return n;

    // We restrict ourselves to execute the Fibonacci function locally.
    hpx::naming::id_type const locality_id = hpx::find_here();

    // Invoking the Fibonacci algorithm twice is inefficient.
    // However, we intentionally demonstrate it this way to create some
    // heavy workload.
    fibonacci_action fib;
    hpx::future<std::uint64_t> n1 =
        hpx::async(fib, locality_id, n - 1);
    hpx::future<std::uint64_t> n2 =
        hpx::async(fib, locality_id, n - 2);

    return n1.get() + n2.get();  // wait for the Futures to return their values
}
```

This block of code is much more straightforward and should look familiar from the previous example. First, if \( n < 2 \), meaning \( n \) is 0 or 1, then we return 0 or 1 (recall the first element of the Fibonacci sequence is 0 and the second is 1). If \( n \) is larger than 1 we spawn two tasks using hpx::async. Each of these futures represents an asynchronous, recursive call to fibonacci. As previously we wait for both futures to finish computing, get the results, add them together, and return that value as our result. The recursive call tree will continue until \( n \) is equal to 0 or 1, at which point the value can be returned because it is implicitly known. When this termination condition is reached, the futures can then be added up, producing the \( n \)-th value of the Fibonacci sequence.
2.4.3 Remote execution with actions: Hello world

This program will print out a hello world message on every OS-thread on every locality. The output will look something like this:

```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 1 on locality 1
hello world from OS-thread 0 on locality 0
hello world from OS-thread 0 on locality 1
```

Setup

The source code for this example can be found here: `hello_world_distributed.cpp`.

To compile this program, go to your HPX build directory (see HPX build system for information on configuring and building HPX) and enter:

```
make examples.quickstart.hello_world_distributed
```

To run the program type:

```
./bin/hello_world_distributed
```

This should print:

```
hello world from OS-thread 0 on locality 0
```

To use more OS-threads use the command line option `--hpx:threads` and type the number of threads that you wish to use. For example, typing:

```
./bin/hello_world_distributed --hpx:threads 2
```

will yield:

```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 0
```

Notice how the ordering of the two print statements will change with subsequent runs. To run this program on multiple localities please see the section How to use HPX applications with PBS.

Walkthrough

Now that you have compiled and run the code, let’s look at how the code works, beginning with `main()`:

```cpp
// Here is the main entry point. By using the include 'hpx/hpx_main.hpp' HPX
// will invoke the plain old C-main() as its first HPX thread.
int main()
{
    // Get a list of all available localities.
    std::vector<hpx::naming::id_type> localities = hpx::find_all_localities();

    // Reserve storage space for futures, one for each locality.
    std::vector<hpx::lcos::future<void>> futures;
    futures.reserve(localities.size());
```

(continues on next page)
In this excerpt of the code we again see the use of futures. This time the futures are stored in a vector so that they can easily be accessed. `hpx::wait_all` is a family of functions that wait on for an `std::vector<future>` of futures to become ready. In this piece of code, we are using the synchronous version of `hpx::wait_all`, which takes one argument (the `std::vector<future>` of futures to wait on). This function will not return until all the futures in the vector have been executed.

In *Asynchronous execution with hpx::async and actions: Fibonacci* we used `hpx::find_here` to specify the target of our actions. Here, we instead use `hpx::find_all_localities`, which returns an `std::vector<id_type>` containing the identifiers of all the machines in the system, including the one that we are on.

As in *Asynchronous execution with hpx::async and actions: Fibonacci* our futures are set using `hpx::async<action_type>(node)`.

The `hello_world_foreman_action` is declared here:

```cpp
// Define the boilerplate code necessary for the function 'hello_world_foreman'
// to be invoked as an HPX action.
HPX.PLAIN_ACTION(hello_world_foreman, hello_world_foreman_action);
```

Another way of thinking about this wrapping technique is as follows: functions (the work to be done) are wrapped in actions, and actions can be executed locally or remotely (e.g. on another machine participating in the computation).

Now it is time to look at the `hello_world_foreman()` function which was wrapped in the action above:

```cpp
void hello_world_foreman()
{
    // Get the number of worker OS-threads in use by this locality.
    std::size_t const os_threads = hpx::get_os_thread_count();

    // Populate a set with the OS-thread numbers of all OS-threads on this
    // locality. When the hello world message has been printed on a particular
    // OS-thread, we will remove it from the set.
    std::set<std::size_t> attendance;
    for (std::size_t os_thread = 0; os_thread < os_threads; ++os_thread)
        attendance.insert(os_thread);

    // As long as there are still elements in the set, we must keep scheduling
    // HPX-threads. Because HPX features work-stealing task schedulers, we have
    // no way of enforcing which worker OS-thread will actually execute
    // each HPX-thread.
    while (!attendance.empty())
    {
        // Each iteration, we create a task for each element in the set of
```
// OS-threads that have not said "Hello world". Each of these tasks
// is encapsulated in a future.
std::vector<hpx::lcos::future<std::size_t>> futures;
futures.reserve(attendance.size());

for (std::size_t worker : attendance)
{
    // Asynchronously start a new task. The task is encapsulated in a
    // future, which we can query to determine if the task has
    // completed. We give the task a hint to run on a particular worker
    // thread, but no guarantees are given by the scheduler that the
    // task will actually run on that worker thread.
hpx::execution::parallel_executor exec(
    hpx::threads::thread_schedule_hint(
        hpx::threads::thread_schedule_hint_mode::thread,
        static_cast<std::int16_t>(worker)));
        futures.push_back(hpx::async(exec, hello_world_worker, worker));

    // Wait for all of the futures to finish. The callback version of the
    // hpx::lcos::wait_each function takes two arguments: a vector of futures,
    // and a binary callback. The callback takes two arguments; the first
    // is the index of the future in the vector, and the second is the
    // return value of the future. hpx::lcos::wait_each doesn't return until
    // all the futures in the vector have returned.
hpx::lcos::local::spinlock mtx;
hpx::lcos::wait_each(hpx::unwrapping([&](std::size_t t) {
        if (std::size_t(-1) != t)
        {
            std::lock_guard<hpx::lcos::local::spinlock> lk(mtx);
            attendance.erase(t);
        }
    }), futures);
}

Now, before we discuss hello_world_foreman(), let's talk about the hpx::wait_each function. The version of hpx::lcos::wait_each invokes a callback function provided by the user, supplying the callback function with the result of the future.

In hello_world_foreman(), an std::set<> called attendance keeps track of which OS-threads have printed out the hello world message. When the OS-thread prints out the statement, the future is marked as ready, and hpx::lcos::wait_each in hello_world_foreman(). If it is not executing on the correct OS-thread, it returns a value of -1, which causes hello_world_foreman() to leave the OS-thread id in attendance.

std::size_t hello_world_worker(std::size_t desired)
{
    // Returns the OS-thread number of the worker that is running this
    // HPX-thread.
    std::size_t current = hpx::get_worker_thread_num();
    if (current == desired)
    {
        // The HPX-thread has been run on the desired OS-thread.
        char const* msg = "hello world from OS-thread {1} on locality {2}\n";
    }
}

2.4. Examples
Because HPX features work stealing task schedulers, there is no way to guarantee that an action will be scheduled on a particular OS-thread. This is why we must use a guess-and-check approach.

2.4.4 Components and actions: Accumulator

The accumulator example demonstrates the use of components. Components are C++ classes that expose methods as a type of HPX action. These actions are called component actions.

Components are globally named, meaning that a component action can be called remotely (e.g., from another machine). There are two accumulator examples in HPX.

In the Asynchronous execution with hpx::async and actions: Fibonacci and the Remote execution with actions: Hello world, we introduced plain actions, which wrapped global functions. The target of a plain action is an identifier which refers to a particular machine involved in the computation. For plain actions, the target is the machine where the action will be executed.

Component actions, however, do not target machines. Instead, they target component instances. The instance may live on the machine that we’ve invoked the component action from, or it may live on another machine.

The component in this example exposes three different functions:

- reset() - Resets the accumulator value to 0.
- add(arg) - Adds arg to the accumulators value.
- query() - Queries the value of the accumulator.

This example creates an instance of the accumulator, and then allows the user to enter commands at a prompt, which subsequently invoke actions on the accumulator instance.

Setup

The source code for this example can be found here: accumulator_client.cpp.

To compile this program, go to your HPX build directory (see HPX build system for information on configuring and building HPX) and enter:

```
make examples.accumulators.accumulator
```

To run the program type:

```
./bin/accumulator_client
```

Once the program starts running, it will print the following prompt and then wait for input. An example session is given below:

```
hpx::util::format_to(hpx::cout, msg, desired, hpx::get_locality_id())
  << std::flush;

  return desired;
}
// This HPX-thread has been run by the wrong OS-thread, make the foreman
// try again by rescheduling it.
  return std::size_t(-1);
```
commands: reset, add [amount], query, help, quit
> add 5
> add 10
> query
15
> add 2
> query
17
> reset
> add 1
> query
1
> quit

Walkthrough

Now, let’s take a look at the source code of the accumulator example. This example consists of two parts: an *HPX* component library (a library that exposes an *HPX* component) and a client application which uses the library. This walkthrough will cover the *HPX* component library. The code for the client application can be found here: accumulator_client.cpp.

An *HPX* component is represented by two C++ classes:

- **A server class** - The implementation of the component’s functionality.
- **A client class** - A high-level interface that acts as a proxy for an instance of the component.

Typically, these two classes both have the same name, but the server class usually lives in different sub-namespaces (server). For example, the full names of the two classes in accumulator are:

- examples::server::accumulator (server class)
- examples::accumulator (client class)

**The server class**

The following code is from: accumulator.hpp.

All *HPX* component server classes must inherit publicly from the *HPX* component base class: hpx::components::component_base

The accumulator component inherits from hpx::components::locking_hook. This allows the runtime system to ensure that all action invocations are serialized. That means that the system ensures that no two actions are invoked at the same time on a given component instance. This makes the component thread safe and no additional locking has to be implemented by the user. Moreover, an accumulator component is a component because it also inherits from hpx::components::component_base (the template argument passed to locking_hook is used as its base class). The following snippet shows the corresponding code:

```cpp
class accumulator
  : public hpx::components::locking_hook<
    hpx::components::component_base<accumulator> >
```

Our accumulator class will need a data member to store its value in, so let’s declare a data member:

```cpp
argument_type value_;
```

The constructor for this class simply initializes value_ to 0:
accumulator() : value_(0) {}
The client class

The following code is from `accumulator.hpp`.

The client class is the primary interface to a component instance. Client classes are used to create components:

```cpp
// Create a component on this locality.
examples::accumulator c = hpx::new_<examples::accumulator>(hpx::find_here());
```

and to invoke component actions:

```cpp
c.add(hpx::launch::apply, 4);
```

Clients, like servers, need to inherit from a base class, this time, `hpx::components::client_base`:

```cpp
class accumulator
  : public hpx::components::client_base<
    accumulator, server::accumulator
  >
```

For readability, we typedef the base class like so:

```cpp
typedef hpx::components::client_base<
  accumulator, server::accumulator
> base_type;
```

Here are examples of how to expose actions through a client class:

There are a few different ways of invoking actions:

- **Non-blocking:** For actions that don’t have return types, or when we do not care about the result of an action, we can invoke the action using fire-and-forget semantics. This means that once we have asked HPX to compute the action, we forget about it completely and continue with our computation. We use `hpx::apply` to invoke an action in a non-blocking fashion.

  ```cpp
  void reset(hpx::launch::apply_policy)
  {
    HPX_ASSERT(this->get_id());

    typedef server::accumulator::reset_action action_type;
    hpx::apply<typename action_type>(this->get_id());
  }
  ```

- **Asynchronous:** Futures, as demonstrated in *Asynchronous execution with hpx::async: Fibonacci*, *Asynchronous execution with hpx::async and actions: Fibonacci*, and the *Remote execution with actions: Hello world*, enable asynchronous action invocation. Here’s an example from the accumulator client class:

  ```cpp
  hpx::future<argument_type> query(hpx::launch::async_policy)
  {
    HPX_ASSERT(this->get_id());

    typedef server::accumulator::query_action action_type;
    return hpx::async<typename action_type>(hpx::launch::async, this->get_id());
  }
  ```

- **Synchronous:** To invoke an action in a fully synchronous manner, we can simply call `hpx::async() .get()` (i.e., create a future and immediately wait on it to be ready). Here’s an example from the accumulator client class:

```cpp
```
```cpp
void add(argument_type arg)
{
    HPX_ASSERT(this->get_id());

typedef server::accumulator::add_action action_type;
    action_type() (this->get_id(), arg);
}
```

Note that `this->get_id()` references a data member of the `hpx::components::client_base` base class which identifies the server accumulator instance.

`hpx::naming::id_type` is a type which represents a global identifier in **HPX**. This type specifies the target of an action. This is the type that is returned by `hpx::find_here` in which case it represents the **locality** the code is running on.

### 2.4.5 Dataflow: Interest calculator

**HPX** provides its users with several different tools to simply express parallel concepts. One of these tools is a **local control object (LCO)** called dataflow. An LCO is a type of component that can spawn a new thread when triggered. They are also distinguished from other components by a standard interface that allow users to understand and use them easily. A Dataflow, being an LCO, is triggered when the values it depends on become available. For instance, if you have a calculation `X` that depends on the results of three other calculations, you could set up a dataflow that would begin the calculation `X` as soon as the other three calculations have returned their values. Dataflows are set up to depend on other dataflows. It is this property that makes dataflow a powerful parallelization tool. If you understand the dependencies of your calculation, you can devise a simple algorithm that sets up a dependency tree to be executed. In this example, we calculate compound interest. To calculate compound interest, one must calculate the interest made in each compound period, and then add that interest back to the principal before calculating the interest made in the next period. A practical person would, of course, use the formula for compound interest:

\[
F = P(1 + i)^n
\]

where `F` is the future value, `P` is the principal value, `i` is the interest rate, and `n` is the number of compound periods.

However, for the sake of this example, we have chosen to manually calculate the future value by iterating:

\[
I = Pi
\]

and

\[
P = P + I
\]

**Setup**

The source code for this example can be found here: `interest_calculator.cpp`.

To compile this program, go to your **HPX** build directory (see **HPX build system** for information on configuring and building **HPX**) and enter:

```
make examples.quickstart.interest_calculator
```

To run the program type:

```
./bin/interest_calculator --principal 100 --rate 5 --cp 6 --time 36
```

This should print:
Walkthrough

Let us begin with main. Here we can see that we again are using Boost.Program Options to set our command line variables (see Asynchronous execution with hpx::async and actions: Fibonacci for more details). These options set the principal, rate, compound period, and time. It is important to note that the units of time for \( cp \) and \( time \) must be the same.

```cpp
int main(int argc, char ** argv)
{
    options_description cmdline("Usage: " HPX_APPLICATION_STRING " \[options]\));
    cmdline.add_options()
        ("principal", value<double>()->default_value(1000), "The principal \[$\]"
        ("rate", value<double>()->default_value(7), "The interest rate [%]"
        ("cp", value<int>()->default_value(12), "The compound period [months]"
        ("time", value<int>()->default_value(12*30), "The time money is invested [months]"
   );
    hpx::init_params init_args;
    init_args.desc_cmdline = cmdline;
    return hpx::init(argc, argv, init_args);
}
```

Next we look at hpx_main.

```cpp
int hpx_main(variables_map & vm)
{
    using hpx::dataflow;
    using hpx::make_ready_future;
    using hpx::shared_future;
    using hpx::unwrapping;
    hpx::naming::id_type here = hpx::find_here();

    double init_principal=vm["principal"].as<double>(); //Initial principal
    double init_rate=vm["rate"].as<double>(); //Interest rate
    int cp=vm["cp"].as<int>(); //Length of a compound period
    int t=vm["time"].as<int>(); //Length of time money is invested
    init_rate/=100; //Rate is a % and must be converted
    t/=cp; //Determine how many times to iterate interest calculation:
        //How many full compound periods can fit in the time invested

    // In non-dataflow terms the implemented algorithm would look like:
    //
    // int t = 5; // number of time periods to use
    // double principal = init_principal;
    // double rate = init_rate;
    //
    // for (int i = 0; i < t; ++i)
    // { (continues on next page)
```

2.4. Examples
Here we find our command line variables read in, the rate is converted from a percent to a decimal, the number of calculation iterations is determined, and then our shared futures are set up. Notice that we first place our principal and rate into shared futures by passing the variables `init_principal` and `init_rate` using `hpx::make_ready_future`. In this way `hpx::shared_future<double> principal` and `rate` will be initialized to `init_principal` and `init_rate` when `hpx::make_ready_future<double>` returns a future containing those initial values. These shared futures then enter the for loop and are passed to `interest`. Next `principal` and `interest` are passed to the reassignment of `principal` using a `hpx::dataflow`. A dataflow will first wait for its arguments to be ready before launching any callbacks, so `add` in this case will not begin until both `principal` and `interest` are ready. This loop continues for each compound period that must be calculated. To see how `interest` and `principal` are calculated in the loop, let us look at `calc_action` and `add_action`:

```cpp
// Calculate interest for one period
double calc(double principal, double rate)
{
    return principal * rate;
}

// Add the amount made to the principal
double add(double principal, double interest)
{
    return principal + interest;
}
```

After the shared future dependencies have been defined in `hpx_main`, we see the following statement:

```cpp
double result = principal.get();
```
This statement calls `hpx::future::get` on the shared future principal which had its value calculated by our for loop. The program will wait here until the entire dataflow tree has been calculated and the value assigned to result. The program then prints out the final value of the investment and the amount of interest made by subtracting the final value of the investment from the initial value of the investment.

### 2.4.6 Local to remote: 1D stencil

When developers write code they typically begin with a simple serial code and build upon it until all of the required functionality is present. The following set of examples were developed to demonstrate this iterative process of evolving a simple serial program to an efficient, fully-distributed HPX application. For this demonstration, we implemented a 1D heat distribution problem. This calculation simulates the diffusion of heat across a ring from an initialized state to some user-defined point in the future. It does this by breaking each portion of the ring into discrete segments and using the current segment’s temperature and the temperature of the surrounding segments to calculate the temperature of the current segment in the next timestep as shown by Fig. ?? below.

![Fig. 2.2: Heat diffusion example program flow.](image)

We parallelize this code over the following eight examples:

- Example 1
- Example 2
- Example 3
- Example 4
- Example 5
- Example 6
- Example 7
- Example 8

The first example is straight serial code. In this code we instantiate a vector `U` that contains two vectors of doubles as seen in the structure `stepper`.

```cpp
struct stepper
{
    // Our partition type
    typedef double partition;

    // Our data for one time step
    typedef std::vector<partition> space;

    // Our operator
```

(continues on next page)
Each element in the vector of doubles represents a single grid point. To calculate the change in heat distribution, the temperature of each grid point, along with its neighbors, is passed to the function `heat`. In order to improve readability, references named `current` and `next` are created which, depending on the time step, point to the first and second vector of doubles. The first vector of doubles is initialized with a simple heat ramp. After calling the heat function with the data in the `current` vector, the results are placed into the `next` vector.

In example 2 we employ a technique called futurization. Futurization is a method by which we can easily transform a code that is serially executed into a code that creates asynchronous threads. In the simplest case this involves replacing a variable with a future to a variable, a function with a future to a function, and adding a `.get()` at the point where a value is actually needed. The code below shows how this technique was applied to the `struct stepper`.

```cpp
struct stepper
{
    // Our partition type
    typedef hpx::shared_future<double> partition;

    // Our data for one time step
    typedef std::vector<partition> space;

    // Our operator
    (continues on next page)
};
```
static double heat(double left, double middle, double right)
{
    return middle + (k*dt/(dx*dx)) * (left - 2*middle + right);
}

// do all the work on 'nx' data points for 'nt' time steps
hpx::future<space> do_work(std::size_t nx, std::size_t nt)
{
    using hpx::dataflow;
    using hpx::unwrapping;
    // U[t][i] is the state of position i at time t.
    std::vector<space> U(2);
    for (space& s : U)
        s.resize(nx);
    // Initial conditions: f(0, i) = i
    for (std::size_t i = 0; i != nx; ++i)
        U[0][i] = hpx::make_ready_future(double(i));
    auto Op = unwrapping(&stepper::heat);
    // Actual time step loop
    for (std::size_t t = 0; t != nt; ++t)
    {
        space const& current = U[t % 2];
        space& next = U[(t + 1) % 2];
        // WHEN U[t][i-1], U[t][i], and U[t][i+1] have been computed, THEN we
        // can compute U[t+1][i]
        for (std::size_t i = 0; i != nx; ++i)
        {
            next[i] = dataflow(
                hpx::launch::async, Op,
                current[idx(i, -1, nx)], current[i], current[idx(i, +1, nx)]
            );
        }
    }
    // Now the asynchronous computation is running; the above for-loop does not
    // wait on anything. There is no implicit waiting at the end of each timestep;
    // the computation of each U[t][i] will begin as soon as its dependencies
    // are ready and hardware is available.
    // Return the solution at time-step 'nt'.
    return hpx::when_all(U[nt % 2]);
}
In example 6, we begin to distribute the partition data on different nodes. This is accomplished in the target for the functions to run on.

heat_part_data

dataflow (found in heat_part have arrived. Therefore, it should come as no surprise that we synchronize this operation with another instance of which, amongst other things, calls heat

unwrapping, which underneath calls .get() on each of the futures so that the function heat will be passed doubles and not futures to doubles.

By setting up the algorithm this way, the program will be able to execute as quickly as the dependencies of each future are met. Unfortunately, this example runs terribly slow. This increase in execution time is caused by the overheads needed to create a future for each data point. Because the work done within each call to heat is very small, the overhead of creating and scheduling each of the three futures is greater than that of the actual useful work! In order to amortize the overheads of our synchronization techniques, we need to be able to control the amount of work that will be done with each future. We call this amount of work per overhead grain size.

In example 3, we return to our serial code to figure out how to control the grain size of our program. The strategy that we employ is to create “partitions” of data points. The user can define how many partitions are created and how many data points are contained in each partition. This is accomplished by creating the struct partition, which contains a member object data_, a vector of doubles that holds the data points assigned to a particular instance of partition.

In example 4, we take advantage of the partition setup by redefining space to be a vector of shared_futures with each future representing a partition. In this manner, each future represents several data points. Because the user can define how many data points are in each partition, and, therefore, how many data points are represented by one future, a user can control the grain size of the simulation. The rest of the code is then futurized in the same manner as example 2. It should be noted how strikingly similar example 4 is to example 2.

Example 4 finally shows good results. This code scales equivalently to the OpenMP version. While these results are promising, there are more opportunities to improve the application’s scalability. Currently, this code only runs on one locality, but to get the full benefit of HPX, we need to be able to distribute the work to other machines in a cluster. We begin to add this functionality in example 5.

In order to run on a distributed system, a large amount of boilerplate code must be added. Fortunately, HPX provides us with the concept of a component, which saves us from having to write quite as much code. A component is an object that can be remotely accessed using its global address. Components are made of two parts: a server and a client class. While the client class is not required, abstracting the server behind a client allows us to ensure type safety instead of having to pass around pointers to global objects. Example 5 renames example 4’s struct partition to partition_data and adds serialization support. Next, we add the server side representation of the data in the structure partition_server. Partition_server inherits from hpx::components::component_base, which contains a server-side component boilerplate. The boilerplate code allows a component’s public members to be accessible anywhere on the machine via its Global Identifier (GID). To encapsulate the component, we create a client side helper class. This object allows us to create new instances of our component and access its members without having to know its GID. In addition, we are using the client class to assist us with managing our asynchrony. For example, our client class partition’s member function get_data() returns a future to partition_data get_data(). This struct inherits its boilerplate code from hpx::components::client_base.

In the structure stepper, we have also had to make some changes to accommodate a distributed environment. In order to get the data from a particular neighboring partition, which could be remote, we must retrieve the data from all of the neighboring partitions. These retrievals are asynchronous and the function heat_part_data, which, amongst other things, calls heat, should not be called unless the data from the neighboring partitions have arrived. Therefore, it should come as no surprise that we synchronize this operation with another instance of dataflow (found in heat_part). This dataflow receives futures to the data in the current and surrounding partitions by calling get_data() on each respective partition. When these futures are ready, dataflow passes them to the unwrapping function, which extracts the shared_array of doubles and passes them to the lambda. The lambda calls heat_part_data on the locality, which the middle partition is on.

Although this example could run distributed, it only runs on one locality, as it always uses hpx::find_here() as the target for the functions to run on.

In example 6, we begin to distribute the partition data on different nodes. This is accomplished in
stepper::do_work() by passing the GID of the locality where we wish to create the partition to the partition constructor.

```cpp
for (std::size_t i = 0; i != np; ++i)
U[0][i] = partition(localities[locidx(i, np, nl)], nx, double(i));
```

We distribute the partitions evenly based on the number of localities used, which is described in the function locidx. Because some of the data needed to update the partition in heat_part could now be on a new locality, we must devise a way of moving data to the locality of the middle partition. We accomplished this by adding a switch in the function get_data() that returns the end element of the buffer data if it is from the left partition or the first element of the buffer if the data is from the right partition. In this way only the necessary elements, not the whole buffer, are exchanged between nodes. The reader should be reminded that this exchange of end elements occurs in the function get_data() and, therefore, is executed asynchronously.

Now that we have the code running in distributed, it is time to make some optimizations. The function heat_part spends most of its time on two tasks: retrieving remote data and working on the data in the middle partition. Because we know that the data for the middle partition is local, we can overlap the work on the middle partition with that of the possibly remote call of get_data(). This algorithmic change, which was implemented in example 7, can be seen below:

```cpp
// The partitioned operator, it invokes the heat operator above on all elements // of a partition.
static partition heat_part(partition const& left,
    partition const& middle, partition const& right)
{
    using hpx::dataflow;
    using hpx::unwrapping;

    hpx::shared_future<partition_data> middle_data =
    middle.get_data(partition_server::middle_partition);

    hpx::future<partition_data> next_middle = middle_data.then(
        unwrapping{
            [middle](partition_data const& m) -> partition_data
            {
                HPX_UNUSED(middle);
                // All local operations are performed once the middle data of // the previous time step becomes available.
                std::size_t size = m.size();
                partition_data next(size);
                for (std::size_t i = 1; i != size-1; ++i)
                    next[i] = heat(m[i-1], m[i], m[i+1]);
                return next;
            }
        });

    return dataflow{
        hpx::launch::async,
        unwrapping{
            [left, middle, right](partition_data next, partition_data const& l,
                partition_data const& m, partition_data const& r) -> partition
            {
                HPX_UNUSED(left);
                HPX_UNUSED(right);
        ```

(continues on next page)
Example 8 completes the futurization process and utilizes the full potential of HPX by distributing the program flow to multiple localities, usually defined as nodes in a cluster. It accomplishes this task by running an instance of HPX main on each locality. In order to coordinate the execution of the program, the struct stepper is wrapped into a component. In this way, each locality contains an instance of stepper that executes its own instance of the function do_work(). This scheme does create an interesting synchronization problem that must be solved. When the program flow was being coordinated on the head node, the GID of each component was known. However, when we distribute the program flow, each partition has no notion of the GID of its neighbor if the next partition is on another locality. In order to make the GIDs of neighboring partitions visible to each other, we created two buffers to store the GIDs of the remote neighboring partitions on the left and right respectively. These buffers are filled by sending the GID of newly created edge partitions to the right and left buffers of the neighboring localities.

In order to finish the simulation, the solution vectors named result are then gathered together on locality 0 and added into a vector of spaces overall_result using the HPX functions gather_id and gather_here.

Example 8 completes this example series, which takes the serial code of example 1 and incrementally morphs it into a fully distributed parallel code. This evolution was guided by the simple principles of futurization, the knowledge of grainsize, and utilization of components. Applying these techniques easily facilitates the scalable parallelization of most applications.

## 2.5 Manual

The manual is your comprehensive guide to HPX. It contains detailed information on how to build and use HPX in different scenarios.

### 2.5.1 Getting HPX

There are HPX packages available for a few Linux distributions. The easiest way to get started with HPX is to use those packages. We keep an up-to-date list with instructions on the HPX Downloads page. If you use one of the available packages you can skip the next section, HPX build system, but we still recommend that you look through it as it contains useful information on how you can customize HPX at compile-time.

If there isn’t a package available for your platform you should either clone our repository:

47 https://hpx.stellar-group.org/downloads/
or download a package with the source files from [HPX Downloads](https://hpx.stellar-group.org/downloads/).

### 2.5.2 HPX build system

The build system for HPX is based on [CMake](https://www.cmake.org). CMake is a cross-platform build-generator tool. CMake does not build the project, it generates the files needed by your build tool (GNU make, Visual Studio, etc.) for building HPX.

This section gives an introduction on how to use our build system to build HPX and how to use HPX in your own projects.

#### CMake basics

CMake is a cross-platform build-generator tool. CMake does not build the project, it generates the files needed by your build tool (gnu make, visual studio, etc.) for building HPX.

In general, the HPX CMake scripts try to adhere to the general CMake policies on how to write CMake-based projects.

#### Basic CMake usage

This section explains basic aspects of CMake, specifically options needed for day-to-day usage.

CMake comes with extensive documentation in the form of html files and on the CMake executable itself. Execute `cmake --help` for further help options.

CMake needs to know which build tool it will generate files for (GNU make, Visual Studio, Xcode, etc.). If not specified on the command line, it will try to guess the build tool based on you environment. Once it has identified the build tool, CMake uses the corresponding generator to create files for your build tool. You can explicitly specify the generator with the command line option `-G "Name of the generator"`. To see the available generators on your platform, execute:

```
  cmake --help
```

This will list the generator names at the end of the help text. Generator names are case-sensitive. Example:

```
  cmake -G "Visual Studio 16 2019" path/to/hpx
```

For a given development platform there can be more than one adequate generator. If you use Visual Studio "NMake Makefiles" is a generator you can use for building with NMake. By default, CMake chooses the more specific generator supported by your development environment. If you want an alternative generator, you must tell this to CMake with the `-G` option.

#### Quick start

Here, you will use the command-line, non-interactive CMake interface.

1. Download and install CMake here: [CMake Downloads](https://www.cmake.org/cmake/resources/software.html). Version 3.17 is the minimum required version for HPX.

2. Open a shell. Your development tools must be reachable from this shell through the `PATH` environment variable.

---

49 [https://www.cmake.org](https://www.cmake.org)
50 [https://www.cmake.org/cmake/resources/software.html](https://www.cmake.org/cmake/resources/software.html)
3. Create a directory for containing the build. Building HPX on the source directory is not supported. cd to this directory:

```bash
mkdir mybuilddir
cd mybuilddir
```

4. Execute this command on the shell replacing `path/to/hpx` with the path to the root of your HPX source tree:

```bash
cmake path/to/hpx
```

CMake will detect your development environment, perform a series of tests and will generate the files required for building HPX. CMake will use default values for all build parameters. See the CMake variables used to configure HPX section for fine-tuning your build.

This can fail if CMake can’t detect your toolset, or if it thinks that the environment is not sane enough. In this case make sure that the toolset that you intend to use is the only one reachable from the shell and that the shell itself is the correct one for you development environment. CMake will refuse to build MinGW makefiles if you have a POSIX shell reachable through the PATH environment variable, for instance. You can force CMake to use various compilers and tools. Please visit CMake Useful Variables for a detailed overview of specific CMake variables.

**Options and variables**

Variables customize how the build will be generated. Options are boolean variables, with possible values ON/OFF. Options and variables are defined on the CMake command line like this:

```bash
cmake -DVARIABLE=value path/to/hpx
```

You can set a variable after the initial CMake invocation for changing its value. You can also undefine a variable:

```bash
cmake -UVARIABLE path/to/hpx
```

Variables are stored on the CMake cache. This is a file named `CMakeCache.txt` on the root of the build directory. Do not hand-edit it.

Variables are listed here appending its type after a colon. You should write the variable and the type on the CMake command line:

```bash
cmake -DVARIABLE:TYPE=value path/to/llvm/source
```

CMake supports the following variable types: BOOL (options), STRING (arbitrary string), PATH (directory name), FILEPATH (file name).

**Prerequisites**

**Supported platforms**

At this time, HPX supports the following platforms. Other platforms may work, but we do not test HPX with other platforms, so please be warned.

---

Software and libraries

In the simplest case, HPX depends on Boost\(^\text{52}\) and Portable Hardware Locality (HWLOC)\(^\text{53}\). So, before you read further, please make sure you have a recent version of Boost\(^\text{54}\) installed on your target machine. HPX currently requires at least Boost V1.66.0 to work properly. It may build and run with older versions, but we do not test HPX with those versions, so please be warned.

The installation of Boost is described in detail in Boost’s Getting Started\(^\text{55}\) document. However, if you’ve never used the Boost libraries (or even if you have), here’s a quick primer: Installing Boost.

It is often possible to download the Boost libraries using the package manager of your distribution. Please refer to the corresponding documentation for your system for more information.

In addition, we require a recent version of hwloc in order to support thread pinning and NUMA awareness. See Installing Hwloc for instructions on building Portable Hardware Locality (HWLOC).

HPX is written in 99.99% Standard C++ (the remaining 0.01% is platform specific assembly code). As such, HPX is compilable with almost any standards compliant C++ compiler. A compiler supporting the C++11 Standard is highly recommended. The code base takes advantage of C++11 language features when available (move semantics, rvalue references, magic statics, etc.). This may speed up the execution of your code significantly. We currently support the following C++ compilers: GCC, MSVC, ICPC and clang. For the status of your favorite compiler with HPX visit HPX Buildbot Website\(^\text{56}\).

Table 2.2: Software prerequisites for HPX on Linux systems.

<td>1.5</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** You need to build the following Boost libraries for HPX: Boost.Filesystem, Boost.ProgramOptions, and Boost.System. The following are not needed by default, but are required in certain configurations: Boost.Chrono, Boost.DateTime, Boost.Log, Boost.LogSetup, Boost.Regex, and Boost.Thread.

Depending on the options you chose while building and installing HPX, you will find that HPX may depend on several other libraries such as those listed below.

**Note:** In order to use a high speed parcelport, we currently recommend configuring HPX to use MPI so that MPI can be used for communication between different localities. Please set the CMake variable `MPI_CXX_COMPILER` to your MPI C++ compiler wrapper if not detected automatically.

Table 2.4: Highly recommended optional software prerequisites for HPX on Linux systems

<table>
<thead>
<tr>
<th>Name</th>
<th>Minimum version</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>google-perftools66</td>
<td>1.7.1</td>
<td>Used as a replacement for the system allocator, and for allocation diagnostics.</td>
</tr>
<tr>
<td>libunwind67</td>
<td>0.97</td>
<td>Dependency of google-perftools on x86-64, used for stack unwinding.</td>
</tr>
<tr>
<td>Open MPI68</td>
<td>1.8.0</td>
<td>Can be used as a highspeed communication library backend for the parcelport.</td>
</tr>
</tbody>
</table>

**Note:** When using OpenMPI please note that Ubuntu (notably 18.04 LTS) and older Debian ship an OpenMPI 2.x built with `--enable-heterogeneous` which may cause communication failures at runtime and should not be used.

<th>Minimum version</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hierarchical Data Format V5 (HDF5)&lt;sup&gt;72&lt;/sup&gt;</td>
<td>1.6.7</td>
<td>Used for data I/O in some example applications. See important note below.</td>
</tr>
</tbody>
</table>

**Important:** The C++ HDF5 libraries must be compiled with enabled thread safety support. This has to be explicitly specified while configuring the HDF5 libraries as it is not the default. Additionally, you must set the following environment variables before configuring the HDF5 libraries (this part only needs to be done on Linux):

```bash
export CFLAGS='-D__H5Datexit=""'
export CPPFLAGS='-D__H5Datexit=""'
```

**Documentation**

To build the *HPX* documentation, you need recent versions of the following packages:

- python3
- sphinx (Python package)
- sphinx_rtd_theme (Python package)
- breathe 4.16.0 (Python package)
- doxygen

If the Python<sup>73</sup> dependencies are not available through your system package manager, you can install them using the Python package manager pip:

```bash
pip install --user sphinx sphinx_rtd_theme breathe
```

You may need to set the following CMake variables to make sure CMake can find the required dependencies.

**DOXYGEN_ROOT**: PATH

Specifies where to look for the installation of the Doxygen<sup>74</sup> tool.

<sup>74</sup> [https://www.doxygen.org](https://www.doxygen.org)
Installing Boost

Important: When building Boost using gcc, please note that it is required to specify a `cxxflags=-std=c++14` command line argument to `b2` (bjam).

Important: On Windows, depending on the installed versions of Visual Studio, you might also want to pass the correct toolset to the `b2` command depending on which version of the IDE you want to use. In addition, passing `address-model=64` is highly recommended. It might also be necessary to add command line argument `--build-type=complete` to the `b2` command on the Windows platform.

The easiest way to create a working Boost installation is to compile Boost from sources yourself. This is particularly important as many high performance resources, even if they have Boost installed, usually only provide you with an older version of Boost. We suggest you download the most recent release of the Boost libraries from here: Boost Downloads. Unpack the downloaded archive into a directory of your choosing. We will refer to this directory as `$BOOST`.

Building and installing the Boost binaries is simple. Regardless of what platform you are on, the basic instructions are as follows (with possible additional platform-dependent command line arguments):

```
cd $BOOST
bootstrap --prefix=<where to install boost>
./b2 -j<N>
./b2 install
```

where: `<where to install boost>` is the directory the built binaries will be installed to, and `<N>` is the number of cores to use to build the Boost binaries.

After the above sequence of commands has been executed (this may take a while!), you will need to specify the directory where Boost was installed as `BOOST_ROOT` (<where to install boost>) while executing CMake for HPX as explained in detail in the sections *How to install HPX on Unix variants* and *How to install HPX on Windows*.

Installing Hwloc

Note: These instructions are for everything except Windows. On Windows there is no need to build hwloc. Instead, download the latest release, extract the files, and set `HWLOC_ROOT` during CMake configuration to the directory in which you extracted the files.

We suggest you download the most recent release of hwloc from here: Hwloc Downloads. Unpack the downloaded archive into a directory of your choosing. We will refer to this directory as `$HWLOC`.

---

75 http://www.sphinx-doc.org
76 https://breathe.readthedocs.io/en/latest
77 https://www.boost.org/users/download/
78 https://www.open-mpi.org/software/hwloc/v1.11
To build hwloc run:

```bash
cd $HWLOC
./configure --prefix=<where to install hwloc>
make -j<N> install
```

where: `<where to install hwloc>` is the directory the built binaries will be installed to, and `<N>` is the number of cores to use to build hwloc.

After the above sequence of commands has been executed, you will need to specify the directory where hwloc was installed as HWLOC_ROOT (`<where to install hwloc>`) while executing CMake for HPX as explained in detail in the sections How to install HPX on Unix variants and How to install HPX on Windows.

Please see Hwloc Documentation⁷⁹ for more information about hwloc.

**Building HPX**

**Basic information**

Once CMake has been run, the build process can be started. The HPX build process is highly configurable through CMake, and various CMake variables influence the build process. The build process consists of the following parts:

- The HPX core libraries (target core): This forms the basic set of HPX libraries. The generated targets are:
  - hpx: The core HPX library (always enabled).
  - hpx_init: The HPX initialization library that applications need to link against to define the HPX entry points (disabled for static builds).
  - hpx_wrap: The HPX static library used to determine the runtime behavior of HPX code and respective entry points for hpx_main.h
  - iostreams_component: The component used for (distributed) IO (always enabled).
  - component_storage_component: The component needed for migration to persistent storage.
  - unordered_component: The component needed for a distributed (partitioned) hash table.
  - partitioned_vector_component: The component needed for a distributed (partitioned) vector.
  - memory_component: A dynamically loaded plugin that exposes memory based performance counters (only available on Linux).
  - io_counter_component: A dynamically loaded plugin that exposes I/O performance counters (only available on Linux).
  - papi_component: A dynamically loaded plugin that exposes PAPI performance counters (enabled with `HPX_WITH_PAPI:BOOL`, default is Off).

- HPX Examples (target examples): This target is enabled by default and builds all HPX examples (disable by setting `HPX_WITH_EXAMPLES:BOOL=Off`). HPX examples are part of the all target and are included in the installation if enabled.

- HPX Tests (target tests): This target builds the HPX test suite and is enabled by default (disable by setting `HPX_WITH_TESTS:BOOL=Off`). They are not built by the all target and have to be built separately.

- HPX Documentation (target docs): This target builds the documentation, and is not enabled by default (enable by setting `HPX_WITH_DOCUMENTATION:BOOL=On`). For more information see Documentation.

⁷⁹ https://www.open-mpi.org/projects/hwloc/doc/
For a complete list of available CMake variables that influence the build of HPX, see CMake variables used to configure HPX.

The variables can be used to refine the recipes that can be found at Platform specific build recipes which show some basic steps on how to build HPX for a specific platform.

In order to use HPX, only the core libraries are required (the ones marked as optional above are truly optional). When building against HPX, the CMake variable HPX_LIBRARIES will contain hpx and hpx_init (for pkgconfig, those are added to the Libs sections). In order to use the optional libraries, you need to specify them as link dependencies in your build (See Creating HPX projects).

As HPX is a modern C++ library, we require a certain minimum set of features from the C++11 standard. In addition, we make use of certain C++14 features if the used compiler supports them. This means that the HPX build system will try to determine the highest support C++ standard flavor and check for availability of those features. That is, the default will be the highest C++ standard version available. If you want to force HPX to use a specific C++ standard version, you can use the following CMake variables:

- HPX_WITH_CXX14: Enables C++14 support (this is the minimum requirement)
- HPX_WITH_CXX17: Enables C++17 support
- HPX_WITH_CXX2A: Enables (experimental) C++20 support

Build types

CMake can be configured to generate project files suitable for builds that have enabled debugging support or for an optimized build (without debugging support). The CMake variable used to set the build type is CMAKE_BUILD_TYPE (for more information see the CMake Documentation). Available build types are:

- **Debug**: Full debug symbols are available as well as additional assertions to help debugging. To enable the debug build type for the HPX API, the C++ Macro HPX_DEBUG is defined.
- **RelWithDebInfo**: Release build with debugging symbols. This is most useful for profiling applications
- **Release**: Release build. This disables assertions and enables default compiler optimizations.
- **RelMinSize**: Release build with optimizations for small binary sizes.

**Important:** We currently don’t guarantee ABI compatibility between Debug and Release builds. Please make sure that applications built against HPX use the same build type as you used to build HPX. For CMake builds, this means that the CMAKE_BUILD_TYPE variables have to match and for projects not using CMake, the HPX_DEBUG macro has to be set in debug mode.

Platform specific notes

Some platforms require users to have special link and/or compiler flags specified to build HPX. This is handled via CMake’s support for different toolchains (see cmake-toolchains(7) for more information). This is also used for cross compilation.

HPX ships with a set of toolchains that can be used for compilation of HPX itself and applications depending on HPX. Please see CMake toolchains shipped with HPX for more information.

---

81. https://www.cmake.org
In order to enable full static linking with the libraries, the CMake variable `HPX_WITH_STATIC_LINKING:BOOL` has to be set to `On`.

**Debugging applications using core files**

For HPX to generate useful core files, HPX has to be compiled without signal and exception handlers `HPX_WITH_DISABLED_SIGNAL_EXCEPTION_HANDLERS:BOOL`. If this option is not specified, the signal handlers change the application state. For example, after a segmentation fault the stack trace will show the signal handler. Similarly, unhandled exceptions are also caught by these handlers and the stack trace will not point to the location where the unhandled exception was thrown.

In general, core files are a helpful tool to inspect the state of the application at the moment of the crash (post-mortem debugging), without the need of attaching a debugger beforehand. This approach to debugging is especially useful if the error cannot be reliably reproduced, as only a single crashed application run is required to gain potentially helpful information like a stacktrace.

To debug with core files, the operating system first has to be told to actually write them. On most Unix systems this can be done by calling:

```
ulimit -c unlimited
```

in the shell. Now the debugger can be started up with:

```
gdb <application> <core file name>
```

The debugger should now display the last state of the application. The default file name for core files is `core`.

**Platform specific build recipes**

*Note:* The following build recipes are mostly user-contributed and may be outdated. We always welcome updated and new build recipes.

**How to install HPX on Unix variants**

- Create a build directory. HPX requires an out-of-tree build. This means you will be unable to run CMake in the HPX source tree.

```bash
cd hpx
mkdir my_hpx_build
cd my_hpx_build
```

- Invoke CMake from your build directory, pointing the CMake driver to the root of your HPX source tree.

```bash
cmake -DBOOST_ROOT=/root/of/boost/installation
-DHWLOC_ROOT=/root/of/hwloc/installation
[other CMake variable definitions]
/path/to/source/tree
```

For instance:

```bash
cmake -DBOOST_ROOT=~packages/boost -DHWLOC_ROOT=~packages/hwloc -DCMAKE_INSTALL_PREFIX=~packages/hpx ~/downloads/hpx_1.5.1
```
• Invoke GNU make. If you are on a machine with multiple cores, add the -jN flag to your make invocation, where N is the number of parallel processes HPX gets compiled with.

\texttt{gmake -j4}

\textbf{Caution:} Compiling and linking HPX needs a considerable amount of memory. It is advisable that at least 2 GB of memory per parallel process is available.

\textbf{Note:} Many Linux distributions use make as an alias for gmake.

• To complete the build and install HPX:

\texttt{gmake install}

\textbf{Important:} These commands will build and install the essential core components of HPX only. In order to build and run the tests, please invoke:

\texttt{gmake tests && gmake test}

and in order to build (and install) all examples invoke:

\texttt{cmake -DHPX\_WITH\_EXAMPLES=On .
gmake examples
gmake install}

For more detailed information about using CMake, please refer to its documentation and also the section \textit{Building HPX}. Please pay special attention to the section about \texttt{HPX\_WITH\_MALLOC:STRING} as this is crucial for getting decent performance.

**How to install HPX on OS X (Mac)**

This section describes how to build HPX for OS X (Mac).

**Build (and install) a recent version of Boost, using Clang and libc++**

To build Boost with Clang and make it link to libc++ as standard library, you’ll need to set up either of the following in your \texttt{~\slash user-config.jam} file:

```bash
# user-config.jam (put this file into your home directory)
# ...

using clang
:
  : "/usr/bin/clang++"
  : <cxxflags>"-std=c++11 -fcolor-diagnostics"
  : <linkflags>"-stdlib=libc++ -L/path/to/libcxx/lib"
  ;
```
(Again, remember to replace /path/to with whatever you used earlier.)

Then, you can use one of the following for your build command:

```
b2 --build-dir=/tmp/build-boost --layout=versioned toolset=clang install -j4
```

or:

```
b2 --build-dir=/tmp/build-boost --layout=versioned toolset=clang install -j4
```

We verified this using Boost V1.53. If you use a different version, just remember to replace /usr/local/include/boost-1_53 with whatever prefix you used in your installation.

**Build HPX, finally**

```
cd /path/to
git clone https://github.com/STEllAR-GROUP/hpx.git
mkdir build-hpx && cd build-hpx
```

To build with Clang, execute:

```
cmake ../hpx
   -DCMAKE_CXX_COMPILER=clang++
   -DBOOST_ROOT=/path/to/boost
   -DHWLOC_ROOT=/path/to/hwloc
   -DHPX_WITH_GENERIC_CONTEXT_COROUTINES=On
make -j
```

For more detailed information about using CMake, please refer its documentation and to the section *Building HPX*.

**Alternative installation method of HPX on OS X (Mac)**

Alternatively, you can install a recent version of gcc as well as all required libraries via MacPorts:

1. Install MacPorts
2. Install CMake, gcc, hwloc:

   ```
sudo brew install cmake
sudo brew install boost
sudo brew install hwloc
sudo brew install make
```
3. You may also want:

   ```
sudo brew install gperftools
```
4. If you need to build Boost manually (the Boost package of MacPorts is built with Clang, and unfortunately doesn’t work with a GCC-build version of HPX):

   ```
wget https://dl.bintray.com/boostorg/release/1.69.0/source/boost_1_69_0.tar.bz2
tar xjf boost_1_69_0.tar.bz2
pushd boost_1_69_0
export BOOST_ROOT=$HOME/boost_1_69_0
./bootstrap.sh --prefix=$BOOST_DIR
```

(continues on next page)
5. Build HPX:

```bash
./b2 -j8
./b2 -j8 install
export DYLD_LIBRARY_PATH=$DYLD_LIBRARY_PATH:$BOOST_ROOT/lib
popd
```

6. Note that you need to set BOOST_ROOT, HPX_ROOT and DYLD_LIBRARY_PATH (for both BOOST_ROOT and HPX_ROOT) every time you configure, build, or run an HPX application.

7. Note that you need to set HPX_WITH_GENERIC_CONTEXT_COROUTINES=On for MacOS.

8. If you want to use HPX with MPI, you need to enable the MPI parcelport, and also specify the location of the MPI wrapper scripts. This can be done using the following command:

```bash
cmake -DHPX_WITH_PARCELPORT_MPI=ON \
-DHPX_ROOT=$HOME/hpx \
-DMPI_CXX_COMPILER=ompiic++ \
-DMPICXX_COMPILER=g++ \
-DMPICXX_FLAGS="-Wno-unused-local-typedefs" \
-DBOOST_ROOT=$BOOST_DIR \
-DHWLOC_ROOT=/opt/local \
-DH分期_INSTALL_PREFIX=$HOME/hpx \
 $(pwd)/../hpx
```

### How to install HPX on Windows

#### Installation of required prerequisites

- Download the Boost c++ libraries from [Boost Downloads](https://www.boost.org/users/download/)
- Install the Boost library as explained in the section *Installing Boost*
- Install the hwloc library as explained in the section *Installing Hwloc*
- Download the latest version of CMake binaries, which are located under the platform section of the downloads page at [CMake Downloads](https://www.cmake.org/cmake/resources/software.html).
- Download the latest version of HPX from the STE||AR website: [HPX Downloads](https://hpx.stellar-group.org/downloads/).

---

83 [https://www.boost.org/users/download/](https://www.boost.org/users/download/)
84 [https://www.cmake.org/cmake/resources/software.html](https://www.cmake.org/cmake/resources/software.html)
85 [https://hpx.stellar-group.org/downloads/](https://hpx.stellar-group.org/downloads/)
Installation of the *HPX* library

- Create a build folder. *HPX* requires an out-of-tree-build. This means that you will be unable to run CMake in the *HPX* source folder.

- Open up the CMake GUI. In the input box labelled “Where is the source code:”, enter the full path to the source folder. The source directory is the one where the sources were checked out. CMakeLists.txt files in the source directory as well as the subdirectories describe the build to CMake. In addition to this, there are CMake scripts (usually ending in .cmake) stored in a special CMake directory. CMake does not alter any file in the source directory and doesn’t add new ones either. In the input box labelled “Where to build the binaries:”, enter the full path to the build folder you created before. The build directory is one where all compiler outputs are stored, which includes object files and final executables.

- Add CMake variable definitions (if any) by clicking the “Add Entry” button. There are two required variables you need to define: `BOOST_ROOT` and `HWLOC_ROOT`. These variables need to be set to point to the root folder of your Boost and hwloc installations. It is recommended to set the variable `CMAKE_INSTALL_PREFIX` as well. This determines where the *HPX* libraries will be built and installed. If this variable is set, it has to refer to the directory where the built *HPX* files should be installed to.

- Press the “Configure” button. A window will pop up asking you which compilers to use. Select the Visual Studio 10 (64Bit) compiler (it usually is the default if available). The Visual Studio 2012 (64Bit) and Visual Studio 2013 (64Bit) compilers are supported as well. Note that while it is possible to build *HPX* for x86, we don’t recommend doing so as 32 bit runs are severely restricted by a 32 bit Windows system limitation affecting the number of *HPX* threads you can create.

- Press “Configure” again. Repeat this step until the “Generate” button becomes clickable (and until no variable definitions are marked in red anymore).

- Press “Generate”.

- Open up the build folder, and double-click hpx.sln.

- Build the INSTALL target.

For more detailed information about using CMake please refer its documentation and also the section *Building HPX*.

**How to build *HPX* under Windows 10 x64 with Visual Studio 2015**

- Download the CMake V3.18.1 installer (or latest version) from [here](https://www.cmake.org)

- Download the hwloc V1.11.0 (or the latest version) from [here](http://www.open-mpi.org/software/hwloc/v1.11/downloads/hwloc-win64-build-1.11.0.zip) and unpack it.

- Download the latest Boost libraries from [here](https://www.boost.org/users/download/) and unpack them.

- Build the Boost DLLs and LIBs by using these commands from Command Line (or PowerShell). Open CMD/PowerShell inside the Boost dir and type in:

```bash
bootstrap.bat
```

This batch file will set up everything needed to create a successful build. Now execute:

```bash
b2.exe link=shared variant=release,debug architecture=x86 address-model=64 threading=multi --build-type=complete install
```

This command will start a (very long) build of all available Boost libraries. Please, be patient.
• Open CMake-GUI.exe and set up your source directory (input field ‘Where is the source code’) to the base directory of the source code you downloaded from HPX’s GitHub pages. Here’s an example of CMake path settings, which point to the Documents/GitHub/hpx folder:

![Example CMake path settings](image)

Inside ‘Where is the source-code’ enter the base directory of your HPX source directory (do not enter the “src” sub-directory!). Inside ‘Where to build the binaries’ you should put in the path where all the building processes will happen. This is important because the building machinery will do an “out-of-tree” build. CMake will not touch or change the original source files in any way. Instead, it will generate Visual Studio Solution Files, which will build HPX packages out of the HPX source tree.

• Set three new environment variables (in CMake, not in Windows environment): BOOST_ROOT, HWLOC_ROOT, CMAKE_INSTALL_PREFIX. The meaning of these variables is as follows:
  - BOOST_ROOT the HPX root directory of the unpacked Boost headers/cpp files.
  - HWLOC_ROOT the HPX root directory of the unpacked Portable Hardware Locality files.
  - CMAKE_INSTALL_PREFIX the HPX root directory where the future builds of HPX should be installed.

**Note:** HPX is a very large software collection, so it is not recommended to use the default C:\Program Files\hpx. Many users may prefer to use simpler paths without whitespace, like C:\bin\hpx or D:\bin\hpx etc.

To insert new env-vars click on “Add Entry” and then insert the name inside “Name”, select PATH as Type and put the path-name in the “Path” text field. Repeat this for the first three variables.
This is how variable insertion will look:

![CMake adding entry](image)

**Fig. 2.4: Example CMake adding entry.**

Alternatively, users could provide `BOOST_LIBRARYDIR` instead of `BOOST_ROOT`; the difference is that `BOOST_LIBRARYDIR` should point to the subdirectory inside Boost root where all the compiled DLLs/LIBs are. For example, `BOOST_LIBRARYDIR` may point to the `bin.v2` subdirectory under the Boost rootdir. It is important to keep the meanings of these two variables separated from each other: `BOOST_DIR` points to the ROOT folder of the Boost library. `BOOST_LIBRARYDIR` points to the subdir inside the Boost root folder where the compiled binaries are.

- Click the ‘Configure’ button of CMake-GUI. You will be immediately presented with a small window where you can select the C++ compiler to be used within Visual Studio. This has been tested using the latest v14 (a.k.a C++ 2015) but older versions should be sufficient too. Make sure to select the 64Bit compiler.
- After the generate process has finished successfully, click the ‘Generate’ button. Now, CMake will put new VS Solution files into the BUILD folder you selected at the beginning.
- Open Visual Studio and load the `HPX.sln` from your build folder.
- Go to CMakePredefinedTargets and build the INSTALL project:
  It will take some time to compile everything, and in the end you should see an output similar to this one:
Fig. 2.5: Visual Studio INSTALL target.

Fig. 2.6: Visual Studio build output.
How to install **HPX** on Fedora distributions

**Important:** There are official **HPX** packages for Fedora. Unless you want to customize your build, you may want to start off with the official packages. Instructions can be found on the **HPX Downloads**[90] page.

**Note:** This section of the manual is based off of our collaborator Patrick Diehl’s blog post Installing **HPX** on Fedora[91].

- Install all packages for minimal installation:

  ```bash
  sudo dnf install gcc-c++ cmake boost-build boost boost-devel hwloc-devel \
  hwloc papi-devel gperftools-devel docbook-dtds \
  docbook-style-xsl libsodium-devel doxygen boost-doc hdf5-devel \
  fop boost-devel boost-openmpi-devel boost-mpich-devel
  ```

- Get the development branch of **HPX**:

  ```bash
  git clone https://github.com/STEllAR-GROUP/hpx.git
  ```

- Configure it with CMake:

  ```bash
  cd hpx
  mkdir build
  cd build
  cmake -DCMAKE_INSTALL_PREFIX=/opt/hpx ..
  make -j
  make install
  ```

  **Note:** To build **HPX** without examples use:

  ```bash
  cmake -DCMAKE_INSTALL_PREFIX=/opt/hpx -DHPX_WITH_EXAMPLES=Off ..
  ```

- Add the library path of **HPX** to ldconfig:

  ```bash
  sudo echo /opt/hpx/lib > /etc/ld.so.conf.d/hpx.conf
  sudo ldconfig
  ```

How to install **HPX** on Arch distributions

**Important:** There are **HPX** packages for Arch in the AUR. Unless you want to customize your build, you may want to start off with those. Instructions can be found on the **HPX Downloads**[92] page.

- Install all packages for a minimal installation:

  [90] https://hpx.stellar-group.org/downloads/
  [92] https://hpx.stellar-group.org/downloads/
For building the documentation, you will need to further install the following:

```bash
sudo pacman -S doxygen python-pip
pip install --user sphinx sphinx_rtd_theme breathe
```

The rest of the installation steps are the same as those for the Fedora or Unix variants.

### How to install HPX on Debian-based distributions

- Install all packages for a minimal installation:
  ```bash
  sudo apt install cmake libboost-all-dev hwloc libgoogle-perftools-dev
  ```

- To build the documentation you will need to further install the following:
  ```bash
  sudo apt install doxygen python-pip
  pip install --user sphinx sphinx_rtd_theme breathe
  ```
  or the following if you prefer to get Python packages from the Debian repositories:
  ```bash
  sudo apt install doxygen python-sphinx python-sphinx-rtd-theme python-breathe
  ```

The rest of the installation steps are same as those for the Fedora or Unix variants.

### CMake toolchains shipped with HPX

In order to compile HPX for various platforms, we provide a variety of toolchain files that take care of setting up various CMake variables like compilers, etc. They are located in the `cmake/toolchains` directory:

- `ARM-gcc`
- `BGION-gcc`
- `BGQ`
- `Cray`
- `CrayKNL`
- `CrayKNLStatic`
- `CrayStatic`
- `XeonPhi`

To use them, pass the `-DCMAKE_TOOLCHAIN_FILE=<toolchain>` argument to the CMake invocation.
ARM-gcc

# HPX Documentation, master

 cảm từ đề cập đến việc sử dụng các công cụ và phương pháp khác nhau để triển khai và tối ưu hóa các ứng dụng bằng HPX. Các công cụ và phương pháp này bao gồm:

- **CMAKE_FIND_ROOT_PATH_MODE_PACKAGE ONLY**
- **CMAKE_CROSSCOMPILING**
- **RDTSCP is available on Xeon/Phis**
- **HPX_WITH_RDTSCP**
- **HPX_WITH_PARCELPORT_TCP**
- **HPX_WITH_PARCELPORT_MPI**
- **HPX_WITH_PARCELPORT_MPI_MULTITHREADED**
- **HPX_WITH_PARCELPORT_LIBFABRIC**
- **HPX_PARCELPORT_LIBFABRIC_PROVIDER**
- **HPX_PARCELPORT_LIBFABRIC_THROTTLE_SEND**
- **HPX_PARCELPORT_LIBFABRIC_WITH_DEV_MODE**
- **HPX_PARCELPORT_LIBFABRIC_WITH_LOGGING**
- **HPX_WITH_ZERO_COPY_SERIALIZE**

Cung cấp thông tin chi tiết về cách sử dụng và cấu hình các công cụ và phương pháp này, cùng với các thay đổi cần thiết để tối ưu hóa hiệu suất và khả năng triển khai của các ứng dụng HPX.

CMake variables used to configure HPX

In order to configure HPX, you can set a variety of options to allow CMake to generate your specific makefiles/project files.

Variables that influence how HPX is built

The options are split into these categories:

- Generic options
- Build Targets options
- Thread Manager options
- AGAS options
- Parcelport options
- Profiling options
- Debugging options
- Modules options

Generic options

- HPX_WITH_ASYNC_CUDA:BOOL
- HPX_WITH_AUTOMATIC.Serialization_REGISTRATION:BOOL
- HPX_WITH_BENCHMARK_SCRIPTS_PATH:PATH
- HPX_WITH_BUILD_BINARY_PACKAGE:BOOL
- HPX_WITH_CHECK_MODULE_DEPENDENCIES:BOOL
- HPX_WITH_COMPILER_WARNINGS:BOOL
- HPX_WITH_COMPILER_WARNINGS_AS_ERRORS:BOOL
- HPX_WITH_COMPRESSION_BZIP2:BOOL
- HPX_WITH_COMPRESSION_SNAPPY:BOOL
- HPX_WITH_COMPRESSION_ZLIB:BOOL
- HPX_WITH_CUDA:BOOL
- HPX_WITH_CUDA_CLANG:BOOL
- HPX_WITH_CUDA_COMPUTE:BOOL
• HPX_WITH_DATAPAR:BOOL
• HPX_WITH_DATAPAR_VC:BOOL
• HPX_WITH_DATAPAR_VC_NO_LIBRARY:BOOL
• HPX_WITH_DEPRECATED_WARNINGS:BOOL
• HPX_WITH_DISABLED_SIGNAL_EXCEPTION_HANDLERS:BOOL
• HPX_WITH_DYNAMIC_HPX_MAIN:BOOL
• HPX_WITH_FAULT_TOLERANCE:BOOL
• HPX_WITH_FULL_RPATH:BOOL
• HPX_WITH_GCC_VERSION_CHECK:BOOL
• HPX_WITH_GENERIC_CONTEXT_COROUTINES:BOOL
• HPX_WITH_HIDDEN_VISIBILITY:BOOL
• HPX_WITH_HIP:BOOL
• HPX_WITH_INIT_START_OVERLOADS_COMPATIBILITY:BOOL
• HPX_WITH_LOGGING:BOOL
• HPX_WITH_MALLOC:STRING
• HPX_WITH_NICE_THREADLEVEL:BOOL
• HPX_WITH_PARCEL_COALEScing:BOOL
• HPX_WITH_PKGCONFIG:BOOL
• HPX_WITH_PRECOMPILED_HEADERS:BOOL
• HPX_WITH_RUN_MAIN_EVERYWHERE:BOOL
• HPX_WITH_STACKOVERFLOW_DETECTION:BOOL
• HPX_WITH_STATIC_LINKING:BOOL
• HPX_WITH.Unity_BUILD:BOOL
• HPX_WITH_VIM_YCM:BOOL
• HPX_WITH_ZERO_COPY_SERIALIzATION_THRESHOLD:STRING

HPX_WITH_ASYNC_CUDA:BOOL
   ON

HPX_WITH_AUTOMATIC_SERIALIzATION_REGISTRATION:BOOL
   Use automatic serialization registration for actions and functions. This affects compatibility between HPX
   applications compiled with different compilers (default ON)

HPX_WITH_BENCHMARK_SCRIPTS_PATH:PATH
   Directory to place batch scripts in

HPX_WITH_BUILD_BINARY_PACKAGE:BOOL
   Build HPX on the build infrastructure on any LINUX distribution (default: OFF).

HPX_WITH_CHECK_MODULE_DEPENDENCIES:BOOL
   Verify that no modules are cross-referenced from a different module category (default: OFF)

HPX_WITH_COMPILER_WARNINGS:BOOL
   Enable compiler warnings (default: ON)
HPX_WITH_COMPILER_WARNINGS_AS_ERRORS:BOOL
   Turn compiler warnings into errors (default: OFF)

HPX_WITH_COMPRESSION_BZIP2:BOOL
   Enable bzip2 compression for parcel data (default: OFF).

HPX_WITH_COMPRESSION_SNAPPY:BOOL
   Enable snappy compression for parcel data (default: OFF).

HPX_WITH_COMPRESSION_ZLIB:BOOL
   Enable zlib compression for parcel data (default: OFF).

HPX_WITH_CUDA:BOOL
   Enable HPX_WITH_ASYNC_CUDA (CUDA or HIP futures) and HPX_WITH_CUDA_COMPUTE (CUDA/HIP enabled parallel algorithms) (default: OFF)

HPX_WITH_CUDA_CLANG:BOOL
   Use clang to compile CUDA code (default: OFF)

HPX_WITH_CUDA_COMPUTE:BOOL
   Enable HPX CUDA/HIP compute capability (parallel algorithms) module (default: ON, dependent on HPX_WITH_CUDA or HPX_WITH_HIP, and HPX_WITH_ASYNC_CUDA) - note: enabling this also enables CUDA/HIP futures via HPX_WITH_ASYNC_CUDA

HPX_WITH_DATAPAR:BOOL
   Enable data parallel algorithm support (default: ON)

HPX_WITH_DATAPAR_VC:BOOL
   Enable data parallel algorithm support using the external Vc library (default: OFF)

HPX_WITH_DATAPAR_VC_NO_LIBRARY:BOOL
   Don’t link with the Vc static library (default: OFF)

HPX_WITH_DEPRECATION_WARNINGS:BOOL
   Enable warnings for deprecated facilities. (default: ON)

HPX_WITH_DISABLED_SIGNAL_EXCEPTION_HANDLERS:BOOL
   Disables the mechanism that produces debug output for caught signals and unhandled exceptions (default: OFF)

HPX_WITH_DYNAMIC_HPX_MAIN:BOOL
   Enable dynamic overload of system main() (Linux and Apple only, default: ON)

HPX_WITH_FAULT_TOLERANCE:BOOL
   Build HPX to tolerate failures of nodes, i.e. ignore errors in active communication channels (default: OFF)

HPX_WITH_FULL_RPATH:BOOL
   Build and link HPX libraries and executables with full RPATHs (default: ON)

HPX_WITH_GCC_VERSION_CHECK:BOOL
   Don’t ignore version reported by gcc (default: ON)

HPX_WITH_GENERIC_CONTEXT_COROUTINES:BOOL
   Use Boost.Context as the underlying coroutines context switch implementation.

HPX_WITH_HIDDEN_VISIBILITY:BOOL
   Use -fvisibility=hidden for builds on platforms which support it (default OFF)

HPX_WITH_HIP:BOOL
   Enable compilation with HIPCC (default: OFF)

HPX_WITH_INIT_START_OVERLOADS_COMPATIBILITY:BOOL
   Enable deprecated init() and start() overloads functions (default: OFF)
HPX documentation

HPX_WITH_LOGGING:BOOL
Build HPX with logging enabled (default: ON).

HPX_WITH_MALLOC:STRING
Define which allocator should be linked in. Options are: system, tcmalloc, jemalloc, mimalloc, tbbmalloc, and custom (default is: tcmalloc)

HPX_WITH_NICE_THREADLEVEL:BOOL
Set HPX worker threads to have high NICE level (may impact performance) (default: OFF)

HPX_WITH_PARCEL_COALESCING:BOOL
Enable the parcel coalescing plugin (default: ON).

HPX_WITH_PKGCONFIG:BOOL
Enable generation of pkgconfig files (default: ON on Linux without CUDA/HIP, otherwise OFF)

HPX_WITH_PRECOMPILED_HEADERS:BOOL
Enable precompiled headers for certain build targets (experimental) (default OFF)

HPX_WITH_RUN_MAIN_EVERYWHERE:BOOL
Run hpx_main by default on all localities (default: OFF).

HPX_WITH_STACKOVERFLOW_DETECTION:BOOL
Enable stackoverflow detection for HPX threads/coroutines. (default: OFF, debug: ON)

HPX_WITH_STATIC_LINKING:BOOL
Compile HPX statically linked libraries (Default: OFF)

HPX_WITH_UNITY_BUILD:BOOL
Enable unity build for certain build targets (default OFF)

HPX_WITH_VIM_YCM:BOOL
Generate HPX completion file for VIM YouCompleteMe plugin

HPX_WITH_ZERO_COPY_SERIALIZATION_THRESHOLD:STRING
The threshold in bytes to when perform zero copy optimizations (default: 128)

Build Targets options

- HPX_WITH_ASIO_TAG:STRING
- HPX_WITH_COMPILE_ONLY_TESTS:BOOL
- HPX_WITH_DISTRIBUTED_RUNTIME:BOOL
- HPX_WITH_DOCUMENTATION:BOOL
- HPX_WITH_DOCUMENTATION_OUTPUT_FORMATS:STRING
- HPX_WITH_EXAMPLES:BOOL
- HPX_WITH_EXAMPLES_HDF5:BOOL
- HPX_WITH_EXAMPLES_OPENMP:BOOL
- HPX_WITH_EXAMPLES_QT4:BOOL
- HPX_WITH_EXAMPLES_QTHREADS:BOOL
- HPX_WITH_EXAMPLES_TBB:BOOL
- HPX_WITH_EXECUTABLE_PREFIX:STRING
- HPX_WITH_FAIL_COMPILE_TESTS:BOOL
• \texttt{HPX\_WITH\_FETCH\_ASIO}:BOOL
• \texttt{HPX\_WITH\_IO\_COUNTERS}:BOOL
• \texttt{HPX\_WITH\_TESTS}:BOOL
• \texttt{HPX\_WITH\_TESTS\_BENCHMARKS}:BOOL
• \texttt{HPX\_WITH\_TESTS\_EXAMPLES}:BOOL
• \texttt{HPX\_WITH\_TESTS\_EXTERNAL\_BUILD}:BOOL
• \texttt{HPX\_WITH\_TESTS\_HEADERS}:BOOL
• \texttt{HPX\_WITH\_TESTS\_REGRESSIONS}:BOOL
• \texttt{HPX\_WITH\_TESTS\_UNIT}:BOOL
• \texttt{HPX\_WITH\_TOOLS}:BOOL

\texttt{HPX\_WITH\_ASIO\_TAG}:STRING
Asio repository tag or branch

\texttt{HPX\_WITH\_COMPILE\_ONLY\_TESTS}:BOOL
Create build system support for compile time only HPX tests (default ON)

\texttt{HPX\_WITH\_DISTRIBUTED\_RUNTIME}:BOOL
Enable the distributed runtime (default: ON). Turning off the distributed runtime completely disallows the creation and use of components and actions. Turning this option off is experimental!

\texttt{HPX\_WITH\_DOCUMENTATION}:BOOL
Build the HPX documentation (default OFF).

\texttt{HPX\_WITH\_DOCUMENTATION\_OUTPUT\_FORMATS}:STRING
List of documentation output formats to generate. Valid options are html;singlehtml;latexpdf;man. Multiple values can be separated with semicolons. (default html).

\texttt{HPX\_WITH\_EXAMPLES}:BOOL
Build the HPX examples (default ON)

\texttt{HPX\_WITH\_EXAMPLES\_HDF5}:BOOL
Enable examples requiring HDF5 support (default: OFF).

\texttt{HPX\_WITH\_EXAMPLES\_OPENMP}:BOOL
Enable examples requiring OpenMP support (default: OFF).

\texttt{HPX\_WITH\_EXAMPLES\_QT4}:BOOL
Enable examples requiring Qt4 support (default: OFF).

\texttt{HPX\_WITH\_EXAMPLES\_QTHREADS}:BOOL
Enable examples requiring QThreads support (default: OFF).

\texttt{HPX\_WITH\_EXAMPLES\_TBB}:BOOL
Enable examples requiring TBB support (default: OFF).

\texttt{HPX\_WITH\_EXECUTABLE\_PREFIX}:STRING
Executable prefix (default none), ‘\texttt{hpx\_}’ useful for system install.

\texttt{HPX\_WITH\_FAIL\_COMPILE\_TESTS}:BOOL
Create build system support for fail compile HPX tests (default ON)

\texttt{HPX\_WITH\_FETCH\_ASIO}:BOOL
Use FetchContent to fetch Asio. By default an installed Asio will be used. (default: OFF)

\texttt{HPX\_WITH\_IO\_COUNTERS}:BOOL
Enable IO counters (default: ON)
HPX WITH_TESTS:BOOL
   Build the HPX tests (default ON)

HPX WITH_TESTS_BENCHMARKS:BOOL
   Build HPX benchmark tests (default: ON)

HPX WITH_TESTS_EXAMPLES:BOOL
   Add HPX examples as tests (default: ON)

HPX WITH_TESTS_EXTERNAL_BUILD:BOOL
   Build external cmake build tests (default: ON)

HPX WITH_TESTS_HEADERS:BOOL
   Build HPX header tests (default: OFF)

HPX WITH_TESTS_REGRESSIONS:BOOL
   Build HPX regression tests (default: ON)

HPX WITH_TESTS_UNIT:BOOL
   Build HPX unit tests (default: ON)

HPX WITH_TOOLS:BOOL
   Build HPX tools (default: OFF)

Thread Manager options

- HPX_COROUTINES_WITH_SWAP_CONTEXT_EMULATION:BOOL
- HPX_SCHEDULER_MAX_TERMINATED_THREADS:STRING
- HPX_WITH_COROUTINE_COUNTERS:BOOL
- HPX_WITH_IO_POOL:BOOL
- HPX WITH_MAX_CPU_COUNT:STRING
- HPX WITH_MAX_NUMA_DOMAIN_COUNT:STRING
- HPX WITH_SCHEDULER_LOCAL_STORAGE:BOOL
- HPX WITH_SPINLOCK_DEADLOCK_DETECTION:BOOL
- HPX WITH_SPINLOCK_POOL_NUM:STRING
- HPX WITH_STACKTRACES:BOOL
- HPX WITH_STACKTRACES_DEMANGLE_SYMBOLS:BOOL
- HPX WITH_STACKTRACES_STATIC_SYMBOLS:BOOL
- HPX WITH_THREAD_BACKTRACE_DEPTH:STRING
- HPX WITH_THREAD_BACKTRACE_ON_SUSPENSION:BOOL
- HPX WITH_THREAD_CREATION_AND_CLEANUP_RATES:BOOL
- HPX WITH_THREAD_CUMULATIVE_COUNTS:BOOL
- HPX WITH_THREAD_IDLE_RATES:BOOL
- HPX WITH_THREAD_LOCAL_STORAGE:BOOL
- HPX WITH_THREAD_MANAGER_IDLE_BACKOFF:BOOL
- HPX WITH_THREAD_QUEUE_WAITTIME:BOOL
• **HPX\_WITH\_THREAD\_STACK\_MMAP**: BOOL
  Emulate SwapContext API for coroutines (Windows only, default: OFF)

• **HPX\_WITH\_THREAD\_STEALING\_COUNTS**: BOOL

• **HPX\_WITH\_THREAD\_TARGET\_ADDRESS**: BOOL

• **HPX\_WITH\_TIMER\_POOL**: BOOL

• **HPX\_COROUTINES\_WITH\_SWAP\_CONTEXT\_EMULATION**: BOOL
  Emulate SwapContext API for coroutines (Windows only, default: OFF)

• **HPX\_SCHEDULER\_MAX\_TERMINATED\_THREADS**: STRING
  [Deprecated] Maximum number of terminated threads collected before those are cleaned up (default: 100)

• **HPX\_WITH\_COROUTINE\_COUNTERS**: BOOL
  Enable keeping track of coroutine creation and rebind counts (default: OFF)

• **HPX\_WITH\_IO\_POOL**: BOOL
  Disable internal IO thread pool, do not change if not absolutely necessary (default: ON)

• **HPX\_WITH\_MAX\_CPU\_COUNT**: STRING
  HPX applications will not use more than this number of OS-Threads (empty string means dynamic) (default: 64)

• **HPX\_WITH\_MAX\_NUMA\_DOMAIN\_COUNT**: STRING
  HPX applications will not run on machines with more NUMA domains (default: 8)

• **HPX\_WITH\_SCHEDULER\_LOCAL\_STORAGE**: BOOL
  Enable scheduler local storage for all HPX schedulers (default: OFF)

• **HPX\_WITH\_SPINLOCK\_DEADLOCK\_DETECTION**: BOOL
  Enable spinlock deadlock detection (default: OFF)

• **HPX\_WITH\_SPINLOCK\_POOL\_NUM**: STRING
  Number of elements a spinlock pool manages (default: 128)

• **HPX\_WITH\_STACKTRACES**: BOOL
  Attach backtraces to HPX exceptions (default: ON)

• **HPX\_WITH\_STACKTRACES\_DEMANGLE\_SYMBOLS**: BOOL
  Thread stack back trace symbols will be demangled (default: ON)

• **HPX\_WITH\_STACKTRACES\_STATIC\_SYMBOLS**: BOOL
  Thread stack back trace will resolve static symbols (default: OFF)

• **HPX\_WITH\_THREAD\_BACKTRACE\_DEPTH**: STRING
  Thread stack back trace depth being captured (default: 20)

• **HPX\_WITH\_THREAD\_BACKTRACE\_ON\_SUSPENSION**: BOOL
  Enable thread stack back trace being captured on suspension (default: OFF)

• **HPX\_WITH\_THREAD\_CREATION\_AND\_CLEANUP\_RATES**: BOOL
  Enable measuring thread creation and cleanup times (default: OFF)

• **HPX\_WITH\_THREAD\_CUMULATIVE\_COUNTS**: BOOL
  Enable keeping track of cumulative thread counts in the schedulers (default: ON)

• **HPX\_WITH\_THREAD\_IDLE\_RATES**: BOOL
  Enable measuring the percentage of overhead times spent in the scheduler (default: OFF)

• **HPX\_WITH\_THREAD\_LOCAL\_STORAGE**: BOOL
  Enable thread local storage for all HPX threads (default: OFF)

• **HPX\_WITH\_THREAD\_MANAGER\_IDLE\_BACKOFF**: BOOL
  HPX scheduler threads do exponential backoff on idle queues (default: ON)
HPX_WITH_THREAD_QUEUE_WAITTIME:BOOL
   Enable collecting queue wait times for threads (default: OFF)

HPX_WITH_THREAD_STACK_MMAP:BOOL
   Use mmap for stack allocation on appropriate platforms

HPX_WITH_THREAD_STEALING_COUNTS:BOOL
   Enable keeping track of counts of thread stealing incidents in the schedulers (default: OFF)

HPX_WITH_THREAD_TARGET_ADDRESS:BOOL
   Enable storing target address in thread for NUMA awareness (default: OFF)

HPX_WITH_TIMER_POOL:BOOL
   Disable internal timer thread pool, do not change if not absolutely necessary (default: ON)

AGAS options

• HPX_WITH_AGAS_DUMP_REFCNT_ENTRIES:BOOL
   Enable dumps of the AGAS refcnt tables to logs (default: OFF)

Parcelport options

• HPX_WITH_NETWORKING:BOOL
• HPX_WITH_PARCELPORT_ACTION_COUNTERS:BOOL
• HPX_WITH_PARCELPORT_LIBFABRIC:BOOL
• HPX_WITH_PARCELPORT_MPI:BOOL
• HPX_WITH_PARCELPORT_TCP:BOOL
• HPX_WITH_PARCEL_PROFILING:BOOL

HPX_WITH_NETWORKING:BOOL
   Enable support for networking and multi-node runs (default: ON)

HPX_WITH_PARCELPORT_ACTION_COUNTERS:BOOL
   Enable performance counters reporting parcelport statistics on a per-action basis.

HPX_WITH_PARCELPORT_LIBFABRIC:BOOL
   Enable the libfabric based parcelport. This is currently an experimental feature

HPX_WITH_PARCELPORT_MPI:BOOL
   Enable the MPI based parcelport.

HPX_WITH_PARCELPORT_TCP:BOOL
   Enable the TCP based parcelport.

HPX_WITH_PARCEL_PROFILING:BOOL
   Enable profiling data for parcels
Profiloring options

- `HPX_WITH_APEX:BOOL`  
  Enable APEX instrumentation support.

- `HPX_WITH_GOOGLE_PERFTOOLS:BOOL`  
  Enable Google Perftools instrumentation support.

- `HPX_WITH_ITTNOTIFY:BOOL`  
  Enable Amplifier (ITT) instrumentation support.

- `HPX_WITH_PAPI:BOOL`  
  Enable the PAPI based performance counter.

Debugging options

- `HPX_WITH_ATTACH_DEBUGGER_ON_TEST_FAILURE:BOOL`  
  Break the debugger if a test has failed (default: OFF)

- `HPX_WITH_PARALLEL_TESTS_BIND_NONE:BOOL`  
  Pass –hpx:bind=none to tests that may run in parallel (cmake -j flag) (default: OFF)

- `HPX_WITH_SANITIZERS:BOOL`  
  Configure with sanitizer instrumentation support.

- `HPX_WITH_TESTS_DEBUG_LOG:BOOL`  
  Turn on debug logs (–hpx:debug-hpx-log) for tests (default: OFF)

- `HPX_WITH_TESTS_DEBUG_LOG_DESTINATION:STRING`  
  Destination for test debug logs (default: cout)
HPX WITH_TESTS_MAX_THREADS_PER_LOCALITY:STRING
  Maximum number of threads to use for tests (default: 0, use the number of threads specified by the test)

HPX WITH_THREAD_DEBUG_INFO:BOOL
  Enable thread debugging information (default: OFF, implicitly enabled in debug builds)

HPX WITH_THREAD_DESCRIPTION_FULL:BOOL
  Use function address for thread description (default: OFF)

HPX WITH_THREAD_GUARD_PAGE:BOOL
  Enable thread guard page (default: ON)

HPX WITH_VALGRIND:BOOL
  Enable Valgrind instrumentation support.

HPX WITH_VERIFY_LOCKS:BOOL
  Enable lock verification code (default: OFF, implicitly enabled in debug builds)

HPX WITH_VERIFY_LOCKS_BACKTRACE:BOOL
  Enable thread stack back trace being captured on lock registration (to be used in combination with
  HPX WITH_VERIFY_LOCKS=ON, default: OFF)

HPX WITH_VERIFY_LOCKS_GLOBALY:BOOL
  Enable global lock verification code (default: OFF, implicitly enabled in debug builds)

Modules options

• HPX DATASTRUCTURES_WITH_ADAPT_STD_TUPLE:BOOL
  Enable compatibility of hpx::tuple with std::tuple. (default: ON)

• HPX_FILESYSTEM_WITH_BOOST_FILESYSTEM_COMPATIBILITY:BOOL
  Enable Boost.FileSystem compatibility. (default: ON)

• HPX_ITERATOR_SUPPORT_WITH_BOOST_ITERATOR_TRAVERSAL_TAG_COMPATIBILITY:BOOL
  Enable Boost.Iterator traversal tag compatibility. (default: OFF)

• HPX_SERIALIZATION_WITH_BOOST_TYPES:BOOL
  Enable serialization of certain Boost types. (default: ON)

• HPX_TOPOLOGY_WITH_ADDITIONAL_HWLOC_TESTING:BOOL
  Enable HWLOC filtering that makes it report no cores, this is purely an
  option supporting better testing - do not enable under normal circumstances. (default: OFF)
Additional tools and libraries used by HPX

Here is a list of additional libraries and tools that are either optionally supported by the build system or are optionally required for certain examples or tests. These libraries and tools can be detected by the HPX build system.

Each of the tools or libraries listed here will be automatically detected if they are installed in some standard location. If a tool or library is installed in a different location, you can specify its base directory by appending _ROOT to the variable name as listed below. For instance, to configure a custom directory for BOOST, specify BOOST_ROOT=/custom/boost/root.

**BOOST_ROOT:** PATH
Specifies where to look for the Boost installation to be used for compiling HPX. Set this if CMake is not able to locate a suitable version of Boost. The directory specified here can be either the root of an installed Boost distribution or the directory where you unpacked and built Boost without installing it (with staged libraries).

**HWLOC_ROOT:** PATH
Specifies where to look for the hwloc library. Set this if CMake is not able to locate a suitable version of hwloc. Hwloc provides platform-independent support for extracting information about the used hardware architecture (number of cores, number of NUMA domains, hyperthreading, etc.). HPX utilizes this information if available.

**PAPI_ROOT:** PATH
Specifies where to look for the PAPI library. The PAPI library is needed to compile a special component exposing PAPI hardware events and counters as HPX performance counters. This is not available on the Windows platform.

**AMPLIFIER_ROOT:** PATH
Specifies where to look for one of the tools of the Intel Parallel Studio product, either Intel Amplifier or Intel Inspector. This should be set if the CMake variable HPX_USE_ITT_NOTIFY is set to ON. Enabling ITT support in HPX will integrate any application with the mentioned Intel tools, which customizes the generated information for your application and improves the generated diagnostics.

In addition, some of the examples may need the following variables:

**HDF5_ROOT:** PATH
Specifies where to look for the Hierarchical Data Format V5 (HDF5) include files and libraries.

2.5.3 Creating HPX projects

Using HPX with pkg-config

How to build HPX applications with pkg-config

After you are done installing HPX, you should be able to build the following program. It prints Hello World! on the locality you run it on.

```cpp
// Including 'hpx/hpx_main.hpp' instead of the usual 'hpx/hpx_init.hpp' enables
// to use the plain C-main below as the direct main HPX entry point.
#include <hpx/hpx_main.hpp>
#include <hpx/iostream.hpp>

int main()
{
    // Say hello to the world!
    hpx::cout << "Hello World!\n" << hpx::flush;
    return 0;
}
```
Copy the text of this program into a file called hello_world.cpp.

Now, in the directory where you put hello_world.cpp, issue the following commands (where $HPX_LOCATION is the build directory or CMAKE_INSTALL_PREFIX you used while building HPX):

```bash
export PKG_CONFIG_PATH=$PKG_CONFIG_PATH:$HPX_LOCATION/lib/pkgconfig
c++ -o hello_world hello_world.cpp \
   `pkg-config --cflags --libs hpx_application` \
   -lhpx_iostreams -DHPX_APPLICATION_NAME=hello_world
```

**Important:** When using pkg-config with HPX, the pkg-config flags must go after the -o flag.

**Note:** HPX libraries have different names in debug and release mode. If you want to link against a debug HPX library, you need to use the _debug suffix for the pkg-config name. That means instead of hpx_application or hpx_component, you will have to use hpx_application_debug or hpx_component_debug Moreover, all referenced HPX components need to have an appended d suffix. For example, instead of -lhpx_iostreams you will need to specify -lhpx_iostreamsd.

**Important:** If the HPX libraries are in a path that is not found by the dynamic linker, you will need to add the path $HPX_LOCATION/lib to your linker search path (for example LD_LIBRARY_PATH on Linux).

To test the program, type:

```bash
./hello_world
```

which should print Hello World! and exit.

**How to build HPX components with pkg-config**

Let’s try a more complex example involving an HPX component. An HPX component is a class that exposes HPX actions. HPX components are compiled into dynamically loaded modules called component libraries. Here’s the source code:

```cpp
#include <hpx/config.hpp>
#if !defined(HPX_COMPUTE_DEVICE_CODE)
#include "hello_world_component.hpp"
#include <hpx/iostream.hpp>
#endif

namespace examples { namespace server {
   void hello_world::invoke()
   {
      hpx::cout << "Hello HPX World!" << std::endl;
   }
}}
HPX_REGISTER_COMPONENT_MODULE();
```

(continues on next page)
```cpp
typedef hpx::components::component<
    examples::server::hello_world
> hello_world_type;

HPX_REGISTER_COMPONENT(hello_world_type, hello_world);

HPX_REGISTER_ACTION(
    examples::server::hello_world::invoke_action, hello_world_invoke_action);
```

**hello_world_component.hpp**

```cpp
#pragma once

#include <hpx/config.hpp>
#if !defined(HPX_COMPUTE_DEVICE_CODE)
#include <hpx/hpx.hpp>
#include <hpx/include/actions.hpp>
#include <hpx/include/lcos.hpp>
#include <hpx/include/components.hpp>
#include <hpx/serialization.hpp>
#include <utility>

namespace examples {
    namespace server {
        struct HPX_COMPONENT_EXPORT hello_world : hpx::components::component_base<hello_world> {
            void invoke();
            HPX_DEFINE_COMPONENT_ACTION(hello_world, invoke);
        };
    }
}
#endif

HPX_REGISTER_ACTION_DECLARATION(
    examples::server::hello_world::invoke_action, hello_world_invoke_action);

namespace examples {
    struct hello_world : hpx::components::client_base<hello_world, server::hello_world> {
        typedef hpx::components::client_base<hello_world, server::hello_world> base_type;

        hello_world(hpx::future<hpx::naming::id_type> && f)
            : base_type(std::move(f))
        {};

        hello_world(hpx::naming::id_type && f)
            : base_type(std::move(f))
        {};

        void invoke()
        {
            hpx::async<server::hello_world::invoke_action>(this->get_id()).get();
        }
    };
}
```
hello_world_client.cpp

```cpp
#include <hpx/config.hpp>
#if defined(HPX_COMPUTE_HOST_CODE)
#include <hpx/wrap_main.hpp>
#include "hello_world_component.hpp"

int main()
{
    // Create a single instance of the component on this locality.
    examples::hello_world client = hpx::new_<examples::hello_world>(hpx::find_here());

    // Invoke the component's action, which will print "Hello World!".
    client.invoke();

    return 0;
}
#endif
```

Copy the three source files above into three files (called `hello_world_component.cpp`, `hello_world_component.hpp` and `hello_world_client.cpp`, respectively).

Now, in the directory where you put the files, run the following command to build the component library. (where `$HPX_LOCATION` is the build directory or `CMAKE_INSTALL_PREFIX` you used while building HPX):

```
export PKG_CONFIG_PATH=$PKG_CONFIG_PATH:$HPX_LOCATION/lib/pkgconfig
c++ -o libhpx_hello_world.so hello_world_component.cpp \
    `pkg-config --cflags --libs hpx_component` \
    -lhpx_iostreams -DHPX_COMPONENT_NAME=hpx_hello_world
```

Now pick a directory in which to install your HPX component libraries. For this example, we’ll choose a directory named `my_hpx_libs`:

```
mkdir ~/my_hpx_libs
mv libhpx_hello_world.so ~/my_hpx_libs
```

**Note:** HPX libraries have different names in debug and release mode. If you want to link against a debug HPX library, you need to use the `_debug` suffix for the pkg-config name. That means instead of `hpx_application` or `hpx_component` you will have to use `hpx_application_debug` or `hpx_component_debug`. Moreover, all referenced HPX components need to have a appended `d` suffix, e.g. instead of `-lhpx_iostreams` you will need to specify `-lhpx_iostreamsd`.

**Important:** If the HPX libraries are in a path that is not found by the dynamic linker. You need to add the path
Now, to build the application that uses this component (hello_world_client.cpp), we do:

```c
export PKG_CONFIG_PATH=$PKG_CONFIG_PATH:$HPX_LOCATION/lib/pkgconfig
c++ -o hello_world_client hello_world_client.cpp \
``pkg-config --cflags --libs hpx_application`` \
-L${HOME}/my_hpx_libs -lhpx_hello_world -lhpx_iostreams
```

**Important:** When using pkg-config with HPX, the pkg-config flags must go after the `-o` flag.

Finally, you’ll need to set your LD_LIBRARY_PATH before you can run the program. To run the program, type:

```bash
export LD_LIBRARY_PATH="${LD_LIBRARY_PATH}:${HOME}/my_hpx_libs"
./hello_world_client
```

which should print `Hello HPX World!` and exit.

### Using HPX with CMake-based projects

In addition to the pkg-config support discussed on the previous pages, HPX comes with full CMake support. In order to integrate HPX into existing or new CMakeLists.txt, you can leverage the `find_package` command integrated into CMake. Following, is a Hello World component example using CMake.

Let’s revisit what we have. We have three files that compose our example application:

- hello_world_component.hpp
- hello_world_component.cpp
- hello_world_client.hpp

The basic structure to include HPX into your CMakeLists.txt is shown here:

```cmake
# Require a recent version of cmake
cmake_minimum_required(VERSION 3.17 FATAL_ERROR)

# This project is C++ based.
project(your_app CXX)

# Instruct cmake to find the HPX settings
find_package(HPX)
```

In order to have CMake find HPX, it needs to be told where to look for the HPXConfig.cmake file that is generated when HPX is built or installed. It is used by `find_package(HPX)` to set up all the necessary macros needed to use HPX in your project. The ways to achieve this are:

- Set the `HPX_DIR` CMake variable to point to the directory containing the HPXConfig.cmake script on the command line when you invoke CMake:

  ```bash
cmake -DHPX_DIR=$HPX_LOCATION/lib/cmake/HPX ...
```

  where `$HPX_LOCATION` is the build directory or `CMAKE_INSTALL_PREFIX` you used when building/configuring HPX.

---

93 https://www.cmake.org/cmake/help/latest/command/find_package.html
• Set the CMAKE_PREFIX_PATH variable to the root directory of your HPX build or install location on the command line when you invoke CMake:

```
cmake -DCMAKE_PREFIX_PATH=$HPX_LOCATION ...
```

The difference between CMAKE_PREFIX_PATH and HPX_DIR is that CMake will add common postfixes, such as lib/cmake/<project>, to the CMAKE_PREFIX_PATH and search in these locations too. Note that if your project uses HPX as well as other CMake-managed projects, the paths to the locations of these multiple projects may be concatenated in the CMAKE_PREFIX_PATH.

• The variables above may be set in the CMake GUI or curses ccmake interface instead of the command line.

Additionally, if you wish to require HPX for your project, replace the find_package(HPX) line with find_package(HPX REQUIRED).

You can check if HPX was successfully found with the HPX_FOUND CMake variable.

### Using CMake targets

The recommended way of setting up your targets to use HPX is to link to the HPX::hpx CMake target:

```
target_link_libraries(hello_world_component PUBLIC HPX::hpx)
```

This requires that you have already created the target like this:

```
add_library(hello_world_component SHARED hello_world_component.cpp)
target_include_directories(hello_world_component PUBLIC ${CMAKE_CURRENT_SOURCE_DIR})
```

When you link your library to the HPX::hpx CMake target, you will be able use HPX functionality in your library. To use main() as the implicit entry point in your application you must additionally link your application to the CMake target HPX::wrap_main. This target is automatically linked to executables if you are using the macros described below (Using macros to create new targets). See Re-use the main() function as the main HPX entry point for more information on implicitly using main() as the entry point.

Creating a component requires setting two additional compile definitions:

```
target_compile_options(hello_world_component
  HPX_COMPONENT_NAME=hello_world
  HPX_COMPONENT_EXPORTS)
```

Instead of setting these definitions manually you may link to the HPX::component target, which sets HPX_COMPONENT_NAME to hpx_<target_name>, where <target_name> is the target name of your library. Note that these definitions should be PRIVATE to make sure these definitions are not propagated transitively to dependent targets.

In addition to making your library a component you can make it a plugin. To do so link to the HPX::plugin target. Similarly to HPX::component this will set HPX_PLUGIN_NAME to hpx_<target_name>. This definition should also be PRIVATE. Unlike regular shared libraries, plugins are loaded at runtime from certain directories and will not be found without additional configuration. Plugins should be installed into a directory containing only plugins. For example, the plugins created by HPX itself are installed into the hpx subdirectory in the library install directory (typically lib or lib64). When using the HPX::plugin target you need to install your plugins into an appropriate directory. You may also want to set the location of your plugin in the build directory with the *_OUTPUT_DIRECTORY* CMake target properties to be able to load the plugins in the build directory. Once you’ve set the install or output directory of your plugin you need to tell your executable where to find it at runtime. You can do this either by setting the environment variable HPX_COMPONENT_PATHS or the ini setting hpx.component_paths (see --hpx:ini) to the directory containing your plugin.
Using macros to create new targets

In addition to the targets described above, *HPX* provides convenience macros to hide optional boilerplate code that may be useful for your project. The link to the targets described above. We recommend that you use the targets directly whenever possible as they tend to compose better with other targets.

The macro for adding an *HPX* component is `add_hpx_component`. It can be used in your `CMakeLists.txt` file like this:

```cmake
# build your application using HPX
add_hpx_component(hello_world
    SOURCES hello_world_component.cpp
    HEADERS hello_world_component.hpp
    COMPONENT_DEPENDENCIES iostreams)
```

**Note:** `add_hpx_component` adds a `_component` suffix to the target name. In the example above, a `hello_world_component` target will be created.

The available options to `add_hpx_component` are:

- **SOURCES**: The source files for that component
- **HEADERS**: The header files for that component
- **DEPENDENCIES**: Other libraries or targets this component depends on
- **COMPONENT_DEPENDENCIES**: The components this component depends on
- **PLUGIN**: Treats this component as a plugin-able library
- **COMPILE_FLAGS**: Additional compiler flags
- **LINK_FLAGS**: Additional linker flags
- **FOLDER**: Adds the headers and source files to this Source Group folder
- **EXCLUDE_FROM_ALL**: Do not build this component as part of the all target

After adding the component, the way you add the executable is as follows:

```cmake
# build your application using HPX
add_hpx_executable(hello_world
    SOURCES hello_world_client.cpp
    COMPONENT_DEPENDENCIES hello_world)
```

**Note:** `add_hpx_executable` automatically adds a `_component` suffix to dependencies specified in `COMPONENT_DEPENDENCIES`, meaning you can directly use the name given when adding a component using `add_hpx_component`.

When you configure your application, all you need to do is set the `HPX_DIR` variable to point to the installation of *HPX*.

**Note:** All library targets built with *HPX* are exported and readily available to be used as arguments to `target_link_libraries` in your targets. The *HPX* include directories are available with the `HPX_INCLUDE_DIRS` CMake...
Using the HPX compiler wrapper hpxcxx

The hpxcxx compiler wrapper helps to compile a HPX component, application, or object file, based on the arguments passed to it.

```
hpxcxx [--exe=<APPLICATION_NAME> | --comp=<COMPONENT_NAME> | -c] FLAGS FILES
```

The hpxcxx command requires that either an application or a component is built or -c flag is specified. If the build is against a debug build, the -g is to be specified while building.

Optional flags

- `-l <LIBRARY> | -l<LIBRARY>`: Links `<LIBRARY>` to the build
- `-g`: Specifies that the application or component build is against a debug build
- `-rd`: Sets `release-with-debug-info` option
- `-mr`: Sets `minsize-release` option

All other flags (like `-o OUTPUT_FILE`) are directly passed to the underlying C++ compiler.

Using macros to set up existing targets to use HPX

In addition to the `add_hpx_component` and `add_hpx_executable`, you can use the `hpx_setup_target` macro to have an already existing target to be used with the HPX libraries:

```
hapsx_setup_target(target)
```

Optional parameters are:

- `EXPORT`: Adds it to the CMake export list HPXTargets
- `INSTALL`: Generates an install rule for the target
- `PLUGIN`: Treats this component as a plugin-able library
- `TYPE`: The type can be: EXECUTABLE, LIBRARY or COMPONENT
- `DEPENDENCIES`: Other libraries or targets this component depends on
- `COMPONENT_DEPENDENCIES`: The components this component depends on
- `COMPILE_FLAGS`: Additional compiler flags
- `LINK_FLAGS`: Additional linker flags

If you do not use CMake, you can still build against HPX, but you should refer to the section on How to build HPX components with pkg-config.

Note: Since HPX relies on dynamic libraries, the dynamic linker needs to know where to look for them. If HPX isn’t installed into a path that is configured as a linker search path, external projects need to either set `RPATH` or adapt `LD_LIBRARY_PATH` to point to where the HPX libraries reside. In order to set `RPATHs`, you can include...
HPX\_SetFullRPATH in your project after all libraries you want to link against have been added. Please also consult the CMake documentation here\textsuperscript{95}.

Using HPX with Makefile

A basic project building with HPX is through creating makefiles. The process of creating one can get complex depending upon the use of cmake parameter HPX\_WITH\_HPX\_MAIN (which defaults to ON).

How to build HPX applications with makefile

If HPX is installed correctly, you should be able to build and run a simple Hello World program. It prints Hello World! on the locality you run it on.

```cpp
// Including 'hpx/hpx_main.hpp' instead of the usual 'hpx/hpx_init.hpp' enables
// to use the plain C-main below as the direct main HPX entry point.
#include <hpx/hpx_main.hpp>
#include <hpx/iostream.hpp>

int main()
{
    // Say hello to the world!
    hpx::cout << "Hello World!\n" << hpx::flush;
    return 0;
}
```

Copy the content of this program into a file called hello_world.cpp.

Now, in the directory where you put hello_world.cpp, create a Makefile. Add the following code:

```makefile
CXX=(CXX) # Add your favourite compiler here or let makefile choose default.
CXXFLAGS=-O3 -std=c++17
BOOST_ROOT=/path/to/boost
HWLOC_ROOT=/path/to/hwloc
TCMALLOC_ROOT=/path/to/tcmalloc
HPX_ROOT=/path/to/hpx

INCLUDE\_DIRECTIVES=$\{(HPX\_ROOT)/include \$(BOOST\_ROOT)/include \$(HWLOC\_ROOT)/include
LIBRARY\_DIRECTIVES=-L\$(HPX\_ROOT)/lib \$(HPX\_ROOT)/lib/hpxp_init.a \$(HPX\_ROOT)/lib/
\-libhpx.so \$(BOOST\_ROOT)/lib/libboost_atomic-mt.so \$(BOOST\_ROOT)/lib/libboost_
\-filesystem-mt.so \$(BOOST\_ROOT)/lib/libboost_program_options-mt.so \$(BOOST\_ROOT)/lib/
\-libboost_regex-mt.so \$(BOOST\_ROOT)/lib/libboost_system-mt.so -lpthread \$(TCMALLOC_\-ROOT)/lib/tcmalloc_minimal.so \$(HWLOC\_ROOT)/libhwloc.so -ldl -lrt
LINK\_FLAGS=$\{(HPX\_ROOT)/lib/libhpx_wrap.a -Wl,-wrap=main # should be left empty for
\-HPX\_WITH\_HPX\_MAIN=OFF
hello_world: hello_world.o
    \$(CXX) \$(CXXFLAGS) -o hello_world hello_world.o \$(LIBRARY\_DIRECTIVES) \$(LINK\_FLAGS)
```

\textsuperscript{95} https://gitlab.kitware.com/cmake/community/wikis/doc/cmake/RPATH-handling
hello_world.o:
$(CXX) $(CXXFLAGS) -c -o hello_world.o hello_world.cpp $(INCLUDE_DIRECTIVES)

**Important:** LINK_FLAGS should be left empty if HPX_WITH_HPX_MAIN is set to OFF. Boost in the above example is build with --layout=tagged. Actual Boost flags may vary on your build of Boost.

To build the program, type:

```
make
```

A successful build should result in hello_world binary. To test, type:

```
./hello_world
```

### How to build **HPX** components with makefile

Let’s try a more complex example involving an **HPX** component. An **HPX** component is a class that exposes **HPX** actions. **HPX** components are compiled into dynamically-loaded modules called component libraries. Here’s the source code:

**hello_world_component.cpp**

```cpp
#include <hpx/config.hpp>
#if !defined(HPX_COMPUTE_DEVICE_CODE)
#include "hello_world_component.hpp"
#include <hpx/iostream.hpp>
#include <iostream>

namespace examples {
  namespace server {
    void hello_world::invoke()
    {
      hpx::cout << "Hello HPX World!" << std::endl;
    }
  }
} HPX_REGISTER_COMPONENT_MODULE();

typedef hpx::components::component<
  examples::server::hello_world
> hello_world_type;

HPX_REGISTER_COMPONENT(hello_world_type, hello_world);

HPX_REGISTER_ACTION(
  examples::server::hello_world::invoke_action, hello_world_invoke_action);
#endif
```

**hello_world_component.hpp**

```cpp
#pragma once
```

(continues on next page)
```cpp
#include <hpx/config.hpp>
#if !defined(HPX_COMPUTE_DEVICE_CODE)
#include <hpx/hpx.hpp>
#include <hpx/include/actions.hpp>
#include <hpx/include/lcos.hpp>
#include <hpx/include/components.hpp>
#include <hpx/serialization.hpp>
#include <utility>
namespace examples {
  namespace server {
    struct HPX_COMPONENT_EXPORT hello_world : hpx::components::component_base<hello_world>
    {
      void invoke();
      HPX_DEFINE_COMPONENT_ACTION(hello_world, invoke);
    };
  }
}
HPX_REGISTER_ACTION_DECLARATION(
    examples::server::hello_world::invoke_action, hello_world_invoke_action);
```

```cpp
namespace examples {
  struct hello_world : hpx::components::client_base<hello_world, server::hello_world>
  {
    typedef hpx::components::client_base<hello_world, server::hello_world> base_type;

    hello_world(hpx::future<hpx::naming::id_type> && f)
    : base_type(std::move(f))
    {}

    hello_world(hpx::naming::id_type && f)
    : base_type(std::move(f))
    {}

    void invoke()
    {
      hpx::async<server::hello_world::invoke_action>(this->get_id()).get();
    }
  };
}
```

```cpp
hello_world_client.cpp
#include <hpx/config.hpp>
#if defined(HPX_COMPUTE_HOST_CODE)
#include <hpx/wrap_main.hpp>
#include "hello_world_component.hpp"

int main()
```

{  
    // Create a single instance of the component on this locality.  
    examples::hello_world client =  
        hpx::new_<examples::hello_world>(hpx::find_here());  
    
    // Invoke the component’s action, which will print "Hello World!".  
    client.invoke();  
}  

return 0;  
}  

Now, in the directory, create a Makefile. Add the following code:

```makefile
CXX=(CXX)  # Add your favourite compiler here or let makefile choose default.
CXXFLAGS=-O3 -std=c++17  
BOOST_ROOT=/path/to/boost  
HWLOC_ROOT=/path/to/hwloc  
TCMALLOC_ROOT=/path/to/tcmalloc  
HPX_ROOT=/path/to/hpx  

INCLUDE_DIRECTIVES=\$(HPX_ROOT)/include \$(BOOST_ROOT)/include \$(HWLOC_ROOT)/include  
LIBRARY_DIRECTIVES=-L\$(HPX_ROOT)/lib \$(HPX_ROOT)/lib/libhpx_init.a \$(HPX_ROOT)/lib/libhpx.so \$(BOOST_ROOT)/lib/libboost_filesystem-mt.so \$(BOOST_ROOT)/lib/libboost_atomic-mt.so \$(BOOST_ROOT)/lib/libboost_regex-mt.so \$(BOOST_ROOT)/lib/libboost_system-mt.so -lpthread \$(TCMALLOC_ROOT)/libtcmalloc_minimal.so \$(HWLOC_ROOT)/libhwloc.so -ldl -lrt  
LINK_FLAGS=\$(HPX_ROOT)/lib/libhpx_wrap.a -Wl,-wrap=main  # should be left empty for \n-HPX_WITH_HPX_MAIN=OFF  

hello_world_client: libhpx_hello_world hello_world_client.o  
    \$(CXX) \$(CXXFLAGS) -o hello_world_client \$(LIBRARY_DIRECTIVES) libhpx_hello_world -\$(LINK_FLAGS)  

hello_world_client.o: hello_world_component.o  
    \$(CXX) \$(CXXFLAGS) -o hello_world_client.o hello_world_component.o -\$(LINK_DIRECTIVES)  

libhpx_hello_world: hello_world_component.o  
    \$(CXX) \$(CXXFLAGS) -o libhpx_hello_world hello_world_component.o -\$(LIBRARY_DIRECTIVES)  

hello_world_component.o: hello_world_component.cpp  
    \$(CXX) \$(CXXFLAGS) -c -o hello_world_component.o hello_world_component.cpp -\$(INCLUDE_DIRECTIVES)  
```

To build the program, type:

```
make
```

A successful build should result in hello_world binary. To test, type:
Note: Due to high variations in CMake flags and library dependencies, it is recommended to build HPX applications and components with pkg-config or CMakeLists.txt. Writing Makefile may result in broken builds if due care is not taken. pkg-config files and CMake systems are configured with CMake build of HPX. Hence, they are stable when used together and provide better support overall.

### 2.5.4 Starting the HPX runtime

In order to write an application which uses services from the HPX runtime system you need to initialize the HPX library by inserting certain calls into the code of your application. Depending on your use case, this can be done in 3 different ways:

- **Minimally invasive**: Re-use the `main()` function as the main HPX entry point.
- **Balanced use case**: Supply your own main HPX entry point while blocking the main thread.
- **Most flexibility**: Supply your own main HPX entry point while avoiding to block the main thread.
- **Suspend and resume**: As above but suspend and resume the HPX runtime to allow for other runtimes to be used.

#### Re-use the `main()` function as the main HPX entry point

This method is the least intrusive to your code. It however provides you with the smallest flexibility in terms of initializing the HPX runtime system. The following code snippet shows what a minimal HPX application using this technique looks like:

```cpp
#include <hpx/hpx_main.hpp>

int main(int argc, char* argv[]) {
    return 0;
}
```

The only change to your code you have to make is to include the file `hpx/hpx_main.hpp`. In this case the function `main()` will be invoked as the first HPX thread of the application. The runtime system will be initialized behind the scenes before the function `main()` is executed and will automatically stop after `main()` has returned. For this method to work you must link your application to the CMake target `HPX::wrap_main`. This is done automatically if you are using the provided macros (`Using macros to create new targets`) to set up your application, but must be done explicitly if you are using targets directly (`Using CMake targets`). All HPX API functions can be used from within the `main()` function now.

**Note:** The function `main()` does not need to expect receiving `argc` and `argv` as shown above, but could expose the signature `int main()`. This is consistent with the usually allowed prototypes for the function `main()` in C++ applications.

All command line arguments specific to HPX will still be processed by the HPX runtime system as usual. However, those command line options will be removed from the list of values passed to `argc/argv` of the function `main()`. The list of values passed to `main()` will hold only the commandline options which are not recognized by the HPX runtime system (see the section `HPX Command Line Options` for more details on what options are recognized by HPX).
Note: In this mode all one-letter-shortcuts are disabled which are normally available on the HPX command line (such as \(-t\) or \(-l\) see HPX Command Line Options). This is done to minimize any possible interaction between the command line options recognized by the HPX runtime system and any command line options defined by the application.

The value returned from the function main() as shown above will be returned to the operating system as usual.

Important: To achieve this seamless integration, the header file hpx/hpx_main.hpp defines a macro:

```cpp
#define main hpx_startup::user_main
```

which could result in unexpected behavior.

Important: To achieve this seamless integration, we use different implementations for different operating systems. In case of Linux or macOS, the code present in hpx_wrap.cpp is put into action. We hook into the system function in case of Linux and provide alternate entry point in case of macOS. For other operating systems we rely on a macro:

```cpp
#define main hpx_startup::user_main
```

provided in the header file hpx/hpx_main.hpp. This implementation can result in unexpected behavior.

Caution: We make use of an override variable include_libhpx_wrap in the header file hpx/hpx_main.hpp to swiftly choose the function call stack at runtime. Therefore, the header file should only be included in the main executable. Including it in the components will result in multiple definition of the variable.

Supply your own main HPX entry point while blocking the main thread

With this method you need to provide an explicit main thread function named hpx_main at global scope. This function will be invoked as the main entry point of your HPX application on the console locality only (this function will be invoked as the first HPX thread of your application). All HPX API functions can be used from within this function.

The thread executing the function hpx::init will block waiting for the runtime system to exit. The value returned from hpx_main will be returned from hpx::init after the runtime system has stopped.

The function hpx::finalize has to be called on one of the HPX localities in order to signal that all work has been scheduled and the runtime system should be stopped after the scheduled work has been executed.

This method of invoking HPX has the advantage of you being able to decide which version of hpx::init to call. This allows to pass additional configuration parameters while initializing the HPX runtime system.

```cpp
#include <hpx/hpx_init.hpp>

int hpx_main(int argc, char* argv[])
{
    // Any HPX application logic goes here...
    return hpx::finalize();
}
```

(continues on next page)
int main(int argc, char* argv[]) {
    // Initialize HPX, run hpx_main as the first HPX thread, and
    // wait for hpx::finalize being called.
    return hpx::init(argc, argv);
}

Note: The function hpx_main does not need to expect receiving argc/argv as shown above, but could expose one of the following signatures:

int hpx_main();
int hpx_main(int argc, char* argv[]);
int hpx_main(hpx::program_options::variables_map& vm);

This is consistent with (and extends) the usually allowed prototypes for the function main() in C++ applications.

The header file to include for this method of using HPX is hpx/hpx_init.hpp.

There are many additional overloads of hpx::init available, such as for instance to provide your own entry point function instead of hpx_main. Please refer to the function documentation for more details (see: hpx/hpx_init.hpp).

Supply your own main HPX entry point while avoiding to block the main thread

With this method you need to provide an explicit main thread function named hpx_main at global scope. This function will be invoked as the main entry point of your HPX application on the console locality only (this function will be invoked as the first HPX thread of your application). All HPX API functions can be used from within this function.

The thread executing the function hpx::start will not block waiting for the runtime system to exit, but will return immediately. The function hpx::finalize has to be called on one of the HPX localities in order to signal that all work has been scheduled and the runtime system should be stopped after the scheduled work has been executed.

This method of invoking HPX is useful for applications where the main thread is used for special operations, such as GUIs. The function hpx::stop can be used to wait for the HPX runtime system to exit and should be at least used as the last function called in main(). The value returned from hpx_main will be returned from hpx::stop after the runtime system has stopped.

#include <hpx/hpx_start.hpp>

int hpx_main(int argc, char* argv[]) {
    // Any HPX application logic goes here...
    return hpx::finalize();
}

int main(int argc, char* argv[]) {
    // Initialize HPX, run hpx_main.
    hpx::start(argc, argv);

    // ...Execute other code here...

    // Wait for hpx::finalize being called.
}
return hpx::stop();
}

Note: The function hpx_main does not need to expect receiving argc/argv as shown above, but could expose one of the following signatures:

```cpp
int hpx_main();
int hpx_main(int argc, char* argv[]);
int hpx_main(hpx::program_options::variables_map& vm);
```

This is consistent with (and extends) the usually allowed prototypes for the function main() in C++ applications.

The header file to include for this method of using HPX is hpx/hpx_start.hpp.

There are many additional overloads of hpx::start available, such as for instance to provide your own entry point function instead of hpx_main. Please refer to the function documentation for more details (see: hpx/hpx_start.hpp).

**Suspending and resuming the HPX runtime**

In some applications it is required to combine HPX with other runtimes. To support this use case HPX provides two functions: hpx::suspend and hpx::resume. hpx::suspend is a blocking call which will wait for all scheduled tasks to finish executing and then put the thread pool OS threads to sleep. hpx::resume simply wakes up the sleeping threads so that they are ready to accept new work. hpx::suspend and hpx::resume can be found in the header hpx/hpx_suspend.hpp.

```cpp
#include <hpx/hpx_start.hpp>
#include <hpx/hpx_suspend.hpp>

int main(int argc, char* argv[]) {
    // Initialize HPX, don't run hpx_main
    hpx::start(nullptr, argc, argv);

    // Schedule a function on the HPX runtime
    hpx::apply(&my_function, ...);

    // Wait for all tasks to finish, and suspend the HPX runtime
    hpx::suspend();

    // Execute non-HPX code here

    // Resume the HPX runtime
    hpx::resume();

    // Schedule more work on the HPX runtime

    // hpx::finalize has to be called from the HPX runtime before hpx::stop
    hpx::apply([]() { hpx::finalize(); });
    return hpx::stop();
}
```
Note: `hpx::suspend` does not wait for `hpx::finalize` to be called. Only call `hpx::finalize` when you wish to fully stop the HPX runtime.

Warning:

`hpx::suspend` only waits for local tasks, i.e. tasks on the current locality, to finish executing. When using `hpx::suspend` in a multi-locality scenario the user is responsible for ensuring that any work required from other localities has also finished.

HPX also supports suspending individual thread pools and threads. For details on how to do that see the documentation for `hpx::threads::thread_pool_base`.

Automatically suspending worker threads

The previous method guarantees that the worker threads are suspended when you ask for it and that they stay suspended. An alternative way to achieve the same effect is to tweak how quickly HPX suspends its worker threads when they run out of work. The following configuration values make sure that HPX idles very quickly:

```cpp
hpx.max_idle_backoff_time = 1000
hpx.max_idle_loop_count = 0
```

They can be set on the command line using `--hpx:ini=hpx.max_idle_backoff_time=1000` and `--hpx:ini=hpx.max_idle_loop_count=0`. See Launching and configuring HPX applications for more details on how to set configuration parameters.

After setting idling parameters the previous example could now be written like this instead:

```cpp
#include <hpx/hpx_start.hpp>

int main(int argc, char* argv[])
{
    // Initialize HPX, don't run hpx_main
    hpx::start(nullptr, argc, argv);

    // Schedule some functions on the HPX runtime
    // NOTE: run_as_hpx_thread blocks until completion.
    hpx::run_as_hpx_thread(&my_function, ...);
    hpx::run_as_hpx_thread(&my_other_function, ...);

    // hpx::finalize has to be called from the HPX runtime before hpx::stop
    hpx::apply([]() { hpx::finalize(); });
    return hpx::stop();
}
```

In this example each call to `hpx::run_as_hpx_thread` acts as a “parallel region”.

2.5. Manual
Working of `hpx_main.hpp`

In order to initialize HPX from `main()`, we make use of linker tricks.

It is implemented differently for different Operating Systems. Method of implementation is as follows:

- **Linux**: Using linker `--wrap` option.
- **Mac OSX**: Using the linker `-e` option.
- **Windows**: Using 
  ```
  #define main hpx_startup::user_main
  ```

**Linux implementation**

We make use of the Linux linker ld's `--wrap` option to wrap the `main()` function. This way any call to `main()` are redirected to our own implementation of main. It is here that we check for the existence of `hpx_main.hpp` by making use of a shadow variable `include_libhpx_wrap`. The value of this variable determines the function stack at runtime.

The implementation can be found in `libhpx_wrap.a`.

**Important**: It is necessary that `hpx_main.hpp` be not included more than once. Multiple inclusions can result in multiple definition of `include_libhpx_wrap`.

**Mac OSX implementation**

Here we make use of yet another linker option `-e` to change the entry point to our custom entry function `initialize_main`. We initialize the HPX runtime system from this function and call main from the initialized system. We determine the function stack at runtime by making use of the shadow variable `include_libhpx_wrap`.

The implementation can be found in `libhpx_wrap.a`.

**Important**: It is necessary that `hpx_main.hpp` be not included more than once. Multiple inclusions can result in multiple definition of `include_libhpx_wrap`.

**Windows implementation**

We make use of a macro 
  ```
  #define main hpx_startup::user_main
  ```

This implementation could result in unexpected behaviors.
2.5.5 Launching and configuring HPX applications

Configuring HPX applications

All HPX applications can be configured using special command line options and/or using special configuration files. This section describes the available options, the configuration file format, and the algorithm used to locate possible predefined configuration files. Additionally, this section describes the defaults assumed if no external configuration information is supplied.

During startup any HPX application applies a predefined search pattern to locate one or more configuration files. All found files will be read and merged in the sequence they are found into one single internal database holding all configuration properties. This database is used during the execution of the application to configure different aspects of the runtime system.

In addition to the ini files, any application can supply its own configuration files, which will be merged with the configuration database as well. Moreover, the user can specify additional configuration parameters on the command line when executing an application. The HPX runtime system will merge all command line configuration options (see the description of the `--hpx:ini`, `--hpx:config`, and `--hpx:app-config` command line options).

The HPX INI File Format

All HPX applications can be configured using a special file format which is similar to the well-known Windows INI file format[^1]. This is a structured text format allowing to group key/value pairs (properties) into sections. The basic element contained in an ini file is the property. Every property has a name and a value, delimited by an equals sign '='. The name appears to the left of the equals sign:

```
name=value
```

The value may contain equal signs as only the first '=' character is interpreted as the delimiter between name and value. Whitespace before the name, after the value and immediately before and after the delimiting equal sign is ignored. Whitespace inside the value is retained.

Properties may be grouped into arbitrarily named sections. The section name appears on a line by itself, in square brackets `[ ]`. All properties after the section declaration are associated with that section. There is no explicit “end of section” delimiter; sections end at the next section declaration, or the end of the file:

```
[section]
```

In HPX sections can be nested. A nested section has a name composed of all section names it is embedded in. The section names are concatenated using a dot `.`:

```
[outer_section.inner_section]
```

Here `inner_section` is logically nested within `outer_section`.

It is possible to use the full section name concatenated with the property name to refer to a particular property. For example in:

```
[a.b.c]
```

```
d = e
```

the property value of `d` can be referred to as `a.b.c.d=e`.

In HPX ini files can contain comments. Hash signs `#` at the beginning of a line indicate a comment. All characters starting with the `#` until the end of line are ignored.

If a property with the same name is reused inside a section, the second occurrence of this property name will override the first occurrence (discard the first value). Duplicate sections simply merge their properties together, as if they occurred contiguously.

In *HPX* ini files, a property value `${FOO:default}` will use the environmental variable `FOO` to extract the actual value if it is set and `default` otherwise. No default has to be specified. Therefore `${FOO}` refers to the environmental variable `FOO`. If `FOO` is not set or empty the overall expression will evaluate to an empty string. A property value `${section.key:default}` refers to the value held by the property `section.key` if it exists and `default` otherwise. No default has to be specified. Therefore `${section.key}` refers to the property `section.key`. If the property `section.key` is not set or empty, the overall expression will evaluate to an empty string.

**Note:** Any property `${section.key:default}` is evaluated whenever it is queried and not when the configuration data is initialized. This allows for lazy evaluation and relaxes initialization order of different sections. The only exception are recursive property values, e.g. values referring to the very key they are associated with. Those property values are evaluated at initialization time to avoid infinite recursion.

### Built-in Default Configuration Settings

During startup any *HPX* application applies a predefined search pattern to locate one or more configuration files. All found files will be read and merged in the sequence they are found into one single internal data structure holding all configuration properties.

As a first step the internal configuration database is filled with a set of default configuration properties. Those settings are described on a section by section basis below.

**Note:** You can print the default configuration settings used for an executable by specifying the command line option `--hpx:dump-config`.

### The `system` configuration section

```
(system)
    pid = <process-id>
    prefix = <current_prefix_path_of_core_HPX_library>
    executable = <current_prefix_path_of_executable>
```

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>system.pid</code></td>
<td>This is initialized to store the current OS-process id of the application instance.</td>
</tr>
<tr>
<td><code>system.prefix</code></td>
<td>This is initialized to the base directory <em>HPX</em> has been loaded from.</td>
</tr>
<tr>
<td><code>system.executable_prefix</code></td>
<td>This is initialized to the base directory the current executable has been loaded from.</td>
</tr>
</tbody>
</table>
The **hpx** configuration section

```ini
[hpx]
location = ${HPX_LOCATION:$[system.prefix]}/lib/hpx:${system.executable_prefix}/lib/hpx:
component_path = ${hpx.location}/lib/hpx:${system.executable_prefix}/lib/hpx:
master_ini_path = ${hpx.location}/share/hpx-<version>:${system.executable_prefix}/
ini_path = ${hpx.master_ini_path}/ini
ini_path = ${hpx.master_ini_path}/ini
os_threads = 1
localities = 1

exception_verbosity = ${HPX_EXCEPTION_VERBOSITY:2}

[hpx.stacks]
small_size = ${HPX_SMALL_STACK_SIZE:<hpx_small_stack_size>}
medium_size = ${HPX_MEDIUM_STACK_SIZE:<hpx_medium_stack_size>}
large_size = ${HPX_LARGE_STACK_SIZE:<hpx_large_stack_size>}
huge_size = ${HPX_HUGE_STACK_SIZE:<hpx_huge_stack_size>}
use_guard_pages = ${HPX_THREAD_GUARD_PAGE:1}
```
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hpx.location</td>
<td>This is initialized to the id of the locality this application instance is running on.</td>
</tr>
<tr>
<td>hpx.component</td>
<td>Duplicates are discarded. This property can refer to a list of directories separated by ';' (Linux, Android, and MacOS) or using ';' (Windows).</td>
</tr>
<tr>
<td>hpx.master_ini</td>
<td>This is initialized to the list of default paths of the main hpx.ini configuration files. This property can refer to a list of directories separated by ';' (Linux, Android, and MacOS) or using ';' (Windows).</td>
</tr>
<tr>
<td>hpx.ini_path</td>
<td>This is initialized to the default path where HPX will look for more ini configuration files. This property can refer to a list of directories separated by ';' (Linux, Android, and MacOS) or using ';' (Windows).</td>
</tr>
<tr>
<td>hpx.os_threads</td>
<td>This setting reflects the number of OS-threads used for running HPX-threads. Defaults to number of detected cores (not hyperthreads/PUs).</td>
</tr>
<tr>
<td>hpx.localities</td>
<td>This setting reflects the number of localities the application is running on. Defaults to 1.</td>
</tr>
<tr>
<td>hpx.program_name</td>
<td>This setting reflects the program name of the application instance. Initialized from the command line argv[0].</td>
</tr>
<tr>
<td>hpx.cmd_line</td>
<td>This setting reflects the actual command line used to launch this application instance.</td>
</tr>
<tr>
<td>hpx.lock_detection</td>
<td>This setting verifies that no locks are being held while a HPX thread is suspended. This setting is applicable only if HPX_WITH_VERIFY_LOCKS is set during configuration in CMake.</td>
</tr>
<tr>
<td>hpx.throw_on_error</td>
<td>This setting causes an exception if during lock detection at least one lock is being held while a HPX thread is suspended. This setting is applicable only if HPX_WITH_VERIFY_LOCKS is set during configuration in CMake. This setting has no effect if hpx.lock_detection=0.</td>
</tr>
<tr>
<td>hpx.minimal_deadlock_detection</td>
<td>This setting enables support for minimal deadlock detection for HPX-threads. By default this is set to 2 (for Debug builds) or to 0 (for Release, RelWithDebInfo, RelMinSize builds), this setting is effective only if HPX_WITH_THREAD_DEADLOCK_DETECTION is set during configuration in CMake.</td>
</tr>
<tr>
<td>hpx.spinlock_deadlock_detection_limit</td>
<td>This setting verifies that spinlocks don’t spin longer than specified using the hpx.spinlock_deadlock_detection_limit. This setting is applicable only if HPX_WITH_SPINLOCK_DEADLOCK_DETECTION is set during configuration in CMake. By default this is set to 1 (for Debug builds) or to 0 (for Release, RelWithDebInfo, RelMinSize builds).</td>
</tr>
<tr>
<td>hpx.spinlock_provider</td>
<td>This setting specifies the upper limit of allowed number of spins that spinlocks are allowed to perform. This setting is applicable only if HPX_WITH_SPINLOCK_DEADLOCK_DETECTION is set during configuration in CMake. By default this is set to 1000000.</td>
</tr>
<tr>
<td>hpx.max_background_threads</td>
<td>This setting defines the number of threads in the scheduler which are used to execute background work. By default this is the same as the number of cores used for the scheduler.</td>
</tr>
<tr>
<td>hpx.max_idle_loop_count</td>
<td>This setting defines the maximum value of the busy-loop counter in the scheduler. By default this is defined by the preprocessor constant HPX_BUSY_LOOP_COUNT_MAX. This is an internal setting which you should change only if you know exactly what you are doing.</td>
</tr>
<tr>
<td>hpx.max_idle_backoff_time_max</td>
<td>This setting defines the maximum time (in milliseconds) for the scheduler to sleep after being idle for hpx.max_idle_loop_count iterations. This setting is applicable only if HPX_WITH_THREAD_MANAGER_IDLE_BACKOFF is set during configuration in CMake. By default this is defined by the preprocessor constant HPX_IDLE_BACKOFF_TIME_MAX. This is an internal setting which you should change only if you know exactly what you are doing.</td>
</tr>
<tr>
<td>hpx.exceptionverbosity</td>
<td>This setting defines the verbosity of exceptions. Valid values are integers. A setting of 2 or higher prints all available information. A setting of 1 leaves out the build configuration and environment variables. A setting of 0 or lower prints only the description of the thrown exception and the file name, function, and line number where the exception was thrown. The default value is 2 or the value of the environment variable HPX_EXCEPTION_VERBOSITY.</td>
</tr>
<tr>
<td>hpx.small_stack_size</td>
<td>This is initialized to the small stack size to be used by HPX-threads. Set by default to the value of the compile time preprocessor constant HPX_SMALL_STACK_SIZE (defaults to 0x8000). This value is used for all HPX threads by default, except for the thread running hpx_main (which runs on a large stack).</td>
</tr>
<tr>
<td>hpx.medium_stack_size</td>
<td>This is initialized to the medium stack size to be used by HPX-threads. Set by default to the value of the compile time preprocessor constant HPX_MEDIUM_STACK_SIZE (defaults to 0x20000).</td>
</tr>
<tr>
<td>hpx.large_stack_size</td>
<td>This is initialized to the large stack size to be used by HPX-threads. Set by default to the value of the compile time preprocessor constant HPX_LARGE_STACK_SIZE (defaults to 0x20000).</td>
</tr>
<tr>
<td>hpx.huge_stack_size</td>
<td>This is initialized to the huge stack size to be used by HPX-threads. Set by default to the value of the compile time preprocessor constant HPX_HUGE_STACK_SIZE (defaults to 0x20000).</td>
</tr>
</tbody>
</table>

This entry controls whether the coroutine library will generate stack guard pages or not. This entry is set during configuration in CMake. This setting has no effect if HPX.lock_detection=0.

When using HPX with the compile time preprocessor constant HPX_HUGE_STACK_SIZE (defaults to 0x8000) the value is used for all HPX threads by default, except for the thread running hpx_main (which runs on a large stack).

For more information about stack guard pages refer to the documentation of the corresponding library the stack guard pages are used for.
The `hpx.threadpools` configuration section

```
[hpx.threadpools]
io_pool_size = ${HPX_NUM_IO_POOL_SIZE:2}
parcel_pool_size = ${HPX_NUM_PARCEL_POOL_SIZE:2}
timer_pool_size = ${HPX_NUM_TIMER_POOL_SIZE:2}
```

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hpx.threadpools.io_pool_size</td>
<td>The value of this property defines the number of OS-threads created for the</td>
</tr>
<tr>
<td></td>
<td>internal I/O thread pool.</td>
</tr>
<tr>
<td>hpx.threadpools.parcel_pool_size</td>
<td>The value of this property defines the number of OS-threads created for the</td>
</tr>
<tr>
<td></td>
<td>internal parcel thread pool.</td>
</tr>
<tr>
<td>hpx.threadpools.timer_pool_size</td>
<td>The value of this property defines the number of OS-threads created for the</td>
</tr>
<tr>
<td></td>
<td>internal timer thread pool.</td>
</tr>
</tbody>
</table>

The `hpx.thread_queue` configuration section

**Important:** These settings control internal values used by the thread scheduling queues in the HPX scheduler. You should not modify these settings except if you know exactly what you are doing.

```
[hpx.thread_queue]
min_tasks_to_steal_pending = ${HPX_THREAD_QUEUE_MIN_TASKS_TO_STEAL_PENDING:0}
min_tasks_to_steal_staged = ${HPX_THREAD_QUEUE_MIN_TASKS_TO_STEAL_STAGED:0}
min_add_new_count = ${HPX_THREAD_QUEUE_MIN_ADD_NEW_COUNT:10}
max_add_new_count = ${HPX_THREAD_QUEUE_MAX_ADD_NEW_COUNT:10}
max_delete_count = ${HPX_THREAD_QUEUE_MAX_DELETE_COUNT:1000}
```

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hpx.thread_queue.min_tasks_to_steal_pending</td>
<td>The value of this property defines the number of pending HPX threads which</td>
</tr>
<tr>
<td></td>
<td>have to be available before neighboring cores are allowed to steal work.</td>
</tr>
<tr>
<td></td>
<td>The default is to allow stealing always.</td>
</tr>
<tr>
<td>hpx.thread_queue.min_tasks_to_steal_staged</td>
<td>The value of this property defines the number of staged HPX tasks which</td>
</tr>
<tr>
<td></td>
<td>have to be available before neighboring cores are allowed to steal work.</td>
</tr>
<tr>
<td></td>
<td>The default is to allow stealing always.</td>
</tr>
<tr>
<td>hpx.thread_queue.min_add_new_count</td>
<td>The value of this property defines the minimal number tasks to be converted into</td>
</tr>
<tr>
<td></td>
<td>HPX threads whenever the thread queues for a core have run empty.</td>
</tr>
<tr>
<td>hpx.thread_queue.max_add_new_count</td>
<td>The value of this property defines the maximal number tasks to be converted into</td>
</tr>
<tr>
<td></td>
<td>HPX threads whenever the thread queues for a core have run empty.</td>
</tr>
<tr>
<td>hpx.thread_queue.max_delete_count</td>
<td>The value of this property defines the number of terminated HPX threads to</td>
</tr>
<tr>
<td></td>
<td>discard during each invocation of the corresponding function.</td>
</tr>
</tbody>
</table>
The **hpx.components** configuration section

```
[hpX.components]
load_external = ${HPX_LOAD_EXTERNAL_COMPONENTS:1}
```

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hpx. components.load_external</td>
<td>This entry defines whether external components will be loaded on this <em>locality</em>. This entry normally is set to 1 and usually there is no need to directly change this value. It is automatically set to 0 for a dedicated AGAS server <em>locality</em>.</td>
</tr>
</tbody>
</table>

Additionally, the section **hpx.components** will be populated with the information gathered from all found components. The information loaded for each of the components will contain at least the following properties:

```
[hpX.components.<component_instance_name>]
name = <component_name>
path = <full_path_of_the_component_module>
enabled = ${hpx.components.load_external}
```

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hpx. components.&lt;component_instance_name&gt;.name</td>
<td>This is the name of a component, usually the same as the second argument to the macro used while registering the component with <code>HPX_REGISTER_COMPONENT</code>. Set by the component factory.</td>
</tr>
<tr>
<td>hpx. components.&lt;component_instance_name&gt;.path</td>
<td>This is either the full path file name of the component module or the directory the component module is located in. In this case, the component module name will be derived from the property <code>hpx.components.&lt;component_instance_name&gt;.name</code>. Set by the component factory.</td>
</tr>
<tr>
<td>hpx. components.&lt;component_instance_name&gt;.enabled</td>
<td>This setting explicitly enables or disables the component. This is an optional property. <code>HPX</code> assumed that the component is enabled if it is not defined.</td>
</tr>
</tbody>
</table>

The value for `<component_instance_name>` is usually the same as for the corresponding `name` property. However generally it can be defined to any arbitrary instance name. It is used to distinguish between different ini sections, one for each component.

The **hpx.parcel** configuration section

```
[hpX.parcel]
address = ${HPX_PARCEL_SERVER_ADDRESS:<hpx_initial_ip_address>}
port = ${HPX_PARCEL_SERVER_PORT:<hpx_initial_ip_port>}
bootstrap = ${HPX_PARCEL_BOOTSTRAP:<hpx_parcel_bootstrap>}
max_connections = ${HPX_PARCEL_MAX_CONNECTIONS:<hpx_parcel_max_connections>}
max_connections_per_locality = ${HPX_PARCEL_MAX_CONNECTIONS_PER_LOCALITY:<hpx_parcel_max_connections_per_locality>}
max_message_size = ${HPX_PARCEL_MAX_MESSAGE_SIZE:<hpx_parcel_max_message_size>}
max_outbound_message_size = ${HPX_PARCEL_MAX_OUTBOUND_MESSAGE_SIZE:<hpx_parcel_max_outbound_message_size>}
array_optimization = ${HPX_PARCEL_ARRAY_OPTIMIZATION:1}
zero_copy_optimization = ${HPX_PARCEL_ZERO_COPY_OPTIMIZATION:$[hpX.parcel.array_optimization]}
```

(continues on next page)
async_serialization = ${HPX_PARCEL_ASYNC.Serialization:1}
message_handlers = ${HPX_PARCEL_MESSAGE_HANDLERS:0}

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hpx.parcel.address</td>
<td>This property defines the default IP address to be used for the parcel layer to listen to. This IP address will be used as long as no other values are specified (for instance using the --hpx:hpx command line option). The expected format is any valid IP address or domain name format which can be resolved into an IP address. The default depends on the compile time preprocessor constant HPX_INITIAL_IP_ADDRESS (&quot;127.0.0.1&quot;).</td>
</tr>
<tr>
<td>hpx.parcel.port</td>
<td>This property defines the default IP port to be used for the parcel layer to listen to. This IP port will be used as long as no other values are specified (for instance using the --hpx:hpx command line option). The default depends on the compile time preprocessor constant HPX_INITIAL_IP_PORT (7910).</td>
</tr>
<tr>
<td>hpx.parcel.bootstrap</td>
<td>This property defines which parcelport type should be used during application bootstrap. The default depends on the compile time preprocessor constant HPX_PARCEL_BOOTSTRAP (&quot;tcp&quot;).</td>
</tr>
<tr>
<td>hpx.parcel.max_connections</td>
<td>This property defines how many network connections between different localities are overall kept alive by each of locality. The default depends on the compile time preprocessor constant HPX_PARCEL_MAX_CONNECTIONS (512).</td>
</tr>
<tr>
<td>hpx.parcel.max_connections_per_locality</td>
<td>This property defines the maximum number of network connections that one locality will open to another locality. The default depends on the compile time preprocessor constant HPX_PARCEL_MAX_CONNECTIONS_PER_LOCALITY (4).</td>
</tr>
<tr>
<td>hpx.parcel.max_message_size</td>
<td>This property defines the maximum allowed message size which will be transferable through the parcel layer. The default depends on the compile time preprocessor constant HPX_PARCEL_MAX_MESSAGE_SIZE (1000000000 bytes).</td>
</tr>
<tr>
<td>hpx.parcel.max_outbound_message_size</td>
<td>This property defines the maximum allowed outbound coalesced message size which will be transferable through the parcel layer. The default depends on the compile time preprocessor constant HPX_PARCEL_MAX_OUTBOUND_MESSAGE_SIZE (1000000 bytes).</td>
</tr>
<tr>
<td>hpx.parcel.array_optimization</td>
<td>This property defines whether this locality is allowed to utilize array optimizations during serialization of parcel data. The default is 1.</td>
</tr>
<tr>
<td>hpx.parcel.zero_copy_optimization</td>
<td>This property defines whether this locality is allowed to utilize zero copy optimizations during serialization of parcel data. The default is the same value as set for hpx.parcel.array_optimization.</td>
</tr>
<tr>
<td>hpx.parcel.async_serialization</td>
<td>This property defines whether this locality is allowed to spawn a new thread for serialization (this is both for encoding and decoding parcels). The default is 1.</td>
</tr>
<tr>
<td>hpx.parcel.message_handlers</td>
<td>This property defines whether message handlers are loaded. The default is 0.</td>
</tr>
</tbody>
</table>

The following settings relate to the TCP/IP parcelport.

```bash
[hpx.parcel.tcp]
enable = ${HPX_HAVE_PARCELPORT_TCP:${hpx.parcel.enabled}}
array_optimization = ${HPX_PARCEL_TCP_ARRAY_OPTIMIZATION:${hpx.parcel.array_optimization}}
zero_copy_optimization = ${HPX_PARCEL_TCP_ZERO_COPY_OPTIMIZATION:${hpx.parcel.zero_copy_optimization}}
async_serialization = ${HPX_PARCEL_TCP_ASYNC_SERIALIZATION:${hpx.parcel.async_serialization}}
parcel_pool_size = ${HPX_PARCEL_TCP_PARCEL_POOL_SIZE:${hpx.threadpools.parcel_pool_size}}
```

(continues on next page)
max_connections = ${HPX_PARCEL_TCP_MAX_CONNECTIONS:$[hpx.parcel.max_connections]}
max_connections_per_locality = ${HPX_PARCEL_TCP_MAX_CONNECTIONS_PER_LOCALITY:$[hpx.parcel.max_connections_per_locality]}
max_message_size = ${HPX_PARCEL_TCP_MAX_MESSAGE_SIZE:$[hpx.parcel.max_message_size]}
max_outbound_message_size = ${HPX_PARCEL_TCP_MAX_OUTBOUND_MESSAGE_SIZE:$[hpx.parcel.max_outbound_message_size]}

<table>

</table>

2.5. Manual
Loading INI files

During startup and after the internal database has been initialized as described in the section *Built-in Default Configuration Settings*, **HPX** will try to locate and load additional ini files to be used as a source for configuration properties. This allows for a wide spectrum of additional customization possibilities by the user and system administrators. The sequence of locations where **HPX** will try loading the ini files is well defined and documented in this section. All ini files found are merged into the internal configuration database. The merge operation itself conforms to the rules as described in the section *The HPX INI File Format*.

1. Load all component shared libraries found in the directories specified by the property `hpx.component_path` and retrieve their default configuration information (see section *Loading components* for more details). This property can refer to a list of directories separated by `:'` (Linux, Android, and MacOS) or using `';'` (Windows).

2. Load all files named `hpx.ini` in the directories referenced by the property `hpx.master_ini_path` This property can refer to a list of directories separated by `:'` (Linux, Android, and MacOS) or using `';'` (Windows).

3. Load a file named `.hpx.ini` in the current working directory, e.g. the directory the application was invoked from.

4. Load a file referenced by the environment variable `HPX_INI`. This variable is expected to provide the full path name of the ini configuration file (if any).

5. Load a file named `/etc/hpx.ini`. This lookup is done on non-Windows systems only.

6. Load a file named `.hpx.ini` in the home directory of the current user, e.g. the directory referenced by the environment variable `HOME`.

7. Load a file named `.hpx.ini` in the directory referenced by the environment variable `PWD`.

8. Load the file specified on the command line using the option `--hpx:config`.

9. Load all properties specified on the command line using the option `--hpx:ini`. The properties will be added to the database in the same sequence as they are specified on the command line. The format for those options is for instance `--hpx:ini=hpx.default_stack_size=0x4000`. In addition to the explicit command line options, this will set the following properties as implied from other settings:
   - `hpx.parcel.address` and `hpx.parcel.port` as set by `--hpx:hpx`
   - `hpx.agas.address`, `hpx.agas.port` and `hpx.agas.service_mode` as set by `--hpx:agas`
   - `hpx.program_name` and `hpx.cmd_line` will be derived from the actual command line
   - `hpx.os_threads` and `hpx.localities` as set by `--hpx:threads` and `--hpx:localities`
   - `hpx.runtime_mode` will be derived from any explicit `--hpx:console`, `--hpx:worker`, or `--hpx:connect`, or it will be derived from other settings, such as `--hpx:node =0` which implies `--hpx:console`

10. Load files based on the pattern `*.ini` in all directories listed by the property `hpx.ini_path`. All files found during this search will be merged. The property `hpx.ini_path` can hold a list of directories separated by `:'` (on Linux or Mac) or `';'` (on Windows).

11. Load the file specified on the command line using the option `--hpx:app-config`. Note that this file will be merged as the content for a top level section `[application]`.

---

**Note:** Any changes made to the configuration database caused by one of the steps will influence the loading process for all subsequent steps. For instance, if one of the ini files loaded changes the property `hpx.ini_path` this will...
influence the directories searched in step 9 as described above.

---

**Important:** The HPX core library will verify that all configuration settings specified on the command line (using the `--hpx:ini` option) will be checked for validity. That means that the library will accept only known configuration settings. This is to protect the user from unintentional typos while specifying those settings. This behavior can be overwritten by appending a '!' to the configuration key, thus forcing the setting to be entered into the configuration database, for instance: `--hpx:ini=hpx.foo! = 1`

If any of the environment variables or files listed above is not found the corresponding loading step will be silently skipped.

**Loading components**

HPX relies on loading application specific components during the runtime of an application. Moreover, HPX comes with a set of preinstalled components supporting basic functionalities useful for almost every application. Any component in HPX is loaded from a shared library, where any of the shared libraries can contain more than one component type. During startup, HPX tries to locate all available components (e.g. their corresponding shared libraries) and creates an internal component registry for later use. This section describes the algorithm used by HPX to locate all relevant shared libraries on a system. As described, this algorithm is customizable by the configuration properties loaded from the ini files (see section *Loading INI files*).

Loading components is a two stage process. First HPX tries to locate all component shared libraries, loads those, and generates default configuration section in the internal configuration database for each component found. For each found component the following information is generated:

```
[hpx.components.<component_instance_name>]
name = <name_of_shared_library>
path = ${component_path}
enabled = ${hpx.components.load_external}
default = 1
```

The values in this section correspond to the expected configuration information for a component as described in the section *Built-in Default Configuration Settings*.

In order to locate component shared libraries, HPX will try loading all shared libraries (files with the platform specific extension of a shared library, Linux: `*.so`, Windows: `*.dll`, MacOS: `*.dylib` found in the directory referenced by the ini property `hpx.component_path`).

This first step corresponds to step 1) during the process of filling the internal configuration database with default information as described in section *Loading INI files*.

After all of the configuration information has been loaded, HPX performs the second step in terms of loading components. During this step, HPX scans all existing configuration sections `[hpx.component.<some_component_instance_name>]` and instantiates a special factory object for each of the successfully located and loaded components. During the application’s life time, these factory objects will be responsible to create new and discard old instances of the component they are associated with. This step is performed after step 11) of the process of filling the internal configuration database with default information as described in section *Loading INI files*. 
Application specific component example

In this section we assume to have a simple application component which exposes one member function as a component action. The header file `app_server.hpp` declares the C++ type to be exposed as a component. This type has a member function `print_greeting()` which is exposed as an action `print_greeting_action`. We assume the source files for this example are located in a directory referenced by `$APP_ROOT`:

```cpp
// file: $APP_ROOT/app_server.hpp
#include <hpx/hpx.hpp>
#include <hpx/include/iostreams.hpp>
namespace app {
    // Define a simple component exposing one action 'print_greeting'
    class HPX_COMPONENT_EXPORT server
        : public hpx::components::component_base<server>
    {
        void print_greeting ()
            {
                hpx::cout << "Hey, how are you?\n" << hpx::flush;
            }

        // Component actions need to be declared, this also defines the
        // type 'print_greeting_action' representing the action.
        HPX_DEFINE_COMPONENT_ACTION(server, print_greeting, print_greeting_action);
    };
}
// Declare boilerplate code required for each of the component actions.
HPX_REGISTER_ACTION_DECLARATION(app::server::print_greeting_action);
```

The corresponding source file contains mainly macro invocations which define boilerplate code needed for HPX to function properly:

```cpp
// file: $APP_ROOT/app_server.cpp
#include "app_server.hpp"
// Define boilerplate required once per component module.
HPX_REGISTER_COMPONENT_MODULE();
// Define factory object associated with our component of type 'app::server'.
HPX_REGISTER_COMPONENT(app::server, app_server);
// Define boilerplate code required for each of the component actions. Use the
// same argument as used for HPX_REGISTER_ACTION_DECLARATION above.
HPX_REGISTER_ACTION(app::server::print_greeting_action);
```

The following gives an example of how the component can be used. We create one instance of the `app::server` component on the current `locality` and invoke the exposed action `print_greeting_action` using the global id of the newly created instance. Note, that no special code is required to delete the component instance after it is not needed anymore. It will be deleted automatically when its last reference goes out of scope, here at the closing brace of the block surrounding the code:

```cpp
// file: $APP_ROOT/use_app_server_example.cpp
#include <hpx/hpx_init.hpp>
#include "app_server.hpp"
(continues on next page)
```
int hpx_main()
{
    // Create an instance of the app_server component on the current locality.
    hpx::naming::id_type app_server_instance =
        hpx::create_component<app::server>(hpx::find_here());

    // Create an instance of the action 'print_greeting_action'.
    app::server::print_greeting_action print_greeting;

    // Invoke the action 'print_greeting' on the newly created component.
    print_greeting(app_server_instance);

    return hpx::finalize();
}

int main(int argc, char* argv[])
{
    return hpx::init(argc, argv);
}

In order to make sure that the application will be able to use the component app::server, special configuration information must be passed to HPX. The simples way to allow HPX to ‘find’ the component is to provide special ini configuration files, which add the necessary information to the internal configuration database. The component should have a special ini file containing the information specific to the component app_server.

# file: $APP_ROOT/app_server.ini
[hpx.components.app_server]
name = app_server
path = $APP_LOCATION/

Here $APP_LOCATION is the directory where the (binary) component shared library is located. HPX will attempt to load the shared library from there. The section name hpx.components.app_server reflects the instance name of the component (app_server is an arbitrary, but unique name). The property value for hpx.components.app_server.name should be the same as used for the second argument to the macro HPX_REGISTER_COMPONENT above.

Additionally a file .hpx.ini which could be located in the current working directory (see step 3 as described in the section Loading INI files) can be used to add to the ini search path for components:

# file: $PWD/.hpx.ini
[hpx]
i ini_path = ${hpx.ini_path}:${APP_ROOT}/

This assumes that the above ini file specific to the component is located in the directory $APP_ROOT.

Note: It is possible to reference the defined property from inside its value. HPX will gracefully use the previous value of hpx.ini_path for the reference on the right hand side and assign the overall (now expanded) value to the property.
Logging

HPX uses a sophisticated logging framework allowing to follow in detail what operations have been performed inside the HPX library in what sequence. This information proves to be very useful for diagnosing problems or just for improving the understanding what is happening in HPX as a consequence of invoking HPX API functionality.

Default logging

Enabling default logging is a simple process. The detailed description in the remainder of this section explains different ways to customize the defaults. Default logging can be enabled by using one of the following:

- a command line switch `--hpx:debug-hpx-log`, which will enable logging to the console terminal
- the command line switch `--hpx:debug-hpx-log=<filename>`, which enables logging to a given file `<filename>`, or
- setting an environment variable `HPX_LOGLEVEL=<loglevel>` while running the HPX application. In this case `<loglevel>` should be a number between (or equal to) 1 and 5 where 1 means minimal logging and 5 causes to log all available messages. When setting the environment variable the logs will be written to a file named `hpx.<PID>.lo` in the current working directory, where `<PID>` is the process id of the console instance of the application.

Customizing logging

Generally, logging can be customized either using environment variable settings or using by an ini configuration file. Logging is generated in several categories, each of which can be customized independently. All customizable configuration parameters have reasonable defaults, allowing to use logging without any additional configuration effort. The following table lists the available categories.

<table>
<thead>
<tr>
<th>Category</th>
<th>Category shortcut</th>
<th>Information to be generated</th>
<th>Environment variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>General</td>
<td>None</td>
<td>Logging information generated by different subsystems of HPX, such as thread-manager, parcel layer, LCOs, etc.</td>
<td>HPX_LOGLEVEL</td>
</tr>
<tr>
<td>AGAS</td>
<td>AGAS</td>
<td>Logging output generated by the AGAS subsystem</td>
<td>HPX_AGAS_LOGLEVEL</td>
</tr>
<tr>
<td>Application</td>
<td>APP</td>
<td>Logging generated by applications.</td>
<td>HPX_APP_LOGLEVEL</td>
</tr>
</tbody>
</table>

By default, all logging output is redirected to the console instance of an application, where it is collected and written to a file, one file for each logging category.

Each logging category can be customized at two levels, the parameters for each are stored in the ini configuration sections `hpx.logging.CATEGORY` and `hpx.logging.console.CATEGORY` (where CATEGORY is the category shortcut as listed in the table above). The former influences logging at the source locality and the latter modifies the logging behaviour for each of the categories at the console instance of an application.
Levels

All HPX logging output has seven different logging levels. These levels can be set explicitly or through environmental variables in the main HPX ini file as shown below. The logging levels and their associated integral values are shown in the table below, ordered from most verbose to least verbose. By default, all HPX logs are set to 0, e.g. all logging output is disabled by default.

<table>
<thead>
<tr>
<th>Logging level</th>
<th>Integral value</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;debug&gt;</td>
<td>5</td>
</tr>
<tr>
<td>&lt;info&gt;</td>
<td>4</td>
</tr>
<tr>
<td>&lt;warning&gt;</td>
<td>3</td>
</tr>
<tr>
<td>&lt;error&gt;</td>
<td>2</td>
</tr>
<tr>
<td>&lt;fatal&gt;</td>
<td>1</td>
</tr>
<tr>
<td>No logging</td>
<td>0</td>
</tr>
</tbody>
</table>

Tip: The easiest way to enable logging output is to set the environment variable corresponding to the logging category to an integral value as described in the table above. For instance, setting HPX_LOGLEVEL=5 will enable full logging output for the general category. Please note that the syntax and means of setting environment variables varies between operating systems.

Configuration

Logs will be saved to destinations as configured by the user. By default, logging output is saved on the console instance of an application to hpx.<CATEGORY>.<PID>.lo (where CATEGORY and PID are placeholders for the category shortcut and the OS process id). The output for the general logging category is saved to hpx.<PID>.log. The default settings for the general logging category are shown here (the syntax is described in the section The HPX INI File Format):

```
[hpx.logging]
level = ${HPX_LOGLEVEL:0}
destination = ${HPX_LOGDESTINATION:console}
format = ${HPX_LOGFORMAT:(%locality%/%hpxthread%/%hpxphase%/%hpxcomponent%) P
--+%parentloc%/%hpxparent%/%hpxparentphase% %time%($hh:$mm.$ss.$mili) [%idx%] }\n}
```

The logging level is taken from the environment variable HPX_LOGLEVEL and defaults to zero, e.g. no logging. The default logging destination is read from the environment variable HPX_LOGDESTINATION. On any of the localities it defaults to console which redirects all generated logging output to the console instance of an application. The following table lists the possible destinations for any logging output. It is possible to specify more than one destination separated by whitespace.

<table>
<thead>
<tr>
<th>Logging destination</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file&lt;filename&gt;</td>
<td>Direct all output to a file with the given &lt;filename&gt;.</td>
</tr>
<tr>
<td>cout</td>
<td>Direct all output to the local standard output of the application instance on this locality.</td>
</tr>
<tr>
<td>cerr</td>
<td>Direct all output to the local standard error output of the application instance on this locality.</td>
</tr>
<tr>
<td>console</td>
<td>Direct all output to the console instance of the application. The console instance has its logging destinations configured separately.</td>
</tr>
<tr>
<td>android_log</td>
<td>Direct all output to the (Android) system log (available on Android systems only).</td>
</tr>
</tbody>
</table>
The logging format is read from the environment variable `HPX_LOGFORMAT` and it defaults to a complex format description. This format consists of several placeholder fields (for instance `%locality%` which will be replaced by concrete values when the logging output is generated. All other information is transferred verbatim to the output. The table below describes the available field placeholders. The separator character `|` separates the logging message prefix formatted as shown and the actual log message which will replace the separator.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>locality</td>
<td>The id of the locality on which the logging message was generated.</td>
</tr>
<tr>
<td>hpxthread</td>
<td>The id of the HPX-thread generating this logging output.</td>
</tr>
<tr>
<td>hpxphase</td>
<td>The phase(^{98}) of the HPX-thread generating this logging output.</td>
</tr>
<tr>
<td>hpxcomponent</td>
<td>The local virtual address of the component which the current HPX-thread is accessing.</td>
</tr>
<tr>
<td>parentloc</td>
<td>The id of the locality where the HPX thread was running which initiated the current HPX-thread. The current HPX-thread is generating this logging output.</td>
</tr>
<tr>
<td>hpxparent</td>
<td>The id of the HPX-thread which initiated the current HPX-thread. The current HPX-thread is generating this logging output.</td>
</tr>
<tr>
<td>hpxparentphase</td>
<td>The phase of the HPX-thread when it initiated the current HPX-thread. The current HPX-thread is generating this logging output.</td>
</tr>
<tr>
<td>time</td>
<td>The time stamp for this logging output line as generated by the source locality.</td>
</tr>
<tr>
<td>idx</td>
<td>The sequence number of the logging output line as generated on the source locality.</td>
</tr>
<tr>
<td>osthread</td>
<td>The sequence number of the OS-thread which executes the current HPX-thread.</td>
</tr>
</tbody>
</table>

Note: Not all of the field placeholder may be expanded for all generated logging output. If no value is available for a particular field it is replaced with a sequence of `'-'` characters.

Here is an example line from a logging output generated by one of the HPX examples (please note that this is generated on a single line, without line break):

```
(T00000000/0000000002d46f90.01/00000000009ebc10) P--------/0000000002d46f80.02 17:49.320 → [000000000000004d] <info> [RT] successfully created component {0000000100ff0001, 0000000000030002} of type: component_barrier[7(3)]
```

The default settings for the general logging category on the console is shown here:

```
[hpx.logging.console]
level = ${HPX_LOGLEVEL:${hpx.logging.level}}
destination = ${HPX_CONSOLE_LOGDESTINATION:file(hpx.${system.pid}.log)}
format = ${HPX_CONSOLE_LOGFORMAT:[]}
```

These settings define how the logging is customized once the logging output is received by the console instance of an application. The logging level is read from the environment variable `HPX_LOGLEVEL` (as set for the console instance of the application). The level defaults to the same values as the corresponding settings in the general logging configuration shown before. The destination on the console instance is set to be a file which name is generated based from its OS process id. Setting the environment variable `HPX_CONSOLE_LOGDESTINATION` allows customization of the naming scheme for the output file. The logging format is set to leave the original logging output unchanged, as received from one of the localities the application runs on.

\(^{98}\) The phase of a HPX-thread counts how often this thread has been activated.
**HPX Command Line Options**

The predefined command line options for any application using `hpx::init` are described in the following subsections.

**HPX options (allowed on command line only)**

`--hpx:help`

print out program usage (default: this message), possible values: full (additionally prints options from components)

`--hpx:version`

print out HPX version and copyright information

`--hpx:info`

print out HPX configuration information

`--hpx:options-file arg`

specify a file containing command line options (alternatively: @filepath)

**HPX options (additionally allowed in an options file)**

`--hpx:worker`

run this instance in worker mode

`--hpx:console`

run this instance in console mode

`--hpx:connect`

run this instance in worker mode, but connecting late

`--hpx:run-agas-server`

run AGAS server as part of this runtime instance

`--hpx:run-hpx-main`

run the hpx_main function, regardless of locality mode

`--hpx:hp arg`

the IP address the HPX parcelport is listening on, expected format: address:port (default: 127.0.0.1:7910)

`--hpx:agas arg`

the IP address the AGAS root server is running on, expected format: address:port (default: 127.0.0.1:7910)

`--hpx:run-agas-server-only`

run only the AGAS server

`--hpx:nodefile arg`

the file name of a node file to use (list of nodes, one node name per line and core)

`--hpx:nodes arg`

the (space separated) list of the nodes to use (usually this is extracted from a node file)

`--hpx:endnodes`

can be used to end the list of nodes specified using the option `--hpx:nodes`

`--hpx:ifsuffix arg`
	suffix to append to host names in order to resolve them to the proper network interconnect
--hpx:ifprefix arg
prefix to prepend to host names in order to resolve them to the proper network interconnect

--hpx:iftransform arg
sed-style search and replace (s/search/replace/) used to transform host names to the proper network interconnect

--hpx:localities arg
the number of localities to wait for at application startup (default: 1)

--hpx:node arg
number of the node this locality is run on (must be unique)

--hpx:ignore-batch-env
ignore batch environment variables

--hpx:expect-connecting-localities
this locality expects other localities to dynamically connect (this is implied if the number of initial localities is larger than 1)

--hpx:pu-offset
the first processing unit this instance of HPX should be run on (default: 0)

--hpx:pu-step
the step between used processing unit numbers for this instance of HPX (default: 1)

--hpx:threads arg
the number of operating system threads to spawn for this HPX locality. Possible values are: numeric values 1, 2, 3 and so on, all (which spawns one thread per processing unit, includes hyperthreads), or cores (which spawns one thread per core) (default: cores).

--hpx:cores arg
the number of cores to utilize for this HPX locality (default: all, i.e. the number of cores is based on the number of threads --hpx:threads assuming --hpx:bind=compact

--hpx:affinity arg
the affinity domain the OS threads will be confined to, possible values: pu, core, numa, machine (default: pu)

--hpx:bind arg
the detailed affinity description for the OS threads, see More details about HPX command line options for a detailed description of possible values. Do not use with --hpx:pu-step, --hpx:pu-offset or --hpx:affinity options. Implies --hpx:numa-sensitive(--hpx:bind=none) disables defining thread affinities.

--hpx:use-process-mask
use the process mask to restrict available hardware resources (implies --hpx:ignore-batch-env)

--hpx:print-bind
print to the console the bit masks calculated from the arguments specified to all --hpx:bind options.

--hpx:queuing arg
the queue scheduling policy to use, options are local, local-priority-fifo, local-priority-lifo, static, static-priority, abp-priority-fifo and abp-priority-lifo (default: local-priority-fifo)

--hpx:high-priority-threads arg
the number of operating system threads maintaining a high priority queue (default: number of OS threads), valid for --hpx:queuing=abp-priority, --hpx:queuing=static-priority and --hpx:queuing=local-priority only
--hpx:numa-sensitive
  makes the scheduler NUMA sensitive

**HPX configuration options**

--hpx:app-config  arg
  load the specified application configuration (ini) file

--hpx:config  arg
  load the specified hpx configuration (ini) file

--hpx:ini  arg
  add a configuration definition to the default runtime configuration

--hpx:exit
  exit after configuring the runtime

**HPX debugging options**

--hpx:list-symbolic-names
  list all registered symbolic names after startup

--hpx:list-component-types
  list all dynamic component types after startup

--hpx:dump-config-initial
  print the initial runtime configuration

--hpx:dump-config
  print the final runtime configuration

--hpx:debug-hpx-log  [arg]
  enable all messages on the HPX log channel and send all HPX logs to the target destination (default: cout)

--hpx:debug-agas-log  [arg]
  enable all messages on the AGAS log channel and send all AGAS logs to the target destination (default: cout)

--hpx:debug-parcel-log  [arg]
  enable all messages on the parcel transport log channel and send all parcel transport logs to the target destination (default: cout)

--hpx:debug-timing-log  [arg]
  enable all messages on the timing log channel and send all timing logs to the target destination (default: cout)

--hpx:debug-app-log  [arg]
  enable all messages on the application log channel and send all application logs to the target destination (default: cout)

--hpx:debug-clp
  debug command line processing

--hpx:attach-debugger  arg
  wait for a debugger to be attached, possible arg values: startup or exception (default: startup)
**HPX options related to performance counters**

`--hpx:print-counter`
print the specified performance counter either repeatedly and/or at the times specified by
`--hpx:print-counter-at` (see also option `--hpx:print-counter-interval`)

`--hpx:print-counter-reset`
print the specified performance counter either repeatedly and/or at the times specified by
`--hpx:print-counter-at` reset the counter after the value is queried. (see also option
`--hpx:print-counter-interval`)  

`--hpx:print-counter-interval`
print the performance counter(s) specified with `--hpx:print-counter` repeatedly after the time interval
(specified in milliseconds), (default: 0, which means print once at shutdown)

`--hpx:print-counter-destination`
print the performance counter(s) specified with `--hpx:print-counter` to the given file (default: console)

`--hpx:list-counters`
list the names of all registered performance counters, possible values: minimal (prints counter name skele-
tons), full (prints all available counter names)

`--hpx:list-counter-infos`
list the description of all registered performance counters, possible values: minimal (prints info for counter
name skeletons), full (prints all available counter infos)

`--hpx:print-counter-format`
print the performance counter(s) specified with `--hpx:print-counter` possible formats in csv format
with header or without any header (see option `--hpx:no-csv-header`, possible values: csv (prints
counter values in CSV format with full names as header), csv-short (prints counter values in CSV for-
mat with shortnames provided with `--hpx:print-counter` as `--hpx:print-counter shortname`,
full-countername)

`--hpx:no-csv-header`
print the performance counter(s) specified with `--hpx:print-counter` and csv or csv-short format
specified with `--hpx:print-counter-format` without header

`--hpx:print-counter-at arg`
print the performance counter(s) specified with `--hpx:print-counter` (or
`--hpx:print-counter-reset` at the given point in time, possible argument values: startup,
shutdown (default), noshutdown

`--hpx:reset-counters`
reset all performance counter(s) specified with `--hpx:print-counter` after they have been evaluated.

`--hpx:print-counters-locally`
Each locality prints only its own local counters. If this is used with
`--hpx:print-counter-destination=<file>`, the code will append a ".<locality_id>" to the file name in order to avoid clashes between localities.
Command line argument shortcuts

Additionally, the following shortcuts are available from every HPX application.

Table 2.11: Predefined command line option shortcuts

<table>
<thead>
<tr>
<th>Shortcut option</th>
<th>Equivalent long option</th>
</tr>
</thead>
<tbody>
<tr>
<td>-a</td>
<td>--hpx:agas</td>
</tr>
<tr>
<td>-c</td>
<td>--hpx:console</td>
</tr>
<tr>
<td>-h</td>
<td>--hpx:help</td>
</tr>
<tr>
<td>-I</td>
<td>--hpx:ini</td>
</tr>
<tr>
<td>-l</td>
<td>--hpx:localities</td>

<tr>
<td>-8</td>
<td>--hpx:node=8</td>
</tr>
<tr>
<td>-9</td>
<td>--hpx:node=9</td>
</tr>
</tbody>
</table>

It is possible to define your own shortcut options. In fact, all of the shortcuts listed above are pre-defined using the technique described here. Also, it is possible to redefine any of the pre-defined shortcuts to expand differently as well.

Shortcut options are obtained from the internal configuration database. They are stored as key-value properties in a special properties section named `hpx.commandline`. You can define your own shortcuts by adding the corresponding definitions to one of the ini configuration files as described in the section *Configuring HPX applications*. For instance, in order to define a command line shortcut `--p` which should expand to `-hpx:print-counter`, the following configuration information needs to be added to one of the ini configuration files:

```
[hpx.commandline.aliases]
--pc = --hpx:print-counter
```

**Note:** Any arguments for shortcut options passed on the command line are retained and passed as arguments to the corresponding expanded option. For instance, given the definition above, the command line option:

```
--pc=/threads{locality#0/total}/count/cumulative
```

would be expanded to:

```
--hpx:print-counter=/threads{locality#0/total}/count/cumulative
```

**Important:** Any shortcut option should either start with a single '-' or with two '--' characters. Shortcuts
starting with a single '-') are interpreted as short options (i.e. everything after the first character following the ' - ' is treated as the argument). Shortcuts starting with ' -- ' are interpreted as long options. No other shortcut formats are supported.

Specifying options for single localities only

For runs involving more than one locality it is sometimes desirable to supply specific command line options to single localities only. When the HPX application is launched using a scheduler (like PBS, for more details see section How to use HPX applications with PBS), specifying dedicated command line options for single localities may be desirable. For this reason all of the command line options which have the general format --hpx:<some_key> can be used in a more general form: --hpx:<N>:<some_key>, where <N> is the number of the locality this command line options will be applied to, all other localities will simply ignore the option. For instance, the following PBS script passes the option --hpx:pu-offset=4 to the locality '1' only.

```bash
#!/bin/bash
#PBS -l nodes=2:ppn=4
APP_PATH=~/packages/hpx/bin/hello_world_distributed
APP_OPTIONS=

pbsdsh -u $APP_PATH $APP_OPTIONS --hpx:1:pu-offset=4 --hpx:nodes=`cat $PBS_NODEFILE`
```

Caution: If the first application specific argument (inside $APP_OPTIONS is a non-option (i.e. does not start with a - or a --), then it must be placed before the option --hpx:nodes, which, in this case, should be the last option on the command line.

Alternatively, use the option --hpx:endnodes to explicitly mark the end of the list of node names:

```bash
pbsdsh -u $APP_PATH --hpx:1:pu-offset=4 --hpx:nodes=`cat $PBS_NODEFILE` --
--hpx:endnodes $APP_OPTIONS
```

More details about HPX command line options

This section documents the following list of the command line options in more detail:

- The command line option --hpx:bind

The command line option --hpx:bind

This command line option allows one to specify the required affinity of the HPX worker threads to the underlying processing units. As a result the worker threads will run only on the processing units identified by the corresponding bind specification. The affinity settings are to be specified using --hpx:bind=<BINDINGS>, where <BINDINGS> have to be formatted as described below.

In addition to the syntax described below one can use --hpx:bind=none to disable all binding of any threads to a particular core. This is mostly supported for debugging purposes.

The specified affinities refer to specific regions within a machine hardware topology. In order to understand the hardware topology of a particular machine it may be useful to run the lstopo tool which is part of Portable Hardware
Locality (HWLOC) to see the reported topology tree. Seeing and understanding a topology tree will definitely help in understanding the concepts that are discussed below.

Affinities can be specified using HWLOC (Portable Hardware Locality (HWLOC)) tuples. Tuples of HWLOC objects and associated indexes can be specified in the form object:index, object:index-index or object:index,...,index. HWLOC objects represent types of mapped items in a topology tree. Possible values for objects are socket, numanode, core and pu (processing unit). Indexes are non-negative integers that specify a unique physical object in a topology tree using its logical sequence number.

Chaining multiple tuples together in the more general form object1:index1[.object2:index2[...]] is permissible. While the first tuple’s object may appear anywhere in the topology, the Nth tuple’s object must have a shallower topology depth than the (N+1)th tuple’s object. Put simply: as you move right in a tuple chain, objects must go deeper in the topology tree. Indexes specified in chained tuples are relative to the scope of the parent object. For example, socket:0.core:1 refers to the second core in the first socket (all indices are zero based).

Multiple affinities can be specified using several --hpx:bind command line options or by appending several affinities separated by a ';'. By default, if multiple affinities are specified, they are added. "all" is a special affinity consisting in the entire current topology.

Note: All ‘names’ in an affinity specification, such as thread, socket, numanode, pu or all can be abbreviated. Thus the affinity specification threads:0-3=socket:0.core:1.pu:1 is fully equivalent to its shortened form t:0-3=s:0.c:1.p:1.

Here is a full grammar describing the possible format of mappings:

```
mappings ::= distribution | mapping (";" mapping)*
distribution ::= "compact" | "scatter" | "balanced" | "numa-balanced"
mapping ::= thread_spec "=" pu_specs
thread_spec ::= "thread:" range_specs
pu_specs ::= pu_spec ("." pu_spec)*
pu_spec ::= type ":" range_specs | "~" pu_spec
range_specs ::= range_spec ("," range_spec)*
range_spec ::= int | int "-" int | "all"
type ::= "socket" | "numanode" | "core" | "pu"
```

The following example assumes a system with at least 4 cores, where each core has more than 1 processing unit (hardware threads). Running hello_world_distributed with 4 OS-threads (on 4 processing units), where each of those threads is bound to the first processing unit of each of the cores, can be achieved by invoking:

```
hello_world_distributed -t4 --hpx:bind=thread:0-3=core:0-3.pu:0
```

Here thread:0-3 specifies the OS threads for which to define affinity bindings, and core:0-3.pu: defines that for each of the cores (core:0-3) only their first processing unit pu:0 should be used.

Note: The command line option --hpx:print-bind can be used to print the bitmasks generated from the affinity mappings as specified with --hpx:bind. For instance, on a system with hyperthreading enabled (i.e. 2 processing units per core), the command line:

```
hello_world_distributed -t4 --hpx:bind=thread:0-3=core:0-3.pu:0 --hpx:print-bind
```

will cause this output to be printed:
where each bit in the bitmasks corresponds to a processing unit the listed worker thread will be bound to run on.

The difference between the four possible predefined distribution schemes (compact, scatter, balanced and numa-balanced) is best explained with an example. Imagine that we have a system with 4 cores and 4 hardware threads per core on 2 sockets. If we place 8 threads the assignments produced by the compact, scatter, balanced and numa-balanced types are shown in the figure below. Notice that compact does not fully utilize all the cores in the system. For this reason it is recommended that applications are run using the scatter or balanced/numa-balanced options in most cases.

Fig. 2.7: Schematic of thread affinity type distributions.

In addition to the predefined distributions it is possible to restrict the resources used by HPX to the process CPU
mask. The CPU mask is typically set by e.g. MPI\textsuperscript{97} and batch environments. Using the command line option \texttt{--hpx:use-process-mask} makes \textit{HPX} act as if only the processing units in the CPU mask are available for use by \textit{HPX}. The number of threads is automatically determined from the CPU mask. The number of threads can still be changed manually using this option, but only to a number less than or equal to the number of processing units in the CPU mask. The option \texttt{--hpx:print-bind} is useful in conjunction with \texttt{--hpx:use-process-mask} to make sure threads are placed as expected.

### 2.5.6 Writing single-node \textit{HPX} applications

\textit{HPX} is a C++ Standard Library for Concurrency and Parallelism. This means that it implements all of the corresponding facilities as defined by the C++ Standard. Additionally, \textit{HPX} implements functionalities proposed as part of the ongoing C++ standardization process. This section focuses on the features available in \textit{HPX} for parallel and concurrent computation on a single node, although many of the features presented here are also implemented to work in the distributed case.

#### Using LCOs

Lightweight Control Objects (LCOs) provide synchronization for \textit{HPX} applications. Most of them are familiar from other frameworks, but a few of them work in slightly different ways adapted to \textit{HPX}. The following synchronization objects are available in \textit{HPX}:

1. future
2. queue
3. object_semaphore
4. barrier

#### Channels

Channels combine communication (the exchange of a value) with synchronization (guaranteeing that two calculations (tasks) are in a known state). A channel can transport any number of values of a given type from a sender to a receiver:

```cpp
hpx::lcos::local::channel<int> c;
hpx::future<int> f = c.get();
HPX_ASSERT(!f.is_ready());
c.set(42);
HPX_ASSERT(f.is_ready());
hpx::cout << f.get() << hpx::endl;
```

Channels can be handed to another thread (or in case of channel components, to other localities), thus establishing a communication channel between two independent places in the program:

```cpp
void do_something(hpx::lcos::local::receive_channel<int> c,
  hpx::lcos::local::send_channel<> done)
{
  // prints 43
  hpx::cout << c.get(hpx::launch::sync) << hpx::endl;
  // signal back
  done.set();
}
```

\textsuperscript{97} http://en.wikipedia.org/wiki/Message_Passing_Interface
void send_receive_channel()
{
    hpx::lcos::local::channel<int> c;
    hpx::lcos::local::channel<> done;

    hpx::apply(&do_something, c, done);

    // send some value
    c.set(43);
    // wait for thread to be done
    done.get().wait();
}

Note how hpx::lcos::local::channel::get without any arguments returns a future which is ready when a value has been set on the channel. The launch policy hpx::launch::sync can be used to make hpx::lcos::local::channel::get block until a value is set and return the value directly.

A channel component is created on one *locality* and can be sent to another *locality* using an action. This example also demonstrates how a channel can be used as a range of values:

```
// channel components need to be registered for each used type (not needed
// for hpx::lcos::local::channel)
HPX_REGISTER_CHANNEL(double);

void channel_sender(hpx::lcos::channel<double> c)
{
    for (double d : c)
        hpx::cout << d << std::endl;
}
HPX_PLAIN_ACTION(channel_sender);

void channel()
{
    // create the channel on this locality
    hpx::lcos::channel<double> c(hpx::find_here());

    // pass the channel to a (possibly remote invoked) action
    hpx::apply(channel_sender_action(), hpx::find_here(), c);

    // send some values to the receiver
    std::vector<double> v = {1.2, 3.4, 5.0};
    for (double d : v)
        c.set(d);

    // explicitly close the communication channel (implicit at destruction)
    c.close();
}
```
Composable guards

Composable guards operate in a manner similar to locks, but are applied only to asynchronous functions. The guard (or guards) is automatically locked at the beginning of a specified task and automatically unlocked at the end. Because guards are never added to an existing task’s execution context, the calling of guards is freely composable and can never deadlock.

To call an application with a single guard, simply declare the guard and call run_guarded() with a function (task):

```cpp
hpx::lcos::local::guard gu;
run_guarded(gu, task);
```

If a single method needs to run with multiple guards, use a guard set:

```cpp
boost::shared<hpx::lcos::local::guard> gu1(new hpx::lcos::local::guard());
boost::shared<hpx::lcos::local::guard> gu2(new hpx::lcos::local::guard());
gs.add(*gu1);
gs.add(*gu2);
run_guarded(gs, task);
```

Guards use two atomic operations (which are not called repeatedly) to manage what they do, so overhead should be extremely low. The following guards are available in HPX:

1. conditional_trigger
2. counting_semaphore
3. dataflow
4. event
5. mutex
6. once
7. recursive_mutex
8. spinlock
9. spinlock_no_backoff
10. trigger

Extended facilities for futures

Concurrency is about both decomposing and composing the program from the parts that work well individually and together. It is in the composition of connected and multicore components where today’s C++ libraries are still lacking.

The functionality of std::future offers a partial solution. It allows for the separation of the initiation of an operation and the act of waiting for its result; however, the act of waiting is synchronous. In communication-intensive code this act of waiting can be unpredictable, inefficient and simply frustrating. The example below illustrates a possible synchronous wait using futures:

```cpp
#include <future>
using namespace std;
int main()
{
    future<int> f = async([]() { return 123; });
    int result = f.get(); // might block
}
```
For this reason, HPX implements a set of extensions to `std::future` (as proposed by __cpp11_n4107__). This proposal introduces the following key asynchronous operations to `hpx::future`, `hpx::shared_future` and `hpx::async`, which enhance and enrich these facilities.

Table 2.13: Facilities extending `std::future`

<table>
<thead>
<tr>
<th>Facility</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>hpx::future::then</code></td>
<td>In asynchronous programming, it is very common for one asynchronous operation, on completion, to invoke a second operation and pass data to it. The current C++ standard does not allow one to register a continuation to a future. With <code>then</code>, instead of waiting for the result, a continuation is “attached” to the asynchronous operation, which is invoked when the result is ready. Continuations registered using <code>then</code> function will help to avoid blocking waits or wasting threads on polling, greatly improving the responsiveness and scalability of an application.</td>
</tr>
<tr>
<td><code>unwrapping constructor for hpx::future</code></td>
<td>In some scenarios, you might want to create a future that returns another future, resulting in nested futures. Although it is possible to write code to unwrap the outer future and retrieve the nested future and its result, such code is not easy to write because users must handle exceptions and it may cause a blocking call. Unwrapping can allow users to mitigate this problem by doing an asynchronous call to unwrap the outermost future.</td>
</tr>
<tr>
<td><code>hpx::future::is_ready</code></td>
<td>There are often situations where a <code>get()</code> call on a future may not be a blocking call, or is only a blocking call under certain circumstances. This function gives the ability to test for early completion and allows us to avoid associating a continuation, which needs to be scheduled with some non-trivial overhead and near-certain loss of cache efficiency.</td>
</tr>
<tr>
<td><code>hpx::make_ready_future</code></td>
<td>Some functions may know the value at the point of construction. In these cases the value is immediately available, but needs to be returned as a future. By using <code>hpx::make_ready_future</code> a future can be created that holds a pre-computed result in its shared state. In the current standard it is non-trivial to create a future directly from a value. First a promise must be created, then the promise is set, and lastly the future is retrieved from the promise. This can now be done with one operation.</td>
</tr>
</tbody>
</table>

The standard also omits the ability to compose multiple futures. This is a common pattern that is ubiquitous in other asynchronous frameworks and is absolutely necessary in order to make C++ a powerful asynchronous programming language. Not including these functions is synonymous to Boolean algebra without AND/OR.

In addition to the extensions proposed by N4313, HPX adds functions allowing users to compose several futures in a more flexible way.

### High level parallel facilities

In preparation for the upcoming C++ Standards, there are currently several proposals targeting different facilities supporting parallel programming. HPX implements (and extends) some of those proposals. This is well aligned with our strategy to align the APIs exposed from HPX with current and future C++ Standards.

At this point, HPX implements several of the C++ Standardization working papers, most notably N4409[^102] (Working Draft, Technical Specification for C++ Extensions for Parallelism), N4411[^103] (Task Blocks), and N4406[^104] (Parallel Algorithms Need Executors).

### Using parallel algorithms

A parallel algorithm is a function template described by this document which is declared in the (inline) namespace `hpx::parallel::v1`.

**Note:** For compilers that do not support inline namespaces, all of the `namespace v1` is imported into the namespace `hpx::parallel`. The effect is similar to what inline namespaces would do, namely all names defined in `hpx::parallel::v1` are accessible from the namespace `hpx::parallel` as well.

All parallel algorithms are very similar in semantics to their sequential counterparts (as defined in the `namespace std`) with an additional formal template parameter named `ExecutionPolicy`. The execution policy is generally...
passed as the first argument to any of the parallel algorithms and describes the manner in which the execution of these algorithms may be parallelized and the manner in which they apply user-provided function objects.

The applications of function objects in parallel algorithms invoked with an execution policy object of type `hpx::execution::sequenced_policy` or `hpx::execution::sequenced_task_policy` execute in sequential order. For `hpx::execution::sequenced_policy` the execution happens in the calling thread.

The applications of function objects in parallel algorithms invoked with an execution policy object of type `hpx::execution::parallel_policy` or `hpx::execution::parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and are indeterminately sequenced within each thread.

**Important:** It is the caller’s responsibility to ensure correctness, such as making sure that the invocation does not introduce data races or deadlocks.

The applications of function objects in parallel algorithms invoked with an execution policy of type `hpx::execution::parallel_unsequenced_policy` is, in HPX, equivalent to the use of the execution policy `hpx::execution::parallel_policy`.

Algorithms invoked with an execution policy object of type `hpx::parallel::v1::execution_policy` execute internally as if invoked with the contained execution policy object. No exception is thrown when an `hpx::parallel::v1::execution_policy` contains an execution policy of type `hpx::execution::sequenced_task_policy` or `hpx::execution::parallel_task_policy` (which normally turn the algorithm into its asynchronous version). In this case the execution is semantically equivalent to the case of passing a `hpx::execution::sequenced_policy` or `hpx::execution::parallel_policy` contained in the `hpx::parallel::v1::execution_policy` object respectively.

**Parallel exceptions**

During the execution of a standard parallel algorithm, if temporary memory resources are required by any of the algorithms and no memory is available, the algorithm throws a `std::bad_alloc` exception.

During the execution of any of the parallel algorithms, if the application of a function object terminates with an uncaught exception, the behavior of the program is determined by the type of execution policy used to invoke the algorithm:

- If the execution policy object is of type `hpx::execution::parallel_unsequenced_policy`, `hpx::terminate` shall be called.
- If the execution policy object is of type `hpx::execution::sequenced_policy`, `hpx::execution::sequenced_task_policy`, `hpx::execution::parallel_policy`, or `hpx::execution::parallel_task_policy`, the execution of the algorithm terminates with an `hpx::exception_list` exception. All uncaught exceptions thrown during the application of user-provided function objects shall be contained in the `hpx::exception_list` object.

For example, the number of invocations of the user-provided function object in `for_each` is unspecified. When `hpx::parallel::v1::for_each` is executed sequentially, only one exception will be contained in the `hpx::exception_list` object.

These guarantees imply that, unless the algorithm has failed to allocate memory and terminated with `std::bad_alloc`, all exceptions thrown during the execution of the algorithm are communicated to the caller. It is unspecified whether an algorithm implementation will “forge ahead” after encountering and capturing a user exception.

The algorithm may terminate with the `std::bad_alloc` exception even if one or more user-provided function objects have terminated with an exception. For example, this can happen when an algorithm fails to allocate memory.
while creating or adding elements to the `hpx::exception_list` object.

**Parallel algorithms**

*HPX* provides implementations of the following parallel algorithms:
Table 2.15: Non-modifying parallel algorithms (in header: `<hpx/algorithm.hpp>`)

### Executor parameters and executor parameter traits

`HPX` introduces the notion of execution parameters and execution parameter traits. At this point, the only parameter that can be customized is the size of the chunks of work executed on a single `HPX` thread (such as the number of loop iterations combined to run as a single task).

An executor parameter object is responsible for exposing the calculation of the size of the chunks scheduled. It abstracts the (potentially platform-specific) algorithms of determining those chunk sizes.

The way executor parameters are implemented is aligned with the way executors are implemented. All functionalities of concrete executor parameter types are exposed and accessible through a corresponding `hpx::parallel::executor_parameter_traits` type.

With `executor_parameter_traits`, clients access all types of executor parameters uniformly:

```cpp
std::size_t chunk_size = 
    executor_parameter_traits<my_parameter_t>::get_chunk_size(my_parameter, 
        my_executor, [](){ return 0; }, num_tasks);
```

This call synchronously retrieves the size of a single chunk of loop iterations (or similar) to combine for execution on a single `HPX` thread if the overall number of tasks to schedule is given by `num_tasks`. The lambda function exposes a means of test-probing the execution of a single iteration for performance measurement purposes. The execution parameter type might dynamically determine the execution time of one or more tasks in order to calculate the chunk size; see `hpx::execution::auto_chunk_size` for an example of this executor parameter type.

Other functions in the interface exist to discover whether an executor parameter type should be invoked once (i.e., it returns a static chunk size; see `hpx::execution::static_chunk_size`) or whether it should be invoked for each scheduled chunk of work (i.e., it returns a variable chunk size; for an example, see `hpx::execution::guided_chunk_size`).

Although this interface appears to require executor parameter type authors to implement all different basic operations, none are required. In practice, all operations have sensible defaults. However, some executor parameter types will naturally specialize all operations for maximum efficiency.

`HPX` implements the following executor parameter types:

- `hpx::execution::auto_chunk_size`: Loop iterations are divided into pieces and then assigned to threads. The number of loop iterations combined is determined based on measurements of how long the execution of 1% of the overall number of iterations takes. This executor parameter type makes sure that as many loop iterations are combined as necessary to run for the amount of time specified.

- `hpx::execution::static_chunk_size`: Loop iterations are divided into pieces of a given size and then assigned to threads. If the size is not specified, the iterations are, if possible, evenly divided contiguously among the threads. This executor parameters type is equivalent to OpenMP’s STATIC scheduling directive.
• **hpx::execution::dynamic_chunk_size**: Loop iterations are divided into pieces of a given size and then dynamically scheduled among the cores; when a core finishes one chunk, it is dynamically assigned another. If the size is not specified, the default chunk size is 1. This executor parameter type is equivalent to OpenMP’s DYNAMIC scheduling directive.

• **hpx::execution::guided_chunk_size**: Iterations are dynamically assigned to cores in blocks as cores request them until no blocks remain to be assigned. This is similar to dynamic_chunk_size except that the block size decreases each time a number of loop iterations is given to a thread. The size of the initial block is proportional to \(\text{number of iterations} / \text{number of cores}\). Subsequent blocks are proportional to \(\text{number of iterations remaining} / \text{number of cores}\). The optional chunk size parameter defines the minimum block size. The default minimal chunk size is 1. This executor parameter type is equivalent to OpenMP’s GUIDED scheduling directive.

### Using task blocks

The `define_task_block`, `run` and the `wait` functions implemented based on N4411\(^{188}\) are based on the `task_block` concept that is a part of the common subset of the Microsoft Parallel Patterns Library (PPL)\(^{189}\) and the Intel Threading Building Blocks (TBB)\(^{190}\) libraries.

These implementations adopt a simpler syntax than exposed by those libraries— one that is influenced by language-based concepts, such as spawn and sync from Cilk++\(^{191}\) and async and finish from X10\(^{192}\). They improve on existing practice in the following ways:

• The exception handling model is simplified and more consistent with normal C++ exceptions.

• Most violations of strict fork-join parallelism can be enforced at compile time (with compiler assistance, in some cases).

• The syntax allows scheduling approaches other than child stealing.

Consider an example of a parallel traversal of a tree, where a user-provided function `compute` is applied to each node of the tree, returning the sum of the results:

```cpp
template <typename Func>
int traverse(node& n, Func && compute) {
    int left = 0, right = 0;
    define_task_block(
        [%](task_block<> & tr) {
            if (n.left)
                tr.run([&] { left = traverse(*n.left, compute); });
            if (n.right)
                tr.run([&] { right = traverse(*n.right, compute); });
        });
    return compute(n) + left + right;
}
```

The example above demonstrates the use of two of the functions, `hpx::parallel::define_task_block` and the `hpx::parallel::task_block::run` member function of `hpx::parallel::task_block`.

The `task_block` function delineates a region in a program code potentially containing invocations of threads spawned by the `run` member function of the `task_block` class. The `run` function spawns an HPX thread, a

\(^{190}\) [https://www.threadingbuildingblocks.org/](https://www.threadingbuildingblocks.org/)

\(^{192}\) [https://x10-lang.org/](https://x10-lang.org/)
unit of work that is allowed to execute in parallel with respect to the caller. Any parallel tasks spawned by \texttt{run} within the task block are joined back to a single thread of execution at the end of the \texttt{define_task_block}. \texttt{run} takes a user-provided function object \texttt{f} and starts it asynchronously—i.e., it may return before the execution of \texttt{f} completes. The \texttt{HPX} scheduler may choose to run \texttt{f} immediately or delay running \texttt{f} until compute resources become available.

A \texttt{task_block} can be constructed only by \texttt{define_task_block} because it has no public constructors. Thus, \texttt{run} can be invoked directly or indirectly only from a user-provided function passed to \texttt{define_task_block}:

```c++
void g();

void f(task_block<> &tr)
{
    tr.run(g);  // OK, invoked from within task_block in \texttt{h}
}

void h()
{
    define_task_block(f);
}

int main()
{
    task_block<> tr;  // Error: no public constructor
    tr.run(g);        // No way to call run outside of a define_task_block
    return 0;
}
```

### Extensions for task blocks

#### Using execution policies with task blocks

\textit{HPX} implements some extensions for \texttt{task_block} beyond the actual standards proposal \texttt{N4411}\textsuperscript{193}. The main addition is that a \texttt{task_block} can be invoked with an execution policy as its first argument, very similar to the parallel algorithms.

An execution policy is an object that expresses the requirements on the ordering of functions invoked as a consequence of the invocation of a task block. Enabling passing an execution policy to \texttt{define_task_block} gives the user control over the amount of parallelism employed by the created \texttt{task_block}. In the following example the use of an explicit \texttt{par} execution policy makes the user’s intent explicit:

```c++
template <typename Func>
int traverse(node *n, Func &compute)
{
    int left = 0, right = 0;

    define_task_block(
        execution::par, // execution::parallel_policy
        [&](task_block<> &tb) {
            if (n->left)
                tb.run([&] { left = traverse(n->left, compute); });
            if (n->right)
                tb.run([&] { right = traverse(n->right, compute); });
        });
}
```

\textsuperscript{193} http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2015/n4411.pdf
This also causes the hpx::parallel::v2::task_block object to be a template in our implementation. The template argument is the type of the execution policy used to create the task block. The template argument defaults to hpx::execution::parallel_policy.

HPX still supports calling hpx::parallel::v2::define_task_block without an explicit execution policy. In this case the task block will run using the hpx::execution::parallel_policy.

HPX also adds the ability to access the execution policy that was used to create a given task_block.

### Using executors to run tasks

Often, users want to be able to not only define an execution policy to use by default for all spawned tasks inside the task block, but also to customize the execution context for one of the tasks executed by task_block::run. Adding an optionally passed executor instance to that function enables this use case:

```cpp
template <typename Func>
int traverse(node *n, Func&& compute)
{
    int left = 0, right = 0;

define_task_block(
    execution::par, // execution::parallel_policy
    [](auto& tb) {
        if (n->left)
            // use explicitly specified executor to run this task
            tb.run(my_executor(), [] { left = traverse(n->left, compute); });
        if (n->right)
            // use the executor associated with the par execution policy
            tb.run([] { right = traverse(n->right, compute); });
    });

    return compute(n) + left + right;
}
```

HPX still supports calling hpx::parallel::v2::task_block::run without an explicit executor object. In this case the task will be run using the executor associated with the execution policy that was used to call hpx::parallel::v2::define_task_block.
2.5.7 Writing distributed HPX applications

This section focuses on the features of HPX needed to write distributed applications, namely the Active Global Address Space (AGAS), remotely executable functions (i.e. actions), and distributed objects (i.e. components).

Global names

HPX implements an Active Global Address Space (AGAS) which is exposing a single uniform address space spanning all localities an application runs on. AGAS is a fundamental component of the ParalleX execution model. Conceptually, there is no rigid demarcation of local or global memory in AGAS; all available memory is a part of the same address space. AGAS enables named objects to be moved (migrated) across localities without having to change the object’s name, i.e., no references to migrated objects have to be ever updated. This feature has significance for dynamic load balancing and in applications where the workflow is highly dynamic, allowing work to be migrated from heavily loaded nodes to less loaded nodes. In addition, immutability of names ensures that AGAS does not have to keep extra indirections (“bread crumbs”) when objects move, hence minimizing complexity of code management for system developers as well as minimizing overheads in maintaining and managing aliases.

The AGAS implementation in HPX does not automatically expose every local address to the global address space. It is the responsibility of the programmer to explicitly define which of the objects have to be globally visible and which of the objects are purely local.

In HPX global addresses (global names) are represented using the hpx::id_type data type. This data type is conceptually very similar to void* pointers as it does not expose any type information of the object it is referring to.

The only predefined global addresses are assigned to all localities. The following HPX API functions allow one to retrieve the global addresses of localities:

- `hpx::find_here`: retrieve the global address of the locality this function is called on.
- `hpx::find_all_localities`: retrieve the global addresses of all localities available to this application (including the locality the function is being called on).
- `hpx::find_remote_localities`: retrieve the global addresses of all remote localities available to this application (not including the locality the function is being called on).
- `hpx::get_num_localities`: retrieve the number of localities available to this application.
- `hpx::find_locality`: retrieve the global address of any locality supporting the given component type.
- `hpx::get_colocation_id`: retrieve the global address of the locality currently hosting the object with the given global address.

Additionally, the global addresses of localities can be used to create new instances of components using the following HPX API function:

- `hpx::components::new_`: Create a new instance of the given Component type on the specified locality.

**Note:** HPX does not expose any functionality to delete component instances. All global addresses (as represented using hpx::id_type) are automatically garbage collected. When the last (global) reference to a particular component instance goes out of scope the corresponding component instance is automatically deleted.
Applying actions

Action type definition

Actions are special types we use to describe possibly remote operations. For every global function and every member function which has to be invoked distantly, a special type must be defined. For any global function the special macro `HPX_PLAIN_ACTION` can be used to define the action type. Here is an example demonstrating this:

```cpp
namespace app {
    void some_global_function(double d) {
        cout << d;
    }
}
// This will define the action type 'some_global_action' which represents
// the function 'app::some_global_function'.
HPX_PLAIN_ACTION(app::some_global_function, some_global_action);
```

**Important:** The macro `HPX_PLAIN_ACTION` has to be placed in global namespace, even if the wrapped function is located in some other namespace. The newly defined action type is placed in the global namespace as well.

If the action type should be defined somewhere not in global namespace, the action type definition has to be split into two macro invocations (`HPX_DEFINE_PLAIN_ACTION` and `HPX_REGISTER_ACTION`) as shown in the next example:

```cpp
namespace app {
    void some_global_function(double d) {
        cout << d;
    }
    // On conforming compilers the following macro expands to:
    // typedef hpx::actions::make_action<
    // decltype(&some_global_function), &some_global_function
    // >::type some_global_action;
    // This will define the action type 'some_global_action' which represents
    // the function 'some_global_function'.
    HPX_DEFINE_PLAIN_ACTION(some_global_function, some_global_action);
}
// The following macro expands to a series of definitions of global objects
// which are needed for proper serialization and initialization support
// enabling the remote invocation of the function"some_global_function"
HPX_REGISTER_ACTION(app::some_global_action, app_some_global_action);
```

The shown code defines an action type `some_global_action` inside the namespace `app`.

**Important:** If the action type definition is split between two macros as shown above, the name of the action type to create has to be the same for both macro invocations (here `some_global_action`).
**Important:** The second argument passed to `HPX_REGISTER_ACTION(app_some_global_action)` has to comprise a globally unique C++ identifier representing the action. This is used for serialization purposes.

For member functions of objects which have been registered with AGAS (e.g. ‘components’) a different registration macro `HPX_DEFINE_COMPONENT_ACTION` has to be utilized. Any component needs to be declared in a header file and have some special support macros defined in a source file. Here is an example demonstrating this. The first snippet has to go into the header file:

```cpp
namespace app {

    struct some_component :
    hpx::components::component_base<some_component>
    {

        int some_member_function(std::string s) {
            return boost::lexical_cast<int>(s);
        }

        // This will define the action type 'some_member_action' which
        // represents the member function 'some_member_function' of the
        // object type 'some_component'.
        HPX_DEFINE_COMPONENT_ACTION(some_component, some_member_function,
                          some_member_action);
    }

    // Note: The second argument to the macro below has to be systemwide-unique
    // C++ identifiers
    HPX_REGISTER_ACTION_DECLARATION(app::some_component::some_member_action, some_˓
                                          →component_some_action);
}
```

The next snippet belongs into a source file (e.g. the main application source file) in the simplest case:

```cpp
typedef hpx::components::component<app::some_component> component_type;
typedef app::some_component some_component;

HPX_REGISTER_COMPONENT(component_type, some_component);

// The parameters for this macro have to be the same as used in the corresponding
// HPX_REGISTER_ACTION_DECLARATION() macro invocation above
typedef some_component::some_member_action some_component_some_action;
HPX_REGISTER_ACTION(some_component_some_action);
```

Granted, these macro invocations are a bit more complex than for simple global functions, however we believe they are still manageable.

The most important macro invocation is the `HPX_DEFINE_COMPONENT_ACTION` in the header file as this defines the action type we need to invoke the member function. For a complete example of a simple component action see [hpx_link examples/quickstart/component_in_executable.cpp..component_in_executable.cpp]
**Action invocation**

The process of invoking a global function (or a member function of an object) with the help of the associated action is called ‘applying the action’. Actions can have arguments, which will be supplied while the action is applied. At the minimum, one parameter is required to apply any action - the id of the *locality* the associated function should be invoked on (for global functions), or the id of the component instance (for member functions). Generally, *HPX* provides several ways to apply an action, all of which are described in the following sections.

Generally, *HPX* actions are very similar to ‘normal’ C++ functions except that actions can be invoked remotely. Fig. 2.8 below shows an overview of the main API exposed by *HPX*. This shows the function invocation syntax as defined by the C++ language (dark gray), the additional invocation syntax as provided through C++ Standard Library features (medium gray), and the extensions added by *HPX* (light gray) where:

- \( f \) function to invoke,
- \( p.. \) (optional) arguments,
- \( R \): return type of \( f \),
- \( \text{action} \): action type defined by, \( \text{HPX} \text{\_define\_plain\_action} \) or \( \text{HPX} \text{\_define\_component\_action} \) encapsulating \( f \),
- \( a \): an instance of the type ‘\text{action}’,
- \( \text{id} \): the global address the action is applied to.

![Fig. 2.8: Overview of the main API exposed by *HPX*.](image)

This figure shows that *HPX* allows the user to apply actions with a syntax similar to the C++ standard. In fact, all action types have an overloaded function operator allowing to synchronously apply the action. Further, *HPX* implements \( \text{hpx} \text{::async} \) which semantically works similar to the way \( \text{std} \text{::async} \) works for plain C++ function.

**Note:** The similarity of applying an action to conventional function invocations extends even further. *HPX* implements \( \text{hpx} \text{::bind} \) and \( \text{hpx} \text{::function} \) two facilities which are semantically equivalent to the \( \text{std} \text{::bind} \) and \( \text{std} \text{::function} \) types as defined by the C++11 Standard. While \( \text{hpx} \text{::async} \) extends beyond the conventional semantics by supporting actions and conventional C++ functions, the *HPX* facilities \( \text{hpx} \text{::bind} \) and \( \text{hpx} \text{::function} \) extend beyond the conventional standard facilities too. The *HPX* facilities not only support conventional functions, but can be used for actions as well.
Additionally, HPX exposes `hpx::apply` and `hpx::async_continue` both of which refine and extend the standard C++ facilities.

The different ways to invoke a function in HPX will be explained in more detail in the following sections.

### Applying an action asynchronously without any synchronization

This method (‘fire and forget’) will make sure the function associated with the action is scheduled to run on the target `locality`. Applying the action does not wait for the function to start running, instead it is a fully asynchronous operation. The following example shows how to apply the action as defined in the previous section on the local `locality` (the `locality` this code runs on):

```cpp
some_global_action act; // define an instance of some_global_action
hpx::apply(act, hpx::find_here(), 2.0);
```

(the function `hpx::find_here()` returns the id of the local `locality`, i.e. the `locality` this code executes on).

Any component member function can be invoked using the same syntactic construct. Given that `id` is the global address for a component instance created earlier, this invocation looks like:

```cpp
some_component_action act; // define an instance of some_component_action
hpx::apply(act, id, "42");
```

In this case any value returned from this action (e.g. in this case the integer 42 is ignored. Please look at Action type definition for the code defining the component action `some_component_action` used.

### Applying an action asynchronously with synchronization

This method will make sure the action is scheduled to run on the target `locality`. Applying the action itself does not wait for the function to start running or to complete, instead this is a fully asynchronous operation similar to using `hpx::apply` as described above. The difference is that this method will return an instance of a `hpx::future<>` encapsulating the result of the (possibly remote) execution. The future can be used to synchronize with the asynchronous operation. The following example shows how to apply the action from above on the local `locality`:

```cpp
some_global_action act; // define an instance of some_global_action
hpx::future<void> f = hpx::async(act, hpx::find_here(), 2.0);
//
// ... other code can be executed here
//
f.get(); // this will possibly wait for the asynchronous operation to 'return'
```

(as before, the function `hpx::find_here()` returns the id of the local `locality` (the `locality` this code is executed on).

**Note:** The use of a `hpx::future<void>` allows the current thread to synchronize with any remote operation not returning any value.

**Note:** Any `std::future<>` returned from `std::async()` is required to block in its destructor if the value has not been set for this future yet. This is not true for `hpx::future<>` which will never block in its destructor, even if the value has not been returned to the future yet. We believe that consistency in the behavior of futures is more important than standards conformance in this case.
Any component member function can be invoked using the same syntactic construct. Given that `id` is the global address for a component instance created earlier, this invocation looks like:

```cpp
some_component_action act; // define an instance of some_component_action
hpx::future<int> f = hpx::async(act, id, "42");
//
// ... other code can be executed here
//
cout << f.get(); // this will possibly wait for the asynchronous operation to return '42
```

**Note:** The invocation of `f.get()` will return the result immediately (without suspending the calling thread) if the result from the asynchronous operation has already been returned. Otherwise, the invocation of `f.get()` will suspend the execution of the calling thread until the asynchronous operation returns its result.

### Applying an action synchronously

This method will schedule the function wrapped in the specified action on the target `locality`. While the invocation appears to be synchronous (as we will see), the calling thread will be suspended while waiting for the function to return. Invoking a plain action (e.g. a global function) synchronously is straightforward:

```cpp
some_global_action act; // define an instance of some_global_action
act(hpx::find_here(), 2.0);
```

While this call looks just like a normal synchronous function invocation, the function wrapped by the action will be scheduled to run on a new thread and the calling thread will be suspended. After the new thread has executed the wrapped global function, the waiting thread will resume and return from the synchronous call.

Equivalently, any action wrapping a component member function can be invoked synchronously as follows:

```cpp
some_component_action act; // define an instance of some_component_action
int result = act(id, "42");
```

The action invocation will either schedule a new thread locally to execute the wrapped member function (as before, `id` is the global address of the component instance the member function should be invoked on), or it will send a parcel to the remote `locality` of the component causing a new thread to be scheduled there. The calling thread will be suspended until the function returns its result. This result will be returned from the synchronous action invocation.

It is very important to understand that this ‘synchronous’ invocation syntax in fact conceals an asynchronous function call. This is beneficial as the calling thread is suspended while waiting for the outcome of a potentially remote operation. The HPX thread scheduler will schedule other work in the meantime, allowing the application to make further progress while the remote result is computed. This helps overlapping computation with communication and hiding communication latencies.

**Note:** The syntax of applying an action is always the same, regardless whether the target `locality` is remote to the invocation `locality` or not. This is a very important feature of HPX as it frees the user from the task of keeping track what actions have to be applied locally and which actions are remote. If the target for applying an action is local, a new thread is automatically created and scheduled. Once this thread is scheduled and run, it will execute the function encapsulated by that action. If the target is remote, HPX will send a parcel to the remote `locality` which encapsulates the action and its parameters. Once the parcel is received on the remote `locality` HPX will create and schedule a new thread there. Once this thread runs on the remote `locality`, it will execute the function encapsulated by the action.
Applying an action with a continuation but without any synchronization

This method is very similar to the method described in section Applying an action asynchronously without any synchronization. The difference is that it allows the user to chain a sequence of asynchronous operations, while handing the (intermediate) results from one step to the next step in the chain. Where hpx::apply invokes a single function using ‘fire and forget’ semantics, hpx::apply_continue asynchronously triggers a chain of functions without the need for the execution flow ‘to come back’ to the invocation site. Each of the asynchronous functions can be executed on a different locality.

Applying an action with a continuation and with synchronization

This method is very similar to the method described in section Applying an action asynchronously with synchronization. In addition to what hpx::async can do, the functions hpx::async_continue takes an additional function argument. This function will be called as the continuation of the executed action. It is expected to perform additional operations and to make sure that a result is returned to the original invocation site. This method chains operations asynchronously by providing a continuation operation which is automatically executed once the first action has finished executing.

As an example we chain two actions, where the result of the first action is forwarded to the second action and the result of the second action is sent back to the original invocation site:

```cpp
// first action
std::int32_t action1(std::int32_t i)
{
    return i+1;
}
HPX_PLAIN_ACTION(action1); // defines action1_type

// second action
std::int32_t action2(std::int32_t i)
{
    return i*2;
}
HPX_PLAIN_ACTION(action2); // defines action2_type

// this code invokes 'action1' above and passes along a continuation
// function which will forward the result returned from 'action1' to
// 'action2'.
action1_type act1;    // define an instance of 'action1_type'
action2_type act2;    // define an instance of 'action2_type'
hpx::future<int> f =
    hpx::async_continue(act1, hpx::make_continuation(act2),
                        hpx::find_here(), 42);
hp::cout << f.get() << "\n"; // will print: 86 ((42 + 1) * 2)
```

By default, the continuation is executed on the same locality as hpx::async_continue is invoked from. If you want to specify the locality where the continuation should be executed, the code above has to be written as:

```cpp
// this code invokes 'action1' above and passes along a continuation
// function which will forward the result returned from 'action1' to
// 'action2'.
action1_type act1;    // define an instance of 'action1_type'
action2_type act2;    // define an instance of 'action2_type'
hpx::future<int> f =
    hpx::async_continue(act1, hpx::make_continuation(act2, hpx::find_here()),
                        (continues on next page)
```
Similarly, it is possible to chain more than 2 operations:

```cpp
action1_type act1;  // define an instance of 'action1_type'
action2_type act2;  // define an instance of 'action2_type'
hpx::future<int> f =
    hpx::async_continue(act1,
                          hpx::make_continuation(act2, hpx::make_continuation(act1)),
                          hpx::find_here(), 42);
hpx::cout << f.get() << "\n";  // will print: 86 ((42 + 1) * 2)
```

The function `hpx::make_continuation` creates a special function object which exposes the following prototype:

```cpp
struct continuation
{
  template <typename Result>
  void operator()(hpx::id_type id, Result&& result) const
  {
    ...
  }
};
```

where the parameters passed to the overloaded function operator `operator()` are:

- the `id` is the global id where the final result of the asynchronous chain of operations should be sent to (in most cases this is the id of the `hpx::future` returned from the initial call to `hpx::async_continue`. Any custom continuation function should make sure this `id` is forwarded to the last operation in the chain.
- the `result` is the result value of the current operation in the asynchronous execution chain. This value needs to be forwarded to the next operation.

**Note:** All of those operations are implemented by the predefined continuation function object which is returned from `hpx::make_continuation`. Any (custom) function object used as a continuation should conform to the same interface.

### Action error handling

Like in any other asynchronous invocation scheme it is important to be able to handle error conditions occurring while the asynchronous (and possibly remote) operation is executed. In `HPX` all error handling is based on standard C++ exception handling. Any exception thrown during the execution of an asynchronous operation will be transferred back to the original invocation `locality`, where it is rethrown during synchronization with the calling thread.

**Important:** Exceptions thrown during asynchronous execution can be transferred back to the invoking thread only for the synchronous and the asynchronous case with synchronization. Like with any other unhandled exception, any exception thrown during the execution of an asynchronous action without synchronization will result in calling `hpx::terminate` causing the running application to exit immediately.

**Note:** Even if error handling internally relies on exceptions, most of the API functions exposed by `HPX` can be used
without throwing an exception. Please see Working with exceptions for more information.

As an example, we will assume that the following remote function will be executed:

```cpp
namespace app {
    void some_function_with_error(int arg) {
        if (arg < 0) {
            HPX_THROW_EXCEPTION(bad_parameter, "some_function_with_error", "some really bad error happened");
        }
        // do something else...
    }
}
```

The use of HPX_THROW_EXCEPTION to report the error encapsulates the creation of a hpx::exception which is initialized with the error code hpx::bad_parameter. Additionally it carries the passed strings, the information about the file name, line number, and call stack of the point the exception was thrown from.

We invoke this action using the synchronous syntax as described before:

```cpp
some_error_action act;  // define an instance of some_error_action
try {
    act(hpx::find_here(), -3);  // exception will be rethrown from here
} catch (hpx::exception const& e) {
    // prints: 'some really bad error happened: HPX(bad parameter)'
    cout << e.what();
}
```

If this action is invoked asynchronously with synchronization, the exception is propagated to the waiting thread as well and is re-thrown from the future's function get():

```cpp
some_error_action act;  // define an instance of some_error_action
hpx::future<void> f = hpx::async(act, hpx::find_here(), -3);
try {
    f.get();  // exception will be rethrown from here
} catch (hpx::exception const& e) {
    // prints: 'some really bad error happened: HPX(bad parameter)'
    cout << e.what();
}
```

For more information about error handling please refer to the section Working with exceptions. There we also explain how to handle error conditions without having to rely on exception.
Writing components

A component in HPX is a C++ class which can be created remotely and for which its member functions can be invoked remotely as well. The following sections highlight how components can be defined, created, and used.

Defining components

In order for a C++ class type to be managed remotely in HPX, the type must be derived from the hpx::components::component_base template type. We call such C++ class types 'components'.

Note that the component type itself is passed as a template argument to the base class:

```cpp
// header file some_component.hpp
#include <hpx/include/components.hpp>

namespace app {

// Define a new component type 'some_component'
struct some_component : hpx::components::component_base<some_component>
{
    // This member function is has to be invoked remotely
    int some_member_function(std::string const & s)
    {
        return boost::lexical_cast<int>(s);
    }

    // This will define the action type 'some_member_action' which
    // represents the member function 'some_member_function' of the
    // object type 'some_component'.
    HPX_DEFINE_COMPONENT_ACTION(some_component, some_member_function, some_member_ →action);
};
}
```

There is more boiler plate code which has to be placed into a source file in order for the component to be usable. Every component type is required to have macros placed into its source file, one for each component type and one macro for each of the actions defined by the component type.

For instance:

```cpp
// source file some_component.cpp
#include "some_component.hpp"

// The following code generates all necessary boiler plate to enable the
```
Defining client side representation classes

Often it is very convenient to define a separate type for a component which can be used on the client side (from
where the component is instantiated and used). This step might seem as unnecessary duplicating code, however it
significantly increases the type safety of the code.

A possible implementation of such a client side representation for the component described in the previous section
could look like:

```cpp
#include <hpx/include/components.hpp>

namespace app {

// Define a client side representation type for the component type
// 'some_component' defined in the previous section.
//
struct some_component_client
    : hpx::components::client_base<some_component_client, some_component>
{
    using base_type = hpx::components::client_base<
        some_component_client, some_component>;

    some_component_client(hpx::future<hpx::id_type> && id)
        : base_type(std::move(id))
    {}

    hpx::future<int> some_member_function(std::string const & s)
    {
        some_component::some_member_action act;
        return hpx::async(act, get_id(), s);
    }
};
}
```

A client side object stores the global id of the component instance it represents. This global id is accessible by calling the function `client_base<>::get_id()`. The special constructor which is provided in the example allows to
create this client side object directly using the API function `hpx::new_`.

**Creating component instances**

Instances of defined component types can be created in two different ways. If the component to create has a defined client side representation type, then this can be used, otherwise use the server type.

The following examples assume that `some_component_type` is the type of the server side implementation of the component to create. All additional arguments (see , , notation below) are passed through to the corresponding constructor calls of those objects:

```cpp
// create one instance on the given locality
hpx::id_type here = hpx::find_here();
hpx::future<hpx::id_type> f =
    hpx::new_<some_component_type>(here, ...);

// create one instance using the given distribution
// policy (here: hpx::colocating_distribution_policy)
hpx::id_type here = hpx::find_here();
hpx::future<hpx::id_type> f =
    hpx::new_<some_component_type>(hpx::colocated(here), ...);

// create multiple instances on the given locality
hpx::id_type here = hpx::find_here();
hpx::future<std::vector<hpx::id_type>> f =
    hpx::new_<some_component_type[]>(here, num, ...);

// create multiple instances using the given distribution
// policy (here: hpx::binpacking_distribution_policy)
    hpx::future<std::vector<hpx::id_type>> f = hpx::new_<some_component_type[]>(
        hpx::binpacking(hpx::find_all_localities()), num, ...);
```

The examples below demonstrate the use of the same API functions for creating client side representation objects (instead of just plain ids). These examples assume that `client_type` is the type of the client side representation of the component type to create. As above, all additional arguments (see , , notation below) are passed through to the corresponding constructor calls of the server side implementation objects corresponding to the `client_type`:

```cpp
// create one instance on the given locality
hpx::id_type here = hpx::find_here();
client_type c = hpx::new_<client_type>(here, ...);

// create one instance using the given distribution
// policy (here: hpx::colocating_distribution_policy)
hpx::id_type here = hpx::find_here();
client_type c = hpx::new_<client_type>(hpx::colocated(here), ...);

// create multiple instances on the given locality
hpx::id_type here = hpx::find_here();
    hpx::future<std::vector<client_type>> f =
        hpx::new_<client_type[]>(here, num, ...);

// create multiple instances using the given distribution
// policy (here: hpx::binpacking_distribution_policy)
    hpx::future<std::vector<client_type>> f = hpx::new_<client_type[]>(
        hpx::binpacking(hpx::find_all_localities()), num, ...);
```
Using component instances

Segmented containers

In parallel programming, there is now a plethora of solutions aimed at implementing “partially contiguous” or segmented data structures, whether on shared memory systems or distributed memory systems. HPX implements such structures by drawing inspiration from Standard C++ containers.

Using segmented containers

A segmented container is a template class that is described in the namespace hpx. All segmented containers are very similar semantically to their sequential counterpart (defined in namespace std but with an additional template parameter named DistPolicy). The distribution policy is an optional parameter that is passed last to the segmented container constructor (after the container size when no default value is given, after the default value if not). The distribution policy describes the manner in which a container is segmented and the placement of each segment among the available runtime localities.

However, only a part of the std container member functions were reimplemented:

- (constructor), (destructor), operator=
- operator[]
- begin, cbegin, end, cend
- size

An example of how to use the partitioned_vector container would be:

```cpp
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(double);

// By default, the number of segments is equal to the current number of
// localities
//
hpx::partitioned_vector<double> va(50);
hpx::partitioned_vector<double> vb(50, 0.0);
```

An example of how to use the partitioned_vector container with distribution policies would be:

```cpp
#include <hpx/include/partitioned_vector.hpp>
#include <hpx/runtime_distributed/find_localities.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(double);

std::size_t num_segments = 10;
std::vector<hpx::id_type> locs = hpx::find_all_localities()
auto layout =
    hpx::container_layout( num_segments, locs );
```

(continues on next page)
By definition, a segmented container must be accessible from any thread although its construction is synchronous only for the thread who has called its constructor. To overcome this problem, it is possible to assign a symbolic name to the segmented container:

```cpp
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(double);

hpx::future<void> fserver = hpx::async([]() {
    hpx::partitioned_vector<double> v(50);
    // Register the 'partitioned_vector' with the name "some_name"
    //
    v.register_as("some_name");
    /* Do some code */
});

hpx::future<void> fclient = hpx::async([]() {
    // Naked 'partitioned_vector'
    //
    hpx::partitioned_vector<double> v;
    // Now the variable v points to the same 'partitioned_vector' that has
    // been registered with the name "some_name"
    //
    v.connect_to("some_name");
    /* Do some code */
});
```

### Segmented containers

`HPX` provides the following segmented containers:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>In header</th>
<th>Class page at cppreference.com</th>
</tr>
</thead>
<tbody>
<tr>
<td>hpx::partitioned</td>
<td>Dynamic segmented contiguous array.</td>
<td><code>&lt;hpx/include/partitioned_vector.hpp&gt;</code></td>
<td><code>vector&lt;1&gt;</code></td>
</tr>
</tbody>
</table>
### Segmented iterators and segmented iterator traits

The basic iterator used in the STL library is only suitable for one-dimensional structures. The iterators we use in *HPX* must adapt to the segmented format of our containers. Our iterators are then able to know when incrementing themselves if the next element of type $T$ is in the same data segment or in another segment. In this second case, the iterator will automatically point to the beginning of the next segment.

**Note:** Note that the dereference operation `operator *` does not directly return a reference of type $T$& but an intermediate object wrapping this reference. When this object is used as an l-value, a remote write operation is performed; When this object is used as an r-value, implicit conversion to $T$ type will take care of performing remote read operation.

It is sometimes useful not only to iterate element by element, but also segment by segment, or simply get a local iterator in order to avoid additional construction costs at each dereferencing operations. To mitigate this need, the `hpx::traits::segmented_iterator_traits` are used.

With `segmented_iterator_traits` users can uniformly get the iterators which specifically iterates over segments (by providing a segmented iterator as a parameter), or get the local begin/end iterators of the nearest local segment (by providing a per-segment iterator as a parameter):

```cpp
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments

HPX_REGISTER_PARTITIONED_VECTOR(double);

using iterator = hpx::partitioned_vector<T>::iterator;
using traits = hpx::traits::segmented_iterator_traits<iterator>;

hpx::partitioned_vector<T> v;
std::size_t count = 0;

auto seg_begin = traits::segment(v.begin());
auto seg_end = traits::segment(v.end());

// Iterate over segments
for (auto seg_it = seg_begin; seg_it != seg_end; ++seg_it)
{
    auto loc_begin = traits::begin(seg_it);
    auto loc_end = traits::end(seg_it);

    // Iterate over elements inside segments
    for (auto lit = loc_begin; lit != loc_end; ++lit, ++count)
    {
        //...
    }
}
```

(continues on next page)

---

194 http://en.cppreference.com/w/cpp/container/vector
195 http://en.cppreference.com/w/cpp/container unordered_map
Which is equivalent to:

```cpp
hpx::partitioned_vector<T> v;
std::size_t count = 0;
auto begin = v.begin();
auto end = v.end();
for (auto it = begin; it != end; ++it, ++count)
{
    *it = count;
}
```

### Using views

The use of multidimensional arrays is quite common in the numerical field whether to perform dense matrix operations or to process images. It exist many libraries which implement such object classes overloading their basic operators (e.g. `+`, `-`, `*`, `(,)`, etc.). However, such operation becomes more delicate when the underlying data layout is segmented or when it is mandatory to use optimized linear algebra subroutines (i.e. BLAS subroutines).

Our solution is thus to relax the level of abstraction by allowing the user to work not directly on n-dimensional data, but on “n-dimensional collections of 1-D arrays”. The use of well-accepted techniques on contiguous data is thus preserved at the segment level, and the composability of the segments is made possible thanks to multidimensional array-inspired access mode.

### Preface: Why SPMD?

Although HPX refutes by design this programming model, the locality plays a dominant role when it comes to implement vectorized code. To maximize local computations and avoid unneeded data transfers, a parallel section (or Single Programming Multiple Data section) is required. Because the use of global variables is prohibited, this parallel section is created via the RAII idiom.

To define a parallel section, simply write an action taking a `spmd_block` variable as a first parameter:

```cpp
#include <hpx/collectives/spmd_block.hpp>

void bulk_function(hpx::lcos::spmd_block block /*, arg0, arg1, ... */) {
    // Parallel section
    /* Do some code */
} 
HPX_PLAIN_ACTION(bulk_function, bulk_action);
```

**Note:** In the following paragraphs, we will use the term “image” several times. An image is defined as a lightweight process whose entry point is a function provided by the user. It’s an “image of the function”.
The `spmd_block` class contains the following methods:

- **[def Team information]** `get_num_images`, `this_image`, `images_per_locality`
- **[def Control statements]** `sync_all`, `sync_images`

Here is a sample code summarizing the features offered by the `spmd_block` class:

```cpp
#include <hpx/collectives/spmd_block.hpp>

void bulk_function(hpx::lcos::spmd_block block /* , arg0, arg1, ... */) {
    std::size_t num_images = block.get_num_images();
    std::size_t this_image = block.this_image();
    std::size_t images_per_locality = block.images_per_locality();

    /* Do some code */

    // Synchronize all images in the team
    block.sync_all();

    /* Do some code */

    // Synchronize image 0 and image 1
    block.sync_images(0,1);

    /* Do some code */

    std::vector<std::size_t> vec_images = {2,3,4};

    // Synchronize images 2, 3 and 4
    block.sync_images(vec_images);

    // Alternative call to synchronize images 2, 3 and 4
    block.sync_images(vec_images.begin(), vec_images.end());

    /* Do some code */

    // Non-blocking version of sync_all()
    hpx::future<void> event =
        block.sync_all(hpx::launch::async);

    // Callback waiting for 'event' to be ready before being scheduled
    hpx::future<void> cb =
        event.then(
            [](hpx::future<void>)
            {
                /* Do some code */
            });

    // Finally wait for the execution tree to be finished
    cb.get();
}

HPX.PLAIN_ACTION(bulk_test_function, bulk_test_action);
```

Then, in order to invoke the parallel section, call the function `define_spmd_block` specifying an arbitrary symbolic name and indicating the number of images per `locality` to create:
void bulk_function(hpx::lcos::spmd_block block, /* , arg0, arg1, ... */)
{
}
HPX.PLAIN_ACTION(bulk_test_function, bulk_test_action);

int main()
{
    /* std::size_t arg0, arg1, ...; */
    bulk_action act;
    std::size_t images_per_locality = 4;
    // Instantiate the parallel section
    hpx::lcos::define_spmd_block(  
        "some_name", images_per_locality, std::move(act) /*, arg0, arg1, ... */);
    return 0;
}

Note: In principle, the user should never call the spmd_block constructor. The define_spmd_block function is responsible of instantiating spmd_block objects and broadcasting them to each created image.

SPMD multidimensional views

Some classes are defined as “container views” when the purpose is to observe and/or modify the values of a container using another perspective than the one that characterizes the container. For example, the values of an std::vector object can be accessed via the expression \[i\]. Container views can be used, for example, when it is desired for those values to be “viewed” as a 2D matrix that would have been flattened in a std::vector. The values would be possibly accessible via the expression vv(i,j) which would call internally the expression v[k].

By default, the partitioned_vector class integrates 1-D views of its segments:

```cpp
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(double);

using iterator = hpx::partitioned_vector<double>::iterator;
using traits = hpx::traits::segmented_iterator_traits<iterator>;

hpx::partitioned_vector<double> v;

// Create a 1-D view of the vector of segments
auto vv = traits::segment(v.begin());

// Access segment i
std::vector<double> v = vv[i];
```

Our views are called “multidimensional” in the sense that they generalize to N dimensions the purpose of segmented_iterator_traits::segment() in the 1-D case. Note that in a parallel section, the 2-D expression \(a(i, j) = b(i, j)\) is quite confusing because without convention, each of the images invoked will race
to execute the statement. For this reason, our views are not only multidimensional but also “spmd-aware”.

**Note:** SPMD-awareness: The convention is simple. If an assignment statement contains a view subscript as an l-value, it is only and only the image holding the r-value who is evaluating the statement. (In MPI sense, it is called a Put operation).

### Subscript-based operations

Here are some examples of using subscripts in the 2-D view case:

```cpp
#include <hpx/components/containers/partitioned_vector/partitioned_vector_view.hpp>
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments

HPX_REGISTER_PARTITIONED_VECTOR(double);

using Vec = hpx::partitioned_vector<double>;
using View_2D = hpx::partitioned_vector_view<double, 2>;

/* Do some code */

Vec v;

// Parallel section (suppose 'block' an spmd_block instance)
{
    std::size_t height, width;

    // Instantiate the view
    View_2D vv(block, v.begin(), v.end(), {height, width});

    // The l-value is a view subscript, the image that owns vv(1,0)
    // evaluates the assignment.
    vv(0,1) = vv(1,0);

    // The l-value is a view subscript, the image that owns the r-value
    // (result of expression 'std::vector<double>(4,1.0)') evaluates the
    // assignment : oops! race between all participating images.
    vv(2,3) = std::vector<double>(4,1.0);
}
```

### Iterator-based operations

Here are some examples of using iterators in the 3-D view case:

```cpp
#include <hpx/components/containers/partitioned_vector/partitioned_vector_view.hpp>
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments

HPX_REGISTER_PARTITIONED_VECTOR(int);
```

(continues on next page)
using Vec = hpx::partitioned_vector<int>;
using View_3D = hpx::partitioned_vector_view<int,3>;

/* Do some code */

Vec v1, v2;

// Parallel section (suppose 'block' an spmd_block instance)
{
    std::size_t sixe_x, size_y, size_z;

    // Instantiate the views
    View_3D vv1(block, v1.begin(), v1.end(), {sixe_x, size_y, size_z});
    View_3D vv2(block, v2.begin(), v2.end(), {sixe_x, size_y, size_z});

    // Save previous segments covered by vv1 into segments covered by vv2
    auto vv2_it = vv2.begin();
    auto vv1_it = vv1.cbegin();
    for(; vv2_it != vv2.end(); vv2_it++, vv1_it++)
    {
        // It’s a Put operation
        *vv2_it = *vv1_it;
    }

    // Ensure that all images have performed their Put operations
    block.sync_all();

    // Ensure that only one image is putting updated data into the different
    // segments covered by vv1
    if(block.this_image() == 0)
    {
        int idx = 0;

        // Update all the segments covered by vv1
        for(auto i = vv1.begin(); i != vv1.end(); i++)
        {
            // It’s a Put operation
            *i = std::vector<float>(elt_size, idx++);
        }
    }
}

Here is an example that shows how to iterate only over segments owned by the current image:

#include <hpx/components/containers/partitioned_vector/partitioned_vector_view.hpp>
#include <hpx/components/containers/partitioned_vector/partitioned_vector_local_view.hpp>
#include <hpx/include/partitioned_vector.hpp>

using Vec = hpx::partitioned_vector<float>;
using View_1D = hpx::partitioned_vector_view<float, 1>;
/* Do some code */
Vec v;

// Parallel section (suppose 'block' an spmd_block instance)
{
    std::size_t num_segments;

    // Instantiate the view
    View_1D vv(block, v.begin(), v.end(), {num_segments});

    // Instantiate the local view from the view
    auto local_vv = hpx::local_view(vv);

    for (auto i = local_vv.begin(); i != local_vv.end(); i++)
    {
        std::vector<float> & segment = *i;
        /* Do some code */
    }
}

### Instantiating sub-views

It is possible to construct views from other views: we call it sub-views. The constraint nevertheless for the subviews is to retain the dimension and the value type of the input view. Here is an example showing how to create a sub-view:

```cpp
#include <hpx/components/containers/partitioned_vector/partitioned_vector_view.hpp>
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments

HPX_REGISTER_PARTITIONED_VECTOR(float);

using Vec = hpx::partitioned_vector<float>;
using View_2D = hpx::partitioned_vector_view<float, 2>;

/* Do some code */
Vec v;

// Parallel section (suppose 'block' an spmd_block instance)
{
    std::size_t N = 20;
    std::size_t tilesize = 5;

    // Instantiate the view
    View_2D vv(block, v.begin(), v.end(), {N, N});

    // Instantiate the subview
    View_2D svv(
```
```c++
block, &vv(tilesize, 0), &vv(2*tilesize-1, tilesize-1), {tilesize, tilesize}, {N, N});

if (block.this_image() == 0)
{
    // Equivalent to 'vv(tilesize, 0) = 2.0f'
    svv(0, 0) = 2.0f;

    // Equivalent to 'vv(2*tilesize-1, tilesize-1) = 3.0f'
    svv(tilesize-1, tilesize-1) = 3.0f;
}
```

**Note:** The last parameter of the subview constructor is the size of the original view. If one would like to create a subview of the subview and so on, this parameter should stay unchanged. \((N, N)\) for the above example.

### C++ co-arrays

Fortran has extended its scalar element indexing approach to reference each segment of a distributed array. In this extension, a segment is attributed a "co-index" and lives in a specific locality. A co-index provides the application with enough information to retrieve the corresponding data reference. In C++, containers present themselves as a "smarter" alternative of Fortran arrays but there are still no corresponding standardized features similar to the Fortran co-indexing approach. We present here an implementation of such features in HPX.

### Preface: co-array, a segmented container tied to a SPMD multidimensional views

As mentioned before, a co-array is a distributed array whose segments are accessible through an array-inspired access mode. We have previously seen that it is possible to reproduce such access mode using the concept of views. Nevertheless, the user must pre-create a segmented container to instantiate this view. We illustrate below how a single constructor call can perform those two operations:

```c++
#include <hpx/components/containers/coarray/coarray.hpp>
#include <hpx/collectives/spmd_block.hpp>

// The following code generates all necessary boiler plate to enable the
// co-creation of 'coarray'
//
HPX_REGISTER_COARRAY(double);

// Parallel section (suppose 'block' an spmd_block instance)
{
    using hpx::container::placeholders::_;

    std::size_t height = 32, width = 4, segment_size = 10;

    hpx::coarray<double, 3> a(block, "a", {height, width, _}, segment_size);

    /* Do some code */
}
```

Unlike segmented containers, a co-array object can only be instantiated within a parallel section. Here is the description of the parameters to provide to the coarray constructor:

2.5. Manual
Table 2.27: Parameters of coarray constructor

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>block</td>
<td>Reference to a spmd_block object</td>
</tr>
<tr>
<td>&quot;a&quot;</td>
<td>Symbolic name of type std::string</td>
</tr>
<tr>
<td>{height, width, _}</td>
<td>Dimensions of the coarray object</td>
</tr>
<tr>
<td>segment_size</td>
<td>Size of a co-indexed element (i.e. size of the object referenced by the expression [a(i, j, k)])</td>
</tr>
</tbody>
</table>

Note that the “last dimension size” cannot be set by the user. It only accepts the constexpr variable hpx::container::placeholders::_. This size, which is considered private, is equal to the number of current images (value returned by block.get_num_images()).

**Note:** An important constraint to remember about coarray objects is that all segments sharing the same “last dimension index” are located in the same image.

### Using co-arrays

The member functions owned by the coarray objects are exactly the same as those of spmd multidimensional views. These are:

- Subscript-based operations
- Iterator-based operations

However, one additional functionality is provided. Knowing that the element \[a(i, j, k)\] is in the memory of the \(k\)th image, the use of local subscripts is possible.

**Note:** For spmd multidimensional views, subscripts are only global as it still involves potential remote data transfers.

Here is an example of using local subscripts:

```cpp
#include <hpx/components/containers/coarray/coarray.hpp>
#include <hpx/collectives/spmd_block.hpp>

// The following code generates all necessary boiler plate to enable the
// co-creation of 'coarray'
// HPX_REGISTER_COARRAY(double);

// Parallel section (suppose 'block' an spmd_block instance)
{
    using hpx::container::placeholders::_;
    std::size_t height=32, width=4, segment_size=10;
    hpx::coarray<double,3> a(block, "a", {height, width, _}, segment_size);
    double idx = block.this_image()*height*width;
    for (std::size_t j = 0; j<width; j++)
        for (std::size_t i = 0; i<height; i++)
            // Use local subscripts here
```

(continues on next page)
// Local write operation performed via the use of local subscript
a(i,j,_) = std::vector<double>(elt_size,idx);
idx++;
}
block.sync_all();

Note: When the “last dimension index” of a subscript is equal to hpx::container::placeholders::_, local subscript (and not global subscript) is used. It is equivalent to a global subscript used with a “last dimension index” equal to the value returned by block.this_image().

2.5.8 Running on batch systems

This section walks you through launching HPX applications on various batch systems.

How to use HPX applications with PBS

Most HPX applications are executed on parallel computers. These platforms typically provide integrated job management services that facilitate the allocation of computing resources for each parallel program. HPX includes support for one of the most common job management systems, the Portable Batch System (PBS).

All PBS jobs require a script to specify the resource requirements and other parameters associated with a parallel job. The PBS script is basically a shell script with PBS directives placed within commented sections at the beginning of the file. The remaining (not commented-out) portions of the file executes just like any other regular shell script. While the description of all available PBS options is outside the scope of this tutorial (the interested reader may refer to in-depth documentation\textsuperscript{196} for more information), below is a minimal example to illustrate the approach. The following test application will use the multithreaded hello_world_distributed program, explained in the section Remote execution with actions: Hello world.

#!/bin/bash
#
#PBS -l nodes=2:ppn=4
APP_PATH=~/packages/hpx/bin/hello_world_distributed
APP_OPTIONS=
pbsdsh -u $APP_PATH $APP_OPTIONS --hpx:nodes=`cat $PBS_NODEFILE`

Caution: If the first application specific argument (inside $APP_OPTIONS) is a non-option (i.e., does not start with a - or a --), then the argument has to be placed before the option --hpx:nodes, which, in this case, should be the last option on the command line.

Alternatively, use the option --hpx:endnodes to explicitly mark the end of the list of node names:

```
pbsdsh -u $APP_PATH --hpx:nodes=`cat $PBS_NODEFILE` --hpx:endnodes $APP_OPTIONS
```

\textsuperscript{196} http://www.clusterresources.com/torquedocs21/
The `#PBS -l nodes=2:ppn=4` directive will cause two compute nodes to be allocated for the application, as specified in the option `nodes`. Each of the nodes will dedicate four cores to the program, as per the option `ppn`, short for “processors per node” (PBS does not distinguish between processors and cores). Note that requesting more cores per node than physically available is pointless and may prevent PBS from accepting the script.

On newer PBS versions the PBS command syntax might be different. For instance, the PBS script above would look like:

```bash
#!/bin/bash
#
#PBS -l select=2:ncpus=4

APP_PATH=/packages/hpx/bin/hello_world_distributed
APP_OPTIONS=

pbsdsh -u $APP_PATH $APP_OPTIONS --hpx:nodes=`cat $PBS_NODEFILE`
```

`APP_PATH` and `APP_OPTIONS` are shell variables that respectively specify the correct path to the executable (`hello_world_distributed` in this case) and the command line options. Since the `hello_world_distributed` application doesn’t need any command line options, `APP_OPTIONS` has been left empty. Unlike in other execution environments, there is no need to use the `--hpx:threads` option to indicate the required number of OS threads per node; the HPX library will derive this parameter automatically from PBS.

Finally, `pbsdsh` is a PBS command that starts tasks to the resources allocated to the current job. It is recommended to leave this line as shown and modify only the PBS options and shell variables as needed for a specific application.

**Important:** A script invoked by `pbsdsh` starts in a very basic environment: the user’s `$HOME` directory is defined and is the current directory, the `LANG` variable is set to `C` and the `PATH` is set to the basic `/usr/local/bin:/usr/bin:/bin` as defined in a system-wide file `pbs_environment`. Nothing that would normally be set up by a system shell profile or user shell profile is defined, unlike the environment for the main job script.

Another choice is for the `pbsdsh` command in your main job script to invoke your program via a shell, like `sh` or `bash`, so that it gives an initialized environment for each instance. Users can create a small script `runme.sh`, which is used to invoke the program:

```bash
#!/bin/bash
# Small script which invokes the program based on what was passed on its
# command line.
#
# This script is executed by the bash shell which will initialize all
# environment variables as usual.
#$
```

Now, the script is invoked using the `pbsdsh` tool:

```bash
#!/bin/bash
#
#PBS -l nodes=2:ppn=4

APP_PATH=/packages/hpx/bin/hello_world_distributed
APP_OPTIONS=

pbsdsh -u runme.sh $APP_PATH $APP_OPTIONS --hpx:nodes=`cat $PBS_NODEFILE`
```

All that remains now is submitting the job to the queuing system. Assuming that the contents of the PBS script were saved in the file `pbs_hello_world.sh` in the current directory, this is accomplished by typing:
If the job is accepted, qsub will print out the assigned job ID, which may look like:

```
$ 42.supercomputer.some.university.edu
```

To check the status of your job, issue the following command:

```
qstat 42.supercomputer.some.university.edu
```

and look for a single-letter job status symbol. The common cases include:

- **Q** - signifies that the job is queued and awaiting its turn to be executed.
- **R** - indicates that the job is currently running.
- **C** - means that the job has completed.

The example qstat output below shows a job waiting for execution resources to become available:

<table>
<thead>
<tr>
<th>Job id</th>
<th>Name</th>
<th>User</th>
<th>Time</th>
<th>Use</th>
<th>S</th>
<th>Queue</th>
</tr>
</thead>
<tbody>
<tr>
<td>42.supercomputer_hello_world.sh</td>
<td>joe_user</td>
<td>0</td>
<td>Q</td>
<td>----</td>
<td></td>
<td>batch</td>
</tr>
</tbody>
</table>

After the job completes, PBS will place two files, `pbs_hello_world.sh.o42` and `pbs_hello_world.sh.e42`, in the directory where the job was submitted. The first contains the standard output and the second contains the standard error from all the nodes on which the application executed. In our example, the error output file should be empty and the standard output file should contain something similar to:

```
hello world from OS-thread 3 on locality 0
hello world from OS-thread 2 on locality 0
hello world from OS-thread 1 on locality 1
hello world from OS-thread 0 on locality 0
hello world from OS-thread 3 on locality 1
hello world from OS-thread 2 on locality 1
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 1
```

Congratulations! You have just run your first distributed HPX application!

### How to use HPX applications with SLURM

Just like PBS (described in section *How to use HPX applications with PBS*), SLURM is a job management system which is widely used on large supercomputing systems. Any HPX application can easily be run using SLURM. This section describes how this can be done.

The easiest way to run an HPX application using SLURM is to utilize the command line tool `srun`, which interacts with the SLURM batch scheduling system:

```
srun -p <partition> -N <number-of-nodes> hpx-application <application-arguments>
```

Here, `<partition>` is one of the node partitions existing on the target machine (consult the machine’s documentation to get a list of existing partitions) and `<number-of-nodes>` is the number of compute nodes that should be used. By default, the HPX application is started with one `locality` per node and uses all available cores on a node. You can change the number of localities started per node (for example, to account for NUMA effects) by specifying the `-n` option of `srun`. The number of cores per `locality` can be set by `-c`. The `<application-arguments>` are any application specific arguments that need to be passed on to the application.
Note: There is no need to use any of the *HPX* command line options related to the number of localities, number of threads, or related to networking ports. All of this information is automatically extracted from the SLURM environment by the *HPX* startup code.

Important: The srun documentation explicitly states: “If -c is specified without -n, as many tasks will be allocated per node as possible while satisfying the -c restriction. For instance on a cluster with 8 CPUs per node, a job request for 4 nodes and 3 CPUs per task may be allocated 3 or 6 CPUs per node (1 or 2 tasks per node) depending upon resource consumption by other jobs.” For this reason, it’s recommended to always specify -n <number-of-instances>, even if <number-of-instances> is equal to one (1).

Interactive shells

To get an interactive development shell on one of the nodes, users can issue the following command:

```
srun -p <node-type> -N <number-of-nodes> --pty /bin/bash -l
```

After the shell has been opened, users can run their *HPX* application. By default, it uses all available cores. Note that if you requested one node, you don’t need to do srun again. However, if you requested more than one node, and want to run your distributed application, you can use srun again to start up the distributed *HPX* application. It will use the resources that have been requested for the interactive shell.

Scheduling batch jobs

The above mentioned method of running *HPX* applications is fine for development purposes. The disadvantage that comes with srun is that it only returns once the application is finished. This might not be appropriate for longer-running applications (for example, benchmarks or larger scale simulations). In order to cope with that limitation, users can use the sbatch command.

The sbatch command expects a script that it can run once the requested resources are available. In order to request resources, users need to add #SBATCH comments in their script or provide the necessary parameters to sbatch directly. The parameters are the same as with run. The commands you need to execute are the same you would need to start your application as if you were in an interactive shell.

2.5.9 Debugging *HPX* applications

Using a debugger with *HPX* applications

Using a debugger such as gdb with *HPX* applications is no problem. However, there are some things to keep in mind to make the experience somewhat more productive.

Call stacks in *HPX* can often be quite unwieldy as the library is heavily templated and the call stacks can be very deep. For this reason it is sometimes a good idea compile *HPX* in RelWithDebInfo mode, which applies some optimizations but keeps debugging symbols. This can often compress call stacks significantly. On the other hand, stepping through the code can also be more difficult because of statements being reordered and variables being optimized away. Also, note that because *HPX* implements user-space threads and context switching, call stacks may not always be complete in a debugger.

*HPX* launches not only worker threads but also a few helper threads. The first thread is the main thread, which typically does no work in an *HPX* application, except at startup and shutdown. If using the default settings, *HPX* will spawn six
additional threads (used for service thread pools). The first worker thread is usually the eighth thread, and most user
codes will be run on these worker threads. The last thread is a helper thread used for HPX shutdown.

Finally, since HPX is a multi-threaded runtime, the following gdb options can be helpful:

<table>
<thead>
<tr>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>set pagination off</td>
</tr>
<tr>
<td>set non-stop on</td>
</tr>
</tbody>
</table>

Non-stop mode allows users to have a single thread stop on a breakpoint without stopping all other threads as well.

Using sanitizers with HPX applications

[Warning: Not all parts of HPX are sanitizer clean. This means that users may end up with false positives from HPX itself when using sanitizers for their applications.]

To use sanitizers with HPX, turn on HPX_WITH_SANITIZERS and turn off HPX_WITH_STACKOVERFLOW_DETECTION during CMake configuration. It’s recommended to also build Boost with the same sanitizers that will be used for HPX. The appropriate sanitizers can then be enabled using CMake by appending -fsanitize=address -fno-omit-frame-pointer to CMAKE_CXX_FLAGS and -fsanitize=address to CMAKE_EXE_LINKER_FLAGS. Replace address with the sanitizer that you want to use.

2.5.10 Optimizing HPX applications

Performance counters

Performance counters in HPX are used to provide information as to how well the runtime system or an application is performing. The counter data can help determine system bottlenecks, and fine-tune system and application performance. The HPX runtime system, its networking, and other layers provide counter data that an application can consume to provide users with information about how well the application is performing.

Applications can also use counter data to determine how much system resources to consume. For example, an application that transfers data over the network could consume counter data from a network switch to determine how much data to transfer without competing for network bandwidth with other network traffic. The application could use the counter data to adjust its transfer rate as the bandwidth usage from other network traffic increases or decreases.

Performance counters are HPX parallel processes that expose a predefined interface. HPX exposes special API functions that allow one to create, manage, and read the counter data, and release instances of performance counters. Performance Counter instances are accessed by name, and these names have a predefined structure which is described in the section Performance counter names. The advantage of this is that any Performance Counter can be accessed remotely (from a different locality) or locally (from the same locality). Moreover, since all counters expose their data using the same API, any code consuming counter data can be utilized to access arbitrary system information with minimal effort.

Counter data may be accessed in real time. More information about how to consume counter data can be found in the section Consuming performance counter data.

All HPX applications provide command line options related to performance counters, such as the ability to list available counter types, or periodically query specific counters to be printed to the screen or save them in a file. For more information, please refer to the section HPX Command Line Options.
Performance counter names

All Performance Counter instances have a name uniquely identifying each instance. This name can be used to access the counter, retrieve all related meta data, and to query the counter data (as described in the section Consuming performance counter data). Counter names are strings with a predefined structure. The general form of a countername is:

```
/objectname{full_instancename}/countername@parameters
```

where full_instancename could be either another (full) counter name or a string formatted as:

```
parentinstancename#parentindex/instancename#instanceindex
```

Each separate part of a countername (e.g., objectname, countername parentinstancename, instancename, and parameters) should start with a letter ('a'...'z', 'A'...'Z') or an underscore character ('_'), optionally followed by letters, digits ('0'...'9'), hyphen ('-'), or underscore characters. Whitespace is not allowed inside a counter name. The characters '/' , '{', '}' , '#' and '@' have a special meaning and are used to delimit the different parts of the counter name.

The parts parentinstanceindex and instanceindex are integers. If an index is not specified, HPX will assume a default of -1.

Two counter name examples

This section gives examples of both simple counter names and aggregate counter names. For more information on simple and aggregate counter names, please see Performance counter instances.

An example of a well-formed (and meaningful) simple counter name would be:

```
/threads{locality#0/total}/count/cumulative
```

This counter returns the current cumulative number of executed (retired) HPX threads for the locality 0. The counter type of this counter is /threads/count/cumulative and the full instance name is locality#0/total. This counter type does not require an instanceindex or parameters to be specified.

In this case, the parentindex (the '0') designates the locality for which the counter instance is created. The counter will return the number of HPX threads retired on that particular locality.

Another example for a well formed (aggregate) counter name is:

```
/statistics{/threads{locality#0/total}/count/cumulative}/average@500
```

This counter takes the simple counter from the first example, samples its values every 500 milliseconds, and returns the average of the value samples whenever it is queried. The counter type of this counter is /statistics/average and the instance name is the full name of the counter for which the values have to be averaged. In this case, the parameters (the '500') specify the sampling interval for the averaging to take place (in milliseconds).
Performance counter types

Every performance counter belongs to a specific performance counter type which classifies the counters into groups of common semantics. The type of a counter is identified by the `objectname` and the `countername` parts of the name.

```
/objectname/countername
```

When an application starts HPX will register all available counter types on each of the localities. These counter types are held in a special performance counter registration database, which can be used to retrieve the meta data related to a counter type and to create counter instances based on a given counter instance name.

Performance counter instances

The `full_instancename` distinguishes different counter instances of the same counter type. The formatting of the `full_instancename` depends on the counter type. There are two types of counters: simple counters, which usually generate the counter values based on direct measurements, and aggregate counters, which take another counter and transform its values before generating their own counter values. An example for a simple counter is given above: counting retired HPX threads. An aggregate counter is shown as an example above as well: calculating the average of the underlying counter values sampled at constant time intervals.

While simple counters use instance names formatted as `parentinstancename#parentindex/instancename#instanceindex`, most aggregate counters have the full counter name of the embedded counter as their instance name.

Not all simple counter types require specifying all four elements of a full counter instance name; some of the parts (`parentinstancename`, `parentindex`, `instancename`, and `instanceindex`) are optional for specific counters. Please refer to the documentation of a particular counter for more information about the formatting requirements for the name of this counter (see Existing HPX performance counters).

The `parameters` are used to pass additional information to a counter at creation time. They are optional, and they fully depend on the concrete counter. Even if a specific counter type allows additional parameters to be given, those usually are not required as sensible defaults will be chosen. Please refer to the documentation of a particular counter for more information about what parameters are supported, how to specify them, and what default values are assumed (see also Existing HPX performance counters).

Every `locality` of an application exposes its own set of performance counter types and performance counter instances. The set of exposed counters is determined dynamically at application start based on the execution environment of the application. For instance, this set is influenced by the current hardware environment for the `locality` (such as whether the `locality` has access to accelerators), and the software environment of the application (such as the number of OS threads used to execute HPX threads).

Using wildcards in performance counter names

It is possible to use wildcard characters when specifying performance counter names. Performance counter names can contain two types of wildcard characters:

- Wildcard characters in the performance counter type
- Wildcard characters in the performance counter instance name

A wildcard character has a meaning which is very close to usual file name wildcard matching rules implemented by common shells (like bash).
Table 2.28: Wildcard characters in the performance counter type

<table>
<thead>
<tr>
<th>Wildcard</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>This wildcard character matches any number (zero or more) of arbitrary characters.</td>
</tr>
<tr>
<td>?</td>
<td>This wildcard character matches any single arbitrary character.</td>
</tr>
<tr>
<td>[ ]</td>
<td>This wildcard character matches any single character from the list of specified within the square brackets.</td>
</tr>
</tbody>
</table>

Table 2.29: Wildcard characters in the performance counter instance name

<table>
<thead>
<tr>
<th>Wildcard</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>This wildcard character matches any <em>locality</em> or any thread, depending on whether it is used for <em>locality#</em> or <em>worker-thread#</em>. No other wildcards are allowed in counter instance names.</td>
</tr>
</tbody>
</table>

### Consuming performance counter data

You can consume performance data using either the command line interface, the *HPX* application or the *HPX* API. The command line interface is easier to use, but it is less flexible and does not allow one to adjust the behaviour of your application at runtime. The command line interface provides a convenience abstraction but simplified abstraction for querying and logging performance counter data for a set of performance counters.

### Consuming performance counter data from the command line

*HPX* provides a set of predefined command line options for every application that uses `hpx::init` for its initialization. While there are many more command line options available (see *HPX Command Line Options*), the set of options related to performance counters allows one to list existing counters, and query existing counters once at application termination or repeatedly after a constant time interval.

The following table summarizes the available command line options:
### Table 2.30: HPX Command Line Options Related to Performance Counters

<table>
<thead>
<tr>
<th>Command line option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--hpx:print-counter</td>
<td>Prints the specified performance counter either repeatedly and/or at the times specified by --hpx:print-counter-at (see also option --hpx:print-counter-interval).</td>
</tr>
<tr>
<td>--hpx:print-counter-reset</td>
<td>Prints the specified performance counter either repeatedly and/or at the times specified by --hpx:print-counter-at. Reset the counter after the value is queried (see also option --hpx:print-counter-interval).</td>
</tr>
<tr>
<td>--hpx:print-counter-interval</td>
<td>Prints the performance counter(s) specified with --hpx:print-counter repeatedly after the time interval (specified in milliseconds) (default: 0 which means print once at shutdown).</td>
</tr>
<tr>
<td>--hpx:print-counter-destination</td>
<td>Prints the performance counter(s) specified with --hpx:print-counter to the given file (default: console).</td>
</tr>
<tr>
<td>--hpx:list-counters</td>
<td>Lists the names of all registered performance counters.</td>
</tr>
<tr>
<td>--hpx:list-counter-infos</td>
<td>Lists the description of all registered performance counters.</td>
</tr>
<tr>
<td>--hpx:print-counter-format</td>
<td>Prints the performance counter(s) specified with --hpx:print-counter. Possible formats in CSV format with header or without any header (see option --hpx:no-csv-header), possible values: csv (prints counter values in CSV format with full names as header) csv-short (prints counter values in CSV format with shortnames provided with --hpx:print-counter as --hpx:print-counter_shortname,full-countername).</td>
</tr>
<tr>
<td>--hpx:no-csv-header</td>
<td>Prints the performance counter(s) specified with --hpx:print-counter and csv or csv-short format specified with --hpx:print-counter-format without header.</td>
</tr>
<tr>
<td>--hpx:print-counter-reset arg</td>
<td>Prints the performance counter(s) specified with --hpx:print-counter (or --hpx:print-counter-reset) at the given point in time. Possible argument values: startup, shutdown (default), noshutdown.</td>
</tr>
<tr>
<td>--hpx:reset-counters</td>
<td>Resets all performance counter(s) specified with --hpx:print-counter after they have been evaluated.</td>

<td>Each locality prints only its own local counters.</td>
</tr>
</tbody>
</table>

While the options --hpx:list-counters and --hpx:list-counter-infos give a short list of all available counters, the full documentation for those can be found in the section *Existing HPX performance counters.*

### A simple example

All of the commandline options mentioned above can be tested using the hello_world_distributed example.

Listing all available counters `hello_world_distributed --hpx:list-counters` yields:

```
List of available counter instances (replace * below with the appropriate sequence number)
-----------------------------------------------------------------------------------------------
/agas/count/allocate /agas/count/bind /agas/count/bind_gid
/agas/count/bind_name ... /threads{locality#*/allocator#*}/count/objects
/threads{locality#*/total}/count/stack-recycles
/threads{locality#*/total}/idle-rate
/threads{locality#*/worker-thread#*/idle-rate
```

Providing more information about all available counters, `hello_world_distributed --hpx:list-counter-infos` yields:
Information about available counter instances (replace * below with the appropriate sequence number)

fullname: /agas/count/allocate helptext: returns the number of invocations of the AGAS service 'allocate' type: counter_raw version: 1.0.0

fullname: /agas/count/bind helptext: returns the number of invocations of the AGAS service 'bind' type: counter_raw version: 1.0.0

fullname: /agas/count/bind_gid helptext: returns the number of invocations of the AGAS service 'bind_gid' type: counter_raw version: 1.0.0

...

This command will not only list the counter names but also a short description of the data exposed by this counter.

**Note:** The list of available counters may differ depending on the concrete execution environment (hardware or software) of your application.

Requesting the counter data for one or more performance counters can be achieved by invoking `hello_world_distributed` with a list of counter names:

```
hello_world_distributed
  --hpx:print-counter=/threads{locality#0/total}/count/cumulative
  --hpx:print-counter=/agas{locality#0/total}/count/bind
```

which yields for instance:

```
hello world from OS-thread 0 on locality 0
/threads{locality#0/total}/count/cumulative,1,0.212527,[s],33
/agas{locality#0/total}/count/bind,1,0.212790,[s],11
```

The first line is the normal output generated by `hello_world_distributed` and has no relation to the counter data listed. The last two lines contain the counter data as gathered at application shutdown. These lines have six fields, the counter name, the sequence number of the counter invocation, the time stamp at which this information has been sampled, the unit of measure for the time stamp, the actual counter value and an optional unit of measure for the counter value.

**Note:** The command line option `--hpx:print-counter-types` will append a seventh field to the generated output. This field will hold an abbreviated counter type.

The actual counter value can be represented by a single number (for counters returning singular values) or a list of numbers separated by `: ` (for counters returning an array of values, like for instance a histogram).

**Note:** The name of the performance counter will be enclosed in double quotes `""` if it contains one or more commas `','`.

Requesting to query the counter data once after a constant time interval with this command line:
The command `--hpx:print-counter-destination=<file>` will redirect all counter data gathered to the specified file name, which avoids cluttering the console output of your application.

The command line option `--hpx:print-counter` supports using a limited set of wildcards for a (very limited) set of use cases. In particular, all occurrences of `#*` as in `locality#*` and in `worker-thread#*` will be automatically expanded to the proper set of performance counter names representing the actual environment for the executed program. For instance, if your program is utilizing four worker threads for the execution of HPX threads (see command line option `--hpx:threads`) the following command line

```bash
hello_world_distributed \
--hpx:threads=4 \
--hpx:print-counter=/threads{locality#0/worker-thread#*}/count/cumulative
```

will print the value of the performance counters monitoring each of the worker threads:

```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 0
hello world from OS-thread 3 on locality 0
hello world from OS-thread 2 on locality 0
```

The command `--hpx:print-counter-format` takes values `csv` and `csv-short` to generate CSV formatted counter values with a header.

With format as csv:

```bash
hello_world_distributed \
--hpx:threads=4 \
--hpx:print-counter-format csv \
--hpx:print-counter /threads{locality#*/total}/count/cumulative \
--hpx:print-counter /threads{locality#*/total}/count/cumulative-phases
```

will print the values of performance counters in CSV format with the full countername as a header:

```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 0
```

With format csv-short:
The command `--hpx:no-csv-header` can be used with `--hpx:print-counter-format` to print performance counter values in CSV format without any header:

```
hello_world_distributed \
--hpx:threads 2 \
--hpx:print-counter-format csv-short \
--hpx:print-counter cumulative,/threads{locality#*/total}/count/cumulative \
--hpx:print-counter phases,/threads{locality#*/total}/count/cumulative-phases \
--hpx:no-csv-header
```

will print:

```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 0
37,91
```

**Consuming performance counter data using the HPX API**

`HPX` provides an API that allows users to discover performance counters and to retrieve the current value of any existing performance counter from any application.
Discover existing performance counters

Retrieve the current value of any performance counter

Performance counters are specialized HPX components. In order to retrieve a counter value, the performance counter needs to be instantiated. HPX exposes a client component object for this purpose:

```cpp
counter(std::string const & name);
```

Instantiating an instance of this type will create the performance counter identified by the given name. Only the first invocation for any given counter name will create a new instance of that counter. All following invocations for a given counter name will reference the initially created instance. This ensures that at any point in time there is never more than one active instance of any of the existing performance counters.

In order to access the counter value (or to invoke any of the other functionality related to a performance counter, like start, stop or reset) member functions of the created client component instance should be called:

```cpp
hpx::performance_counters::performance_counter count("/threads{locality#0/total}/count/cumulative");
hpx::cout << count.get_value<int>().get() << hpx::endl;
```

Providing performance counter data

HPX offers several ways by which you may provide your own data as a performance counter. This has the benefit of exposing additional, possibly application-specific information using the existing Performance Counter framework, unifying the process of gathering data about your application.

An application that wants to provide counter data can implement a performance counter to provide the data. When a consumer queries performance data, the HPX runtime system calls the provider to collect the data. The runtime system uses an internal registry to determine which provider to call.

Generally, there are two ways of exposing your own performance counter data: a simple, function-based way and a more complex, but more powerful way of implementing a full performance counter. Both alternatives are described in the following sections.
Exposing performance counter data using a simple function

The simplest way to expose arbitrary numeric data is to write a function which will then be called whenever a consumer queries this counter. Currently, this type of performance counter can only be used to expose integer values. The expected signature of this function is:

```
std::int64_t some_performance_data(bool reset);
```

The argument `bool reset` (which is supplied by the runtime system when the function is invoked) specifies whether the counter value should be reset after evaluating the current value (if applicable).

For instance, here is such a function returning how often it was invoked:

```
// The atomic variable 'counter' ensures the thread safety of the counter.
boost::atomic<std::int64_t> counter(0);

std::int64_t some_performance_data(bool reset)
{
    std::int64_t result = ++counter;
    if (reset)
        counter = 0;
    return result;
}
```

This example function exposes a linearly-increasing value as our performance data. The value is incremented on each invocation, i.e., each time a consumer requests the counter data of this performance counter.

The next step in exposing this counter to the runtime system is to register the function as a new raw counter type using the HPX API function `hpx::performance_counters::install_counter_type`. A counter type represents certain common characteristics of counters, like their counter type name and any associated description information. The following snippet shows an example of how to register the function `some_performance_data`, which is shown above, for a counter type named "/test/data". This registration has to be executed before any consumer instantiates, and queries an instance of this counter type:

```
#include <hpx/include/performance_counters.hpp>

void register_counter_type()
{
    // Call the HPX API function to register the counter type.
    hpx::performance_counters::install_counter_type("/test/data",
        &some_performance_data, // function providing counter data
        "returns a linearly increasing counter value", // description text (optional)
        "", // unit of measure (optional)
    );
}
```

Now it is possible to instantiate a new counter instance based on the naming scheme "/test{locality#*/total}/data" where * is a zero-based integer index identifying the locality for which the counter instance should be accessed. The function `hpx::performance_counters::install_counter_type` enables users to instantiate exactly one counter instance for each locality. Repeated requests to instantiate such a counter will return the same instance, i.e., the instance created for the first request.

If this counter needs to be accessed using the standard HPX command line options, the registration has to be performed during application startup, before `hpx_main` is executed. The best way to achieve this is to register an HPX startup function using the API function `hpx::register_startup_function` before calling `hpx::init` to initialize the runtime system:
```cpp
int main(int argc, char* argv[])
{
    // By registering the counter type we make it available to any consumer
    // who creates and queries an instance of the type "/test/data".
    // This registration should be performed during startup. The
    // function 'register_counter_type' should be executed as an HPX thread right
    // before hpx_main is executed.
    hpx::register_startup_function(&register_counter_type);

    // Initialize and run HPX.
    return hpx::init(argc, argv);
}
```

Please see the code in `simplest_performance_counter.cpp` for a full example demonstrating this functionality.

**Implementing a full performance counter**

Sometimes, the simple way of exposing a single value as a performance counter is not sufficient. For that reason, HPX provides a means of implementing full performance counters which support:

- Retrieving the descriptive information about the performance counter
- Retrieving the current counter value
- Resetting the performance counter (value)
- Starting the performance counter
- Stopping the performance counter
- Setting the (initial) value of the performance counter

Every full performance counter will implement a predefined interface:

```cpp
#pragma once
#include <hpx/config.hpp>
#include <hpx/async_base/launch_policy.hpp>
#include <hpx/components/client_base.hpp>
#include <hpx/functional/bind_front.hpp>
#include <hpx/futures/future.hpp>
#include <hpx/modules/execution.hpp>
#include <hpx/performance_counters/counters_fwd.hpp>
#include <hpx/performance_counters/server/base_performance_counter.hpp>
#include <string>
#include <utility>
#include <vector>
```

(continues on next page)
namespace hpx { namespace performance_counters {

namespace hpx { namespace performance_counters {

struct HPX_EXPORT performance_counter {
    // components::client_base<performance_counter,
    // server::base_performance_counter>

    using base_type = components::client_base<performance_counter,
    server::base_performance_counter>;

    performance_counter() = default;

    performance_counter(std::string const& name);

    performance_counter(
        std::string const& name, hpx::id_type const& locality);

    performance_counter(id_type const& id)
        : base_type(id)
    {
    }

    performance_counter(future<id_type>&& id)
        : base_type(std::move(id))
    {
    }

    performance_counter(hpx::future<performance_counter>&& c)
        : base_type(std::move(c))
    {
    }

// Return all counters matching the given name (with optional wild cards).
HPX_EXPORT std::vector<performance_counter> discover_counters(
    std::string const& name, error_code& ec = throws);

}} // namespace hpx::performance_counters

In order to implement a full performance counter, you have to create an HPX component exposing this interface. To
simplify this task, *HPX* provides a ready-made base class which handles all the boiler plate of creating a component for you. The remainder of this section will explain the process of creating a full performance counter based on the Sine example, which you can find in the directory `examples/performance_counters/sine/`.

The base class is defined in the header file `hpx/performance_counters/base_performance_counter.hpp` as:

```cpp
#include <hpx/config.hpp>
#include <hpx/actions_base/component_action.hpp>
#include <hpx/components_base/component_type.hpp>
#include <hpx/components_base/server/component_base.hpp>
#include <hpx/performance_counters/counters.hpp>
#include <hpx/performance_counters/server/base_performance_counter.hpp>

namespace hpx {
    namespace performance_counters {
        template <typename Derived>
        class base_performance_counter {
            private:
                typedef hpx::components::component_base<Derived> base_type;
            public:
                typedef Derived type_holder;
                typedef hpx::performance_counters::server::base_performance_counter base_type_holder;

                base_performance_counter() {}

                base_performance_counter(
                    hpx::performance_counters::counter_info const& info)
                : base_type_holder(info)
                {
                }

                // Disambiguate finalize() which is implemented in both base classes
                void finalize()
                {
                    base_type_holder::finalize();
                    base_type::finalize();
                }
        }  // namespace hpx::performance_counters
    }  // namespace hpx
}  // namespace hpx::performance_counters
```

(continues on next page)
The single template parameter is expected to receive the type of the derived class implementing the performance counter. In the Sine example this looks like:

```cpp
namespace hpx::performance_counters
{
    namespace sine
    {
        namespace server
        {
            /////////////////////////////////////////////////////////////////////////////
            // bearer
            class sine_counter
                : public hpx::performance_counters::base_performance_counter<sine_counter>
            //
            
            public:
                sine_counter() : current_value_(0), evaluated_at_(0) {} 
                explicit sine_counter( 
                    hpx::performance_counters::counter_info const info);

                // This function will be called in order to query the current value of 
                // this performance counter
                hpx::performance_counters::counter_value get_counter_value(bool reset);

                // The functions below will be called to start and stop collecting 
                // counter values from this counter.
                bool start();
                bool stop();

                // finalize() will be called just before the instance gets destructed
                void finalize();

            protected:
                bool evaluate();

            private:
                typedef hpx::lcos::local::spinlock mutex_type;

                mutable mutex_type mtx_; 
            }
        }
    }
}
```
i.e., the type `sine_counter` is derived from the base class passing the type as a template argument (please see `simplest_performance_counter.cpp` for the full source code of the counter definition). For more information about this technique (called Curiously Recurring Template Pattern - CRTP), please see for instance the corresponding Wikipedia article\(^\text{197}\). This base class itself is derived from the `performance_counter` interface described above.

Additionally, a full performance counter implementation not only exposes the actual value but also provides information about:

- The point in time a particular value was retrieved.
- A (sequential) invocation count.
- The actual counter value.
- An optional scaling coefficient.
- Information about the counter status.

**Existing HPX performance counters**

The HPX runtime system exposes a wide variety of predefined performance counters. These counters expose critical information about different modules of the runtime system. They can help determine system bottlenecks and fine-tune system and application performance.

Table 2.31: AGAS performance counters

<table>

<td>Any full performance name. The referenced performance counter is queried at fixed time intervals as specified by the first parameter.</td>
<td>Returns the current (statistically estimated) median value calculated based on the values queried from the underlying counter (the one specified as the instance name).</td>
<td>Any parameter will be interpreted as a list of up to two comma separated (integer) values, where the first is the time interval (in milliseconds) at which the underlying counter should be queried. If no value is specified, the counter will assume 1000 [ms] as the default. The second value can be either 0 or 1 and specifies whether the underlying counter should be reset during evaluation 1 or not 0. The default value is 0.</td>
</tr>
</tbody>
</table>
Table 2.37: Performance counters for elementary arithmetic operations

<table>
<thead>
<tr>
<th>Counter type</th>
<th>Counter instance formatting</th>
<th>Description</th>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>/arithmetics/add</td>
<td>None</td>
<td>Returns the sum calculated based on the values queried from the underlying counters (the ones specified as the parameters).</td>
<td>The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.</td>
</tr>
<tr>
<td>/arithmetics/subtract</td>
<td>None</td>
<td>Returns the difference calculated based on the values queried from the underlying counters (the ones specified as the parameters).</td>
<td>The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.</td>
</tr>
<tr>
<td>/arithmetics/multiply</td>
<td>None</td>
<td>Returns the product calculated based on the values queried from the underlying counters (the ones specified as the parameters).</td>
<td>The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.</td>
</tr>
<tr>
<td>/arithmetics/divide</td>
<td>None</td>
<td>Returns the result of division of the values queried from the underlying counters (the ones specified as the parameters).</td>
<td>The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.</td>
</tr>
<tr>
<td>/arithmetics/mean</td>
<td>None</td>
<td>Returns the average value of all values queried from the underlying counters (the ones specified as the parameters).</td>
<td>The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.</td>
</tr>
<tr>
<td>/arithmetics/variance</td>
<td>None</td>
<td>Returns the standard deviation of all values queried from the underlying counters (the ones specified as the parameters).</td>
<td>The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.</td>
</tr>
<tr>
<td>/arithmetics/median</td>
<td>None</td>
<td>Returns the median value of all values queried from the underlying counters (the ones specified as the parameters).</td>
<td>The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.</td>
</tr>
<tr>
<td>/arithmetics/min</td>
<td>None</td>
<td>Returns the minimum value of all values queried from the underlying counters (the ones specified as the parameters).</td>
<td>The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.</td>
</tr>
<tr>
<td>/arithmetics/max</td>
<td>None</td>
<td>Returns the maximum value of all values queried from the underlying counters (the ones specified as the parameters).</td>
<td>The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.</td>
</tr>
<tr>
<td>/arithmetics/count</td>
<td>None</td>
<td>Returns the count value of all values queried from the underlying counters (the ones specified as the parameters).</td>
<td>The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.</td>
</tr>
</tbody>
</table>

Note: The /arithmetics counters can consume an arbitrary number of other counters. For this reason those have to be specified as parameters (a comma separated list of counters appended after a '@'). For instance:

```
./bin/hello_world_distributed -t2 \n
(continues on next page)
```
hello world from OS-thread 0 on locality 0
hello world from OS-thread 1 on locality 0
/threads{locality#0/worker-thread#0}/count/cumulative,1,0.515640,\[s\],25
/threads{locality#0/worker-thread#1}/count/cumulative,1,0.515520,\[s\],36
/arithmetics/add@/threads{locality#0/worker-thread#*}/count/cumulative,1,0.516445,\[s\],
→64

Since all wildcards in the parameters are expanded, this example is fully equivalent to specifying both counters separately to /arithmetics/add:

```bash
./bin/hello_world_distributed -t2
  --hpx:print-counter=/threads{locality#0/worker-thread#*}/count/cumulative \
  --hpx:print-counter=/arithmetics/add@/threads{locality#0/worker-thread#*}/count/ 
  →cumulative
```

2.5. Manual 227
Table 2.38: Performance counters tracking parcel coalescing

<table>
<thead>
<tr>
<th>Counter type</th>
<th>Description</th>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>/coalescing/parcels/locality##*</td>
<td>Returns the number of parcels handled by the message handler associated with the action which is given by the counter parameter.</td>
<td>The action type. This is the string which has been used while registering the action with HPX, e.g. which has been passed as the second parameter to the macro HPX_REGISTER_ACTION or HPX_REGISTER_ACTION_ID.</td>
</tr>
<tr>
<td>/coalescing/messages/locality##*</td>
<td>Returns the number of messages generated by the message handler associated with the action which is given by the counter parameter.</td>
<td>The action type. This is the string which has been used while registering the action with HPX, e.g. which has been passed as the second parameter to the macro HPX_REGISTER_ACTION or HPX_REGISTER_ACTION_ID.</td>
</tr>
<tr>
<td>/coalescing/average-parcels-per-message/locality##*</td>
<td>Returns the average number of parcels sent in a message generated by the message handler associated with the action which is given by the counter parameter.</td>
<td>The action type. This is the string which has been used while registering the action with HPX, e.g. which has been passed as the second parameter to the macro HPX_REGISTER_ACTION or HPX_REGISTER_ACTION_ID.</td>
</tr>
<tr>
<td>/coalescing/average-parcel-arrival-time/locality##*</td>
<td>Returns the average time between arriving parcels for the action which is given by the counter parameter.</td>
<td>The action type. This is the string which has been used while registering the action with HPX, e.g. which has been passed as the second parameter to the macro HPX_REGISTER_ACTION or HPX_REGISTER_ACTION_ID.</td>
</tr>
</tbody>
</table>
Note: The performance counters related to parcel coalescing are available only if the configuration time constant HPX_WITH_PARCEL_COALESCEING is set to ON (default: ON). However, even in this case it will be available only for actions that are enabled for parcel coalescing (see the macros HPX_ACTION_USES_MESSAGE_COALESCEING and HPX_ACTION_USES_MESSAGE_COALESCEING_NOTHROW).

APEX integration

HPX provides integration with APEX\(^{199}\), which is a framework for application profiling using task timers and various performance counters. It can be added as a git submodule by turning on the option HPX_WITH_APEX:BOOL during CMake configuration. TAU\(^{200}\) is an optional dependency when using APEX.

To build HPX with APEX, add HPX_WITH_APEX=ON, and, optionally, TAUS_ROOT=$PATH_TO_TAU to your CMake configuration. In addition, you can override the tag used for APEX with the HPX_WITH_APEX_TAG option. Please see the APEX HPX documentation\(^{201}\) for detailed instructions on using APEX with HPX.

2.5.11 HPX runtime and resources

**HPX thread scheduling policies**

The HPX runtime has five thread scheduling policies: local-priority, static-priority, local, static and abp-priority. These policies can be specified from the command line using the command line option --hpx:queuing. In order to use a particular scheduling policy, the runtime system must be built with the appropriate scheduler flag turned on (e.g. cmake -DHPX_THREAD_SCHEDULERS=local, see CMake variables used to configure HPX for more information).

**Priority local scheduling policy (default policy)**

- default or invoke using: --hpx:queuing local-priority fifo

The priority local scheduling policy maintains one queue per operating system (OS) thread. The OS thread pulls its work from this queue. By default the number of high priority queues is equal to the number of OS threads; the number of high priority queues can be specified on the command line using --hpx:high-priority-threads. High priority threads are executed by any of the OS threads before any other work is executed. When a queue is empty work will be taken from high priority queues first. There is one low priority queue from which threads will be scheduled only when there is no other work.

For this scheduling policy there is an option to turn on NUMA sensitivity using the command line option --hpx:numa-sensitive. When NUMA sensitivity is turned on work stealing is done from queues associated with the same NUMA domain first, only after that work is stolen from other NUMA domains.

This scheduler is enabled at build time by default and will be available always.

This scheduler can be used with two underlying queuing policies (FIFO: first-in-first-out, and LIFO: last-in-first-out). The default is FIFO. In order to use the LIFO policy use the command line option --hpx:queuing=local-priority-lifo.

Static priority scheduling policy

- invoke using: `--hpx:queuing=static-priority (or -qs)`
- flag to turn on for build: `HPX_THREAD_SCHEDULERS=all or HPX_THREAD_SCHEDULERS=static-priority`

The static scheduling policy maintains one queue per OS thread from which each OS thread pulls its tasks (user threads). Threads are distributed in a round robin fashion. There is no thread stealing in this policy.

Local scheduling policy

- invoke using: `--hpx:queuing=local (or -ql)`
- flag to turn on for build: `HPX_THREAD_SCHEDULERS=all or HPX_THREAD_SCHEDULERS=local`

The local scheduling policy maintains one queue per OS thread from which each OS thread pulls its tasks (user threads).

Static scheduling policy

- invoke using: `--hpx:queuing=static`
- flag to turn on for build: `HPX_THREAD_SCHEDULERS=all or HPX_THREAD_SCHEDULERS=static`

The static scheduling policy maintains one queue per OS thread from which each OS thread pulls its tasks (user threads). Threads are distributed in a round robin fashion. There is no thread stealing in this policy.

Priority ABP scheduling policy

- invoke using: `--hpx:queuing=abp-priority-fifo`
- flag to turn on for build: `HPX_THREAD_SCHEDULERS=all or HPX_THREAD_SCHEDULERS=abp-priority`

Priority ABP policy maintains a double ended lock free queue for each OS thread. By default the number of high priority queues is equal to the number of OS threads; the number of high priority queues can be specified on the command line using `--hpx:high-priority-threads`. High priority threads are executed by the first OS threads before any other work is executed. When a queue is empty work will be taken from high priority queues first. There is one low priority queue from which threads will be scheduled only when there is no other work. For this scheduling policy there is an option to turn on NUMA sensitivity using the command line option `--hpx:numa-sensitive`. When NUMA sensitivity is turned on work stealing is done from queues associated with the same NUMA domain first, only after that work is stolen from other NUMA domains.

This scheduler can be used with two underlying queuing policies (FIFO: first-in-first-out, and LIFO: last-in-first-out). In order to use the LIFO policy use the command line option `--hpx:queuing=abp-priority-lifo`. 
The **HPX** resource partitioner

The **HPX** resource partitioner lets you take the execution resources available on a system—processing units, cores, and numa domains—and assign them to thread pools. By default **HPX** creates a single thread pool name `default`. While this is good for most use cases, the resource partitioner lets you create multiple thread pools with custom resources and options.

Creating custom thread pools is useful for cases where you have tasks which absolutely need to run without interference from other tasks. An example of this is when using MPI\(^2\)\(^2\)\(^2\) for distribution instead of the built-in mechanisms in **HPX** (useful in legacy applications). In this case one can create a thread pool containing a single thread for MPI\(^2\)\(^2\)\(^2\) communication. MPI\(^2\)\(^2\)\(^2\) tasks will then always run on the same thread, instead of potentially being stuck in a queue behind other threads.

Note that **HPX** thread pools are completely independent from each other in the sense that task stealing will never happen between different thread pools. However, tasks running on a particular thread pool can schedule tasks on another thread pool.

**Note:** It is simpler in some situations to schedule important tasks with high priority instead of using a separate thread pool.

**Using the resource partitioner**

The `hpx::resource::partitioner` is now created during **HPX** runtime initialization without explicit action needed from the user. To specify some of the initialization parameters you can use the `hpx::init_params`.

```cpp
#include <hpx/local/init.hpp>

int hpx_main()
{
    return hpx::local::finalize();
}

int main(int argc, char** argv)
{
    // Setup the init parameters
    hpx::local::init_params init_args;
    hpx::local::init(hpx_main, argc, argv, init_args);
}
```

The resource partitioner callback is the interface to add thread pools to the **HPX** runtime and to assign resources to the thread pools. In order to create custom thread pools you can specify the resource partitioner callback `hpx::init_params::rp_callback` which will be called once the resource partitioner will be created, see the example below. You can also specify other parameters, see `hpx::init_params`.

To add a thread pool use the `hpx::resource::partitioner::create_thread_pool` method. If you simply want to use the default scheduler and scheduler options it is enough to call `rp.create_thread_pool("my-thread-pool")`.

Then, to add resources to the thread pool you can use the `hpx::resource::partitioner::add_resource` method. The resource partitioner exposes the hardware topology retrieved using Portable Hardware Locality

\(^2\)\(^2\)\(^2\) [https://en.wikipedia.org/wiki/Message_Passing_Interface](https://en.wikipedia.org/wiki/Message_Passing_Interface)

\(^2\)\(^2\)\(^2\) [https://en.wikipedia.org/wiki/Message_Passing_Interface](https://en.wikipedia.org/wiki/Message_Passing_Interface)

\(^2\)\(^2\)\(^2\) [https://en.wikipedia.org/wiki/Message_Passing_Interface](https://en.wikipedia.org/wiki/Message_Passing_Interface)
and lets you iterate through the topology to add the wanted processing units to the thread pool. Below is an example of adding all processing units from the first NUMA domain to a custom thread pool, unless there is only one NUMA domain in which case we leave the first processing unit for the default thread pool:

```cpp
#include <hpx/local/init.hpp>
#include <hpx/modules/resource_partitioner.hpp>
#include <iostream>

int hpx_main()
{
    return hpx::local::finalize();
}

void init_resource_partitioner_handler(hpx::resource::partitioner& rp,
                        hpx::program_options::variables_map const& /*vm*/)
{
    rp.create_thread_pool("my-thread-pool");

    bool one_numa_domain = rp.numa_domains().size() == 1;
    bool skipped_first_pu = false;

    hpx::resource::numa_domain const& d = rp.numa_domains()[0];

    for (hpx::resource::core const& c : d.cores())
    {
        for (hpx::resource::pu const& p : c.pus())
        {
            if (one_numa_domain && !skipped_first_pu)
            {
                skipped_first_pu = true;
                continue;
            }

            rp.add_resource(p, "my-thread-pool");
        }
    }
}

int main(int argc, char* argv[])
{
    // Set the callback to init the thread pools
    hpx::local::init_params init_args;
    init_args rp_callback = &init_resource_partitioner_handler;

    hpx::local::init(hpx_main, argc, argv, init_args);
}
```

**Note:** Whatever processing units not assigned to a thread pool by the time `hpx::init` is called will be added to the default thread pool. It is also possible to explicitly add processing units to the default thread pool, and to create the default thread pool manually (in order to e.g. set the scheduler type).

**Tip:** The command line option `--hpx:print-bind` is useful for checking that the thread pools have been set up.

---

(WLLOC)²⁰⁵ and lets you iterate through the topology to add the wanted processing units to the thread pool. Below is an example of adding all processing units from the first NUMA domain to a custom thread pool, unless there is only one NUMA domain in which case we leave the first processing unit for the default thread pool:

```cpp
#include <hpx/local/init.hpp>
#include <hpx/modules/resource_partitioner.hpp>
#include <iostream>

int hpx_main()
{
    return hpx::local::finalize();
}

void init_resource_partitioner_handler(hpx::resource::partitioner& rp,
                        hpx::program_options::variables_map const& /*vm*/)
{
    rp.create_thread_pool("my-thread-pool");

    bool one_numa_domain = rp.numa_domains().size() == 1;
    bool skipped_first_pu = false;

    hpx::resource::numa_domain const& d = rp.numa_domains()[0];

    for (hpx::resource::core const& c : d.cores())
    {
        for (hpx::resource::pu const& p : c.pus())
        {
            if (one_numa_domain && !skipped_first_pu)
            {
                skipped_first_pu = true;
                continue;
            }

            rp.add_resource(p, "my-thread-pool");
        }
    }
}

int main(int argc, char* argv[])
{
    // Set the callback to init the thread pools
    hpx::local::init_params init_args;
    init_args rp_callback = &init_resource_partitioner_handler;

    hpx::local::init(hpx_main, argc, argv, init_args);
}
```

**Note:** Whatever processing units not assigned to a thread pool by the time `hpx::init` is called will be added to the default thread pool. It is also possible to explicitly add processing units to the default thread pool, and to create the default thread pool manually (in order to e.g. set the scheduler type).

**Tip:** The command line option `--hpx:print-bind` is useful for checking that the thread pools have been set up.

²⁰⁵ https://www.open-mpi.org/projects/hwloc/
the way you expect.

### Difference between the old and new version

In the old version, you had to create an instance of the `resource_partitioner` with `argc` and `argv`.

```cpp
int main(int argc, char** argv)
{
    hpx::resource::partitioner rp(argc, argv);
    hpx::init();
}
```

From **HPX** 1.5.0 onwards, you just pass `argc` and `argv` to `hpx::init()` or `hpx::start()` for the binding options to be parsed by the resource partitioner.

```cpp
int main(int argc, char** argv)
{
    hpx::init_params init_args;
    hpx::init(argc, argv, init_args);
}
```

In the old version, when creating a custom thread pool, you just called the utilities on the resource partitioner instantiated previously.

```cpp
int main(int argc, char** argv)
{
    hpx::resource::partitioner rp(argc, argv);
    rp.create_thread_pool("my-thread-pool");

    bool one_numa_domain = rp.numa_domains().size() == 1;
    bool skipped_first_pu = false;

    hpx::resource::numa_domain const & d = rp.numa_domains()[0];

    for (const hpx::resource::core & c : d.cores())
    {
        for (const hpx::resource::pu & p : c.pus())
        {
            if (one_numa_domain && !skipped_first_pu)
            {
                skipped_first_pu = true;
                continue;
            }

            rp.add_resource(p, "my-thread-pool");
        }
    }

    hpx::init();
}
```

You now specify the resource partitioner callback which will tie the resources to the resource partitioner created during runtime initialization.
```cpp
void init_resource_partitioner_handler(hpx::resource::partitioner& rp)
{
    rp.create_thread_pool("my-thread-pool");

    bool one_numa_domain = rp.numa_domains().size() == 1;
    bool skipped_first_pu = false;

    hpx::resource::numa_domain const& d = rp.numa_domains()[0];

    for (const hpx::resource::core& c : d.cores())
    {
        for (const hpx::resource::pu& p : c.pus())
        {
            if (one_numa_domain && !skipped_first_pu)
            {
                skipped_first_pu = true;
                continue;
            }

            rp.add_resource(p, "my-thread-pool");
        }
    }
}

int main(int argc, char* argv[])
{
    hpx::init_params init_args;
    init_args.rp_callback = &init_resource_partitioner_handler;

    hpx::init(argc, argv, init_args);
}
```

### Advanced usage

It is possible to customize the built in schedulers by passing scheduler options to `hpx::resource::partitioner::create_thread_pool`. It is also possible to create and use custom schedulers.

**Note:** It is not recommended to create your own scheduler. The **HPX** developers use this to experiment with new scheduler designs before making them available to users via the standard mechanisms of choosing a scheduler (command line options). If you would like to experiment with a custom scheduler the resource partitioner example `shared_priority_queue_scheduler.cpp` contains a fully implemented scheduler with logging etc. to make exploration easier.

To choose a scheduler and custom mode for a thread pool, pass additional options when creating the thread pool like this:

```cpp
rp.create_thread_pool("my-thread-pool",
    hpx::resource::policies::local_priority_lifo,
    hpx::policies::scheduler_mode(
        hpx::policies::scheduler_mode::default |
        hpx::policies::scheduler_mode::enable_elasticity));
```

The available schedulers are documented here: `hpx::resource::scheduling_policy`, and the avail-
able scheduler modes here: `hpx::threads::policies::scheduler_mode`. Also see the examples folder for examples of advanced resource partitioner usage: `simple_resource_partitioner.cpp` and `oversubscribing_resource_partitioner.cpp`.

### 2.5.12 Miscellaneous

#### Error handling

Like in any other asynchronous invocation scheme, it is important to be able to handle error conditions occurring while the asynchronous (and possibly remote) operation is executed. In **HPX** all error handling is based on standard C++ exception handling. Any exception thrown during the execution of an asynchronous operation will be transferred back to the original invocation *locality*, where it will be rethrown during synchronization with the calling thread.

The source code for this example can be found here: `error_handling.cpp`.

#### Working with exceptions

For the following description assume that the function `raise_exception()` is executed by invoking the plain action `raise_exception_type`.

```cpp
#include <hpx/iostream.hpp>
#include <hpx/modules/runtime_local.hpp>

// [error_handling_raise_exception
void raise_exception()
{
    // Error reporting using exceptions
    // [exception_diagnostic_information
    hpx::cout << "Error reporting using exceptions\n";
    try {
        // invoke raise_exception() which throws an exception
        raise_exception_action do_it;
        do_it(hpx::find_here());
    }
    catch (hpx::exception const & e) {
        // Print just the essential error information.
        hpx::cout << "caught exception: " << e.what() << "\n";

        // Print all of the available diagnostic information as stored with
        // the exception.
    }
}
```

>Note: The exception is transferred back to the invocation site even if it is executed on a different *locality*.}
Additionally, this example demonstrates how an exception thrown by an (possibly remote) action can be handled. It shows the use of `hpx::diagnostic_information`, which retrieves all available diagnostic information from the exception as a formatted string. This includes, for instance, the name of the source file and line number, the sequence number of the OS thread and the HPX thread id, the locality id and the stack backtrace of the point where the original exception was thrown.

Under certain circumstances it is desirable to output only some of the diagnostics, or to output those using different formatting. For this case, HPX exposes a set of lower-level functions as demonstrated in the following code snippet:

```cpp
// Detailed error reporting using exceptions
hpx::cout << "Detailed error reporting using exceptions\n";
try {
    // Invoke raise_exception() which throws an exception.
    raise_exception_action do_it;
    do_it(hpx::find_here());
} catch (hpx::exception const & e) {
    // Print the elements of the diagnostic information separately.
    hpx::cout << "{what}: " << hpx::get_error_what(e) << "\n";
    hpx::cout << "{locality-id}: " << hpx::get_error_locality_id(e) << "\n";
    hpx::cout << "{hostname}: " << hpx::get_error_host_name(e) << "\n";
    hpx::cout << "{pid}: " << hpx::get_error_process_id(e) << "\n";
    hpx::cout << "{function}: " << hpx::get_error_function_name(e) << "\n";
    hpx::cout << "{file}: " << hpx::get_error_file_name(e) << "\n";
    hpx::cout << "{line}: " << hpx::get_error_line_number(e) << "\n";
    hpx::cout << "{os-thread}: " << hpx::get_error_os_thread(e) << "\n";
    hpx::cout << "{thread-id}: " << std::hex << hpx::get_error_thread_id(e) << "\n";
    hpx::cout << "{thread-description}: " << hpx::get_error_thread_description(e) << "\n";
    hpx::cout << "{state}: " << std::hex << hpx::get_error_state(e) << "\n";
}
```

### Working with error codes

Most of the API functions exposed by HPX can be invoked in two different modes. By default those will throw an exception on error as described above. However, sometimes it is desirable not to throw an exception in case of an error condition. In this case an object instance of the `hpx::error_code` type can be passed as the last argument to the API function. In case of an error, the error condition will be returned in that `hpx::error_code` instance. The following example demonstrates extracting the full diagnostic information without exception handling:

```cpp
///////////////////////////////////////////////////////////////////////
// Error reporting using error code
hpx::cout << "Error reporting using error code\n";
// Create a new error_code instance.
hpx::error_code ec;
// If an instance of an error_code is passed as the last argument while
// invoking the action, the function will not throw in case of an error
// but store the error information in this error_code instance instead.
```

(continues on next page)
raise_exception_action do_it;
do_it(hpx::find_here(), ec);

    if (ec) {
        // Print just the essential error information.
        hpx::cout << "returned error: " << ec.get_message() << "\n";

        // Print all of the available diagnostic information as stored with
        // the exception.
        hpx::cout << "diagnostic information:"
    } 

Note: The error information is transferred back to the invocation site even if it is executed on a different locality.

This example shows how an error can be handled without having to resolve to exceptions and that the returned hpx::error_code instance can be used in a very similar way as the hpx::exception type above. Simply pass it to the hpx::diagnostic_information, which retrieves all available diagnostic information from the error code instance as a formatted string.

As for handling exceptions, when working with error codes, under certain circumstances it is desirable to output only some of the diagnostics, or to output those using different formatting. For this case, HPX exposes a set of lower-level functions usable with error codes as demonstrated in the following code snippet:

    // Detailed error reporting using error code
    {
        // Create a new error_code instance.
        hpx::error_code ec;

        // If an instance of an error_code is passed as the last argument while
        // invoking the action, the function will not throw in case of an error
        // but store the error information in this error_code instance instead.
        raise_exception_action do_it;
do_it(hpx::find_here(), ec);

        if (ec) {
            // Print the elements of the diagnostic information separately.
            hpx::cout << "{what}: "       << hpx::get_error_what(ec)       << "\n";
            hpx::cout << "{locality-id}: " << hpx::get_error_locality_id(ec) << "\n";
            hpx::cout << "{hostname}: "   << hpx::get_error_host_name(ec)   << "\n";
            hpx::cout << "{pid}: "        << hpx::get_error_process_id(ec) << "\n";
            hpx::cout << "{function}: "   << hpx::get_error_function_name(ec) << "\n";
            hpx::cout << "{file}: "       << hpx::get_error_file_name(ec)       << "\n";
            hpx::cout << "{line}: "       << hpx::get_error_line_number(ec)       << "\n";
            hpx::cout << "{os-thread}: "  << hpx::get_error_os_thread(ec)  << "\n";
            hpx::cout << "{thread-id}: "  << std::hex
                << hpx::get_error_thread_id(ec) << "\n";
        }
    }"
For more information please refer to the documentation of `hpx::get_error_what`, `hpx::get_error_locality_id`, `hpx::get_error_host_name`, `hpx::get_error_process_id`, `hpx::get_error_function_name`, `hpx::get_error_file_name`, `hpx::get_error_line_number`, `hpx::get_error_os_thread`, `hpx::get_error_thread_id`, `hpx::get_error_thread_description`, `hpx::get_error_backtrace`, `hpx::get_error_env`, and `hpx::get_error_state`.

### Lightweight error codes

Sometimes it is not desirable to collect all the ambient information about the error at the point where it happened as this might impose too much overhead for simple scenarios. In this case, HPX provides a lightweight error code facility that will hold the error code only. The following snippet demonstrates its use:

```cpp
// Error reporting using lightweight error code
{
    // Compile lightweight_error_handling_diagnostic_information
    hpx::cout << "Error reporting using an lightweight error code\n";

    // Create a new error_code instance.
    hpx::error_code ec(hpx::lightweight);

    // If an instance of an error_code is passed as the last argument while
    // invoking the action, the function will not throw in case of an error
    // but store the error information in this error_code instance instead.
    raise_exception_action do_it;
    do_it(hpx::find_here(), ec);
    if (ec) {
        // Print just the essential error information.
        hpx::cout << "returned error: " << ec.get_message() << "\n";

        // Print all of the available diagnostic information as stored with
        // the exception.
    }
}
```

All functions that retrieve other diagnostic elements from the `hpx::error_code` will fail if called with a lightweight error_code instance.

### Utilities in HPX

In order to ease the burden of programming, HPX provides several utilities to users. The following section documents those facilities.
Checkpoint

See checkpoint.

The HPX I/O-streams component

The HPX I/O-streams subsystem extends the standard C++ output streams `std::cout` and `std::cerr` to work in the distributed setting of an HPX application. All of the output streamed to `hpx::cout` will be dispatched to `std::cout` on the console `locality`. Likewise, all output generated from `hpx::cerr` will be dispatched to `std::cerr` on the console `locality`.

Note: All existing standard manipulators can be used in conjunction with `hpx::cout` and `hpx::cerr` Historically, HPX also defines `hpx::endl` and `hpx::flush` but those are just aliases for the corresponding standard manipulators.

In order to use either `hpx::cout` or `hpx::cerr`, application codes need to `#include <hpx/include/iostreams.hpp>`. For an example, please see the following 'Hello world’ program:

```cpp
#include <hpx/include/iostreams.hpp>

int main()
{
    // Say hello to the world!
    hpx::cout << "Hello World!\n" << hpx::flush;
    return 0;
}
```

Additionally, those applications need to link with the iostreams component. When using CMake this can be achieved by using the `COMPONENT_DEPENDENCIES` parameter; for instance:

```cmake
include(HPX_AddExecutable)
add_hpx_executable(
    hello_world
    SOURCES hello_world.cpp
    COMPONENT_DEPENDENCIES iostreams
)
```

Note: The `hpx::cout` and `hpx::cerr` streams buffer all output locally until a `std::endl` or `std::flush` is
encountered. That means that no output will appear on the console as long as either of these is explicitly used.

### 2.5.13 Troubleshooting

This section contains commonly encountered problems when compiling or using HPX.

**Undefined reference to boost::program_options**

Boost.ProgramOptions is not ABI compatible between all C++ versions and compilers. Because of this you may see linker errors similar to this:

```plaintext
...: undefined reference to `boost::program_options::operator<<(std::ostream&, boost::program_options::options_description const&)
```

... if you are not linking to a compatible version of Boost.ProgramOptions. We recommend that you use `hpx::program_options`, which is part of HPX, as a replacement for `boost::program_options` (see *program_options*). Until you have migrated to use `hpx::program_options` we recommend that you always build Boost libraries and HPX with the same compiler and C++ standard.

**Undefined reference to hpx::cout**

You may see an linker error message that looks a bit like this:

```plaintext
hello_world.cpp: (.text+0x5aa): undefined reference to `hpx::cout'
hello_world.cpp: (.text+0x5c3): undefined reference to `hpx::iostreams::flush'
```

This usually happens if you are trying to use HPX iostreams functionality such as `hpx::cout` but are not linking against it. The iostreams functionality is not part of the core HPX library, and must be linked to explicitly. Typically this can be solved by adding `COMPONENT_DEPENDENCIES iostreams` to a call to `add_hpx_library/add_hpx_executable/hpx_setup_target` if using CMake. See *Creating HPX projects* for more details.

2.7 Overview

HPX is organized into different sub-libraries and those in turn into modules. The libraries and modules are independent, with clear dependencies and no cycles. As an end-user, the use of these libraries is completely transparent. If you use e.g. `add_hpx_executable` to create a target in your project you will automatically get all modules as dependencies. See below for a list of the available libraries and modules. Currently these are nothing more than an internal grouping and do not affect usage. They cannot be consumed individually at the moment.

2.7.1 Core modules

affinity

The affinity module contains helper functionality for mapping worker threads to hardware resources. See the API reference of the module for more details.

allocator_support

This module provides utilities for allocators. It contains `hpx::util::internal_allocator` which directly forwards allocation calls to `jemalloc`. This utility is mainly useful on Windows. See the API reference of the module for more details.

asio

The asio module is a thin wrapper around the Boost.ASIO library, providing a few additional helper functions. See the API reference of the module for more details.

assertion

The assertion library implements the macros `HPX_ASSERT` and `HPX_ASSERT_MSG`. Those two macros can be used to implement assertions which are turned off during a release build.

By default, the location and function where the assert has been called from are displayed when the assertion fires. This behavior can be modified by using `hpx::assertion::set_assertion_handler`. When HPX initializes, it uses this function to specify a more elaborate assertion handler. If your application needs to customize this, it needs to do so before calling `hpx::hpx_init`, `hpx::hpx_main` or using the C-main wrappers. See the API reference of the module for more details.

cache

This module provides two cache data structures:

- `hpx::util::cache::local_cache`
- `hpx::util::cache::lru_cache`

See the API reference of the module for more details.
concepts

This module provides helpers for emulating concepts. It provides the following macros:

- `HPX_CONCEPT_REQUIRES`
- `HPX_HAS_MEMBER_XXX_TRAIT_DEF`
- `HPX_HAS_XXX_TRAIT_DEF`

See the API reference of the module for more details.

concurrency

This module provides concurrency primitives useful for multi-threaded programming such as:

- `hpx::util::barrier`
- `hpx::util::cache_line_data` and `hpx::util::cache_aligned_data`: wrappers for aligning and padding data to cache lines.
- various lockfree queue data structures

See the API reference of the module for more details.

config

The config module contains various configuration options, typically hidden behind macros that choose the correct implementation based on the compiler and other available options.

See the API reference of the module for more details.

config_registry

The config_registry module is a low level module providing helper functionality for registering configuration entries to a global registry from other modules. The `hpx::config_registry::add_module_config` function is used to add configuration options, and `hpx::config_registry::get_module_configs` can be used to retrieve configuration entries registered so far. `add_module_config_helper` can be used to register configuration entries through static global options.

See the API reference of this module for more details.

coroutines

The coroutines module provides coroutine (user-space thread) implementations for different platforms.

See the API reference of the module for more details.
datastructures

The datastructures module provides basic data structures (typically provided for compatibility with older C++ standards):

- `hpx::util::basic_any`
- `hpx::util::optional`
- `hpx::util::tuple`

See the API reference of the module for more details.

debugging

This module provides helpers for demangling symbol names.

See the API reference of the module for more details.

effects

This module provides support for exceptions and error codes:

- `hpx::exception`
- `hpx::error_code`
- `hpx::error`

See the API reference of the module for more details.

effect_base

The basic execution module is the main entry point to implement parallel and concurrent operations. It is modeled after P0443 with some additions and implementations for the described concepts. Most notably, it provides an abstraction for execution resources, execution contexts and execution agents in such a way, that it provides customization points that those aforementioned concepts can be replaced and combined with ease.

For that purpose, three virtual base classes are provided to be able to provide implementations with different properties:

- **resource_base:** This is the abstraction for execution resources, that is for example CPU cores or an accelerator.

- **context_base:** An execution context uses execution resources and is able to spawn new execution agents, as new threads of executions on the available resources.

- **agent_base:** The execution agent represents the thread of execution, and can be used to yield, suspend, resume or abort a thread of execution.

---

211 http://wg21.link/p0443
filesystem

This module provides a compatibility layer for the C++17 filesystem library. If the filesystem library is available this module will simply forward its contents into the `hpx::filesystem` namespace. If the library is not available it will fall back to Boost.Filesystem instead.

See the API reference of the module for more details.

format

The format module exposes the `format` and `format_to` functions for formatting strings.

See the API reference of the module for more details.

functional

This module provides function wrappers and helpers for managing functions and their arguments.

- `hpx::util::function`
- `hpx::util::function_ref`
- `hpx::util::unique_function`
- `hpx::util::bind`
- `hpx::util::bind_back`
- `hpx::util::bind_front`
- `hpx::util::deferred_call`
- `hpx::util::invoke`
- `hpx::util::invoke_fused`
- `hpx::util::mem_fn`
- `hpx::util::one_shot`
- `hpx::util::protect`
- `hpx::util::result_of`

See the API reference of the module for more details.

hardware

The hardware module abstracts away hardware specific details of timestamps and CPU features.

See the API reference of the module for more details.
hashing

The hashing module provides two hashing implementations:

- `hpx::util::fibhash`
- `hpx::util::jenkins_hash`

See the API reference of the module for more details.

ini

TODO: High-level description of the module.

See the API reference of this module for more details.

io_service

This module provides an abstraction over Boost.ASIO, combining multiple `asio::io_context`s into a single pool. `hpx::util::io_service_pool` provides a simple pool of `asio::io_context`s with an API similar to `asio::io_context`. `hpx::threads::detail::io_service_thread_pool` wraps `hpx::util::io_service_pool` into an interface derived from `hpx::threads::detail::thread_pool_base`.

See the API reference of this module for more details.

iterator_support

This module provides helpers for iterators. It provides `hpx::util::iterator_facade` and `hpx::util::iterator_adaptor` for creating new iterators, and the trait `hpx::util::is_iterator` along with more specific iterator traits.

See the API reference of the module for more details.

itt_notify

This module provides support for profiling with Intel VTune\(^2\).\(^2\)

See the API reference of this module for more details.

logging

This module provides useful macros for logging information.

See the API reference of the module for more details.

memory

Part of this module is a forked version of boost::intrusive_ptr from Boost.SmartPtr.
See the API reference of the module for more details.

plugin

This module provides base utilities for creating plugins.
See the API reference of the module for more details.

prefix

This module provides utilities for handling the prefix of an HPX application, i.e. the paths used for searching components and plugins.
See the API reference of this module for more details.

preprocessor

This library contains useful preprocessor macros:

- `HPX_PP_CAT`
- `HPX_PP_EXPAND`
- `HPX_PP_NARGS`
- `HPX_PP_STRINGIZE`
- `HPX_PP_STRIP_PARENS`

See the API reference of the module for more details.

properties

This module implements the prefer customization point for properties in terms of P2220\(^{11}\). This differs from P1393\(^{14}\) in that it relies fully on tag_dispatch overloads and fewer base customization points. Actual properties are defined in modules. All functionality is experimental and can be accessed through the `hpx::experimental` namespace.

See the API reference of this module for more details.

\(^{11}\) [http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2020/p2220r0.pdf](http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2020/p2220r0.pdf)

\(^{14}\) [http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2019/p1393r0.html](http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2019/p1393r0.html)
**schedulers**

This module provides schedulers used by thread pools in the `thread_pools` module. There are currently three main schedulers:

- `hpx::threads::policies::local_priority_queue_scheduler`
- `hpx::threads::policies::static_priority_queue_scheduler`
- `hpx::threads::policies::shared_priority_queue_scheduler`

Other schedulers are specializations or variations of the above schedulers. See the examples of the `resource_partitioner` module for examples of specifying a custom scheduler for a thread pool.

See the *API reference* of this module for more details.

**serialization**

This module provides serialization primitives and support for all built-in types as well as all C++ Standard Library collection and utility types. This list is extended by `HPX` vocabulary types with proper support for global reference counting. `HPX`’s mode of serialization is derived from Boost’s serialization model and, as such, is mostly interface compatible with its Boost counterpart.

The purest form of serializing data is to copy the content of the payload bit by bit; however, this method is impractical for generic C++ types, which might be composed of more than just regular built-in types. Instead, `HPX`’s approach to serialization is derived from the Boost Serialization library, and is geared towards allowing the programmer of a given class explicit control and syntax of what to serialize. It is based on operator overloading of two special archive types that hold a buffer or stream to store the serialized data and is responsible for dispatching the serialization mechanism to the intrusive or non-intrusive version. The serialization process is recursive. Each member that needs to be serialized must be specified explicitly. The advantage of this approach is that the serialization code is written in C++ and leverages all necessary programming techniques. The generic, user-facing interface allows for effective application of the serialization process without obstructing the algorithms that need special code for packing and unpacking. It also allows for optimizations in the implementation of the archives.

See the *API reference* of the module for more details.

**static_reinit**

This module provides a simple wrapper around static variables that can be reinitialized.

See the *API reference* of this module for more details.

**statistics**

This module provide some statistics utilities like rolling min/max and histogram.

See the *API reference* of the module for more details.

---

215 https://www.boost.org/doc/libs/1_72_0/libs/serialization/doc/index.html
string_util

This module contains string utilities inspired by the Boost string algorithms library. See the API reference of this module for more details.

synchronization

This module provides synchronization primitives which should be used rather than the C++ standard ones in HPX threads:

- `hpx::lcos::local::barrier`
- `hpx::lcos::local::condition_variable`
- `hpx::lcos::local::counting_semaphore`
- `hpx::lcos::local::event`
- `hpx::lcos::local::latch`
- `hpx::lcos::local::mutex`
- `hpx::lcos::local::no_mutex`
- `hpx::lcos::local::once_flag`
- `hpx::lcos::local::recursive_mutex`
- `hpx::lcos::local::shared_mutex`
- `hpx::lcos::local::sliding_semaphore`
- `hpx::lcos::local::spinlock` *(std::mutex compatible spinlock)*
- `hpx::lcos::local::spinlock_no_backoff` *(boost::mutex compatible spinlock)*
- `hpx::lcos::local::spinlock_pool`

See `lcos_local`, `async_combinators`, and `async` for higher level synchronization facilities. See the API reference of this module for more details.

testing

The testing module contains useful macros for testing. The results of tests can be printed with `hpx::util::report_errors`. The following macros are provided:

- `HPX_TEST`
- `HPX_TEST_MSG`
- `HPX_TEST_EQ`
- `HPX_TEST_NEQ`
- `HPX_TEST_LT`
- `HPX_TEST_LTE`
- `HPX_TEST_RANGE`
- `HPX_TEST_EQ_MSG`
- `HPX_TEST_NEQ_MSG`
2.7. Overview

- **HPX_SANITY**
- **HPX_SANITY_MSG**
- **HPX_SANITY_EQ**
- **HPX_SANITY_NEQ**
- **HPX_SANITY_LT**
- **HPX_SANITY_LTE**
- **HPX_SANITY_RANGE**
- **HPX_SANITY_EQ_MSG**

See the *API reference* of the module for more details.

**thread_pools**

This module defines the thread pools and utilities used by the HPX runtime. The only thread pool implementation provided by this module is `hpx::threads::detail::scheduled_thread_pool`, which is derived from `hpx::threads::detail::thread_pool_base` defined in the *threading_base* module.

See the *API reference* of this module for more details.

**thread_support**

This module provides miscellaneous utilities for threading and concurrency.

See the *API reference* of the module for more details.

**threading_base**

This module contains the base class definition required for threads. The base class `hpx::threads::thread_data` is inherited by two specializations for stackful and stackless threads: `hpx::threads::thread_data_stackful` and `hpx::threads::thread_data_stackless`. In addition, the module defines the base classes for schedulers and thread pools: `hpx::threads::policies::scheduler_base` and `hpx::threads::thread_pool_base`.

See the API reference of this module for more details.

**timing**

This module provides the timing utilities (clocks and timers).

See the *API reference* of the module for more details.
topology

This module provides the class `hpx::threads::topology` which represents the hardware resources available on a node. The class is a light wrapper around the Portable Hardware Locality (HWLOC)\textsuperscript{216} library. The `hpx::threads::cpu_mask` is a small companion class that represents a set of resources on a node.

See the API reference of the module for more details.

type_support

This module provides helper facilities related to types.

See the API reference of the module for more details.

util

The util module provides miscellaneous standalone utilities.

See the API reference of the module for more details.

version

This module macros and functions for accessing version information about HPX and its dependencies.

See the API reference of this module for more details.

2.7.2 Parallelism modules

algorithms

The algorithms module exposes the full set of algorithms defined by the C++ standard. There is also partial support for C++ ranges.

See the API reference of the module for more details.

async_base

The async_base module defines the basic functionality for spawning tasks on thread pools. This module does not implement any functionality on its own, but is extended by `async_local` and `modules_async_distributed` with implementations for the local and distributed cases.

See the API reference of this module for more details.

\textsuperscript{216} https://www.open-mpi.org/projects/hwloc/
async_combinators

This module contains combinators for futures. The `when_` functions allow you to turn multiple futures into a single future which is ready when all, any, some, or each of the given futures are ready. The `wait_` combinators are equivalent to the `when_` functions except that they do not return a future.

The `split_future` combinator takes a single future of a container (e.g. `tuple`) and turns it into a container of futures.

See `lcos_local`, `synchronization`, and `async` for other synchronization facilities.

See the API reference of this module for more details.

async_local

This module extends `async_base` to provide local implementations of `hpx::async`, `hpx::apply`, `hpx::sync`, and `hpx::dataflow`.

See the API reference of this module for more details.

execution

This library implements executors and execution policies for use with parallel algorithms and other facilities related to managing the execution of tasks.

See the API reference of the module for more details.

executors

The executors module exposes executors and execution policies. Most importantly, it exposes the following classes and constants:

- `hpx::execution::sequenced_executor`
- `hpx::execution::parallel_executor`
- `hpx::execution::sequenced_policy`
- `hpx::execution::parallel_policy`
- `hpx::execution::parallel_unsequenced_policy`
- `hpx::execution::sequenced_task_policy`
- `hpx::execution::parallel_task_policy`
- `hpx::execution::seq`
- `hpx::execution::par`
- `hpx::execution::par_unseq`
- `hpx::execution::task`

See the API reference of this module for more details.
futures

This module defines the `hpx::lcos::future` and `hpx::lcos::shared_future` classes corresponding to the C++ standard library classes `std::future` and `std::shared_future`. Note that the specializations of `hpx::lcos::future::then` for executors and execution policies are defined in the `execution` module.

See the API reference of this module for more details.

lcos_local

This module provides the following local LCOs:

- `hpx::lcos::local::and_gate`
- `hpx::lcos::local::channel`
- `hpx::lcos::local::one_element_channel`
- `hpx::lcos::local::receive_channel`
- `hpx::lcos::local::send_channel`
- `hpx::lcos::local::guard`
- `hpx::lcos::local::guard_set`
- `hpx::lcos::local::run_guarded`
- `hpx::lcos::local::conditional_trigger`
- `hpx::lcos::local::packaged_task`
- `hpx::lcos::local::promise`
- `hpx::lcos::local::receive_buffer`
- `hpx::lcos::local::trigger`

See `lcos_distributed` for distributed LCOs. Basic synchronization primitives for use in HPX threads can be found in `synchronization`. `async_combinators` contains useful utility functions for combining futures.

See the API reference of this module for more details.

pack_traversal

This module exposes the basic functionality for traversing various packs, both synchronously and asynchronously: `hpx::util::traverse_pack` and `hpx::util::traverse_pack_async`. It also exposes the higher level functionality of unwrapping nested futures: `hpx::util::unwrap` and its function object form `hpx::util::functional::unwrap`.

See the API reference of this module for more details.
In HPX, a program failure is a manifestation of a failing task. This module exposes several APIs that allow users to manage failing tasks in a convenient way by either replaying a failed task or by replicating a specific task.

Task replay is analogous to the Checkpoint/Restart mechanism found in conventional execution models. The key difference being localized fault detection. When the runtime detects an error, it replays the failing task as opposed to completely rolling back the entire program to the previous checkpoint.

Task replication is designed to provide reliability enhancements by replicating a set of tasks and evaluating their results to determine a consensus among them. This technique is most effective in situations where there are few tasks in the critical path of the DAG which leaves the system underutilized or where hardware or software failures may result in an incorrect result instead of an error. However, the drawback of this method is the additional computational cost incurred by repeating a task multiple times.

The following API functions are exposed:

- `hpx::resiliency::experimental::async_replay`: This version of task replay will catch user-defined exceptions and automatically reschedule the task N times before throwing an `hpx::resiliency::experimental::abort_replay_exception` if no task is able to complete execution without an exception.

- `hpx::resiliency::experimental::async_replay_validate`: This version of replay adds an argument to async replay which receives a user-provided validation function to test the result of the task against. If the task’s output is validated, the result is returned. If the output fails the check or an exception is thrown, the task is replayed until no errors are encountered or the number of specified retries has been exceeded.

- `hpx::resiliency::experimental::async_replicate`: This is the most basic implementation of the task replication. The API returns the first result that runs without detecting any errors.

- `hpx::resiliency::experimental::async_replicate_validate`: This API additionally takes a validation function which evaluates the return values produced by the threads. The first task to compute a valid result is returned.

- `hpx::resiliency::experimental::async_replicate_vote`: This API adds a vote function to the basic replicate function. Many hardware or software failures are silent errors which do not interrupt program flow. In order to detect errors of this kind, it is necessary to run the task several times and compare the values returned by every version of the task. In order to determine which return value is “correct”, the API allows the user to provide a custom consensus function to properly form a consensus. This voting function then returns the “correct” answer.

- `hpx::resiliency::experimental::async_replicate_vote_validate`: This combines the features of the previously discussed replicate set. Replicate vote validate allows a user to provide a validation function to filter results. Additionally, as described in replicate vote, the user can provide a “voting function” which returns the consensus formed by the voting logic.

- `hpx::resiliency::experimental::dataflow_replay`: This version of dataflow replay will catch user-defined exceptions and automatically reschedules the task N times before throwing an `hpx::resiliency::experimental::abort_replay_exception` if no task is able to complete execution without an exception. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.

- `hpx::resiliency::experimental::dataflow_replay_validate`: This version of replay adds an argument to dataflow replay which receives a user-provided validation function to test the result of the task against. If the task’s output is validated, the result is returned. If the output fails the check or an exception is thrown, the task is replayed until no errors are encountered or the number of specified retries have been exceeded. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.
- `hpx::resiliency::experimental::dataflow_replicate`: This is the most basic implementation of the task replication. The API returns the first result that runs without detecting any errors. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.

- `hpx::resiliency::experimental::dataflow_replicate_validate`: This API additionally takes a validation function which evaluates the return values produced by the threads. The first task to compute a valid result is returned. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.

- `hpx::resiliency::experimental::dataflow_replicate_vote`: This API adds a vote function to the basic replicate function. Many hardware or software failures are silent errors which do not interrupt program flow. In order to detect errors of this kind, it is necessary to run the task several times and compare the values returned by every version of the task. In order to determine which return value is “correct”, the API allows the user to provide a custom consensus function to properly form a consensus. This voting function then returns the “correct” answer. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.

- `hpx::resiliency::experimental::dataflow_replicate_vote_validate`: This combines the features of the previously discussed replicate set. Replicate vote validate allows a user to provide a validation function to filter results. Additionally, as described in replicate vote, the user can provide a “voting function” which returns the consensus formed by the voting logic. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.

See the API reference of the module for more details.

**thread_pool_util**

This module contains helper functions for asynchronously suspending and resuming thread pools and their worker threads.

See the API reference of this module for more details.

**threading**

This module provides the equivalents of `std::thread` and `std::jthread` for lightweight HPX threads:

- `hpx::thread`
- `hpx::jthread`

See the API reference of this module for more details.

**timed_execution**

This module provides extensions to the executor interfaces defined in the execution module that allow timed submission of tasks on thread pools (at or after a specified time).

See the API reference of this module for more details.
2.7.3 Main HPX modules

actions

TODO: High-level description of the library.
See the API reference of this module for more details.

actions_base

TODO: High-level description of the library.
See the API reference of this module for more details.

agas

TODO: High-level description of the module.
See the API reference of this module for more details.

agas_base

This module holds the implementation of the four AGAS services: primary namespace, locality namespace, component namespace, and symbol namespace.
See the API reference of this module for more details.

async_colocated

TODO: High-level description of the module.
See the API reference of this module for more details.

async_cuda

This library adds a simple API that enables the user to retrieve a future from a cuda stream. Typically, a user may launch one or more kernels and then get a future from the stream that will become ready when those kernels have completed. The act of getting a future from the cuda_stream_helper object in this library hides the creation of a cuda stream event and the attachment of this event to the promise that is backing the future returned.

The usage is best illustrated by looking at an example

```cpp
// create a cuda target using device number 0,1,2...
hpx::cuda::experimental::target target(device);
// create a stream helper object
hpx::cuda::experimental::cuda_future_helper helper(device);

// launch a kernel and return a future
auto fn = &cuda_trivial_kernel<double>;
double d = 3.1415;
auto f = helper.async(fn, d);

// attach a continuation to the future
f.then([](hpx::future<void>&& f) {
```
Kernels and CPU work may be freely intermixed/overlapped and synchronized with futures.

It is important to note that multiple kernels may be launched without fetching a future, and multiple futures may be obtained from the helper. Please refer to the unit tests and examples for further examples.

CMake variables

HPX_WITH_CUDA - this is a general option that will enable both HPX_WITH_ASYNC_CUDA and HPX_WITH_CUDA_COMPUTE when turned ON.

HPX_WITH_ASYNC_CUDA=ON enables the building of this module which requires only the presence of CUDA on the system and only exposes cuda+fuures support (HPX_WITH_ASYNC_CUDA may be used when HPX_WITH_CUDA_COMPUTE=OFF).

HPX_WITH_CUDA_COMPUTE=ON enables building HPX compute features that allow parallel algorithms to be passed through to the GPU/CUDA backend.

See the API reference of this module for more details.

async

This module contains functionality for asynchronously launching work on remote localities: hpx::async, hpx::apply. This module extends the local-only functions in libs_async_local.

See the API reference of this module for more details.

async_mpi

The MPI library is intended to simplify the process of integrating MPI based codes with the HPX runtime. Any MPI function that is asynchronous and uses an MPI_Request may be converted into an hpx::future. The syntax is designed to allow a simple replacement of the MPI call with a futurized async version that accepts an executor instead of a communicator, and returns a future instead of assigning a request. Typically, an MPI call of the form

```cpp
int MPI_Isend(buf, count, datatype, rank, tag, comm, request);
```

becomes

```cpp
hpx::future<int> f = hpx::async(executor, MPI_Isend, buf, count, datatype, rank, tag);
```

When the MPI operation is complete, the future will become ready. This allows communication to integrated cleanly with the rest of HPX, in particular the continuation style of programming may be used to build up more complex code. Consider the following example, that chains user processing, sends and receives using continuations…

```cpp
// create an executor for MPI dispatch
hpx::mpi::experimental::executor exec(MPI_COMM_WORLD);

// post an asynchronous receive using MPI_Irecv
hpx::future<int> f_recv = hpx::async(
    exec, MPI_Irecv, &data, rank, MPI_INT, rank_from, i);

// attach a continuation to run when the recv completes,
```
The example above makes use of `MPI_Isend` and `MPI_Irecv`, but any MPI function that uses requests may be futurized in this manner. The following is a (non exhaustive) list of MPI functions that should be supported, though not all have been tested at the time of writing (please report any problems to the issue tracker).

```cpp
int MPI_Isend(...);
int MPI_Ibsend(...);
int MPI_Issend(...);
int MPI_Irsend(...);
int MPI_Irecv(...);
int MPI_Imrecv(...);
int MPI_Ibarrier(...);
int MPI_Ibcast(...);
int MPI_Igather(...);
int MPI_Igatherv(...);
int MPI_Iscatter(...);
int MPI_Iscatterv(...);
int MPI_Iallgather(...);
int MPI_Iallgatherv(...);
int MPI_Ialltoall(...);
int MPI_Ialltoallv(...);
int MPI_Ialltoallw(...);
int MPI_Ireduce(...);
int MPI_Iallreduce(...);
int MPI_Ireduce_scatter(...);
int MPI_Ireduce_scatter_block(...);
int MPI_Iscan(...);
int MPI_Iexscan(...);
int MPI_Ineighbor_allgather(...);
int MPI_Ineighbor_allgatherv(...);
int MPI_Ineighbor_alltoall(...);
int MPI_Ineighbor_alltoallv(...);
int MPI_Ineighbor_alltoallw(...);
``` 

Note that the HPX mpi futurization wrapper should work with any asynchronous MPI call, as long as the function signature has the last two arguments `MPI_...` - internally these two parameters will be substituted by the executor and future data parameters that are supplied by template instantiations inside the `hpx::mpi` code.

See the API reference of this module for more details.
batch_environments

This module allows for the detection of execution as batch jobs, a series of programs executed without user intervention. All data is preselected and will be executed according to preset parameters, such as date or completion of another task. Batch environments are especially useful for executing repetitive tasks.

HPX supports the creation of batch jobs through the Portable Batch System (PBS) and SLURM. For more information on batch environments, see Running on batch systems and the API reference for the module.

checkpoint

A common need of users is to periodically backup an application. This practice provides resiliency and potential restart points in code. HPX utilizes the concept of a checkpoint to support this use case.

Found in hpx/util/checkpoint.hpp, checkpoints are defined as objects that hold a serialized version of an object or set of objects at a particular moment in time. This representation can be stored in memory for later use or it can be written to disk for storage and/or recovery at a later point. In order to create and fill this object with data, users must use a function called save_checkpoint. In code the function looks like this:

```cpp
hpx::future<hpx::util::checkpoint> hpx::util::save_checkpoint(a, b, c, ...);
```

save_checkpoint takes arbitrary data containers, such as int, double, float, vector, and future, and serializes them into a newly created checkpoint object. This function returns a future to a checkpoint containing the data. Here's an example of a simple use case:

```cpp
using hpx::util::checkpoint;
using hpx::util::save_checkpoint;
std::vector<int> vec{1,2,3,4,5};
hpx::future<checkpoint> save_checkpoint(vec);
```

Once the future is ready, the checkpoint object will contain the vector vec and its five elements.

prepare_checkpoint takes arbitrary data containers (same as for save_checkpoint), such as int, double, float, vector, and future, and calculates the necessary buffer space for the checkpoint that would be created if save_checkpoint was called with the same arguments. This function returns a future to a checkpoint that is appropriately initialized. Here's an example of a simple use case:

```cpp
using hpx::util::checkpoint;
using hpx::util::prepare_checkpoint;
std::vector<int> vec{1,2,3,4,5};
hpx::future<checkpoint> prepare_checkpoint(vec);
```

Once the future is ready, the checkpoint object will be initialized with an appropriately sized internal buffer.

It is also possible to modify the launch policy used by save_checkpoint. This is accomplished by passing a launch policy as the first argument. It is important to note that passing hpx::launch::sync will cause save_checkpoint to return a checkpoint instead of a future to a checkpoint. All other policies passed to save_checkpoint will return a future to a checkpoint.

Sometimes checkpoint s must be declared before they are used. save_checkpoint allows users to move pre-created checkpoint s into the function as long as they are the first container passing into the function (In the case where a launch policy is used, the checkpoint will immediately follow the launch policy). An example of these features can be found below:
Once users can create checkpoints, they must now be able to restore the objects they contain into memory. This is accomplished by the function restore_checkpoint. This function takes a checkpoint and fills its data into the containers it is provided. It is important to remember that the containers must be ordered in the same way they were placed into the checkpoint. For clarity see the example below:

```cpp
char character2;
int integer2;
float flt2;
bool boolean2;
std::string str2;
std::vector<char> vec2;
restore_checkpoint(data, character2, integer2, flt2, boolean2, str2, vec2);
```

The core utility of checkpoint is in its ability to make certain data persistent. Often, this means that the data needs to be stored in an object, such as a file, for later use. HPX has two solutions for these issues: stream operator overloads and access iterators.

HPX contains two stream overloads, `operator<<` and `operator>>`, to stream data out of and into checkpoint. Here is an example of the overloads in use below:

```cpp
double a9 = 1.0, b9 = 1.1, c9 = 1.2;
std::ofstream test_file_9("test_file_9.txt");
hpx::future<checkpoint> f_9 = save_checkpoint(
    std::move(archive), character, integer, flt, boolean, str, vec);
test_file_9 << f_9.get();
test_file_9.close();

double a9_1, b9_1, c9_1;
std::ifstream test_file_9_1("test_file_9.txt");
checkpoint archive9;
test_file_9_1 >> archive9;
restore_checkpoint(archive9, a9_1, b9_1, c9_1);
```

This is the primary way to move data into and out of a checkpoint. It is important to note, however, that users should be cautious when using a stream operator to load data and another function to remove it (or vice versa). Both `operator<<` and `operator>>` rely on a `.write()` and a `.read()` function respectively. In order to know how much data to read from the `std::istream`, the `operator<<` will write the size of the checkpoint before writing the checkpoint data. Correspondingly, the `operator>>` will read the size of the stored data before reading the data into a new instance of checkpoint. As long as the user employs the `operator<<` and `operator>>` to stream the data, this detail can be ignored.

**Important:** Be careful when mixing `operator<<` and `operator>>` with other facilities to read and write to a checkpoint. `operator<<` writes an extra variable, and `operator>>` reads this variable back separately. Used
together the user will not encounter any issues and can safely ignore this detail.

Users may also move the data into and out of a checkpoint using the exposed .begin() and .end() iterators. An example of this use case is illustrated below.

```cpp
std::ofstream test_file_7("checkpoint_test_file.txt");
std::vector<float> vec7{1.02f, 1.03f, 1.04f, 1.05f};
hpx::future<checkpoint> fut_7 = save_checkpoint(vec7);
checkpoint archive7 = fut_7.get();
std::copy(archive7.begin(), // Write data to ofstream
         archive7.end(), // ie. the file
         std::ostream_iterator<char>(test_file_7));
test_file_7.close();

std::vector<float> vec7_1;
std::vector<char> char_vec;
std::ifstream test_file_7_1("checkpoint_test_file.txt");
if (test_file_7_1)
    { test_file_7_1.seekg(0, test_file_7_1.end);
      auto length = test_file_7_1.tellg();
      test_file_7_1.seekg(0, test_file_7_1.beg);
      char_vec.resize(length);
      test_file_7_1.read(char_vec.data(), length);
    }
checkpoint archive7_1(std::move(char_vec)); // Write data to checkpoint
restore_checkpoint(archive7_1, vec7_1);
```

### Checkpointing components

`save_checkpoint` and `restore_checkpoint` are also able to store components inside checkpoints. This can be done in one of two ways. First a client of the component can be passed to `save_checkpoint`. When the user wishes to resurrect the component she can pass a client instance to `restore_checkpoint`. This technique is demonstrated below:

```cpp
// Try to checkpoint and restore a component with a client
std::vector<int> vec3{10, 10, 10, 10, 10};

// Create a component instance through client constructor
data_client D(hpx::find_here(), std::move(vec3));
hpx::future<checkpoint> f3 = save_checkpoint(D);

// Create a new client
data_client E;

// Restore server inside client instance
restore_checkpoint(f3.get(), E);
```

The second way a user can save a component is by passing a `shared_ptr` to the component to `save_checkpoint`. This component can be resurrected by creating a new instance of the component type and passing a `shared_ptr` to the new instance to `restore_checkpoint`. This technique is demonstrated below:
// test checkpoint a component using a shared_ptr
std::vector<int> vec{1, 2, 3, 4, 5};
data_client A(hpx::find_here(), std::move(vec));

// Checkpoint Server
hpx::id_type old_id = A.get_id();

hpx::future<std::shared_ptr<data_server>> f_a_ptr =
    hpx::get_ptr<data_server>(A.get_id());
std::shared_ptr<data_server> a_ptr = f_a_ptr.get();
hpx::future<checkpoint> f = save_checkpoint(a_ptr);
auto&& data = f.get();

// test prepare_checkpoint API
checkpoint c = prepare_checkpoint(hpx::launch::sync, a_ptr);
HPX_TEST(c.size() == data.size());

// Restore Server
// Create a new server instance
std::shared_ptr<data_server> b_server;
restore_checkpoint(data, b_server);

**checkpoint_base**

The checkpoint_base module contains lower level facilities that wrap simple check-pointing capabilities. This module does not implement special handling for futures or components, but simply serializes all arguments to or from a given container.

This module exposes the hpx::util::save_checkpoint_data, hpx::util::restore_checkpoint_data, and hpx::util::prepare_checkpoint_data APIs. These functions encapsulate the basic serialization functionalities necessary to save/restore a variadic list of arguments to/from a given data container.

See the *API reference* of this module for more details.

**collectives**

The collectives module exposes a set of distributed collective operations. Those can be used to exchange data between participating sites in a coordinated way. At this point the module exposes the following collective primitives:

- *hpx::collectives::all_reduce*: performs a reduction on data from each participating site to each participating site.
- *hpx::collectives::all_to_all*: each participating site provides its element of the data to collect while all participating sites receive the data from every other site.
- *hpx::lcos::barrier*: distributed barrier.
- *hpx::lcos::broadcast*: performs a given action on all given global identifiers.
- *hpx::lcos::fold*: performs a fold with a given action on all given global identifiers.
- *hpx::lcos::gather*: gathers values from all participating sites.
- *hpx::lcos::latch*: distributed latch.
- *hpx::lcos::reduce*: performs a reduction on data from each participating site to a root site.
- *hpx::lcos::spmd_block*: performs the same operation on a local image while providing handles to the other images.
See the API reference of the module for more details.

**command_line_handling**

The command_line_handling module defines and handles the command-line options required by the HPX runtime, combining them with configuration options defined by the runtime_configuration module. The actual parsing of command line options is handled by the program_options module.

See the API reference of the module for more details.

**command_line_handling_local**

TODO: High-level description of the module.

See the API reference of this module for more details.

**components**

TODO: High-level description of the module.

See the API reference of this module for more details.

**components_base**

TODO: High-level description of the library.

See the API reference of this module for more details.

**compute**

The compute module provides utilities for handling task and memory affinity on host systems. The compute_cuda for extensions to CUDA programmable GPU devices.

See the API reference of the module for more details.

**compute_cuda**

This module extends the compute module to handle CUDA programmable GPU devices.

See the API reference of the module for more details.

**distribution_policies**

TODO: High-level description of the module.

See the API reference of this module for more details.
executors_distributed

This module provides the executor `hpx::parallel::execution::distribution_policy_executor`. It allows one to create work that is implicitly distributed over multiple localities.

See the API reference of this module for more details.

include

This module provides no functionality in itself. Instead it provides headers that group together other headers that often appear together.

See the API reference of this module for more details.

include_local

This module provides no functionality in itself. Instead it provides headers that group together other headers that often appear together. This module provides local-only headers.

See the API reference of this module for more details.

init_runtime

TODO: High-level description of the library.

See the API reference of this module for more details.

init_runtime_local

TODO: High-level description of the module.

See the API reference of this module for more details.

lcos_distributed

This module contains distributed LCOs. Currently the only LCO provided is `cpp:lib::hpx::lcos::channel`, a construct for sending values from one locality to another. See `libs_lcos_local` for local LCOs.

See the API reference of this module for more details.

mpi_base

This module provides helper functionality for detecting MPI environments.

See the API reference of this module for more details.
naming

TODO: High-level description of the module.
See the API reference of this module for more details.

naming_base

This module provides a forward declaration of address_type, component_type and invalid_locality_id.
See the API reference of this module for more details.

performance_counters

This module provides the basic functionality required for defining performance counters. See Performance counters for more information about performance counters.
See the API reference of this module for more details.

program_options

The module program_options is a direct fork of the Boost.ProgramOptions library (Boost V1.70.0). For more information about this library please see here\textsuperscript{217}. In order to be included as an HPX module, the Boost.ProgramOptions library has been moved to the namespace hpx::program_options. We have also replaced all Boost facilities the library depends on with either the equivalent facilities from the standard library or from HPX. As a result, the HPX program_options module is fully interface compatible with Boost.ProgramOptions (sans the hpx namespace and the \#include <hpx/modules/program_options.hpp> changes that need to be applied to all code relying on this library).

All credit goes to Vladimir Prus, the author of the excellent Boost.ProgramOptions library. All bugs have been introduced by us.
See the API reference of the module for more details.

resiliency_distributed

Software resiliency features of HPX were introduced in the resiliency module. This module extends the APIs to run on distributed-memory systems allowing the user to invoke the failing task on other localities at runtime. This is useful in cases where a node is identified to fail more often (e.g., for certain ALU computes) as the task can now be replayed or replicated among different localities. The API exposed allows for an easy integration with the local only resiliency APIs as well.

Distributed software resilience APIs have a similar function signature and lives under the same namespace of hpx::resiliency::experimental. The difference arises in the formal parameters where distributed APIs takes the localities as the first argument, and an action as opposed to a function or a function object. The localities signify the order in which the API will either schedule (in case of Task Replay) tasks in a round robin fashion or replicate the tasks onto the list of localities.

The list of APIs exposed by distributed resiliency modules is the same as those defined in local resiliency module.
See the API reference of this module for more details.

\textsuperscript{217} https://www.boost.org/doc/libs/1_70_0/doc/html/program_options.html
**resource_partitioner**

The resource_partitioner module defines `hpx::resource::partitioner`, the class used by the runtime and users to partition available hardware resources into thread pools. See *Using the resource partitioner* for more details on using the resource partitioner in applications.

See the *API reference* of this module for more details.

**runtime_components**

TODO: High-level description of the module.

See the *API reference* of this module for more details.

**runtime_configuration**

This module handles the configuration options required by the runtime.

See the *API reference* of this module for more details.

**runtime_distributed**

TODO: High-level description of the module.

See the *API reference* of this module for more details.

**runtime_local**

TODO: High-level description of the library.

See the *API reference* of this module for more details.

**segmented_algorithms**

Segmented algorithms extend the usual parallel *algorithms* by providing overloads that work with distributed containers, such as partitioned vectors.

See the *API reference* of the module for more details.

**thread_manager**

This module defines the `hpx::threads::threadmanager` class. This is used by the runtime to manage the creation and destruction of thread pools. The *resource_partitioner* module handles the partitioning of resources into thread pools, but not the creation of thread pools.

See the API reference of this module for more details.
2.8 API reference

HPX follows a versioning scheme with three numbers: major.minor.patch. We guarantee no breaking changes in the API for patch releases. Minor releases may remove or break existing APIs, but only after a deprecation period of at least two minor releases. In rare cases do we outright remove old and unused functionality without a deprecation period.

We do not provide any ABI compatibility guarantees between any versions, debug and release builds, and builds with different C++ standards.

The public API of HPX is presented below. Clicking on a name brings you to the full documentation for the class or function. Including the header specified in a heading brings in the features listed under that heading.

Note: Names listed here are guaranteed stable with respect to semantic versioning. However, at the moment the list is incomplete and certain unlisted features are intended to be in the public API. While we work on completing the list, if you’re unsure about whether a particular unlisted name is part of the public API you can get into contact with us or open an issue and we’ll clarify the situation.

2.8.1 Public API

All names below are also available in the top-level hpx namespace unless otherwise noted. The names in hpx should be preferred. The names in sub-namespaces will eventually be removed.

**Header hpx/algorithm.hpp**

This header includes Header hpx/local/algorithm.hpp and contains overloads of the algorithms for segmented iterators.

**Header hpx/local/algorithm.hpp**

Corresponds to the C++ standard library header algorithm. See Using parallel algorithms for more information about the parallel algorithms.

**Classes**

- hpx::parallel::v2::reduction
- hpx::parallel::v2::induction

**Functions**

- hpx::adjacent_find
- hpx::all_of
- hpx::any_of
- hpx::copy
- hpx::copy_if

---

• hpx::copy_n
• hpx::count
• hpx::count_if

• `hpx::ranges::for_loop_strided`

**Header** `hpx_any.hpp`

This header includes *Header hpx/local/any.hpp*.  

Header `hpx/local/any.hpp`

Corresponds to the C++ standard library header `any`\(^{219}\). `hpx::any` is compatible with `std::any`.

**Classes**

- `hpx::any`
- `hpx::any_nonser`
- `hpx::bad_any_cast`
- `hpx::unique_any_nonser`

**Functions**

- `hpx::any_cast`
- `hpx::make_any`
- `hpx::make_any_nonser`
- `hpx::make_unique_any_nonser`

Header `hpx/assert.hpp`

Corresponds to the C++ standard library header `cassert`\(^{220}\). `HPX_ASSERT` is the HPX equivalent to `assert` in `cassert`. `HPX_ASSERT` can also be used in CUDA device code.

**Macros**

- `HPX_ASSERT`
- `HPX_ASSERT_MSG`

Header `hpx/barrier.hpp`

This header includes `Header hpx/local/barrier.hpp` and contains a distributed barrier implementation. This functionality is also exposed through the `hpx::distributed` namespace. The name in `hpx::distributed` should be preferred.

---

Classes

• `hpx::lcos::barrier`

Header `hpx/local/barrier.hpp`

Corresponds to the C++ standard library header `barrier`\(^{221}\).

Classes

• `hpx::lcos::local::cpp20_barrier`

Header `hpx/channel.hpp`

This header includes `Header hpx/local/channel.hpp` and contains a distributed channel implementation. This functionality is also exposed through the `hpx::distributed` namespace. The name in `hpx::distributed` should be preferred.

Classes

• `hpx::lcos::channel`

Header `hpx/local/channel.hpp`

Contains a local channel implementation.

Classes

• `hpx::lcos::local::channel`

Header `hpx/chrono.hpp`

This header includes `Header hpx/local/chrono.hpp`.

Header `hpx/local/chrono.hpp`

Corresponds to the C++ standard library header `chrono`\(^{222}\). The following replacements and extensions are provided compared to `chrono`\(^{223}\). The classes below are also available in the `hpx::chrono` namespace, not in the top-level `hpx` namespace.

Classes

- `hpx::chrono::high_resolution_clock`
- `hpx::chrono::high_resolution_timer`
- `hpx::chrono::steady_time_point`

**Header hpx/condition_variable.hpp**

This header includes `Header hpx/local/condition_variable.hpp`.

**Header hpx/local/condition_variable.hpp**

Corresponds to the C++ standard library header `condition_variable`[^224].

Classes

- `hpx::lcos::local::condition_variable`
- `hpx::lcos::local::condition_variable_any`
- `hpx::lcos::local::cv_status`

**Header hpx/exception.hpp**

This header includes `Header hpx/local/exception.hpp`.

**Header hpx/local/exception.hpp**

Corresponds to the C++ standard library header `exception`[^225]. `hpx::exception` extends `std::exception` and is the base class for all exceptions thrown in HPX. `HPX_THROW_EXCEPTION` can be used to throw HPX exceptions with file and line information attached to the exception.

**Macros**

- `HPX_THROW_EXCEPTION`

**Classes**

- `hpx::exception`

**Header hpx/execution.hpp**

This header includes *Header hpx/local/execution.hpp*.

**Header hpx/local/execution.hpp**

Corresponds to the C++ standard library header `execution`\(^{226}\). See *High level parallel facilities*, *Using parallel algorithms* and *Executor parameters and executor parameter traits* for more information about execution policies and executor parameters.

**Note:** These names are only available in the `hpx::execution` namespace, not in the top-level `hpx` namespace.

**Constants**

- `hpx::execution::seq`
- `hpx::execution::par`
- `hpx::execution::par_unseq`
- `hpx::execution::task`

**Classes**

- `hpx::execution::sequenced_policy`
- `hpx::execution::parallel_policy`
- `hpx::execution::parallel_unsequenced_policy`
- `hpx::execution::sequenced_task_policy`
- `hpx::execution::parallel_task_policy`
- `hpx::execution::auto_chunk_size`
- `hpx::execution::dynamic_chunk_size`
- `hpx::execution::guided_chunk_size`
- `hpx::execution::persistent_auto_chunk_size`
- `hpx::execution::static_chunk_size`

Header `hpx/functional.hpp`

This header includes `Header hpx/local/functional.hpp`.

Header `hpx/local/functional.hpp`

Corresponds to the C++ standard library header `functional`\(^{227}\). `hpx::util::function` is a more efficient and serializable replacement for `std::function`.

Constants

The following constants are also available in `hpx::placeholders`, not the top-level `hpx` namespace.

- `hpx::util::placeholders::_1`
- `hpx::util::placeholders::_2`
- ...
- `hpx::util::placeholders::_9`

Classes

- `hpx::util::function`
- `hpx::util::function_nonser`
- `hpx::util::function_ref`
- `hpx::util::unique_function`
- `hpx::util::unique_function_nonser`
- `hpx::traits::is_bind_expression`
- `hpx::traits::is_placeholder`

Functions

- `hpx::util::bind`
- `hpx::util::bind_back`
- `hpx::util::bind_front`
- `hpx::util::invoke`
- `hpx::util::invoke_fused`
- `hpx::util::mem_fn`

**Header hpx/future.hpp**

This header includes *Header hpx/local/future.hpp* and contains overloads of *hpx::async, hpx::apply, hpx::sync,* and *hpx::dataflow* that can be used with actions. See *Action invocation* for more information about invoking actions.

**Note:** The alias from *hpx::promise* to *hpx::lcos::promise* is deprecated and will be removed in a future release. The alias *hpx::distributed::promise* should be used in new applications.

**Classes**

- *hpx::lcos::promise*

**Functions**

- *hpx::async*
- *hpx::apply*
- *hpx::sync*
- *hpx::dataflow*

**Header hpx/local/future.hpp**

Corresponds to the C++ standard library header *future*. See *Extended facilities for futures* for more information about extensions to futures compared to the C++ standard library.

**Note:** All names except *hpx::lcos::local::promise* are also available in the top-level *hpx* namespace. *hpx::promise* refers to *hpx::lcos::promise*, a distributed variant of *hpx::lcos::local::promise*, but will eventually refer to *hpx::lcos::local::promise* after a deprecation period.

**Classes**

- *hpx::lcos::future*
- *hpx::lcos::shared_future*
- *hpx::lcos::local::promise*
- *hpx::launch*  

Functions

- `hpx::lcos::make_future`
- `hpx::lcos::make_shared_future`
- `hpx::lcos::make_ready_future`
- `hpx::async`
- `hpx::apply`
- `hpx::sync`
- `hpx::dataflow`
- `hpx::when_all`
- `hpx::when_any`
- `hpx::when_some`
- `hpx::when_each`
- `hpx::wait_all`
- `hpx::wait_any`
- `hpx::wait_some`
- `hpx::wait_each`

Examples

```cpp
#include <hpx/assert.hpp>
#include <hpx/future.hpp>
#include <hpx/hpx_main.hpp>
#include <hpx/tuple.hpp>
#include <iostream>
#include <utility>

int main()
{
  // Asynchronous execution with futures
  hpx::future<void> f1 = hpx::async(hpx::launch::async, [] {});
  hpx::shared_future<int> f2 =
    hpx::async(hpx::launch::async, [] {} ( return 42; ));
  hpx::future<int> f3 =
    f2.then([[]](hpx::shared_future<int>&& f) { return f.get() * 3; });

  hpx::lcos::local::promise<double> p;

    return 0;
}
**Header hpx/init.hpp**

This header contains functionality for starting, stopping, suspending, and resuming the HPX runtime. This is the main way to explicitly start the HPX runtime. See *Starting the HPX runtime* for more details on starting the HPX runtime.

**Classes**

- `hpx::init_params`
- `hpx::runtime_mode`

**Functions**

- `hpx::init`
- `hpx::start`
- `hpx::finalize`
- `hpx::disconnect`
- `hpx::suspend`
- `hpx::resume`

**Header hpx/latch.hpp**

This header includes `Header hpx/local/latch.hpp` and contains a distributed latch implementation. This functionality is also exposed through the `hpx::distributed` namespace. The name in `hpx::distributed` should be preferred.

**Classes**

- `hpx::lcos::latch`

**Header hpx/local/latch.hpp**

Corresponds to the C++ standard library header `latch`\(^{229}\).

**Classes**

- `hpx::lcos::local::cpp20_latch`

Header `hpx/mutex.hpp`

This header includes `Header hpx/local/mutex.hpp`.

Header `hpx/local/mutex.hpp`

Corresponds to the C++ standard library header `mutex`\(^{230}\).

Classes

- `hpx::lcos::local::mutex`
- `hpx::lcos::local::no_mutex`
- `hpx::lcos::local::once_flag`
- `hpx::lcos::local::recursive_mutex`
- `hpx::lcos::local::spinlock`
- `hpx::lcos::local::timed_mutex`
- `hpx::lcos::local::unlock_guard`

Functions

- `hpx::lcos::local::call_once`

Header `hpx/memory.hpp`

This header includes `Header hpx/local/memory.hpp`.

Header `hpx/local/memory.hpp`

Corresponds to the C++ standard library header `memory`\(^{231}\). It contains parallel versions of the copy, fill, move, and construct helper functions in `memory`\(^{232}\). See *Using parallel algorithms* for more information about the parallel algorithms.

Functions

- `hpx::parallel::v1::uninitialized_copy`
- `hpx::parallel::v1::uninitialized_copy_n`
- `hpx::parallel::v1::uninitialized_default_construct`
- `hpx::parallel::v1::uninitialized_default_construct_n`
- `hpx::parallel::v1::uninitialized_fill`
- `hpx::parallel::v1::uninitialized_fill_n`

• `hpx::parallel::v1::uninitialized_move`
• `hpx::parallel::v1::uninitialized_move_n`
• `hpx::parallel::v1::uninitialized_value_construct`
• `hpx::parallel::v1::uninitialized_value_construct_n`

**Header `hpx/numeric.hpp`**

This header includes `Header hpx/local/numeric.hpp`.

**Header `hpx/local/numeric.hpp`**

Corresponds to the C++ standard library header `numeric`. See *Using parallel algorithms* for more information about the parallel algorithms.

**Functions**

• `hpx::parallel::v1::adjacent_difference`
• `hpx::parallel::v1::exclusive_scan`
• `hpx::parallel::v1::inclusive_scan`
• `hpx::reduce`
• `hpx::parallel::v1::transform-exclusive_scan`
• `hpx::parallel::v1::transform-inclusive_scan`
• `hpx::transform_reduce`

**Header `hpx/optional.hpp`**

This header includes `Header hpx/local/optional.hpp`.

**Header `hpx/local/optional.hpp`**

Corresponds to the C++ standard library header `optional`. `hpx::util::optional` is compatible with `std::optional`.

**Constants**

• `hpx::util::nullopt`

---

Classes

- `hpx::util::optional`
- `hpx::util::nullopt_t`
- `hpx::util::bad_optional_access`

Functions

- `hpx::util::make_optional`

Header `hpx/runtime.hpp`

This header includes `hpx/local/runtime.hpp` and contains functions for accessing distributed runtime information.

Functions

- `hpx::find_root_locality`
- `hpx::find_all_localities`
- `hpx::find_remote_localities`
- `hpx::find_locality`
- `hpx::get_colocation_id`
- `hpx::get_locality_id`

Header `hpx/local/runtime.hpp`

This header contains functions for accessing local runtime information.

Typedefs

- `hpx::startup_function_type`
- `hpx::shutdown_function_type`

Functions

- `hpx::get_num_worker_threads`
- `hpx::get_worker_thread_num`
- `hpx::get_thread_name`
- `hpx::register_pre_startup_function`
- `hpx::register_startup_function`
- `hpx::register_pre_shutdown_function`
• `hpx::register_shutdown_function`
• `hpx::get_num_localities`
• `hpx::get_locality_name`

**Header hpx/system_error.hpp**

This header includes `Header hpx/local/system_error.hpp`.

**Header hpx/local/system_error.hpp**

Corresponds to the C++ standard library header `system_error`\(^{235}\).

**Classes**

• `hpx::error_code`

**Header hpx/task_block.hpp**

This header includes `Header hpx/local/task_block.hpp`.

**Header hpx/local/task_block.hpp**

Corresponds to the `task_block` feature in N4411\(^{236}\). See *Using task blocks* for more details on using task blocks.

**Classes**

• `hpx::parallel::v2::task_canceled_exception`
• `hpx::parallel::v2::task_block`

**Functions**

• `hpx::parallel::v2::define_task_block`
• `hpx::parallel::v2::define_task_block_restore_thread`

---

**Header hpx/thread.hpp**

This header includes *Header hpx/local/thread.hpp*.

**Header hpx/local/thread.hpp**

Corresponds to the C++ standard library header `thread`\(^{237}\). The functionality in this header is equivalent to the standard library thread functionality, with the exception that the *HPX* equivalents are implemented on top of lightweight threads and the *HPX* runtime.

**Classes**

- `hpx::thread`
- `hpx::jthread`

**Functions**

- `hpx::this_thread::yield`
- `hpx::this_thread::get_id`
- `hpx::this_thread::sleep_for`
- `hpx::this_thread::sleep_until`

**Header hpx/semaphore.hpp**

This header includes *Header hpx/local/semaphore.hpp*.

**Header hpx/local/semaphore.hpp**

Corresponds to the C++ standard library header `semaphore`\(^{238}\).

**Classes**

- `hpx::lcos::local::cpp20_binary_semaphore`
- `hpx::lcos::local::cpp20_counting_semaphore`

\(^{237}\) [http://en.cppreference.com/w/cpp/header/thread]

\(^{238}\) [http://en.cppreference.com/w/cpp/header/semaphore]
Header `hpx/shared_mutex.hpp`

This header includes `hpx/local/shared_mutex.hpp`.

Header `hpx/local/shared_mutex.hpp`

Corresponds to the C++ standard library header `shared_mutex`\(^{239}\).

Classes

- `hpx::lcos::local::shared_mutex`

Header `hpx/stop_token.hpp`

This header includes `hpx/local/stop_token.hpp`.

Header `hpx/local/stop_token.hpp`

Corresponds to the C++ standard library header `stop_token`\(^{240}\).

Constants

- `hpx::nostopstate`

Classes

- `hpx::stop_callback`
- `hpx::stop_source`
- `hpx::stop_token`
- `hpx::nostopstate_t`

Header `hpx/tuple.hpp`

This header includes `hpx/local/tuple.hpp`.

Header `hpx/local/tuple.hpp`

Corresponds to the C++ standard library header `tuple`\(^{241}\). `hpx::tuple` can be used in CUDA device code, unlike `std::tuple`.

**Constants**

- `hpx::ignore`

**Classes**

- `hpx::tuple`
- `hpx::tuple_size`
- `hpx::tuple_element`

**Functions**

- `hpx::make_tuple`
- `hpx::tie`
- `hpx::forward_as_tuple`
- `hpx::tuple_cat`
- `hpx::get`

Header `hpx/type_traits.hpp`

This header includes `Header hpx/local/type_traits.hpp`.

Header `hpx/local/type_traits.hpp`

Corresponds to the C++ standard library header `type_traits`\(^{242}\).

**Classes**

- `hpx::is_invocable`
- `hpx::is_invocable_r`

Header `hpx/unwrap.hpp`

This header includes `Header hpx/local/unwrap.hpp`.

Header `hpx/local/unwrap.hpp`

Contains utilities for unwrapping futures.

Classes

- `hpx::functional::unwrap`
- `hpx::functional::unwrap_n`
- `hpx::functional::unwrap_all`

Functions

- `hpx::unwrap`
- `hpx::unwrap_n`
- `hpx::unwrap_all`
- `hpx::unwrapping`
- `hpx::unwrapping_n`
- `hpx::unwrapping_all`

Header `hpx/version.hpp`

This header provides version information about `HPX`.

Macros

- `HPX_VERSION_MAJOR`
- `HPX_VERSION_MINOR`
- `HPX_VERSION_SUBMINOR`
- `HPX_VERSION_FULL`
- `HPX_VERSION_DATE`
- `HPX_VERSION_TAG`
- `HPX_AGAS_VERSION`
Functions

- `hpx::major_version`
- `hpx::minor_version`
- `hpx::subminor_version`
- `hpx::full_version`
- `hpx::full_version_as_string`
- `hpx::tag`
- `hpx::agas_version`
- `hpx::build_type`
- `hpx::build_date_time`

Header `hpx/wrap_main.hpp`

This header does not provide any direct functionality but is used for implicitly using `main` as the runtime entry point. See `Re-use the main() function as the main HPX entry point` for more details on implicitly starting the `HPX` runtime.

2.8.2 Full API

The full API of `HPX` is presented below. The listings for the public API above refer to the full documentation below.

**Note:** Most names listed in the full API reference are implementation details or considered unstable. They are listed mostly for completeness. If there is a particular feature you think deserves being in the public API we may consider promoting it. In general we prioritize making sure features corresponding to C++ standard library features are stable and complete.

Main `HPX` library

This lists functionality in the main `HPX` library that has not been moved to modules yet.

```cpp
namespace hpx

namespace components

Functions

template<typename Component>
future<naming::id_type> migrate_from_storage (naming::id_type const &to_resurrect,
                                         naming::id_type const &target = naming::invalid_id)

Migrate the component with the given id from the specified target storage (resurrect the object)

The function `migrate_from_storage<Component>` will migrate the component referenced by `to_resurrect` from the storage facility specified where the object is currently stored on. It returns a future referring to the migrated component instance. The component instance is resurrected on the locality specified by `target_locality`.```
Return A future representing the global id of the migrated component instance. This should be the same as `to_resurrect`.

Parameters

- `to_resurrect`: [in] The global id of the component to migrate.
- `target`: [in] The optional locality to resurrect the object on. By default the object is resurrected on the locality it was located on last.

Template Parameters

- The only template argument specifies the component type of the component to migrate from the given storage facility.

```cpp
template<typename Component>
future<naming::id_type> migrate_to_storage(naming::id_type const &to_migrate, naming::id_type const &target_storage)
```

Migrate the component with the given id to the specified target storage.

The function `migrate_to_storage<Component>` will migrate the component referenced by `to_migrate` to the storage facility specified with `target_storage`. It returns a future referring to the migrated component instance.

Return A future representing the global id of the migrated component instance. This should be the same as `migrate_to`.

Parameters

- `to_migrate`: [in] The global id of the component to migrate.
- `target_storage`: [in] The id of the storage facility to migrate this object to.

Template Parameters

- The only template argument specifies the component type of the component to migrate to the given storage facility.

```cpp
template<typename Derived, typename Stub>
Derived migrate_to_storage(client_base<Derived, Stub> const &to_migrate,
hpx::components::component_storage const &target_storage)
```

Migrate the given component to the specified target storage.

The function `migrate_to_storage` will migrate the component referenced by `to_migrate` to the storage facility specified with `target_storage`. It returns a future referring to the migrated component instance.

Return A client side representation of representing of the migrated component instance. This should be the same as `migrate_to`.

Parameters

- `to_migrate`: [in] The client side representation of the component to migrate.
- `target_storage`: [in] The id of the storage facility to migrate this object to.
The contents of this module can be included with the header `hpx/modules/affinity.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/affinity.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

```cpp
namespace hpx
{
    namespace threads
    {

        // Functions

        void parse_affinity_options (std::string const &spec, std::vector<mask_type> &affinities, std::size_t used_cores, std::size_t max_cores, std::size_t num_threads, std::vector<std::size_t> &numpus, bool use_process_mask, error_code &ec = throws);

        void parse_affinity_options (std::string const &spec, std::vector<mask_type> &affinities, error_code &ec = throws);

    }
}
```
allocator_support

The contents of this module can be included with the header `hpx/modules/allocator_support.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/allocator_support.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

Functions

```c
void *__aligned_alloc (std::size_t alignment, std::size_t size)
void __aligned_free (void *p)
```

namespace hpx

```c
namespace util
```

Functions

```c
template<typename T>
constexpr bool operator== (aligned_allocator<T> const&, aligned_allocator<T> const&)
```

```c
template<typename T>

assertion

The contents of this module can be included with the header `hpx/modules/assertion.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/assertion.hpp`, not the particular header in which the functionality you would like to use is defined. See `Public API` for a list of names that are part of the public `HPX` API.

Defines

`HPX_ASSERT_CURRENT_FUNCTION`

namespace `hpx`

    namespace assertion

    Functions

    `std::ostream &operator<<(std::ostream &os, source_location const &loc)`

    `struct source_location`
    `#include <source_location.hpp>` This contains the location information where `HPX_ASSERT` has been called

    Public Members

    `const char *file_name`
    `unsigned line_number`
    `const char *function_name`

Defines

`HPX_ASSERT(expr)`

This macro asserts that `expr` evaluates to true.

If `expr` evaluates to false, The source location and `msg` is being printed along with the expression and additional. Afterwards the program is being aborted. The assertion handler can be customized by calling `hpx::assertion::set_assertion_handler()`.

Parameters

- `expr`: The expression to assert on. This can either be an expression that’s convertible to bool or a callable which returns bool
- `msg`: The optional message that is used to give further information if the assert fails. This should be convertible to a std::string

Asserts are enabled if `HPX_DEBUG` is set. This is the default for `CMAKE_BUILD_TYPE=Debug`

`HPX_ASSERT_MSG(expr, msg)`

See `HPX_ASSERT`
namespace hpx

namespace assertion

Typedefs

using assertion_handler = void (*)(source_location const &loc, const char *expr, std::string const &msg)

The signature for an assertion handler.

Functions

void set Assertion_handler (assertion_handler handler)

Set the assertion handler to be used within a program. If the handler has been set already once, the
 call to this function will be ignored.

Note: This function is not thread safe.

cache

The contents of this module can be included with the header hpx/modules/cache.hpp. These headers may be
used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own
risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header
hpx/modules/cache.hpp, not the particular header in which the functionality you would like to use is defined. See Public API
for a list of names that are part of the public HPX API.

namespace hpx

namespace util

namespace cache

template<typename Key, typename Entry, typename UpdatePolicy = std::less<Entry>, typename InsertPolicy = policies::always, typename CacheStorage = std::map<Key, Entry>, typename Statistics = statistics::no_statistics>
class local_cache

#include <hpx/cache/local_cache.hpp> The local_cache implements the basic functionality
 needed for a local (non-distributed) cache.

Template Parameters

- Key: The type of the keys to use to identify the entries stored in the cache
- Entry: The type of the items to be held in the cache, must model the CacheEntry concept
- UpdatePolicy: A (optional) type specifying a (binary) function object used to sort the
  cache entries based on their ‘age’. The ‘oldest’ entries (according to this sorting criteria)
  will be discarded first if the maximum capacity of the cache is reached. The default is
  std::less<Entry>. The function object will be invoked using 2 entry instances of the type
  Entry. This type must model the UpdatePolicy model.
- InsertPolicy: A (optional) type specifying a (unary) function object used to allow
  global decisions whether a particular entry should be added to the cache or not. The default
  is policies::always, imposing no global insert related criteria on the cache. The function ob-
  ject will be invoked using the entry instance to be inserted into the cache. This type must
  model the InsertPolicy model.
• CacheStorage: A (optional) container type used to store the cache items. The container must be an associative and STL compatible container. The default is a std::map<Key, Entry>.
• Statistics: A (optional) type allowing to collect some basic statistics about the operation of the cache instance. The type must conform to the CacheStatistics concept. The default value is the type statistics::no_statistics which does not collect any numbers, but provides empty stubs allowing the code to compile.

Public Types

typedef Key key_type
typedef Entry entry_type
typedef UpdatePolicy update_policy_type
typedef InsertPolicy insert_policy_type
typedef CacheStorage storage_type
typedef Statistics statistics_type
typedef entry_type::value_type value_type
typedef storage_type::size_type size_type
typedef storage_type::value_type storage_value_type

Public Functions

local_cache(size_type max_size = 0, update_policy_type const &up = update_policy_type(), insert_policy_type const &ip = insert_policy_type())
Construct an instance of a local_cache.

Parameters
• max_size: [in] The maximal size this cache is allowed to reach any time. The default is zero (no size limitation). The unit of this value is usually determined by the unit of the values returned by the entry’s get_size function.
• up: [in] An instance of the UpdatePolicy to use for this cache. The default is to use a default constructed instance of the type as defined by the UpdatePolicy template parameter.
• ip: [in] An instance of the InsertPolicy to use for this cache. The default is to use a default constructed instance of the type as defined by the InsertPolicy template parameter.

local_cache(local_cache &&other)

size_type size() const
Return The current size of the cache.

size_type capacity() const
Access the maximum size the cache is allowed to grow to.

Note The unit of this value is usually determined by the unit of the return values of the entry’s function entry::get_size.
Return The maximum size this cache instance is currently allowed to reach. If this number is zero the cache has no limitation with regard to a maximum size.
bool reserve(size_type max_size)
Change the maximum size this cache can grow to.

Return This function returns true if successful. It returns false if the new max_size is smaller than the current limit and the cache could not be shrunk to the new maximum size.

Parameters
• max_size: [in] The new maximum size this cache will be allowed to grow to.

bool holds_key(key_type const &k) const
Check whether the cache currently holds an entry identified by the given key.

Note This function does not call the entry’s function entry::touch. It just checks if the cache contains an entry corresponding to the given key.

Return This function returns true if the cache holds the referenced entry, otherwise it returns false.

Parameters
• k: [in] The key for the entry which should be looked up in the cache.

bool get_entry(key_type const &k, key_type &realkey, entry_type &val)
Get a specific entry identified by the given key.

Note The function will call the entry’s entry::touch function if the value corresponding to the provided key is found in the cache.

Return This function returns true if the cache holds the referenced entry, otherwise it returns false.

Parameters
• k: [in] The key for the entry which should be retrieved from the cache.
• val: [out] If the entry indexed by the key is found in the cache this value on successful return will be a copy of the corresponding entry.

bool get_entry(key_type const &k, entry_type &val)
Get a specific entry identified by the given key.

Note The function will call the entry’s entry::touch function if the value corresponding to the provided key is found in the cache.

Return This function returns true if the cache holds the referenced entry, otherwise it returns false.

Parameters
• k: [in] The key for the entry which should be retrieved from the cache.
• val: [out] If the entry indexed by the key is found in the cache this value on successful return will be a copy of the corresponding entry.

bool get_entry(key_type const &k, value_type &val)
Get a specific entry identified by the given key.

Note The function will call the entry’s entry::touch function if the value corresponding to the provided is found in the cache.

Return This function returns true if the cache holds the referenced entry, otherwise it returns false.

Parameters
• k: [in] The key for the entry which should be retrieved from the cache.
• val: [out] If the entry indexed by the key is found in the cache this value on successful return will be a copy of the corresponding value.
bool insert (key_type const &k, value_type const &val)
Insert a new element into this cache.

**Note** This function invokes both, the insert policy as provided to the constructor and the function entry::insert of the newly constructed entry instance. If either of these functions returns false the key/value pair doesn’t get inserted into the cache and the insert function will return false. Other reasons for this function to fail (return false) are a) the key/value pair is already held in the cache or b) inserting the new value into the cache maxed out its capacity and it was not possible to free any of the existing entries.

**Return** This function returns true if the entry has been successfully added to the cache, otherwise it returns false.

**Parameters**
- k: [in] The key for the entry which should be added to the cache.
- value: [in] The value which should be added to the cache.

bool insert (key_type const &k, entry_type &e)
Insert a new entry into this cache.

**Note** This function invokes both, the insert policy as provided to the constructor and the function entry::insert of the provided entry instance. If either of these functions returns false the key/value pair doesn’t get inserted into the cache and the insert function will return false. Other reasons for this function to fail (return false) are a) the key/value pair is already held in the cache or b) inserting the new value into the cache maxed out its capacity and it was not possible to free any of the existing entries.

**Return** This function returns true if the entry has been successfully added to the cache, otherwise it returns false.

**Parameters**
- k: [in] The key for the entry which should be added to the cache.
- value: [in] The entry which should be added to the cache.

bool update (key_type const &k, value_type const &val)
Update an existing element in this cache.

**Note** The function will call the entry’s entry::touch function if the indexed value is found in the cache.

**Note** The difference to the other overload of the insert function is that this overload replaces the cached value only, while the other overload replaces the whole cache entry, updating the cache entry properties.

**Return** This function returns true if the entry has been successfully updated, otherwise it returns false. If the entry currently is not held by the cache it is added and the return value reflects the outcome of the corresponding insert operation.

**Parameters**
- k: [in] The key for the value which should be updated in the cache.
- value: [in] The value which should be used as a replacement for the existing value in the cache. Any existing cache entry is not changed except for its value.

template<typename F>
bool update_if (key_type const &k, value_type const &val, F f)
Update an existing element in this cache.

**Note** The function will call the entry’s entry::touch function if the indexed value is found in the cache.
**Note** The difference to the other overload of the *insert* function is that this overload replaces the cached value only, while the other overload replaces the whole cache entry, updating the cache entry properties.

**Return** This function returns *true* if the entry has been successfully updated, otherwise it returns *false*. If the entry currently is not held by the cache it is added and the return value reflects the outcome of the corresponding insert operation.

**Parameters**
- `k`: [in] The key for the value which should be updated in the cache.
- `value`: [in] The value which should be used as a replacement for the existing value in the cache. Any existing cache entry is not changed except for its value.
- `f`: [in] A callable taking two arguments, `k` and the key found in the cache (in that order). If `f` returns true, then the update will continue. If `f` returns false, then the update will not succeed.

```plaintext
bool update (key_type const &k, entry_type &e)
Update an existing entry in this cache.
```

**Note** The function will call the entry’s `entry::touch` function if the indexed value is found in the cache.

**Note** The difference to the other overload of the *insert* function is that this overload replaces the whole cache entry, while the other overload replaces the cached value only, leaving the cache entry properties untouched.

**Return** This function returns *true* if the entry has been successfully updated, otherwise it returns *false*. If the entry currently is not held by the cache it is added and the return value reflects the outcome of the corresponding insert operation.

**Parameters**
- `k`: [in] The key for the entry which should be updated in the cache.
- `value`: [in] The entry which should be used as a replacement for the existing entry in the cache. Any existing entry is first removed and then this entry is added.

```plaintext
template<typename Func>
size_type erase (Func const &ep = policies::always<storage_value_type>())
Remove stored entries from the cache for which the supplied function object returns true.
```

**Return** This function returns the overall size of the removed entries (which is the sum of the values returned by the `entry::get_size` functions of the removed entries).

**Parameters**
- `ep`: [in] This parameter has to be a (unary) function object. It is invoked for each of the entries currently held in the cache. An entry is considered for removal from the cache whenever the value returned from this invocation is *true*. Even then the entry might not be removed from the cache as its `entry::remove` function might return false.

```plaintext
size_type erase ()
Remove all stored entries from the cache.
```

**Note** All entries are considered for removal, but in the end an entry might not be removed from the cache as its `entry::remove` function might return false. This function is very useful for instance in conjunction with an entry’s `entry::remove` function enforcing additional criteria like entry expiration, etc.

**Return** This function returns the overall size of the removed entries (which is the sum of the values returned by the `entry::get_size` functions of the removed entries).

```plaintext
void clear ()
Clear the cache.
```
Unconditionally removes all stored entries from the cache.

```
statistics_type const &get_statistics() const
```

Allow to access the embedded statistics instance.

**Return** This function returns a reference to the statistics instance embedded inside this cache

```
statistics_type &get_statistics()
```

**Protected Functions**

```
bool free_space (long num_free)

```

```cpp
namespace hpx

namespace util

namespace cache

template<typename Key, typename Entry, typename Statistics = statistics::no_statistics>
class lru_cache
```

```cpp
#include <hpx/cache/lru_cache.hpp>
The lru_cache implements the basic functionality needed for a local (non-distributed) LRU cache.
```

Template Parameters

- **Key**: The type of the keys to use to identify the entries stored in the cache
- **Entry**: The type of the items to be held in the cache.
- **Statistics**: A (optional) type allowing to collect some basic statistics about the operation of the cache instance. The type must conform to the CacheStatistics concept. The default value is the type statistics::no_statistics which does not collect any numbers, but provides empty stubs allowing the code to compile.

Public Types

```cpp
typedef Key key_type

typedef Entry entry_type

typedef Statistics statistics_type

typedef std::pair<key_type, entry_type> entry_pair

typedef std::list<entry_pair> storage_type

typedef std::map<Key, typename storage_type::iterator> map_type

typedef std::size_t size_type
```

Public Functions

```cpp
lru_cache(size_type max_size = 0)

Construct an instance of a lru_cache.
```

Parameters

- **max_size**: [in] The maximal size this cache is allowed to reach any time. The default is zero (no size limitation). The unit of this value is usually determined by the unit of the values returned by the entry’s `get_size` function.

```cpp
lru_cache(lru_cache &&other)
```
size_type **size**() const
Return current size of the cache.

**Return** The current size of this cache instance.

size_type **capacity**() const
Access the maximum size the cache is allowed to grow to.

**Note** The unit of this value is usually determined by the unit of the return values of the entry’s function entry::get_size.
**Return** The maximum size this cache instance is currently allowed to reach. If this number is zero the cache has no limitation with regard to a maximum size.

void **reserve**(size_type max_size)
Change the maximum size this cache can grow to.

**Parameters**
- max_size: [in] The new maximum size this cache will be allowed to grow to.

bool **holds_key**(key_type const &key)
Check whether the cache currently holds an entry identified by the given key.

**Note** This function does not call the entry’s function entry::touch. It just checks if the cache contains an entry corresponding to the given key.
**Return** This function returns true if the cache holds the referenced entry, otherwise it returns false.

**Parameters**
- k: [in] The key for the entry which should be looked up in the cache.

bool **get_entry**(key_type const &key, key_type &realkey, entry_type &entry)
Get a specific entry identified by the given key.

**Note** The function will “touch” the entry and mark it as recently used if the key was found in the cache.
**Return** This function returns true if the cache holds the referenced entry, otherwise it returns false.

**Parameters**
- key: [in] The key for the entry which should be retrieved from the cache.
- entry: [out] If the entry indexed by the key is found in the cache this value on successful return will be a copy of the corresponding entry.

bool **get_entry**(key_type const &key, entry_type &entry)
Get a specific entry identified by the given key.

**Note** The function will “touch” the entry and mark it as recently used if the key was found in the cache.
**Return** This function returns true if the cache holds the referenced entry, otherwise it returns false.

**Parameters**
- key: [in] The key for the entry which should be retrieved from the cache.
- entry: [out] If the entry indexed by the key is found in the cache this value on successful return will be a copy of the corresponding entry.
bool insert (key_type const &key, entry_type const &entry)
Insert a new entry into this cache.

**Note** This function assumes that the entry is not in the cache already. Inserting an already existing entry is considered undefined behavior

**Parameters**
- **key**: [in] The key for the entry which should be added to the cache.
- **entry**: [in] The entry which should be added to the cache.

void insert_nonexist (key_type const &key, entry_type const &entry)
void update (key_type const &key, entry_type const &entry)
Update an existing element in this cache.

**Note** The function will “touch” the entry and mark it as recently used if the key was found in the cache.

**Note** The difference to the other overload of the insert function is that this overload replaces the cached value only, while the other overload replaces the whole cache entry, updating the cache entry properties.

**Parameters**
- **key**: [in] The key for the value which should be updated in the cache.
- **entry**: [in] The entry which should be used as a replacement for the existing value in the cache. Any existing cache entry is not changed except for its value.

template<typename Func>

bool update_if (key_type const &key, entry_type const &entry, Func &&f)
Update an existing element in this cache.

**Note** The function will “touch” the entry and mark it as recently used if the key was found in the cache.

**Note** The difference to the other overload of the insert function is that this overload replaces the cached value only, while the other overload replaces the whole cache entry, updating the cache entry properties.

**Return** This function returns true if the entry has been successfully updated, otherwise it returns false. If the entry currently is not held by the cache it is added and the return value reflects the outcome of the corresponding insert operation.

**Parameters**
- **key**: [in] The key for the value which should be updated in the cache.
- **entry**: [in] The value which should be used as a replacement for the existing value in the cache. Any existing cache entry is not changed except for its value.
- **f**: [in] A callable taking two arguments, k and the key found in the cache (in that order). If f returns true, then the update will continue. If f returns false, then the update will not succeed.

template<typename Func>

size_type erase (Func const &ep)
Remove stored entries from the cache for which the supplied function object returns true.

**Return** This function returns the overall size of the removed entries (which is the sum of the values returned by the entry::get_size functions of the removed entries).

**Parameters**
- **ep**: [in] This parameter has to be a (unary) function object. It is invoked for each of the entries currently held in the cache. An entry is considered for removal from the cache.

2.8. API reference
whenever the value returned from this invocation is `true`.

```cpp
size_type erase()
Remove all stored entries from the cache.
```

**Return** This function returns the overall size of the removed entries (which is the sum of the values returned by the `entry::get_size` functions of the removed entries).

```cpp
size_type clear()
Clear the cache.
Unconditionally removes all stored entries from the cache.
```

```cpp
statistics_type const &get_statistics() const
Allow to access the embedded statistics instance.
```

**Return** This function returns a reference to the statistics instance embedded inside this cache.

```cpp
statistics_type &get_statistics()
```

304 Chapter 2. What’s so special about HPX?
Template Parameters

- **Value**: The data type to be stored in a cache. It has to be default constructible, copy constructible and less_than_comparable.
- **Derived**: The (optional) type for which this type is used as a base class.

Public Types

typedef Value value_type

Public Functions

**entry()**
Any cache entry has to be default constructible.

**entry(value_type const &val)**
Construct a new instance of a cache entry holding the given value.

**bool touch()**
The function touch is called by a cache holding this instance whenever it has been requested (touched).

**bool insert()**
The function insert is called by a cache whenever it is about to be inserted into the cache.

**bool remove()**
The function remove is called by a cache holding this instance whenever it is about to be removed from the cache.

**std::size_t get_size() const**
Return the 'size' of this entry. By default the size of each entry is just one (1), which is sensible if the cache has a limit (capacity) measured in number of entries.

**value_type &get()**
Get a reference to the stored data value.

Note This function is part of the CacheEntry concept
value_type const & get() const

Private Members

value_type value_

Friends

bool operator< (entry const & lhs, entry const & rhs)
   Forwarding operator< allowing to compare entries instead of the values.

namespace hpx

namespace util

namespace cache

namespace entries

template<typename Value>
class fifo_entry: public hpx::util::cache::entries::entry<Value, fifo_entry<Value>>
   #include <hpx/cache/entries/fifo_entry.hpp> The fifo_entry type can be used to store arbitrary values in a cache. Using this type as the cache’s entry type makes sure that the least recently inserted entries are discarded from the cache first.

Note The fifo_entry conforms to the CacheEntry concept.
Note This type can be used to model a ‘last in first out’ cache policy if it is used with a std::greater as the caches’ UpdatePolicy (instead of the default std::less).

Template Parameters
   • Value: The data type to be stored in a cache. It has to be default constructible, copy constructible and less_than_comparable.

Public Functions

fifo_entry()
   Any cache entry has to be default constructible.

fifo_entry(Value const & val)
   Construct a new instance of a cache entry holding the given value.

bool insert()
   The function insert is called by a cache whenever it is about to be inserted into the cache.

Note This function is part of the CacheEntry concept
Return This function should return true if the entry should be added to the cache, otherwise it should return false.

std::chrono::steady_clock::time_point const & get_creation_time() const
**Private Types**

```cpp
typedef entry<Value, fifo_entry<Value>> base_type
```

**Private Members**

```cpp
std::chrono::steady_clock::time_point insertion_time_
```

**Friends**

```cpp
bool operator< (fifo_entry const &lhs, fifo_entry const &rhs)
```

Compare the ‘age’ of two entries. An entry is ‘older’ than another entry if it has been created earlier (FIFO).

```cpp
namespace hpx
```

```cpp
namespace util
```

```cpp
namespace cache
```

```cpp
namespace entries
```

```cpp
template<typename Value>
class lfu_entry : public hpx::util::cache::entries::entry<Value, lfu_entry<Value>>
```

The `lfu_entry` type can be used to store arbitrary values in a cache. Using this type as the cache’s entry type makes sure that the least frequently used entries are discarded from the cache first.

**Note** The `lfu_entry` conforms to the CacheEntry concept.

**Note** This type can be used to model a ‘most frequently used’ cache policy if it is used with a `std::greater` as the caches’ UpdatePolicy (instead of the default `std::less`).

**Template Parameters**

- `Value`: The data type to be stored in a cache. It has to be default constructible, copy constructible and `less_than_comparable`.

**Public Functions**

```cpp
lfu_entry ()
```

Any cache entry has to be default constructible.

```cpp
lfu_entry (Value const &val)
```

Construct a new instance of a cache entry holding the given value.

```cpp
bool touch ()
```

The function `touch` is called by a cache holding this instance whenever it has been requested (touched).

In the case of the LFU entry we store the reference count tracking the number of times this entry has been requested. This which will be used to compare the age of an entry during the invocation of the `operator<()`.
Return This function should return true if the cache needs to update it’s internal heap. Usually this is needed if the entry has been changed by touch() in a way influencing the sort order as mandated by the cache’s UpdatePolicy.

unsigned long const & get_access_count () const

Private Types

typedef entry<Value, lfu_entry<Value>> base_type

Private Members

unsigned long ref_count_

Friends

bool operator< (lfu_entry const & lhs, lfu_entry const & rhs)
  Compare the ‘age’ of two entries. An entry is ‘older’ than another entry if it has been accessed less frequently (LFU).

namespace hpx

namespace util

namespace cache

namespace entries

template< typename Value >
class lru_entry : public hpx::util::cache::entries::entry<Value, lfu_entry<Value>>
  #include <hpx/cache/entries/lru_entry.hpp> The lru_entry type can be used to store arbitrary values in a cache. Using this type as the cache’s entry type makes sure that the least recently used entries are discarded from the cache first.

Note The lru_entry conforms to the CacheEntry concept.

Note This type can be used to model a ‘most recently used’ cache policy if it is used with a std::greater as the caches’ UpdatePolicy (instead of the default std::less).

Template Parameters
  • Value: The data type to be stored in a cache. It has to be default constructible, copy constructible and less_than_comparable.
Public Functions

**lru_entry()**

Any cache entry has to be default constructible.

**lru_entry(Value const &val)**

Construct a new instance of a cache entry holding the given value.

bool **touch()**

The function *touch* is called by a cache holding this instance whenever it has been requested (touched).

In the case of the LRU entry we store the time of the last access which will be used to compare the age of an entry during the invocation of the *operator<()*.

Return: This function should return true if the cache needs to update its internal heap. Usually this is needed if the entry has been changed by *touch()* in a way influencing the sort order as mandated by the cache’s UpdatePolicy.

```cpp
std::chrono::steady_clock::time_point const &get_access_time() const
```

Returns the last access time of the entry.

Private Types

**typedef entry<Value, lru_entry<Value>> base_type**

Private Members

```cpp
std::chrono::steady_clock::time_point access_time_
```

Friends

```cpp
bool operator<(lru_entry const &lhs, lru_entry const &rhs)
```

Compare the ‘age’ of two entries. An entry is ‘older’ than another entry if it has been accessed less recently (LRU).

```
namespace hpx
```

```
namespace util
```

```
namespace cache
```

```
namespace entries
```

```cpp
class size_entry
```

#include <hpx/cache/entries/size_entry.hpp> The size_entry type can be used to store values in a cache which have a size associated (such as files, etc.). Using this type as the cache’s entry type makes sure that the entries with the biggest size are discarded from the cache first.
Note The size_entry conforms to the CacheEntry concept.
Note This type can be used to model a ‘discard smallest first’ cache policy if it is used with a std::greater as the caches’ UpdatePolicy (instead of the default std::less).

Template Parameters
• Value: The data type to be stored in a cache. It has to be default constructible, copy constructible and less_than_comparable.
• Derived: The (optional) type for which this type is used as a base class.

Public Functions

size_entry()
Any cache entry has to be default constructible.

size_entry(Value const &val, std::size_t size)
Construct a new instance of a cache entry holding the given value.

std::size_t get_size() const
Return the 'size' of this entry.

Private Types

namespace hpx

namespace util

namespace cache

namespace statistics

Enums

enum method
   Values:
      method_get_entry = 0
      method_insert_entry = 1
      method_update_entry = 2
      method_erase_entry = 3

class no_statistics
   Subclassed by hpx:util::cache::statistics::local_statistics

Public Functions

void got_hit()  
   The function got_hit will be called by a cache instance whenever a entry got touched.

void got_miss()  
   The function got_miss will be called by a cache instance whenever a requested entry has not been found in the cache.

void got_insertion()  
   The function got_insertion will be called by a cache instance whenever a new entry has been inserted.

void got_eviction()  
   The function got_eviction will be called by a cache instance whenever an entry has been removed from the cache because a new inserted entry let the cache grow beyond its capacity.
void clear()

Reset all statistics.

std::int64_t get_get_entry_count (bool)

The function get_get_entry_count returns the number of invocations of the get_entry() API function of the cache.

std::int64_t get_insert_entry_count (bool)

The function get_insert_entry_count returns the number of invocations of the insert_entry() API function of the cache.

std::int64_t get_update_entry_count (bool)

The function get_update_entry_count returns the number of invocations of the update_entry() API function of the cache.

std::int64_t get_erase_entry_count (bool)

The function get_erase_entry_count returns the number of invocations of the erase() API function of the cache.

std::int64_t get_get_entry_time (bool)

The function get_get_entry_time returns the overall time spent executing of the get_entry() API function of the cache.

std::int64_t get_insert_entry_time (bool)

The function get_insert_entry_time returns the overall time spent executing of the insert_entry() API function of the cache.

std::int64_t get_update_entry_time (bool)

The function get_update_entry_time returns the overall time spent executing of the update_entry() API function of the cache.

std::int64_t get_erase_entry_time (bool)

The function get_erase_entry_time returns the overall time spent executing of the erase() API function of the cache.

struct update_on_exit

#include <no_statistics.hpp> Helper class to update timings and counts on function exit.

Public Functions

update_on_exit (no_statistics const&, method)

concepts

The contents of this module can be included with the header hpx/modules/concepts.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/concepts.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.
Defines

HPX_CONCEPT_REQUIRES_(...)  
HPX_CONCEPT_REQUIRES(...)  
HPX_CONCEPT_ASSERT(...)  

Defines

HPX_HAS_MEMBER_XXX_TRAIT_DEF (MEMBER)  
This macro creates a boolean unary meta-function which result is true if and only if its parameter type has  
member function with MEMBER name (no matter static it is or not). The generated trait ends up in a namespace  
where the macro itself has been placed.

Defines

HPX_HAS_XXX_TRAIT_DEF (Name)  
This macro creates a boolean unary meta-function such that for any type X, has_name<X>::value == true if and  
only if X is a class type and has a nested type member x::name. The generated trait ends up in a namespace  
where the macro itself has been placed.

 concurrency

The contents of this module can be included with the header hpx/modules/concurrency.hpp. These headers  
may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these  
at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including  
the module header hpx/modules/concurrency.hpp, not the particular header in which the functionality you  
would like to use is defined. See Public API for a list of names that are part of the public HPX API.

cfg

The contents of this module can be included with the header `hpx/modules/config.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/config.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

Defines

```
HPX_INITIAL_IP_PORT
This is the default ip/port number used by the parcel subsystem.

HPX_CONNECTING_IP_PORT

HPX_INITIAL_IP_ADDRESS

HPX_RUNTIME_INSTANCE_LIMIT
This defines the maximum number of possible runtime instances in one executable

HPX.Parcel_BOOTSTRAP
This defines the type of the parcelport to be used during application bootstrap. This value can be changed at runtime by the configuration parameter:

    hpx.parcel.bootstrap = ...

(or by setting the corresponding environment variable HPX.Parcel_BOOTSTRAP).

HPX.Parcel_MAX_CONNECTIONS
This defines the number of outgoing (parcel-) connections kept alive (to all other localities). This value can be changed at runtime by setting the configuration parameter:

    hpx.parcel.max_connections = ...

(or by setting the corresponding environment variable HPX.Parcel_MAX_CONNECTIONS).

2.8. API reference
HPX_PARCEL_IPC_DATA_BUFFER_CACHE_SIZE
This defines the number of outgoing ipc (parcel-) connections kept alive (to each of the other localities on the
same node). This value can be changed at runtime by setting the configuration parameter:

\[
\text{hpx.parcel.ipc.data_buffer_cache_size} = \ldots
\]
(or by setting the corresponding environment variable HPX_PARCEL_IPC_DATA_BUFFER_CACHE_SIZE).

HPX_PARCEL_MPI_MAX_REQUESTS
This defines the number of MPI requests in flight This value can be changed at runtime by setting the configu-
ration parameter:

\[
\text{hpx.parcel.mpi.max_requests} = \ldots
\]
(or by setting the corresponding environment variable HPX_PARCEL_MPI_MAX_REQUESTS).

HPX_PARCEL_MAX_CONNECTIONS_PER_LOCALITY
This defines the number of outgoing (parcel-) connections kept alive (to each of the other localities). This value
can be changed at runtime by setting the configuration parameter:

\[
\text{hpx.parcel.max_connections_per_locality} = \ldots
\]
(or by setting the corresponding environment variable HPX_PARCEL_MAX_CONNECTIONS_PER_LOCALITY).

HPX_PARCEL_MAX_MESSAGE_SIZE
This defines the maximally allowed message size for messages transferred between localities. This value can be
changed at runtime by setting the configuration parameter:

\[
\text{hpx.parcel.max_message_size} = \ldots
\]
(or by setting the corresponding environment variable HPX_PARCEL_MAX_MESSAGE_SIZE).

HPX_PARCEL_MAX_OUTBOUND_MESSAGE_SIZE
This defines the maximally allowed outbound message size for coalescing messages transferred between locali-
ties. This value can be changed at runtime by setting the configuration parameter:

\[
\text{hpx.parcel.max_outbound_message_size} = \ldots
\]
(or by setting the corresponding environment variable HPX_PARCEL_MAX_OUTBOUND_MESSAGE_SIZE).

HPX_PARCEL_SERIALIZATION_OVERHEAD
HPX_AGAS_LOCAL_CACHE_SIZE
This defines the number of AGAS address translations kept in the local cache. This is just the initial size which
may be adjusted depending on the load of the system (not implemented yet), etc. It must be a minimum of 3 for
AGAS v3 bootstrapping.

This value can be changes at runtime by setting the configuration parameter:

\[
\text{hpx.agas.local_cache_size} = \ldots
\]
(or by setting the corresponding environment variable HPX_AGAS_LOCAL_CACHE_SIZE)

HPX_INITIAL_AGAS_MAX_PENDING_REF_CNT_REQUESTS
HPX_GLOBALCREDIT_INITIAL
This defines the initial global reference count associated with any created object.

HPX_NUM_IO_POOL_SIZE
This defines the default number of OS-threads created for the different internal thread pools

HPX_NUM_PARCEL_POOL_SIZE
HPX_NUM_TIMER_POOL_SIZE
**HPX_SPINLOCK_DEADLOCK_DETECTION_LIMIT**

By default, enable minimal thread deadlock detection in debug builds only.

**HPX_COROUTINE_NUM_HEAPS**

This defines the default number of coroutine heaps.

**HPX_HAVE_THREAD_BACKTRACE_DEPTH**

By default, enable storing the thread phase in debug builds only.

By default, enable storing the parent thread information in debug builds only. By default, enable storing the thread description in debug builds only. By default, enable storing the target address of the data the thread is accessing in debug builds only. By default we do not maintain stack back-traces on suspension. This is a pure debugging aid to be able to see in the debugger where a suspended thread got stuck. By default we capture only 20 levels of stack back trace on suspension.

Defines

HPX_NOINLINE
Function attribute to tell compiler not to inline the function.

HPX_NORETURN
Function attribute to tell compiler that the function does not return.

HPX_DEPRECATED (x)
Marks an entity as deprecated. The argument x specifies a custom message that is included in the compiler warning. For more details see <>__.

HPX_FALLTHROUGH
Indicates that the fall through from the previous case label is intentional and should not be diagnosed by a compiler that warns on fallthrough. For more details see <>__.

HPX_NODISCARD
If a function declared nodiscard or a function returning an enumeration or class declared nodiscard by value is called from a discarded-value expression other than a cast to void, the compiler is encouraged to issue a warning. For more details see __.

HPX_NO_UNIQUE_ADDRESS
Indicates that this data member need not have an address distinct from all other non-static data members of its class. For more details see __.

Defines

HPX_LIKELY (expr)
Hint at the compiler that expr is likely to be true.

HPX_UNLIKELY (expr)
Hint at the compiler that expr is likely to be false.

Defines

HPX_COMPILER_FENCE
Generates assembly that serves as a fence to the compiler CPU to disable optimization. Usually implemented in the form of a memory barrier.

HPX_SMT_PAUSE
Generates assembly the executes a “pause” instruction. Useful in spinning loops.
Defines

**HPX_NATIVE_TLS**
This macro is replaced with the compiler specific keyword attribute to mark a variable as thread local. For more details see `<__`. This macro is deprecated. It is always replaced with the `thread_local` keyword. Prefer using `thread_local` directly instead.

Defines

**HPX_GCC_VERSION**
Returns the GCC version HPX is compiled with. Only set if compiled with GCC.

**HPX_CLANG_VERSION**
Returns the Clang version HPX is compiled with. Only set if compiled with Clang.

**HPX_INTEL_VERSION**
Returns the Intel Compiler version HPX is compiled with. Only set if compiled with the Intel Compiler.

**HPX_MSVC**
This macro is set if the compilation is with MSVC.

**HPX_MINGW**
This macro is set if the compilation is with Mingw.

**HPX_WINDOWS**
This macro is set if the compilation is for Windows.

**HPX_NATIVE_MIC**
This macro is set if the compilation is for Intel Knights Landing.

Defines

**HPX_CONSTEXPR**
This macro evaluates to `constexpr` if the compiler supports it.
This macro is deprecated. It is always replaced with the `constexpr` keyword. Prefer using `constexpr` directly instead.

**HPX_CONSTEXPR_OR_CONST**
This macro evaluates to `constexpr` if the compiler supports it, `const` otherwise.
This macro is deprecated. It is always replaced with the `constexpr` keyword. Prefer using `constexpr` directly instead.

**HPX_INLINE_CONSTEXPR_VARIABLE**
This macro evaluates to `inline constexpr` if the compiler supports it, `constexpr` otherwise.

**HPX_STATIC_CONSTEXPR**
This macro evaluates to `static constexpr` if the compiler supports it, `static const` otherwise.
This macro is deprecated. It is always replaced with the `static constexpr` keyword. Prefer using `static constexpr` directly instead.
Defines

**HPX_DEBUG**
Defined if HPX is compiled in debug mode.

**HPX_BUILD_TYPE**
Evaluates to `debug` if compiled in debug mode, `release` otherwise.

Defines

**HPX_HAVE_DEPRECATION_WARNINGS_V1_4**
**HPX_DEPRECATED_V1_4** *(x)*

**HPX_HAVE_DEPRECATION_WARNINGS_V1_5**
**HPX_DEPRECATED_V1_5** *(x)*

**HPX_HAVE_DEPRECATION_WARNINGS_V1_6**
**HPX_DEPRECATED_V1_6** *(x)*

**HPX_HAVE_DEPRECATION_WARNINGS_V1_7**
**HPX_DEPRECATED_V1_7** *(x)*

**HPX_DEPRECATED_V** *(major, minor, x)*

Defines

**HPX_NON_COPYABLE** *(cls)*
Marks a class as non-copyable and non-movable.

Defines

**HPX_EXPORT**
Marks a class or function to be exported from HPX or imported if it is consumed.

Defines

**HPX_FORCEINLINE**
Marks a function to be forced inline.

Defines

**HPX_CAPTURE_FORWARD** *(var)*
Evaluates to `var = std::forward<decltype(var)>(var)` if the compiler supports C++14 Lambdas. Defaults to `var`.

This macro is deprecated. Prefer using `var = std::forward<decltype((var))>(var)` directly instead.

**HPX_CAPTURE_MOVE** *(var)*
Evaluates to `var = std::move(var)` if the compiler supports C++14 Lambdas. Defaults to `var`.

This macro is deprecated. Prefer using `var = std::move(var)` directly instead.

HPX_THREAD_STATE_EX_UNSCOPED_ENUM_DEPRECATION_MSG
HPX_THREAD_STACKSIZE_UNSCOPED_ENUM_DEPRECATION_MSG
HPX_THREAD_SCHEDULE_HINT_UNSCOPED_ENUM_DEPRECATION_MSG
namespace hpx

namespace threads

 Enums

enum thread_schedule_state
The thread_schedule_state enumerator encodes the current state of a thread instance
Values:
unknown = 0
active = 1
thread is currently active (running, has resources)
pending = 2
    thread is pending (ready to run, but no hardware resource available)

suspended = 3
    thread has been suspended (waiting for synchronization event, but still known and under control
    of the thread-manager)

depleted = 4
    thread has been depleted (deeply suspended, it is not known to the thread-manager)

terminated = 5
    thread has been stopped an may be garbage collected

staged = 6
    this is not a real thread state, but allows to reference staged task descriptions, which eventually
    will be converted into thread objects

pending_do_not_schedule = 7

pending_boost = 8

enum thread_priority
    This enumeration lists all possible thread-priorities for HPX threads.
    Values:
    unknown = -1
    default_ = 0
        Will assign the priority of the task to the default (normal) priority.
    low = 1
        Task goes onto a special low priority queue and will not be executed until all high/normal priority
        tasks are done, even if they are added after the low priority task.
    normal = 2
        Task will be executed when it is taken from the normal priority queue, this is usually a first in-
        first-out ordering of tasks (depending on scheduler choice). This is the default priority.
    high_recursive = 3
        The task is a high priority task and any child tasks spawned by this task will be made high priority
        as well - unless they are specifically flagged as non default priority.
    boost = 4
        Same as thread_priority_high except that the thread will fall back to thread_priority_normal if
        resumed after being suspended.
    high = 5
        Task goes onto a special high priority queue and will be executed before normal/low priority tasks
        are taken (some schedulers modify the behavior slightly and the documentation for those should
        be consulted).
    bound = 6
        Task goes onto a special high priority queue and will never be stolen by another thread after initial
        assignment. This should be used for thread placement tasks such as OpenMP type for loops.

enum thread_restart_state
    The thread_restart_state enumerator encodes the reason why a thread is being restarted
    Values:
    unknown = 0
signaled = 1
The thread has been signaled.

timeout = 2
The thread has been reactivated after a timeout

terminate = 3
The thread needs to be terminated.

abort = 4
The thread needs to be aborted.

enum thread_stacksize
A thread_stacksize references any of the possible stack-sizes for HPX threads.
Values:

unknown = -1
small_ = 1
use small stack size (the underscore is to work around small being defined to char on Windows)

medium = 2
use medium sized stack size

large = 3
use large stack size

huge = 4
use very large stack size

nostack = 5
this thread does not suspend (does not need a stack)

current = 6
use size of current thread’s stack

default_ = small_
use default stack size

minimal = small_
use minimally stack size

maximal = huge
use maximally stack size

enum thread_schedule_hint_mode
The type of hint given when creating new tasks.
Values:

none = 0
A hint that leaves the choice of scheduling entirely up to the scheduler.

thread = 1
A hint that tells the scheduler to prefer scheduling a task on the local thread number associated with this hint. Local thread numbers are indexed from zero. It is up to the scheduler to decide how to interpret thread numbers that are larger than the number of threads available to the scheduler. Typically thread numbers will wrap around when too large.

numa = 2
A hint that tells the scheduler to prefer scheduling a task on the NUMA domain associated with this hint. NUMA domains are indexed from zero. It is up to the scheduler to decide how to
interpret NUMA domain indices that are larger than the number of available NUMA domains to the scheduler. Typically indices will wrap around when too large.

**Functions**

```cpp
std::ostream &operator<< (std::ostream &os, thread_schedule_state const t)
```

char *get_thread_state_name (thread_schedule_state state)

Get the readable string representing the name of the given thread_state constant.

**Parameters**

- `state`: this represents the thread state.

```cpp
std::ostream &operator<< (std::ostream &os, thread_priority const t)
```

char *get_thread_priority_name (thread_priority priority)

Get the readable string representing the name of the given thread_priority constant.

**Parameters**

- `this`: represents the thread priority.

```cpp
std::ostream &operator<< (std::ostream &os, thread_restart_state const t)
```

char *get_thread_state_ex_name (thread_restart_state state)

Get the readable string representing the name of the given thread_restart_state constant.

char *get_thread_state_name (thread_state state)

Get the readable string representing the name of the given thread_state constant.

```cpp
std::ostream &operator<< (std::ostream &os, thread_stacksize const t)
```

char *get_stack_size_enum_name (thread_stacksize size)

Returns the stack size name.

Get the readable string representing the given stack size constant.

**Parameters**

- `size`: this represents the stack size

```cpp
hpx::threads::HPX_DEPRECATED_V(1, 6, HPX_THREAD_SCHEDULE_HINT_UNSCOPED_ENUM_DEPRECATION_MSG) const
```

**Variables**

```cpp
constexpr thread_schedule_state unknown = thread_schedule_state::unknown
constexpr thread_schedule_state active = thread_schedule_state::active
constexpr thread_schedule_state pending = thread_schedule_state::pending
constexpr thread_schedule_state suspended = thread_schedule_state::suspended
constexpr thread_schedule_state depleted = thread_schedule_state::depleted
```

constexpr thread_restart_state wait_abort = thread_restart_state::abort
constexpr thread_stacksize thread_stacksize_unknown = thread_stacksize::unknown
constexpr thread_stacksize thread_stacksize_small = thread_stacksize::small_
constexpr thread_stacksize thread_stacksize_medium = thread_stacksize::medium
constexpr thread_stacksize thread_stacksize_large = thread_stacksize::large
constexpr thread_stacksize thread_stacksize_huge = thread_stacksize::huge
constexpr thread_stacksize thread_stacksize_nostack = thread_stacksize::nostack
constexpr thread_stacksize thread_stacksize_current = thread_stacksize::current
constexpr thread_stacksize thread_stacksize_default = thread_stacksize::default_
constexpr thread_stacksize thread_stacksize_minimal = thread_stacksize::minimal
constexpr thread_stacksize thread_stacksize_maximal = thread_stacksize::maximal

struct thread_schedule_hint
#include <thread_enums.hpp> A hint given to a scheduler to guide where a task should be scheduled.

A scheduler is free to ignore the hint, or modify the hint to suit the resources available to the scheduler.
Public Functions

`constexpr thread_schedule_hint()`  
Construct a default hint with mode `thread_schedule_hint_mode::none`.

`constexpr thread_schedule_hint(std::int16_t thread_hint)`  
Construct a hint with mode `thread_schedule_hint_mode::thread` and the given hint as the local thread number.

`constexpr thread_schedule_hint(thread_schedule_hint_mode mode, std::int16_t hint)`  
Construct a hint with the given mode and hint. The numerical hint is unused when the mode is `thread_schedule_hint_mode::none`.

Public Members

`thread_schedule_hint_mode mode`  
The mode of the scheduling hint.

`std::int16_t hint`  
The hint associated with the mode. The interpretation of this hint depends on the given mode.

datastructures

The contents of this module can be included with the header hpx/modules/datastructures.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/datastructures.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

errors

The contents of this module can be included with the header hpx/modules/errors.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/errors.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

namespace hpx

Enums

```cpp
enum error
```

Possible error conditions.

This enumeration lists all possible error conditions which can be reported from any of the API functions.

Values:

- `success` = 0
  - The operation was successful.

- `no_success` = 1
  - The operation did fail, but not in an unexpected manner.
not_implemented = 2
    The operation is not implemented.
out_of_memory = 3
    The operation caused an out of memory condition.
bad_action_code = 4
bad_component_type = 5
    The specified component type is not known or otherwise invalid.
network_error = 6
    A generic network error occurred.
version_too_new = 7
    The version of the network representation for this object is too new.
version_too_old = 8
    The version of the network representation for this object is too old.
version_unknown = 9
    The version of the network representation for this object is unknown.
unknown_component_address = 10
duplicate_component_address = 11
    The given global id has already been registered.
invalid_status = 12
    The operation was executed in an invalid status.
bad_parameter = 13
    One of the supplied parameters is invalid.
internal_server_error = 14
service_unavailable = 15
bad_request = 16
repeated_request = 17
lock_error = 18
duplicate_console = 19
    There is more than one console locality.
no_registered_console = 20
    There is no registered console locality available.
startup_timed_out = 21
uninitialized_value = 22
bad_response_type = 23
deadlock = 24
assertion_failure = 25
null_thread_id = 26
    Attempt to invoke a API function from a non-HPX thread.
invalid_data = 27
yield_aborted = 28
    The yield operation was aborted.
dynamic_link_failure = 29

commandline_option_error = 30
    One of the options given on the command line is erroneous.

serialization_error = 31
    There was an error during serialization of this object.

unhandled_exception = 32
    An unhandled exception has been caught.

kernel_error = 33
    The OS kernel reported an error.

broken_task = 34
    The task associated with this future object is not available anymore.

task_moved = 35
    The task associated with this future object has been moved.

task_already_started = 36
    The task associated with this future object has already been started.

future_already_retrieved = 37
    The future object has already been retrieved.

promise_already_satisfied = 38
    The value for this future object has already been set.

future_does_not_support_cancellation = 39
    The future object does not support cancellation.

future_can_not_be_cancelled = 40
    The future can’t be canceled at this time.

no_state = 41
    The future object has no valid shared state.

broken.promise = 42
    The promise has been deleted.

thread_resource_error = 43

future_cancelled = 44

thread_cancelled = 45

thread_not_interruptable = 46

duplicate_component_id = 47
    The component type has already been registered.

unknown_error = 48
    An unknown error occurred.

bad_plugin_type = 49
    The specified plugin type is not known or otherwise invalid.

filesystem_error = 50
    The specified file does not exist or other filesystem related error.

bad_function_call = 51
    equivalent of std::bad_function_call
task_canceled_exception = 52
    parallel::v2::task_canceled_exception

task_block_not_active = 53
    task_region is not active

out_of_range = 54
    Equivalent to std::out_of_range.

length_error = 55
    Equivalent to std::length_error.

migration_needs_retry = 56
    migration failed because of global race, retry

namespace hpx

Unnamed Group

error_code make_error_code (error e, throwmode mode = plain)
    Returns a new error_code constructed from the given parameters.

error_code make_error_code (error e, char const *func, char const *file, long line, throwmode mode = plain)

error_code make_error_code (error e, char const *msg, throwmode mode = plain)
    Returns error_code(e, msg, mode).

error_code make_error_code (error e, char const *msg, char const *func, char const *file, long line, throwmode mode = plain)

error_code make_error_code (error e, std::string const &msg, throwmode mode = plain)
    Returns error_code(e, msg, mode).

error_code make_error_code (error e, std::string const &msg, char const *func, char const *file, long line, throwmode mode = plain)

error_code make_error_code (std::exception_ptr const &e)

Functions

std::error_category const &get_hpx_category ()
    Returns generic HPX error category used for new errors.

std::error_category const &get_hpx_rethrow_category ()
    Returns generic HPX error category used for errors re-thrown after the exception has been de-serialized.

error_code make_success_code (throwmode mode = plain)
    Returns error_code(hpx::success, “success”, mode).

class error_code: public error_code
    #include <error_code.hpp> A hpx::error_code represents an arbitrary error condition.

    The class hpx::error_code describes an object used to hold error code values, such as those originating from the operating system or other low-level application program interfaces.

    Note Class hpx::error_code is an adjunct to error reporting by exception
Public Functions

**error_code** *(throwmode mode = plain)*
Construct an object of type error_code.

**Parameters**
- **mode**: The parameter mode specifies whether the constructed hpx::error_code belongs to the error category hpx_category (if mode is plain, this is the default) or to the category hpx_category_rethrow (if mode is rethrow).

**Exceptions**
- **nothing**: error_code (error e, throwmode mode = plain)
Construct an object of type error_code.

**Parameters**
- **e**: The parameter e holds the hpx::error code the new exception should encapsulate.
- **mode**: The parameter mode specifies whether the constructed hpx::error_code belongs to the error category hpx_category (if mode is plain, this is the default) or to the category hpx_category_rethrow (if mode is rethrow).

**Exceptions**
- **nothing**: error_code (error e, char const *func, char const *file, long line, throwmode mode = plain)
Construct an object of type error_code.

**Parameters**
- **e**: The parameter e holds the hpx::error code the new exception should encapsulate.
- **func**: The name of the function where the error was raised.
- **file**: The file name of the code where the error was raised.
- **line**: The line number of the code line where the error was raised.
- **mode**: The parameter mode specifies whether the constructed hpx::error_code belongs to the error category hpx_category (if mode is plain, this is the default) or to the category hpx_category_rethrow (if mode is rethrow).

**Exceptions**
- **nothing**: error_code (error e, char const *msg, throwmode mode = plain)
Construct an object of type error_code.

**Parameters**
- **e**: The parameter e holds the hpx::error code the new exception should encapsulate.
- **msg**: The parameter msg holds the error message the new exception should encapsulate.
- **mode**: The parameter mode specifies whether the constructed hpx::error_code belongs to the error category hpx_category (if mode is plain, this is the default) or to the category hpx_category_rethrow (if mode is rethrow).

**Exceptions**
- **std::bad_alloc**: (if allocation of a copy of the passed string fails).

**error_code** *(error e, char const *msg, char const *func, char const *file, long line, throwmode mode = plain)*
Construct an object of type error_code.
Parameters
• e: The parameter e holds the hpx::error code the new exception should encapsulate.
• msg: The parameter msg holds the error message the new exception should encapsulate.
• func: The name of the function where the error was raised.
• file: The file name of the code where the error was raised.
• line: The line number of the code line where the error was raised.
• mode: The parameter mode specifies whether the constructed hpx::error_code belongs to the error category hpx_category (if mode is plain, this is the default) or to the category hpx_category_rethrow (if mode is rethrow).

Exceptions
• std::bad_alloc: (if allocation of a copy of the passed string fails).

error_code (error e, std::string const &msg, throwmode mode = plain)
Construct an object of type error_code.

Parameters
• e: The parameter e holds the hpx::error code the new exception should encapsulate.
• msg: The parameter msg holds the error message the new exception should encapsulate.
• func: The name of the function where the error was raised.
• file: The file name of the code where the error was raised.
• line: The line number of the code line where the error was raised.
• mode: The parameter mode specifies whether the constructed hpx::error_code belongs to the error category hpx_category (if mode is plain, this is the default) or to the category hpx_category_rethrow (if mode is rethrow).

Exceptions
• std::bad_alloc: (if allocation of a copy of the passed string fails).

error_code (error e, std::string const &msg, char const *func, char const *file, long line, throwmode mode = plain)
Construct an object of type error_code.

Parameters
• e: The parameter e holds the hpx::error code the new exception should encapsulate.
• msg: The parameter msg holds the error message the new exception should encapsulate.
• func: The name of the function where the error was raised.
• file: The file name of the code where the error was raised.
• line: The line number of the code line where the error was raised.
• mode: The parameter mode specifies whether the constructed hpx::error_code belongs to the error category hpx_category (if mode is plain, this is the default) or to the category hpx_category_rethrow (if mode is rethrow).

Exceptions
• std::bad_alloc: (if allocation of a copy of the passed string fails).

std::string get_message () const
Return a reference to the error message stored in the hpx::error_code.

Exceptions
• nothing:

void clear ()
Clear this error_code object. The postconditions of invoking this method are.

• value() == hpx::success and category() == hpx::get_hpx_category()

error_code (error_code const &rhs)
Copy constructor for error_code
**Note** This function maintains the error category of the left hand side if the right hand side is a success code.

```cpp
error_code &operator= (error_code const &rhs)
```
Assignment operator for error_code

**Note** This function maintains the error category of the left hand side if the right hand side is a success code.

### Private Functions

```cpp
error_code (int err, hpx::exception const &e)
error_code (std::exception_ptr const &e)
```

### Private Members

```cpp
std::exception_ptr exception_
```

### Friends

```cpp
friend hpx::exception

error_code make_error_code (std::exception_ptr const &e)
```

```cpp
namespace hpx

```

### Typedefs

```cpp
using custom_exception_info_handler_type = std::function<hpx::exception_info (std::string const&, std::string const&, long, std::string const&)>;
```

```cpp
using pre_exception_handler_type = std::function<void ()>;
```

### Functions

```cpp
void set_custom_exception_info_handler (custom_exception_info_handler_type f)
```

```cpp
void set_pre_exception_handler (pre_exception_handler_type f)
```

```cpp
std::string get_error_what (exception_info const &xi)
```

Return the error message of the thrown exception.

The function `hpx::get_error_what` can be used to extract the diagnostic information element representing the error message as stored in the given exception instance.
Return The error message stored in the exception if the exception instance does not hold this information, the function will return an empty string.

See hpx::diagnostic_information(), hpx::get_error_host_name(), hpx::get_error_process_id(), hpx::get_error_function_name(), hpx::get_error_file_name(), hpx::get_error_line_number(), hpx::get_error_os_thread(), hpx::get_error_thread_id(), hpx::get_error_thread_description(), hpx::get_error(), hpx::get_error_backtrace(), hpx::get_error_env(), hpx::get_error_config(), hpx::get_error_state()

Parameters

• xi: The parameter e will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: hpx::exception_info, hpx::error_code, std::exception, or std::exception_ptr.

Exceptions

• std::bad_alloc: (if one of the required allocations fails)

error get_error (hpx::exception const &e)

Return the error code value of the exception thrown.

The function hpx::get_error can be used to extract the diagnostic information element representing the error value code as stored in the given exception instance.

Return The error value code of the locality where the exception was thrown. If the exception instance does not hold this information, the function will return hpx::naming::invalid_locality_id.

See hpx::diagnostic_information(), hpx::get_error_host_name(), hpx::get_error_process_id(), hpx::get_error_function_name(), hpx::get_error_file_name(), hpx::get_error_line_number(), hpx::get_error_os_thread(), hpx::get_error_thread_id(), hpx::get_error_thread_description(), hpx::get_error_backtrace(), hpx::get_error_env(), hpx::get_error_what(), hpx::get_error_config(), hpx::get_error_state()

Parameters

• e: The parameter e will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: hpx::exception, hpx::error_code, or std::exception_ptr.

Exceptions

• nothing:

error get_error (hpx::error_code const &e)

std::string get_error_function_name (hpx::exception_info const &xi)

Return the function name from which the exception was thrown.

The function hpx::get_error_function_name can be used to extract the diagnostic information element representing the name of the function as stored in the given exception instance.

Return The name of the function from which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

See hpx::diagnostic_information(), hpx::get_error_host_name(), hpx::get_error_process_id(), hpx::get_error_file_name(), hpx::get_error_line_number(), hpx::get_error_os_thread(), hpx::get_error_thread_id(), hpx::get_error_thread_description(), hpx::get_error(),
hpx::get_error_backtrace(), hpx::get_error_env(), hpx::get_error_what(), hpx::get_error_config(), hpx::get_error_state()  

Parameters

• xi: The parameter e will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: hpx::exception_info, hpx::error_code, std::exception, or std::exception_ptr.

Exceptions

• std::bad_alloc: (if one of the required allocations fails)

std::string get_error_file_name (hpx::exception_info const &xi)

Return the (source code) file name of the function from which the exception was thrown.

The function hpx::get_error_file_name can be used to extract the diagnostic information element representing the name of the source file as stored in the given exception instance.

Return The name of the source file of the function from which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

See hpx::diagnostic_information(), hpx::get_error_host_name(), hpx::get_error_process_id(), hpx::get_error_function_name(), hpx::get_error_line_number(), hpx::get_error_os_thread(), hpx::get_error_thread_id(), hpx::get_error_thread_description(), hpx::get_error_backtrace(), hpx::get_error_env(), hpx::get_error_what(), hpx::get_error_config(), hpx::get_error_state()  

Parameters

• xi: The parameter e will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: hpx::exception_info, hpx::error_code, std::exception, or std::exception_ptr.

Exceptions

• std::bad_alloc: (if one of the required allocations fails)

long get_error_line_number (hpx::exception_info const &xi)

Return the line number in the (source code) file of the function from which the exception was thrown.

The function hpx::get_error_line_number can be used to extract the diagnostic information element representing the line number as stored in the given exception instance.

Return The line number of the place where the exception was thrown. If the exception instance does not hold this information, the function will return -1.

See hpx::diagnostic_information(), hpx::get_error_host_name(), hpx::get_error_process_id(), hpx::get_error_function_name(), hpx::get_error_file_name(), hpx::get_error_thread_id(), hpx::get_error_thread_description(), hpx::get_error_backtrace(), hpx::get_error_env(), hpx::get_error_what(), hpx::get_error_config(), hpx::get_error_state()  

Parameters

• xi: The parameter e will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: hpx::exception_info, hpx::error_code, std::exception, or std::exception_ptr.

Exceptions
class exception : public system_error
#include <exception.hpp>
A hpx::exception is the main exception type used by HPX to report errors.

The hpx::exception type is the main exception type used by HPX to report errors. Any exceptions thrown by functions in the HPX library are either of this type or of a type derived from it. This implies that it is always safe to use this type only in catch statements guarding HPX library calls.

Subclassed by hpx::exception_list

Public Functions

exception (error e = success)
Construct a hpx::exception from a hpx::error.

Parameters
• e: The parameter e holds the hpx::error code the new exception should encapsulate.

exception (std::system_error const &e)
Construct a hpx::exception from a boost::system_error.

exception (std::error_code const &e)
Construct a hpx::exception from a boost::system::error_code (this is new for Boost V1.69). This constructor is required to compensate for the changes introduced as a resolution to LWG3162 (https://cplusplus.github.io/LWG/issue3162).

exception (error e, char const *msg, throwmode mode = plain)
Construct a hpx::exception from a hpx::error and an error message.

Parameters
• e: The parameter e holds the hpx::error code the new exception should encapsulate.
• msg: The parameter msg holds the error message the new exception should encapsulate.
• mode: The parameter mode specifies whether the returned hpx::error_code belongs to the error category hpx_category (if mode is plain, this is the default) or to the category hpx_category_rethrow (if mode is rethrow).

exception (error e, std::string const &msg, throwmode mode = plain)
Construct a hpx::exception from a hpx::error and an error message.

Parameters
• e: The parameter e holds the hpx::error code the new exception should encapsulate.
• msg: The parameter msg holds the error message the new exception should encapsulate.
• mode: The parameter mode specifies whether the returned hpx::error_code belongs to the error category hpx_category (if mode is plain, this is the default) or to the category hpx_category_rethrow (if mode is rethrow).

~exception()
Destruct a hpx::exception

Exceptions
• nothing:
**error get_error() const**

The function get_error() returns the hpx::error code stored in the referenced instance of a hpx::exception. It returns the hpx::error code this exception instance was constructed from.

**Exceptions**

- nothing:

**error_code get_error_code(throwmode mode = plain) const**

The function get_error_code() returns a hpx::error_code which represents the same error condition as this hpx::exception instance.

**Parameters**

- mode: The parameter mode specifies whether the returned hpx::error_code belongs to the error category hpx_category (if mode is plain, this is the default) or to the category hpx_category_rethrow (if mode is rethrow).

**struct thread_interrupted**: public exception

#include <exception.hpp> A hpx::thread_interrupted is the exception type used by HPX to interrupt a running HPX thread.

The hpx::thread_interrupted type is the exception type used by HPX to interrupt a running thread.

A running thread can be interrupted by invoking the interrupt() member function of the corresponding hpx::thread object. When the interrupted thread next executes one of the specified interruption points (or if it is currently blocked whilst executing one) with interruption enabled, then a hpx::thread_interrupted exception will be thrown in the interrupted thread. If not caught, this will cause the execution of the interrupted thread to terminate. As with any other exception, the stack will be unwound, and destructors for objects of automatic storage duration will be executed.

If a thread wishes to avoid being interrupted, it can create an instance of hpx::this_thread::disable_interruption. Objects of this class disable interruption for the thread that created them on construction, and restore the interruption state to whatever it was before on destruction.

```cpp
void f()
{
    // interruption enabled here
    {
        hpx::this_thread::disable_interruption di;
        // interruption disabled
        {
            hpx::this_thread::disable_interruption di2;
            // interruption still disabled
        } // di2 destroyed, interruption state restored
        // interruption still disabled
    } // di destroyed, interruption state restored
    // interruption now enabled
}
```

The effects of an instance of hpx::this_thread::disable_interruption can be temporarily reversed by constructing an instance of hpx::this_thread::restore_interruption, passing in the hpx::this_thread::disable_interruption object in question. This will restore the interruption state to what it was when the hpx::this_thread::disable_interruption object was constructed, and then disable interruption again when the hpx::this_thread::restore_interruption object is destroyed.
```cpp
void g()
{
    // interruption enabled here
    {
        hpx::this_thread::disable_interruption di;
        // interruption disabled
        {
            hpx::this_thread::restore_interruption ri(di);
            // interruption now enabled
        } // ri destroyed, interruption disable again
        // di destroyed, interruption state restored
        // interruption now enabled
    }
    // interruption enabled here
}
```

At any point, the interruption state for the current thread can be queried by calling `hpx::this_thread::interruption_enabled()`.

**namespace hpx**

**Enums**

```cpp
enum throwmode
{
    Encode error category for new `error_code`

    Values:
        plain = 0
        rethrow = 1
        lightweight = 0x80
}
```

**Variables**

```cpp
error_code throws
Predefined `error_code` object used as “throw on error” tag.

The predefined `hpx::error_code` object `hpx::throws` is supplied for use as a “throw on error” tag.

Functions that specify an argument in the form `error_code& ec=throws` (with appropriate namespace qualifiers), have the following error handling semantics:

If `&ec != &throws` and an error occurred: `ec.value()` returns the implementation specific error number for the particular error that occurred and `ec.category()` returns the error_category for `ec.value()`.

If `&ec != &throws` and an error did not occur, `ec.clear()`.

If an error occurs and `&ec == &throws`, the function throws an exception of type `hpx::exception` or of a type derived from it. The exception’s `get_errorcode()` member function returns a reference to an `hpx::error_code` object with the behavior as specified above.

namespace hpx

class exception_list: public hpx::exception
#include <exception_list.hpp> The class exception_list is a container of exception_ptr objects parallel algorithms may use to communicate uncaught exceptions encountered during parallel execution to the caller of the algorithm.

The type exception_list::const_iterator fulfills the requirements of a forward iterator.

Public Types

using iterator = exception_list_type::const_iterator

bidirectional iterator

Public Functions

std::size_t size() const

The number of exception_ptr objects contained within the exception_list.

Note Complexity: Constant time.

exception_list_type::const_iterator begin() const

An iterator referring to the first exception_ptr object contained within the exception_list.

exception_list_type::const_iterator end() const

An iterator which is the past-the-end value for the exception_list.
Defines

**HPX_THROW_EXCEPTION** *(errcode, f, ...)*

Throw a `hpx::exception` initialized from the given parameters.

The macro `HPX_THROW_EXCEPTION` can be used to throw a `hpx::exception`. The purpose of this macro is to prepend the source file name and line number of the position where the exception is thrown to the error message. Moreover, this associates additional diagnostic information with the exception, such as file name and line number, locality id and thread id, and stack backtrace from the point where the exception was thrown.

The parameter `errcode` holds the `hpx::error` code the new exception should encapsulate. The parameter `f` is expected to hold the name of the function exception is thrown from and the parameter `msg` holds the error message the new exception should encapsulate.

```cpp
void raise_exception()
{
    // Throw a hpx::exception initialized from the given parameters.
    // Additionally associate with this exception some detailed
    // diagnostic information about the throw-site.
    HPX_THROW_EXCEPTION(hpx::no_success, "raise_exception", "simulated error");
}
```

Example:

**HPX_THROWS_IF** *(ec, errcode, f, ...)*

Either throw a `hpx::exception` or initialize `hpx::error_code` from the given parameters.

The macro `HPX_THROWS_IF` can be used to either throw a `hpx::exception` or to initialize a `hpx::error_code` from the given parameters. If `&ec` `==` `&hpx::throws`, the semantics of this macro are equivalent to `HPX_THROW_EXCEPTION`. If `&ec` `!=` `&hpx::throws`, the `hpx::error_code` instance `ec` is initialized instead.

The parameter `errcode` holds the `hpx::error` code from which the new exception should be initialized. The parameter `f` is expected to hold the name of the function exception is thrown from and the parameter `msg` holds the error message the new exception should encapsulate.

**execution_base**

The contents of this module can be included with the header `hpx/modules/execution_base.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/execution_base.hpp`, not the particular header in which the functionality you would like to use is defined. See **Public API** for a list of names that are part of the public **HPX API**.

const expr bool is_nothrow_receiver_of_v = is_nothrow_receiver_of<T, As...>::value

struct is_receiver
{
    #include <receiver.hpp> Receiving values from asynchronous computations is handled by the
}
Receiver concept. A Receiver needs to be able to receive an error or be marked as being canceled. As such, the Receiver concept is defined by having the following two customization points defined, which form the completion-signal operations:

- `hpx::execution::experimental::set_done`
- `hpx::execution::experimental::set_error`

Those two functions denote the completion-signal operations. The Receiver contract is as follows:

- None of a Receiver’s completion-signal operation shall be invoked before `hpx::execution::experimental::start` has been called on the operation state object that was returned by connecting a Receiver to a sender.
- `hpx::execution::experimental::connect`

- Once `hpx::execution::start` has been called on the operation state object, exactly one of the Receiver’s completion-signal operation shall complete without an exception before the Receiver is destroyed.

Once one of the Receiver’s completion-signal operation has been completed without throwing an exception, the Receiver contract has been satisfied. In other words: The asynchronous operation has been completed.

See `hpx::execution::experimental::is_receiver_of`

```cpp
template<typename T, typename ...As>
struct is_receiver_of {
    #include <receiver.hpp> The receiver_of concept is a refinement of the Receiver concept by requiring one additional completion-signal operation:
    - `hpx::execution::set_value`

    This completion-signal operation adds the following to the Receiver’s contract:
    - If `hpx::execution::set_value` exits with an exception, it is still valid to call `hpx::execution::set_error` or `hpx::execution::set_done`.

    See `hpx::execution::traits::is_receiver`

typedef hpx::util::invoke_result<connect_t, S, R>::type connect_result_t;
```}

Functions

```cpp
template<typename E, typename F>
void execute(E&& e, F&& f)
```}

execute is a customization point object. For some subexpression e and f, let E be decltype((e)) and let F be decltype((F)). The expression `execute(e, f)` is ill-formed if F does not model `invocable`, or if E does not model either `executor` or `sender`. The result of the expression `hpx::execution::experimental::execute(e, f)` is then equivalent to:

- e.execute(f), if that expression is valid. If the function selected does not execute the function object f on the executor e, the program is ill-formed with no diagnostic required.
- Otherwise, `execute(e, f)` if that expression is valid, with overload resolution performed in a context that includes the declaration `void execute();` and that does not include a declaration of `hpx::execution::experimental::execute`. If the function selected by overload resolution does not execute the function object f on the executor e, the program is ill-formed with no diagnostic required.
- Otherwise, `execution::submit(e, as-receiver<remove_cvref_t<F>, E>{forward<F>(f)})` if
  - F is not an instance of `as-invocable<R,E'>` for some type R where E and E’ name the same type ignoring cv and reference qualifiers, and
  - `invocable<remove_cvref_t<F>>& && sender_to<E, as-receiver<remove_cvref_t<F>, E>>` is true
where as-receiver is some implementation-defined class template equivalent to:
template<class F, class>
struct as-receiver {
    F f_; 
    void set_value() noexcept(is_nothrow_invocable_v<F&>) { 
        invoke(f_); 
    }
    template<class E>
    [[noreturn]] void set_error(E&&) noexcept { 
        terminate(); 
    }
    void set_done() noexcept {} 
};

The customization is implemented in terms of hpx::functional::tag_dispatch.

template<typename S, typename R>
void connect (S &&s, R &&r)
connect is a customization point object. For some subexpression s and r, let S be the type such that decltype((s)) is S and let R be the type such that decltype((r)) is R. The result of the expression hpx::execution::experimental::connect(s, r) is then equivalent to:
* s.connect(r), if that expression is valid and returns a type satisfying the operation_state( See hpx::execution::experimental::traits::is_operation_state) and if S satisfies the sender concept.
* s.connect(r), if that expression is valid and returns a type satisfying the operation_state( See hpx::execution::experimental::traits::is_operation_state) and if S satisfies the sender concept. Overload resolution is performed in a context that include the declaration void connect();
* Otherwise, as-operation{s, r}, if
  – r is not an instance of as-receiver<F, S'> for some type F where S and S’ name the same type ignoring cv and reference qualifiers, and
  – receiver_of<R> && executor-of-impl<remove_cvref_t

template<typename S, typename R>
auto submit (S &&s, R &&r)

The name submit denotes a customization point object.

For some subexpressions s and r, let S be decltype((s)) and let R be decltype((r)). The expression submit(s, r) is ill-formed if sender_to<S, R> is not true. Otherwise, it is expression-equivalent to:
* s.submit(r), if that expression is valid and S models sender. If the function selected does not submit the receiver object r via the sender s, the program is ill-formed with no diagnostic required.
* Otherwise, submit(s, r), if that expression is valid and S models sender, with overload resolution performed in a context that includes the declaration

    void submit();
and that does not include a declaration of execution::submit. If the function selected by overload resolution does not submit the receiver object r via the sender s, the program is ill-formed with no diagnostic required.

* Otherwise, start((new submit-state<S, R>{s,r})→state_), where submit-state is an implementation-defined class template equivalent to

```cpp
template<class S, class R>
struct submit-state {
    struct submit-receiver {
        submit-state * p_;
        template<class...As>
        requires receiver_of<R, As...>
        void set_value(As&&... as) && noexcept(isnothrow_receiver_˓→of_v<R, As...>) {
            set_value(std::move(p_->r_), (As&&) as...);
            delete p_;}
    template<class E>
    requires receiver<R, E>
    void set_error(E&& e) && noexcept {
        set_error(std::move(p_->r_), (E&&) e);
        delete p_;}
    void set_done() && noexcept {
        set_done(std::move(p_->r_));
        delete p_;}
};
remove_cvref_t<R> r_; connect_result_t<S, submit-receiver> state_; submit-state(S&& s, R&& r)
: r_((R&&) r), state_(connect((S&&) s, submit-receiver(this))) {}};
```

The customization is implemented in terms of hpx::functional::tag_dispatch.

```cpp
template<typename Executor, typename F, typename = std::enable_if_t<hpx::is_invocable<std::decay_t<F>>&>::value>
constexpr auto tag_fallback_dispatch (execute_f, Executor &&executor, F &&f)
```

#include <sender.hpp> The name schedule denotes a customization point object. For some subexpression s, let S be decltype((s)). The expression schedule(s) is expression-equivalent to:

- s.schedule(), if that expression is valid and its type models sender.
- Otherwise, schedule(s), if that expression is valid and its type models sender with overload resolution performed in a context that includes the declaration

```cpp
void schedule();
```

and that does not include a declaration of schedule.

- Otherwise, as-sender<remove_cvref_t<S>>(s) if S satisfies executor, where as-sender is an implementation-defined class

```cpp
template<class E>
struct as-sender {
  private:
    E ex_;
  public:
```
The customization is implemented in terms of `hpx::functional::tag_dispatch`. A sender is a type that is describing an asynchronous operation. The operation itself might not have started yet. In order to get the result of this asynchronous operation, a sender needs to be connected to a receiver with the corresponding value, error and done channels:

- `hpx::execution::experimental::connect`

In addition, `hpx::execution::experimental::sender_traits` needs to be specialized in some form.

A sender's destructor shall not block pending completion of submitted operations.

```
template<typename Sender, typename Receiver>
struct is_sender_to
#include <sender.hpp>
See is_sender

struct schedule_t : public hpx::functional::tag_priority<schedule_r>

Friends

namespace hpx

namespace util

**Functions**

template<typename F, typename ...Ts>
constexpr util::invoke_result<F, Ts...>::type invoke (F &&f, Ts&&... vs)

Invokes the given callable object f with the content of the argument pack vs

**Return** The result of the callable object when it's called with the given argument types.

**Note** This function is similar to `std::invoke` (C++17)

**Parameters**

- **f**: Requires to be a callable object. If f is a member function pointer, the first argument in the pack will be treated as the callee (this object).
- **vs**: An arbitrary pack of arguments

**Exceptions**

- `std::exception`: like objects thrown by call to object f with the argument types vs.

**Template Parameters**

- **R**: The result type of the function when it's called with the content of the given argument types vs.

Functions

template<typename F, typename Tuple>
constexpr detail::invoke_fused_result<F, Tuple>::type invoke_fused(F &&f, Tuple&& t)
     Invokes the given callable object f with the content of the sequenced type t (tuples, pairs)

Return  The result of the callable object when it’s called with the content of the given sequenced type.
Note   This function is similar to std::apply (C++17)
Parameters
     • f: Must be a callable object. If f is a member function pointer, the first argument in the
       sequenced type will be treated as the callee (this object).
     • t: A type which is content accessible through a call to hpx::util::get.
Exceptions
     • std::exception: like objects thrown by call to object f with the arguments contained in
       the sequenceable type t.

template<typename R, typename F, typename Tuple>
constexpr R invoke_fused_r(F &&f, Tuple&& t)
     Template Parameters
     • R: The result type of the function when it’s called with the content of the given sequenced type.

namespace hpx

namespace functional

Typedefs

template<typename Tag, typename ... Args>
using tag_dispatch_result = invoke_result<decltype(tag_dispatch), Tag, Args...>

hp::functional::tag_dispatch_result<Tag, Args...> is the trait returning the result type of the call hp::functional::tag_dispatch. This can be used in a SFINAE context.

template<typename Tag, typename ... Args>
using tag_dispatch_result_t = typename tag_dispatch_result<Tag, Args...>::type

hp::functional::tag_dispatch_result_t<Tag, Args...> evaluates to hp::functional::tag_dispatch_result_t<Tag, Args...>::type

Variables

cconstexpr unspecified tag_dispatch = unspecified

The hp::functional::tag_dispatch name defines a constexpr object that is invocable with one or more arguments. The first argument is a ‘tag’ (typically a DPO). It is only invocable if an overload of tag_dispatch() that accepts the same arguments could be found via ADL.

The evaluation of the expression hp::functional::tag_dispatch(tag, args...) is equivalent to evaluating the unqualified call to tag_dispatch(decay-copy(tag), std::forward<Args>(args)...).

hp::functional::tag_dispatch is implemented against P1895.

Example: Defining a new customization point foo:

```cpp
namespace mylib {
    inline constexpr
    struct foo_fn final : hp::functional::tag<foo_fn>
    {
        foo{};
    }
}
```

Defining an object bar which customizes foo:

```cpp
struct bar
{
    int x = 42;

    friend constexpr int tag_dispatch(mylib::foo_fn, bar const& x)
};
```

(continues on next page)
Using the customization point:

```cpp
static_assert(42 == mylib::foo(bar{}), "The answer is 42");
```

template<typename Tag, typename ...Args>
constexpr bool is_tag_dispatchable_v = is_tag_dispatchable<Tag, Args...>::value
  hpx::functional::is_tag_dispatchable_v<Tag, Args...> evaluates to
  hpx::functional::is_tag_dispatchable_v<Tag, Args...>::value

template<typename Tag, typename ...Args>
constexpr bool is_nothrow_tag_dispatchable_v = is_nothrow_tag_dispatchable<Tag, Args...>::value
  hpx::functional::is_nothrow_tag_dispatchable_v<Tag, Args...> evaluates to
  hpx::functional::is_nothrow_tag_dispatchable_v<Tag, Args...>::value

namespace hpx

namespace functional
Typedefs

template<typename Tag, typename ...Args>
using tag_fallback_dispatch_result = invoke_result<decltype(tag_fallback_dispatch), Tag, Args...>
hpx::functional::tag_fallback_dispatch_result<Tag, Args...> is the trait returning the result type of the call hpx::functional::tag_fallback_dispatch. This can be used in a SFINAE context.

template<typename Tag, typename ...Args>
using tag_fallback_dispatch_result_t = typename tag_fallback_dispatch_result<Tag, Args...>::type
hpx::functional::tag_fallback_dispatch_result_t<Tag, Args...> evaluates to hpx::functional::tag_fallback_dispatch_result<Tag, Args...>::type

Variables

constexpr unspecified tag_fallback_dispatch = unspecified
The hpx::functional::tag_fallback_dispatch name defines a constexpr object that is invocable with one or more arguments. The first argument is a ‘tag’ (typically a DPO). It is only invocable if an overload of tag_fallback_dispatch() that accepts the same arguments could be found via ADL.

The evaluation of the expression hpx::functional::tag_fallback_dispatch(tag, args...) is equivalent to evaluating the unqualified call to tag_fallback_dispatch(decay-copy(tag), std::forward<Args>(args)).

hpx::functional::tag_fallback_dispatch is implemented against P1895.

Example: Defining a new customization point foo:

```cpp
namespace mylib {
    inline constexpr
    struct foo_fn final : hpx::functional::tag_fallback<foo_fn>
    {
        } foo{};
}
```

Defining an object bar which customizes foo:

```cpp
struct bar
{
    int x = 42;

    friend constexpr int tag_fallback_dispatch(mylib::foo_fn, bar const &x)
    {
        return b.x;
    }
};
```

Using the customization point:

```cpp
static_assert(42 == mylib::foo(bar{}), "The answer is 42");
```
constexpr bool is_tag_fallback_dispatchable_v = is_tag_fallback_dispatchable<Tag, Args...>::value
hpx::functional::is_tag_fallback_dispatchable_v<Tag, Args...> evaluates to hpx::functional::is_tag_fallback_dispatchable<Tag, Args...>::value

template<typename Tag, typename ...Args>
constexpr bool is_nothrow_tag_fallback_dispatchable_v = is_nothrow_tag_fallback_dispatchable<Tag, Args...>::value
hpx::functional::is_tag_fallback_dispatchable_v<Tag, Args...> evaluates to hpx::functional::is_tag_fallback_dispatchable<Tag, Args...>::value

template<typename Tag, typename ...Args>
struct is_nothrow_tag_fallback_dispatchable
#include <tag_fallback_dispatch.hpp> hpx::functional::is_nothrow_tag_fallback_dispatchable<Tag, Args...> is std::true_type if an overload of tag_fallback_dispatch(tag, args...) can be found via ADL and is noexcept.

template<typename Tag, typename ...Args>
struct is_tag_fallback_dispatchable
#include <tag_fallback_dispatch.hpp> hpx::functional::is_tag_fallback_dispatchable<Tag, Args...> is std::true_type if an overload of tag_fallback_dispatch(tag, args...) can be found via ADL.

namespace hpx
namespace functional

typedefs

template<typename Tag, typename ...Args>
using tag_override_dispatch_result = invoke_result<decltype(tag_override_dispatch), Tag, Args...>
hpx::functional::tag_override_dispatch_result<Tag, Args...> is the trait returning the result type of the call hpx::functioanl::tag_override_dispatch. This can be used in a SFINAE context.

template<typename Tag, typename ...Args>
using tag_override_dispatch_result_t = typename tag_override_dispatch_result<Tag, Args...>::type
hpx::functional::tag_override_dispatch_result_t<Tag, Args...> evaluates to hpx::functional::tag_override_dispatch_result_t<Tag, Args...>::type
Variables

`constexpr` unspecified `tag_override_dispatch` = unspecified

The `hpx::functional::tag_override_dispatch` name defines a constexpr object that is
invocable with one or more arguments. The first argument is a ‘tag’ (typically a DPO). It is only
invocable if an overload of `tag_override_dispatch()` that accepts the same arguments could be found
via ADL.

The evaluation of the expression `hpx::functional::tag_override_dispatch(tag, args...)` is equivalent to evaluating the unqualified call to
tag_override_dispatch(decay-copy(tag), std::forward<Args>(args).
..).

`hpx::functional::tag_override_dispatch` is implemented against P1895.

Example: Defining a new customization point `foo`:

```cpp
define functional mylib {
    inline constexpr struct foo_fn final : hpx::functional::tag_override<foo_fn>
    {
        } foo{
    }
}
```

Defining an object `bar` which customizes `foo`:

```cpp
define struct bar {
    int x = 42;
    friend constexpr int tag_override_dispatch(mylib::foo_fn, bar const &x) {
        return b.x;
    }
}
```

Using the customization point:

```cpp
define static assert(42 == mylib::foo(bar{}), "The answer is 42");
```

`template<typename Tag, typename ...Args>`

`constexpr` bool `is_tag_override_dispatchable_v = is_tag_override_dispatchable<Tag, Args...>::value`

`hpx::functional::is_tag_override_dispatchable_v<Tag, Args...>` evaluates to `hpx::functional::is_tag_override_dispatchable<Tag, Args...>::value`

`template<typename Tag, typename ...Args>`

`constexpr` bool `is_nothrow_tag_override_dispatchable_v = is_nothrow_tag_override_dispatchable<Tag, Args...>::value`

`hpx::functional::is_nothrow_tag_override_dispatchable_v<Tag, Args...>` evaluates to `hpx::functional::is_nothrow_tag_override_dispatchable<Tag, Args...>::value`

`template<typename Tag, typename ...Args>`

`struct is_nothrow_tag_override_dispatchable`

`#include <tag_priority_dispatch.hpp>`

`hpx::functional::is_nothrow_tag_override_dispatchable_v<Tag, Args...>` is std::true_type if an overload of `tag_override_dispatch(tag, args...)` can be found via ADL and is noexcept.
template<typename Tag, typename ... Args>
struct is_tag_override_dispatchable
#include <tag_priority_dispatch.hpp> hpx::functional::is_tag_override_dispatchable<Tag, Args...> is std::true_type if an overload of tag_override_dispatch(tag, args...) can be found via ADL.

template<typename Tag>
struct tag_override
#include <tag_priority_dispatch.hpp> hpx::functional::tag_override<Tag> defines a base class that implements the necessary tag dispatching functionality for a given type Tag

template<typename Tag>
struct tag_override_noexcept
#include <tag_priority_dispatch.hpp> hpx::functional::tag_override_noexcept<Tag> defines a base class that implements the necessary tag dispatching functionality for a given type Tag where the implementation is required to be noexcept

namespace util

class jenkins_hash

#include <jenkins_hash.hpp> The jenkins_hash class encapsulates a hash calculation function published by Bob Jenkins here: [http://burtleburtle.net/bob/hash](http://burtleburtle.net/bob/hash)

Public Types

```cpp
enum seedenum

The seedenum is used as a dummy parameter to distinguish the different constructors

Values:

```cpp
seed = 1

typedef std::uint32_t size_type

this is the type representing the result of this hash

Public Functions

```cpp
jenkins_hash()

constructors and destructor

```cpp
jenkins_hash(size_type size)

```cpp
jenkins_hash(size_type seedval, seedenum)

```cpp
~jenkins_hash()```
size_type operator() (std::string const &key) const
calculate the hash value for the given key

size_type operator() (char const *key) const

bool reset (size_type size)
re-seed the hash generator

void set_seed (size_type seedval)
initialize the hash generator to a specific seed

void swap (jenkins_hash &rhs)
support for std::swap

Protected Functions

size_type hash (const char *k, std::size_t length) const

Private Members

io_service

The contents of this module can be included with the header hpx/modules/io_service.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/io_service.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

namespace hpx
namespace util

class io_service_pool
#include <io_service_pool.hpp> A pool of io_service objects.

Public Functions

HPX_NON_COPYABLE (io_service_pool)

io_service_pool (std::size_t pool_size = 2, threads::policies::callback_notifier const &notifier = threads::policies::callback_notifier(), char const *pool_name = "", char const *name_postfix = "")
Construct the io_service pool.

Parameters
• pool_size: [in] The number of threads to run to serve incoming requests
• start_thread: [in]

io_service_pool (threads::policies::callback_notifier const &notifier, char const *pool_name = "", char const *name_postfix = "")
Construct the io_service pool.

Parameters
• start_thread: [in]

~io_service_pool ()

bool run (bool join_threads = true, barrier *startup = nullptr)
Run all io_service objects in the pool. If join_threads is true this will also wait for all threads to complete

bool run (std::size_t num_threads, bool join_threads = true, barrier *startup = nullptr)
Run all io_service objects in the pool. If join_threads is true this will also wait for all threads to complete

void stop ()
Stop all io_service objects in the pool.

void join ()
Join all io_service threads in the pool.

void clear ()
Clear all internal data structures.

void wait ()
Wait for all work to be done.

bool stopped ()

asio::io_context &get_io_service (int index = -1)
Get an io_service to use.

std::thread &get_os_thread_handle (std::size_t thread_num)
access underlying thread handle
std::size_t size() const
    Get number of threads associated with this I/O service.

void thread_run (std::size_t index, barrier *startup = nullptr)
    Activate the thread index for this thread pool.

char const *get_name () const
    Return name of this pool.

Protected Functions

bool run_locked (std::size_t num_threads, bool join_threads, barrier *startup)

void stop_locked()

void join_locked()

void clear_locked()

void wait_locked()

Private Types

using io_service_ptr = std::unique_ptr<asio::io_context>

using work_type = asio::io_context::work

Private Functions

work_type initialize_work (asio::io_context &io_service)

Private Members

std::mutex mtx_

std::vector<io_service_ptr> io_services_
    The pool of io_services.

std::vector<thread> threads_

std::vector<work_type> work_
    The work that keeps the io_services running.

std::size_t next_io_service_
    The next io_service to use for a connection.

bool stopped_
    set to true if stopped

std::size_t pool_size_
    initial number of OS threads to execute in this pool

threads::policies::callback_notifier const &notifier_
    call this for each thread start/stop

char const *pool_name_
iterator_support

logging

The contents of this module can be included with the header `hpx/modules/logging.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/logging.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

```cpp
namespace hpx
{
    namespace util
    {
        namespace logging
        {

            Enums
            
            enum level
            {
                disable_all = static_cast<unsigned int>(-1),
                enable_all = 0,
                debug = 1000,
                info = 2000,
                warning = 3000,
                error = 4000,
                fatal = 5000,
                always = 6000
            }

            enum level, Handling levels - classes that can hold and/or deal with levels.

            • filters and level holders
            By default we have these levels:

            - debug (smallest level),
            - info,
            - warning ,
            - error ,
            - fatal (highest level)

            Depending on which level is enabled for your application, some messages will reach the log: those messages having at least that level. For instance, if info level is enabled, all logged messages will reach the log. If warning level is enabled, all messages are logged, but the warnings. If debug level is enabled, messages that have levels debug, error, fatal will be logged.

            Values:
            disable_all = static_cast<unsigned int>(-1)
            enable_all = 0
            debug = 1000
            info = 2000
            warning = 3000
            error = 4000
            fatal = 5000
            always = 6000
        }
    }
}
```
Functions

void format_value (std::ostream &os, boost::string_ref spec, level value)

Include this file when you’re using the logging lib, but don’t necessarily want to use formatters and destinations. If
you want to use formatters and destinations, then you can include this one instead:

#include <hpx/logging/format.hpp>

namespace hpx

namespace util

namespace logging

namespace destination

Destination is a manipulator. It contains a place where the message, after being formatted, is to be written to.

Some viable destinations are: the console, a file, a socket, etc.

struct manipulator

#include <manipulator.hpp> What to use as base class, for your destination classes.

Subclassed by hpx::util::logging::destination::cerr, hpx::util::logging::destination::cout,
hpx::util::logging::destination::dbg_window, hpx::util::logging::destination::file,
hpx::util::logging::destination::stream

Public Functions

virtual void operator() (message const&) = 0

virtual void configure (std::string const&)

Override this if you want to allow configuration through scripting.

That is, this allows configuration of your manipulator at run-time.

virtual ~manipulator ()

Protected Functions

manipulator ()

namespace formatter

Formatter is a manipulator. It allows you to format the message before writing it to the destination(s)

Examples of formatters are: prepend the time, prepend high-precision time, prepend the index of the message, etc.
**struct manipulator**  
#include <manipulator.hpp> What to use as base class, for your formatter classes.  
Subclassed by hpx::util::logging::formatter::high_precision_time,  
hpx::util::logging::formatter::idx, hpx::util::logging::formatter::thread_id

### Public Functions

**virtual void operator()** (std::ostream & const = 0

**virtual void configure** (std::string const &)  
Override this if you want to allow configuration through scripting.  
That is, this allows configuration of your manipulator at run-time.

**virtual ~manipulator** ()

### Protected Functions

**manipulator** ()

### Friends

void **format_value** (std::ostream & os, boost::string_ref, manipulator const &value)

---

**namespace hpx**

**namespace util**

**namespace logging**

**class message**  
#include <message.hpp> Optimizes the formatting for prepending and/or appending strings to the original message.  
It keeps all the modified message in one string. Useful if some formatter needs to access the whole string at once.  
reserve() - the size that is reserved for prepending (similar to string::reserve function)  
Note : as strings are prepended, reserve() shrinks.

### Public Functions

**message** ()

**message** (std::stringstream msg)

#### Parameters

- **msg** - the message that is originally cached

**message** (message &&other)
template<
type T>  
message &operator<<( T &v)

template<
type ..Args>  
message &format (boost::string_ref format_str, Args const&... args)

std::string const &full_string() const  
returns the full string

bool empty() const

**Private Members**

std::stringstream m_str  
bool m_full_msg_computed  
std::string m_full_msg

**Friends**

std::ostream &operator<<( std::ostream &os, message const &value)  

**namespace hpx**

**namespace util**

**namespace logging**

**namespace destination**

Destination is a manipulator. It contains a place where the message, after being formatted, is to be written to.

Some viable destinations are: the console, a file, a socket, etc.

**struct cerr** : public hpx::util::logging::destination::manipulator  
#include <destinations.hpp> Writes the string to cerr.

**Public Functions**

~cerr()

**Public Static Functions**

static std::unique_ptr<cerr> make ()
Protected Functions

cerr()

struct cout : public hpx::util::logging::destination::manipulator
#include <destinations.hpp> Writes the string to console.

Public Functions

~cout()

Public Static Functions

static std::unique_ptr<cout> make()

Protected Functions

cout()

struct dbg_window : public hpx::util::logging::destination::manipulator
#include <destinations.hpp> Writes the string to output debug window.
For non-Windows systems, this is the console.

Public Functions

~dbg_window()

Public Static Functions

static std::unique_ptr<dbg_window> make()

Protected Functions

dbg_window()

struct file : public hpx::util::logging::destination::manipulator
#include <destinations.hpp> Writes the string to a file.

Public Functions

~file()
Public Static Functions

```cpp
static std::unique_ptr<file> make (std::string const &file_name, file_settings set = {}) constructs the file destination
```

Parameters
- `file_name`: name of the file
- `set`: [optional] file settings - see `file_settings` class, and dealing_with_flags

Protected Functions

```cpp
file (std::string const &file_name, file_settings set)
```

Protected Attributes

```cpp
std::string name
file_settings settings
```

```cpp
struct file_settings
#include <destinations.hpp> settings for when constructing a file class. To see how it’s used, see dealing_with_flags.
```

Public Functions

```cpp
file_settings ()
```

Public Members

```cpp
bool flush_each_time : 1
  if true (default), flushes after each write

bool initial_overwrite : 1

bool do_append : 1

std::ios_base::openmode extra_flags
  just in case you have some extra flags to pass, when opening the file
```

```cpp
struct stream: public hpx::util::logging::destination::manipulator
#include <destinations.hpp> writes to stream.
```

Note: The stream must outlive this object! Or, clear() the stream, before the stream is deleted.
Public Functions

~stream()

void set_stream (std::ostream *stream_ptr)
   resets the stream. Further output will be written to this stream

void clear()
   clears the stream. Further output will be ignored

namespace hpx

namespace util

namespace logging

namespace formatter

Formatter is a manipulator. It allows you to format the message before writing it to the destination(s)

Examples of formatters are: prepend the time, prepend high-precision time, prepend the index of the message, etc.

struct high_precision_time : public hpx::util::logging::formatter::manipulator
   #include <formatters.hpp> Prefixes the message with a high-precision time (. You pass the format string at construction.

#include <hpx/logging/format/formatter/high_precision_time.hpp>

Internally, it uses hpx::util::date_time::microsec_time_clock. So, our precision matches this class.

The format can contain escape sequences: $dd - day, 2 digits $MM - month, 2 digits $yy - year, 2 digits $yyyy - year, 4 digits $hh - hour, 2 digits $mm - minute, 2 digits $ss - second, 2 digits $mili - milliseconds $micro - microseconds (if the high precision clock allows; otherwise, it pads zeros) $nano - nanoseconds (if the high precision clock allows; otherwise, it pads zeros)

Example:
```cpp
high_precision_time("$mm:$ss:$micro");
```

**Parameters**

- **convert**: [optional] In case there needs to be a conversion between std::(w)string and the string that holds your logged message. See `convert_format`.

**Public Functions**

```cpp
~high_precision_time()
```

**Public Static Functions**

```cpp
static std::unique_ptr<high_precision_time> make(std::string const &format)
```

**Protected Functions**

```cpp
high_precision_time(std::string const &format)
```

```cpp
struct idx : public hpx::util::logging::formatter::manipulator
#include <formatters.hpp> prefixes each message with an index.
```

Example:

```cpp
L_ << "my message";
L_ << "my 2nd message";
```

This will output something similar to:

```
[1] my message
[2] my 2nd message
```

**Public Functions**

```cpp
~idx()
```

**Public Static Functions**

```cpp
static std::unique_ptr<idx> make()
```
Protected Functions

\texttt{idx}()

\textbf{struct thread\textunderscore id:} \textbf{public} \texttt{hpx::util::logging::formatter::manipulator}  
\texttt{#include <formatters.hpp>} \texttt{W}rites \texttt{the thread\textunderscore id} to the log.

\textbf{Parameters}

\begin{itemize}
  \item \texttt{convert:} [optional] In case there needs to be a conversion between \texttt{std:\textbackslash{}(w)string} and the string that holds your logged message. See convert\_format.
\end{itemize}

Public Functions

\texttt{~thread\textunderscore id()}  

Public Static Functions

\texttt{\textbf{static std::unique\_ptr<thread\_id>} make()}  

Protected Functions

\texttt{name\_space hpx}  
\texttt{name\_space util}  
\texttt{name\_space logging}  
\texttt{name\_space writer}  

\textbf{struct named\_write}  
\texttt{#include <named\_write.hpp>} \texttt{Composed of a named formatter and a named destinations. Thus, you can specify the formatting and destinations as strings.}

\texttt{#include <hpx/logging/format/named\_write.hpp>}  

Contains a very easy interface for using formatters and destinations:  
\begin{itemize}
  \item at construction, specify 2 params: the formatter string and the destinations string
\end{itemize}

Setting the formatters and destinations to write to is extremely simple:

\begin{verbatim}
// Set the formatters (first param) and destinations (second step) in one step  
g\_l()\rightarrow writer().write("%time\%(hh:mm:ss.\milli\) [%idx\%] \n",  
"cout file(out.txt) debug");
\end{verbatim}
// set the formatter(s)
g_l()->writer().format("%time%($hh:$mm:$ss.$mili) [%idx%] |

// set the destination(s)
g_l()->writer().destination("cout file(out.txt) debug");

**Public Functions**

**named_write()**

void **format**(std::string const &format_str)

sets the format string: what should be before, and what after the original message, separated by “|”

Example: “[%idx%] \n” - this writes “[%idx%] ” before the message, and “\n” after the message

If “|” is not present, the whole message is prepended to the message

void **destination**(std::string const &destination_str)

sets the destinations string - where should logged messages be outputted

void **write**(std::string const &format_str, std::string const &destination_str)

Specifies the formats and destinations in one step.

void **operator()**(message const &msg) const

**template<typename Formatter>**

void **set_formatter**(std::string const &name, Formatter fmt)

Replaces a formatter from the named formatter.

You can use this, for instance, when you want to share a formatter between multiple named writers.

**template<typename Formatter, typename ... Args>**

void **set_formatter**(std::string const &name, Args&&... args)

**template<typename Destination>**

void **set_destination**(std::string const &name, Destination dest)

Replaces a destination from the named destination.

You can use this, for instance, when you want to share a destination between multiple named writers.

**template<typename Destination, typename ... Args>**

void **set_destination**(std::string const &name, Args&&... args)

preprocessor

The contents of this module can be included with the header hpx/modules/preprocessor.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/preprocessor.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

Defines

HPX_PP_CAT (A, B)

Concatenates the tokens A and B into a single token. Evaluates to AB

Parameters

• A: First token
• B: Second token

Defines

HPX_PP_EXPAND (X)

The HPX_PP_EXPAND macro performs a double macro-expansion on its argument. This macro can be used to produce a delayed preprocessor expansion.

Parameters

• X: Token to be expanded twice

Example:

#define MACRO(a, b, c) (a)(b)(c)
#define ARGS() (1, 2, 3)

HPX_PP_EXPAND (MACRO ARGS())  // expands to (1)(2)(3)
Defines

**HPX_PP_IDENTITY (...)**

Defines **HPX_PP_NARGS (...)**

Expands to the number of arguments passed in

```
HPX_PP_NARGS(hpx, pp, nargs)
HPX_PP_NARGS(hpx, pp)
HPX_PP_NARGS(hpx)
```

**Parameters**

- . . . : The variadic number of arguments

Expands to:

```
3
2
1
```

Defines

**HPX_PP_STRINGIZE (X)**

The **HPX_PP_STRINGIZE** macro stringizes its argument after it has been expanded.

The passed argument `X` will expand to "X". Note that the stringizing operator (#) prevents arguments from expanding. This macro circumvents this shortcoming.

**Parameters**

- `X`: The text to be converted to a string literal

Defines

**HPX_PP_STRIP_PARENS (X)**

For any symbol `X`, this macro returns the same symbol from which potential outer parens have been removed. If no outer parens are found, this macro evaluates to `X` itself without error.

The original implementation of this macro is from Steven Watanbe as shown in [http://boost.2283326.n4.nabble.com/preprocessor-removing-parentheses-td2591973.html#a2591976](http://boost.2283326.n4.nabble.com/preprocessor-removing-parentheses-td2591973.html#a2591976)

```
HPX_PP_STRIP_PARENS(no_parens)
HPX_PP_STRIP_PARENS((with_parens))
```

Example Usage:
Parameters

- $X$: Symbol to strip parens from

This produces the following output

```
no_parens
with_parens
```

**properties**

The contents of this module can be included with the header `hpx/modules/properties.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/properties.hpp`, not the particular header in which the functionality you would like to use is defined. See *Public API* for a list of names that are part of the public *HPX* API.

```cpp
namespace hpx
{
    namespace experimental
    {
        Variables
        {
            hpx::experimental::prefer_t prefer
            {
                struct prefer_t : public hpx::functional::tag_fallback<prefer_t>
            }
        }
    }
}
```

**Friends**

```cpp
template<
    typename Tag, 
    typename ...Tn>
friend constexpr auto tag_fallback_dispatch (prefer_t, Tag tag, Tn&&... tn)

template<
    typename Tag, 
    typename T0, 
    typename ...Tn>
friend constexpr auto tag_fallback_dispatch (prefer_t, Tag, T0 &&t0, Tn&&...)
```

**schedulers**

The contents of this module can be included with the header `hpx/modules/schedulers.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/schedulers.hpp`, not the particular header in which the functionality you would like to use is defined. See *Public API* for a list of names that are part of the public *HPX* API.

```cpp
namespace hpx
{
    namespace threads
    {
        namespace policies
        {
        }
    }
}
```
Typedefs

```cpp
using default_local_priority_queue_scheduler_terminated_queue = lockfree_fifo
```

```cpp
template<typename Mutex = std::mutex, typename PendingQueuing = lockfree_fifo,
  typename StagedQueuing = lockfree_fifo, typename TerminatedQueuing =
default_local_priority_queue_scheduler_terminated_queue>
class local_priority_queue_scheduler : public scheduler_base
```

```cpp
#include <local_priority_queue_scheduler.hpp>
The `local_priority_queue_scheduler` maintains exactly one queue of work items (threads) per OS thread, where this OS thread pulls its next work from. Additionally it maintains separate queues: several for high priority threads and one for low priority threads. High priority threads are executed by the first N OS threads before any other work is executed. Low priority threads are executed by the last OS thread whenever no other work is available.

Public Types

```cpp
typedef std::false_type has_periodic_maintenance
typedef thread_queue<Mutex, PendingQueuing, StagedQueuing, TerminatedQueuing> thread_queue_type
typedef init_parameter init_parameter_type
```

Public Functions

```cpp
local_priority_queue_scheduler (init_parameter_type const &init, bool deferred_initialization = true)
~local_priority_queue_scheduler ()
void abort_all_suspended_threads ()
bool cleanup_terminated (bool delete_all)
bool cleanup_terminated (std::size_t num_thread, bool delete_all)
void create_thread (thread_init_data &data, thread_id_type *id, error_code &ec)
bool get_next_thread (std::size_t num_thread, bool running, threads::thread_data *thrd, bool enable_stealing)
  Return the next thread to be executed, return false if none is available
void schedule_thread (threads::thread_data *thrd, threads::thread_schedule_hint schedulehint, bool allow_fallback = false, thread_priority priority = thread_priority::normal)
  Schedule the passed thread.
void schedule_thread_last (threads::thread_data *thrd, threads::thread_schedule_hint schedulehint, bool allow_fallback = false, thread_priority priority = thread_priority::normal)
void destroy_thread (threads::thread_data *thrd)
  Destroy the passed thread as it has been terminated.
std::int64_t get_queue_length (std::size_t num_thread = std::size_t(-1)) const
```
\begin{verbatim}
std::int64_t get_thread_count (thread_schedule_state state = thread_schedule_state::unknown, thread_priority priority = thread_priority::default_, std::size_t num_thread = std::size_t(-1), bool = false) const

bool is_core_idle (std::size_t num_thread) const

bool enumerate_threads (util::function_nonser<bool> thread_id_type
    > const &f, thread_schedule_state state = thread_schedule_state::unknown const

bool wait_or_add_new (std::size_t num_thread, bool running, std::int64_t &idle_loop_count, bool enable_stealing, std::size_t &added)

This is a function which gets called periodically by the thread manager to allow for maintenance tasks to be executed in the scheduler. Returns true if the OS thread calling this function has to be terminated (i.e. no more work has to be done).

void on_start_thread (std::size_t num_thread)

void on_stop_thread (std::size_t num_thread)

template<typename Mutex = std::mutex, typename PendingQueuing = concurrentqueue_fifo, typename TerminatedQueuing = default_shared_priority_queue_scheduler_terminated_queue>
class shared_priority_queue_scheduler : public scheduler_base
#include <shared_priority_queue_scheduler.hpp> The shared_priority_queue_scheduler maintains a set of high, normal, and low priority queues. For each priority level there is a core/queue ratio which determines how many cores share a single queue. If the high priority core/queue ratio is 4 the first 4 cores will share a single high priority queue, the next 4 will share another one and so on. In addition, the shared_priority_queue_scheduler is NUMA-aware and takes NUMA scheduling hints into account when creating and scheduling work.

Warning: PendingQueuing lifo causes lockup on termination

template<typename Mutex = std::mutex, typename PendingQueuing = lockfree_fifo, typename StagedQueuing = lockfree_fifo, typename TerminatedQueuing = default_static_priority_queue_scheduler_terminated_queue>
class static_priority_queue_scheduler : public hpx::threads::policies::local_priority_queue_scheduler
#include <static_priority_queue_scheduler.hpp> The static_priority_queue_scheduler maintains exactly one queue of work items (threads) per OS thread, where this OS thread pulls its next work from. Additionally it maintains separate queues: several for high priority threads and one for low priority threads. High priority threads are executed by the first N OS threads before any other work is executed. Low priority threads are executed by the last OS thread whenever no other work is available. This scheduler does not do any work stealing.

The contents of this module can be included with the header hpx/modules/serialization.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/serialization.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

The contents of this module can be included with the header `hpx/modules/synchronization.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/synchronization.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

```cpp
namespace hpx

namespace experimental

template<typename ReadWriteT, typename ReadT, typename Allocator>
class async_rw_mutex
#include <async_rw_mutex.hpp> Read-write mutex where access is granted to a value through senders.

The wrapped value is accessed through read and readwrite, both of which return senders which call set_value on a connected receiver when the wrapped value is safe to read or write. The senders send the value through a wrapper type which is implicitly convertible to a reference of the wrapped value. Read-only senders send wrappers that are convertible to const references.

A read-write sender gives exclusive access to the wrapped value, while a read-only sender gives shared (with other read-only senders) access to the value.

A void mutex acts as a mutex around some user-managed resource, i.e. the void mutex does not manage any value and the types sent by the senders are not convertible. The sent types are copyable and release access to the protected resource when released.

The order in which senders call set_value is determined by the order in which the senders are retrieved from the mutex. Connecting and starting the senders is thread-safe.

Retrieving senders from the mutex is not thread-safe.

The mutex is movable and non-copyable.

namespace hpx

```cpp
namespace lcos
```
namespace local

class barrier
#include <barrier.hpp> A barrier can be used to synchronize a specific number of threads, blocking all of the entering threads until all of the threads have entered the barrier.

Note A barrier is not a LCO in the sense that it has no global id and it can’t be triggered using the action (parcel) mechanism. It is just a low level synchronization primitive allowing to synchronize a given number of threads.

Public Functions

barrier (std::size_t number_of_threads)
~barrier ()
void wait ()
    The function wait will block the number of entering threads (as given by the constructor parameter number_of_threads), releasing all waiting threads as soon as the last thread entered this function.

void count_up ()
    The function count_up will increase the number of threads to be waited in wait function.

void reset (std::size_t number_of_threads)
    The function reset will reset the number of threads as given by the function parameter number_of_threads. The new coming threads executing the function wait will be waiting until total_ is equal to barrier_flag. The last thread exiting the wait function will notify the newer threads waiting and the newer threads will get the reset number_of_threads_. The function reset can be executed while previous threads executing waiting after they have been waken up. Thus total_ can not be reset to barrier_flag which will break the comparison condition under the function wait.

class cpp20_latch
   #include <latch.hpp> Latches are a thread coordination mechanism that allow one or more threads to block until an operation is completed. An individual latch is a single-use object; once the operation has been completed, the latch cannot be reused.

Subclassed by hpx::lcos::local::latch

Public Functions

HPX_NON_COPYABLE (cpp20_latch)

cpp20_latch (std::ptrdiff_t count)
   Initialize the latch
   Requires: count >= 0. Synchronization: None Postconditions: counter_ == count.

~cpp20_latch ()
   Requires: No threads are blocked at the synchronization point.

   Note May be called even if some threads have not yet returned from wait() or count_down_and_wait(), provided that counter_ is 0.

   Note The destructor might not return until all threads have exited wait() or count_down_and_wait().

   Note It is the caller’s responsibility to ensure that no other thread enters wait() after one thread has called the destructor. This may require additional coordination.

void count_down (std::ptrdiff_t update)
   Decrements counter_ by n. Does not block.
   Requires: counter_ >= n and n >= 0.

   Synchronization: Synchronizes with all calls that block on this latch and with all try_wait calls on this latch that return true .

Exceptions

   • Nothing.

bool try_wait () const
   Returns: With very low probability false. Otherwise counter == 0.
void \textbf{wait} \() \textbf{const} \\
\text{If counter\_ is 0, returns immediately. Otherwise, blocks the calling thread at the synchronization point until counter\_ reaches 0.}

\textbf{Exceptions}  
\begin{itemize}  
\item Nothing.:  
\end{itemize}

void \textbf{arrive_and_wait} (std::ptrdiff_t \textbf{update} = 1) \\
\text{Effects: Equivalent to: count_down(update); wait();}

\textbf{Public Static Functions}  

\textbf{static constexpr std::ptrdiff_t}() \textbf{hpx::lcos::local::cpp20_latch::max()}  
\text{Returns: The maximum value of counter that the implementation supports.}

\textbf{Protected Types}  

\textbf{using mutex\_type} = lcos::local::spinlock

\textbf{Protected Attributes}  

util::cache\_line\_data<mutex\_type> \textbf{mtx\_}

util::cache\_line\_data<local::detail::condition\_variable> \textbf{cond\_}

std::atomic<std::ptrdiff_t> \textbf{counter\_}

bool \textbf{notified\_}

\textbf{class latch::public hpx::lcos::local::cpp20\_latch}  

\#include <latch.hpp> A latch maintains an internal counter\_ that is initialized when the latch is created. Threads may block at a synchronization point waiting for counter\_ to be decremented to 0. When counter\_ reaches 0, all such blocked threads are released.

Calls to \textbf{countdown\_and\_wait()}, \textbf{count\_down()}, \textbf{wait()}, \textbf{is\_ready()}, \textbf{count\_up()}, and \textbf{reset()} behave as atomic operations.

\textbf{Note} A local::latch is not an LCO in the sense that it has no global id and it can’t be triggered using the action (parcel) mechanism. Use lcos::latch instead if this is required. It is just a low level synchronization primitive allowing to synchronize a given number of threads.

\textbf{Public Functions}  

\textbf{HPX\_NON\_COPYABLE} (latch)  

\textbf{latch} (std::ptrdiff_t \textbf{count})  
\text{Initialize the latch}  
\text{Requires: count >= 0. Synchronization: None Postconditions: counter\_ == count.}

\textbf{~latch()}  
\text{Requires: No threads are blocked at the synchronization point.}
Note May be called even if some threads have not yet returned from \texttt{wait()} or \texttt{count_down_and_wait()}, provided that \texttt{counter_} is 0.

Note The destructor might not return until all threads have exited \texttt{wait()} or \texttt{count_down_and_wait()}.

Note It is the caller’s responsibility to ensure that no other thread enters \texttt{wait()} after one thread has called the destructor. This may require additional coordination.

\begin{verbatim}
void count_down_and_wait()
    Decrements \texttt{counter_} by 1. Blocks at the synchronization point until \texttt{counter_} reaches 0.
    Requires: \texttt{counter_} > 0.
    Synchronization: Synchronizes with all calls that block on this latch and with all \texttt{is_ready} calls on this latch that return true.

Exceptions
    • Nothing.
\end{verbatim}

\begin{verbatim}
bool is_ready() const
    Returns: \texttt{counter_} == 0. Does not block.

Exceptions
    • Nothing.
\end{verbatim}

\begin{verbatim}
void abort_all()

void count_up(std::ptrdiff_t n)
    Increments \texttt{counter_} by \texttt{n}. Does not block.
    Requires: \texttt{n} \geq 0.

Exceptions
    • Nothing.
\end{verbatim}

\begin{verbatim}
void reset(std::ptrdiff_t n)
    Reset \texttt{counter_} to \texttt{n}. Does not block.
    Requires: \texttt{n} \geq 0.

Exceptions
    • Nothing.
\end{verbatim}

typedef sliding_semaphore_var sliding_semaphore

template<typename Mutex = hpx::lcos::local::spinlock>
class sliding_semaphore_var

#include <sliding_semaphore.hpp> A semaphore is a protected variable (an entity storing a value) or abstract data type (an entity grouping several variables that may or may not be numerical) which constitutes the classic method for restricting access to shared resources, such as shared memory, in a multiprogramming environment. Semaphores exist in many variants, though usually the term refers to a counting semaphore, since a binary semaphore is better known as a mutex. A counting semaphore is a counter for a set of available resources, rather than a locked/unlocked flag of a single resource. It was invented by Edsger Dijkstra. Semaphores are the classic solution to preventing race conditions in the dining philosophers problem, although they do not prevent resource deadlocks.

Sliding semaphores can be used for synchronizing multiple threads as well: one thread waiting for several other threads to touch (signal) the semaphore, or several threads waiting for one other thread to touch this semaphore. The difference to a counting semaphore is that a sliding semaphore will not limit the number of threads which are allowed to proceed, but will make sure that the difference between the (arbitrary) number passed to set and wait does not exceed a given threshold.

Public Functions

sliding_semaphore_var (std::int64_t max_difference, std::int64_t lower_limit = 0)
Construct a new sliding semaphore.

Parameters
  • max_difference: [in] The max difference between the upper limit (as set by wait()) and the lower limit (as set by signal()) which is allowed without suspending any thread calling wait().
  • lower_limit: [in] The initial lower limit.

void set_max_difference (std::int64_t max_difference, std::int64_t lower_limit = 0)
Set/Change the difference that will cause the semaphore to trigger.

Parameters
  • max_difference: [in] The max difference between the upper limit (as set by wait()) and the lower limit (as set by signal()) which is allowed without suspending any thread calling wait().
- **lower_limit**: [in] The initial lower limit.

```cpp
void wait (std::int64_t upper_limit)
Wait for the semaphore to be signaled.
```

**Parameters**
- **upper_limit**: [in] The new upper limit. The calling thread will be suspended if the difference between this value and the largest lower_limit which was set by `signal()` is larger than the max_difference.

```cpp
bool try_wait (std::int64_t upper_limit = 1)
Try to wait for the semaphore to be signaled.
```

**Return** The function returns true if the calling thread would not block if it was calling `wait()`.

**Parameters**
- **upper_limit**: [in] The new upper limit. The calling thread will be suspended if the difference between this value and the largest lower_limit which was set by `signal()` is larger than the max_difference.

```cpp
void signal (std::int64_t lower_limit)
Signal the semaphore.
```

**Parameters**
- **lower_limit**: [in] The new lower limit. This will update the current lower limit of this semaphore. It will also re-schedule all suspended threads for which their associated upper limit is not larger than the lower limit plus the max_difference.

```cpp
std::int64_t signal_all ()
```

testing

The contents of this module can be included with the header `hpx/modules/testing.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/testing.hpp`, not the particular header in which the functionality you would like to use is defined. See `Public API` for a list of names that are part of the public HPX API.

thread_function_type make_thread_function(F &&f)
```

```cpp
template<typename F>
thread_function_type make_thread_function_nullary(F &&f)
```

```cpp
threads::thread_id_type register_thread(threads::thread_init_data &data, threads::thread_pool_base *pool, error_code &ec = throws)
```

Create a new thread using the given data.
Return This function will return the internal id of the newly created HPX-thread.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters
• data: [in] The data to use for creating the thread.
• pool: [in] The thread pool to use for launching the work.
• ec: [in,out] This represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

Exceptions
• invalid_status: if the runtime system has not been started yet.

threads::thread_id_type register_thread (threads::thread_init_data &data, error_code &ec = throws)
Create a new thread using the given data on the same thread pool as the calling thread, or on the default thread pool if not on an HPX thread.

Return This function will return the internal id of the newly created HPX-thread.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters
• data: [in] The data to use for creating the thread.
• ec: [in,out] This represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

Exceptions
• invalid_status: if the runtime system has not been started yet.

void register_work (threads::thread_init_data &data, threads::thread_pool_base *pool, error_code &ec = throws)
Create a new work item using the given data.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters
• data: [in] The data to use for creating the thread.
• pool: [in] The thread pool to use for launching the work.
• ec: [in,out] This represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

Exceptions
• invalid_status: if the runtime system has not been started yet.

void register_work (threads::thread_init_data &data, error_code &ec = throws)
Create a new work item using the given data on the same thread pool as the calling thread, or on the default thread pool if not on an HPX thread.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters
• data: [in] The data to use for creating the thread.
• ec: [in,out] This represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

Exceptions
• invalid_status: if the runtime system has not been started yet.

namespace hpx

namespace threads

namespace policies

Enums

```cpp
define scheduler_mode

This enumeration describes the possible modes of a scheduler.

Values:

nothing_special = 0x000
As the name suggests, this option can be used to disable all other options.

do_background_work = 0x001
The scheduler will periodically call a provided callback function from a special HPX thread
to enable performing background-work, for instance driving networking progress or garbage-
collect AGAS.

reduce_thread_priority = 0x002
The kernel priority of the os-thread driving the scheduler will be reduced below normal.
```
**delay_exit** = 0x004
The scheduler will wait for some unspecified amount of time before exiting the scheduling loop while being terminated to make sure no other work is being scheduled during processing the shutdown request.

**fast_idle_mode** = 0x008
Some schedulers have the capability to act as ‘embedded’ schedulers. In this case it needs to periodically invoke a provided callback into the outer scheduler more frequently than normal. This option enables this behavior.

**enable_elasticity** = 0x010
This option allows for the scheduler to dynamically increase and reduce the number of processing units it runs on. Setting this value not succeed for schedulers that do not support this functionality.

**enable_stealing** = 0x020
This option allows schedulers that support work thread/stealing to enable/disable it

**enable_stealing_numa** = 0x040
This option allows schedulersthat support it to disallow stealing between numa domains

**assign_work_round_robin** = 0x080
This option tells schedulersthat support it to add tasks round robin to queues on each core

**assign_work_thread_parent** = 0x100
This option tells schedulers that support it to add tasks round to the same core/queue that the parent task is running on

**steal_high_priority_first** = 0x200
This option tells schedulers that support it to always (try to) steal high priority tasks from other queues before finishing their own lower priority tasks

**steal_after_local** = 0x400
This option tells schedulers that support it to steal tasks only when their local queues are empty

**enable_idle_backoff** = 0x0800
This option allows for certain schedulers to explicitly disable exponential idle-back off

**default_mode** = do_background_work | reduce_thread_priority | delay_exit | enable_stealing | enable_stealing_numa | assign_work_round_robin | assign_work_thread_parent | steal_high_priority_first | steal_after_local | enable_idle_backoff
This option represents the default mode.

**all_flags** = do_background_work | reduce_thread_priority | delay_exit | fast_idle_mode | enable_elasticity | enable_stealing | enable_stealing_numa | assign_work_round_robin | assign_work_thread_parent | steal_high_priority_first | steal_after_local | enable_idle_backoff
This enables all available options.

namespace threads

Functions

constexpr thread_data *get_thread_id_data (thread_id_type const &id)

thread_self &get_self ()

    The function get_self returns a reference to the (OS thread specific) self reference to the current HPX thread.

thread_self *get_self_ptr ()

    The function get_self_ptr returns a pointer to the (OS thread specific) self reference to the current HPX thread.

thread_self_impl_type *get_ctx_ptr ()

    The function get_ctx_ptr returns a pointer to the internal data associated with each coroutine.

thread_self *get_self_ptr_checked (error_code &ec = throws)

    The function get_self_ptr_checked returns a pointer to the (OS thread specific) self reference to the current HPX thread.

thread_id_type get_self_id ()

    The function get_self_id returns the HPX thread id of the current thread (or zero if the current thread is not a HPX thread).

thread_data *get_self_id_data ()

    The function get_self_id_data returns the data of the HPX thread id associated with the current thread (or nullptr if the current thread is not a HPX thread).

thread_id_type get_parent_id ()

    The function get_parent_id returns the HPX thread id of the current thread’s parent (or zero if the current thread is not a HPX thread).

Note This function will return a meaningful value only if the code was compiled with HPX_HAVE_THREAD_PARENT_REFERENCE being defined.
std::size_t get_parent_phase()

The function `get_parent_phase` returns the HPX phase of the current thread’s parent (or zero if the current thread is not a HPX thread).

**Note** This function will return a meaningful value only if the code was compiled with HPX_HAVE_THREAD_PARENT_REFERENCE being defined.

std::ptrdiff_t get_self_stacksize()

The function `get_self_stacksize` returns the stack size of the current thread (or zero if the current thread is not a HPX thread).

`thread_stacksize` get_self_stacksize_enum()

The function `get_self_stacksize_enum` returns the stack size of the I.

std::uint32_t get_parent_locality_id()

The function `get_parent_locality_id` returns the id of the locality of the current thread’s parent (or zero if the current thread is not a HPX thread).

**Note** This function will return a meaningful value only if the code was compiled with HPX_HAVE_THREAD_PARENT_REFERENCE being defined.

std::uint64_t get_self_component_id()

The function `get_self_component_id` returns the lva of the component the current thread is acting on.

**Note** This function will return a meaningful value only if the code was compiled with HPX_HAVE_THREAD_TARGET_ADDRESS being defined.

**class thread_data**

#include <thread_data.hpp> A thread is the representation of a ParalleX thread. It’s a first class object in ParalleX. In our implementation this is a user level thread running on top of one of the OS threads spawned by the thread-manager.

A thread encapsulates:

- A thread status word (see the functions `thread::get_state` and `thread::set_state`)
- A function to execute (the thread function)
- A frame (in this implementation this is a block of memory used as the threads stack)
- A block of registers (not implemented yet)

Generally, threads are not created or executed directly. All functionality related to the management of threads is implemented by the thread-manager.

Subclassed by hpx::threads::thread_data_stackful, hpx::threads::thread_data_stackless

**Public Types**

```cpp
using spinlock_pool = util::spinlock_pool<thread_data>
```
**Public Functions**

`thread_data (thread_data const&)`

`thread_data (thread_data&&)`

`thread_data &operator= (thread_data const&)`

`thread_data &operator= (thread_data&&)`

`thread_state get_state (std::memory_order order = std::memory_order_acquire) const`

The `get_state` function queries the state of this thread instance.

**Return** This function returns the current state of this thread. It will return one of the values as defined by the `thread_state` enumeration.

**Note** This function will be seldom used directly. Most of the time the state of a thread will be retrieved by using the function `threadmanager::get_state`.

`thread_state set_state (thread_schedule_state state, thread_restart_state state_ex = thread_restart_state::unknown, std::memory_order load_order = std::memory_order_acquire, std::memory_order exchange_order = std::memory_order_seq_cst)`

The `set_state` function changes the state of this thread instance.

**Note** This function will be seldom used directly. Most of the time the state of a thread will have to be changed using the threadmanager. Moreover, changing the thread state using this function does not change its scheduling status. It only sets the thread’s status word. To change the thread’s scheduling status `threadmanager::set_state` should be used.

**Parameters**

- `newstate`: [in] The new state to be set for the thread.

`bool set_state_tagged (thread_schedule_state newstate, thread_state &prev_state, thread_state &new_tagged_state, std::memory_order exchange_order = std::memory_order_seq_cst)`

`bool restore_state (thread_state new_state, thread_state old_state, std::memory_order load_order = std::memory_order_relaxed, std::memory_order load_exchange = std::memory_order_seq_cst)`

The `restore_state` function changes the state of this thread instance depending on its current state. It will change the state atomically only if the current state is still the same as passed as the second parameter. Otherwise it won’t touch the thread state of this instance.

**Note** This function will be seldom used directly. Most of the time the state of a thread will have to be changed using the threadmanager. Moreover, changing the thread state using this function does not change its scheduling status. It only sets the thread’s status word. To change the thread’s scheduling status `threadmanager::set_state` should be used.

**Return** This function returns `true` if the state has been changed successfully

**Parameters**

- `newstate`: [in] The new state to be set for the thread.
- `oldstate`: [in] The old state of the thread which still has to be the current state.

`bool restore_state (thread_schedule_state new_state, thread_restart_state state_ex, thread_state old_state, std::memory_order load_exchange = std::memory_order_seq_cst)`
constexpr std::uint64_t get_component_id() const

Protected Functions

thread_restart_state set_state_ex (thread_restart_state new_state)
The set_state function changes the extended state of this thread instance.

Note This function will be seldom used directly. Most of the time the state of a thread will have to be changed using the threadmanager.

Parameters
• newstate: [in] The new extended state to be set for the thread.

namespace threads

class thread_data_stackful : public hpx::threads::thread_data
#include <thread_data_stackful.hpp> A thread is the representation of a ParalleX thread. It’s a first class object in ParalleX. In our implementation this is a user level thread running on top of one of the OS threads spawned by the thread-manager.
A thread encapsulates:
• A thread status word (see the functions thread::get_state and thread::set_state)
• A function to execute (the thread function)
• A frame (in this implementation this is a block of memory used as the threads stack)
• A block of registers (not implemented yet)
Generally, threads are not created or executed directly. All functionality related to the management of threads is implemented by the thread-manager.

Functions

`util::thread_description get_thread_description(thread_id_type const &id, error_code &ec = throws)`

The function `get_thread_description` is part of the thread related API allows to query the description of one of the threads known to the thread-manager.

Return This function returns the description of the thread referenced by the `id` parameter. If the thread is not known to the thread-manager the return value will be the string “<unknown>”.

Note As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

Parameters

- `id`: [in] The thread id of the thread being queried.
- `ec`: [in,out] This represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

`util::thread_description set_thread_description(thread_id_type const &id, util::thread_description const &desc = util::thread_description(), error_code &ec = throws)`

`util::thread_description get_thread_lco_description(thread_id_type const &id, error_code &ec = throws)`

The function `suspend` will return control to the thread manager (suspends the current thread). It sets the new state of this thread to the thread state passed as the parameter.

**Note** Must be called from within a HPX-thread.

**Exceptions**
- If \&\&ec != \&\&throws, never throws, but will set \ec to an appropriate value when an error occurs. Otherwise, this function will throw an `hpx::exception` with an error code of `hpx::yield_aborted` if it is signaled with `wait_aborted`. If called outside of a HPX-thread, this function will throw an `hpx::exception` with an error code of `hpx::null_thread_id`. If this function is called while the thread-manager is not running, it will throw an `hpx::exception` with an error code of `hpx::invalid_status`.

The function `suspend` will return control to the thread manager (suspends the current thread). It sets the new state of this thread to `suspended` and schedules a wakeup for this thread at the given time.

**Note** Must be called from within a HPX-thread.

**Exceptions**
- If \&\&ec != \&\&throws, never throws, but will set \ec to an appropriate value when an error occurs. Otherwise, this function will throw an `hpx::exception` with an error code of `hpx::yield_aborted` if it is signaled with `wait_aborted`. If called outside of a HPX-thread, this function will throw an `hpx::exception` with an error code of `hpx::null_thread_id`. If this function is called while the thread-manager is not running, it will throw an `hpx::exception` with an error code of `hpx::invalid_status`.

2.8. API reference
The function `suspend` will return control to the thread manager (suspends the current thread). It sets the new state of this thread to **suspended** and schedules a wakeup for this threads at the given time.

**Note**  Must be called from within a HPX-thread.

**Exceptions**

- If: &ec != &throws, never throws, but will set `ec` to an appropriate value when an error occurs. Otherwise, this function will throw an `hpx::exception` with an error code of `hpx::yield_aborted` if it is signaled with `wait_aborted`. If called outside of a HPX-thread, this function will throw an `hpx::exception` with an error code of `hpx::null_thread_id`. If this function is called while the thread-manager is not running, it will throw an `hpx::exception` with an error code of `hpx::invalid_status`.

The function `suspend` will return control to the thread manager (suspends the current thread). It sets the new state of this thread to **suspended** and schedules a wakeup for this threads after the given duration.

**Note**  Must be called from within a HPX-thread.

**Exceptions**

- If: &ec != &throws, never throws, but will set `ec` to an appropriate value when an error occurs. Otherwise, this function will throw an `hpx::exception` with an error code of `hpx::yield_aborted` if it is signaled with `wait_aborted`. If called outside of a HPX-thread, this function will throw an `hpx::exception` with an error code of `hpx::null_thread_id`. If this function is called while the thread-manager is not running, it will throw an `hpx::exception` with an error code of `hpx::invalid_status`.

The function `suspend` will return control to the thread manager (suspends the current thread). It sets the new state of this thread to **suspended** and schedules a wakeup for this threads after the given duration.

**Note**  Must be called from within a HPX-thread.

**Exceptions**

- If: &ec != &throws, never throws, but will set `ec` to an appropriate value when an error occurs. Otherwise, this function will throw an `hpx::exception` with an error code of `hpx::yield_aborted` if it is signaled with `wait_aborted`. If called outside of a HPX-thread, this function will throw an `hpx::exception` with an error code of `hpx::null_thread_id`. If this function is called while the thread-manager is not running, it will throw an `hpx::exception` with an error code of `hpx::invalid_status`.

The function `suspend` will return control to the thread manager (suspends the current thread). It sets the new state of this thread to **suspended** and schedules a wakeup for this threads after the given duration.
The function `suspend` will return control to the thread manager (suspends the current thread). It sets the new state of this thread to `suspended` and schedules a wakeup for this thread after the given time (specified in milliseconds).

**Note** Must be called from within a HPX-thread.

**Exceptions**
- If `&ec != &throws`, never throws, but will set `ec` to an appropriate value when an error occurs. Otherwise, this function will throw an `hpx::exception` with an error code of `hpx::yield_aborted` if it is signaled with `wait_aborted`. If called outside of a HPX-thread, this function will throw an `hpx::exception` with an error code of `hpx::null_thread_id`. If this function is called while the thread-manager is not running, it will throw an `hpx::exception` with an error code of `hpx::invalid_status`.

`threads::thread_pool_base *get_pool(error_code &ec = throws)`

Returns a pointer to the pool that was used to run the current thread

**Exceptions**
- If `&ec != &throws`, never throws, but will set `ec` to an appropriate value when an error occurs. Otherwise, this function will throw an `hpx::exception` with an error code of `hpx::yield_aborted` if it is signaled with `wait_aborted`. If called outside of a HPX-thread, this function will throw an `hpx::exception` with an error code of `hpx::null_thread_id`. If this function is called while the thread-manager is not running, it will throw an `hpx::exception` with an error code of `hpx::invalid_status`.

namespace threads

**Functions**

`thread_state set_thread_state(thread_id_type const &id, thread_schedule_state state = thread_schedule_state::pending, thread_restart_state stateex = thread_restart_state::signaled, thread_priority priority = thread_priority::normal, bool retry_on_active = true, hpx::error_code &ec = throws)`

Set the thread state of the thread referenced by the thread_id `id`.

**Note** If the thread referenced by the parameter `id` is in `thread_state::active` state this function schedules a new thread which will set the state of the thread as soon as its not active anymore. The function returns `thread_state::active` in this case.

**Return** This function returns the previous state of the thread referenced by the `id` parameter. It will return one of the values as defined by the `thread_state` enumeration. If the thread is not known to the thread-manager the return value will be `thread_state::unknown`.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Parameters**
- `id`: [in] The thread id of the thread the state should be modified for.
- `state`: [in] The new state to be set for the thread referenced by the `id` parameter.
- `stateex`: [in] The new extended state to be set for the thread referenced by the `id` parameter.
- `priority`: [in]
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.
thread_id_type set_thread_state (thread_id_type const &id,
hpx::chrono::steady_time_point const &abs_time,
std::atomic<bool> *started, thread_schedule_state state
= thread_schedule_state::pending, thread_restart_state
stateex = thread_restart_state::timeout, thread_priority
priority = thread_priority::normal, bool retry_on_active =
true, error_code &ec = throws)

Set the thread state of the thread referenced by the thread_id id.

Set a timer to set the state of the given thread to the given new value after it expired (at the given time)

Return
Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters
• id: [in] The thread id of the thread the state should be modified for.
• abs_time: [in] Absolute point in time for the new thread to be run
• started: [in,out] A helper variable allowing to track the state of the timer helper thread
• state: [in] The new state to be set for the thread referenced by the id parameter.
• stateex: [in] The new extended state to be set for the thread referenced by the id parameter.
• priority:
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

thread_id_type set_thread_state (thread_id_type const &id,
hpx::chrono::steady_time_point const &abs_time,
thread_schedule_state state = thread_schedule_state::pending,
thread_restart_state stateex = thread_restart_state::timeout, thread_priority
priority = thread_priority::normal, bool retry_on_active =
true, error_code& = throws)

thread_id_type set_thread_state (thread_id_type const &id, hpx::chrono::steady_duration
const &rel_time, thread_schedule_state state =
thread_schedule_state::pending, thread_restart_state
stateex = thread_restart_state::timeout, thread_priority
priority = thread_priority::normal, bool retry_on_active =
true, error_code &ec = throws)

Set the thread state of the thread referenced by the thread_id id.

Set a timer to set the state of the given thread to the given new value after it expired (after the given duration)

Return
Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters
• id: [in] The thread id of the thread the state should be modified for.
• rel_time: [in] Time duration after which the new thread should be run
• state: [in] The new state to be set for the thread referenced by the id parameter.
• stateex: [in] The new extended state to be set for the thread referenced by the id parameter.
• priority:
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.
thread_state get_thread_state(thread_id_type const &id, error_code &ec = throws)

The function get_thread_backtrace is part of the thread related API allows to query the currently stored thread back trace (which is captured during thread suspension).

Return This function returns the currently captured stack back trace of the thread referenced by the id parameter. If the thread is not known to the thread-manager the return value will be the zero.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception. The function get_thread_state is part of the thread related API. It queries the state of one of the threads known to the thread-manager.

Return This function returns the thread state of the thread referenced by the id parameter. If the thread is not known to the thread-manager the return value will be terminated.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters
• id: [in] The thread id of the thread being queried.
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

Parameters
• id: [in] The thread id of the thread the state should be modified for.
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

std::size_t get_thread_phase(thread_id_type const &id, error_code &ec = throws)

The function get_thread_phase is part of the thread related API. It queries the phase of one of the threads known to the thread-manager.

Return This function returns the thread phase of the thread referenced by the id parameter. If the thread is not known to the thread-manager the return value will be ~0.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters
• id: [in] The thread id of the thread the phase should be modified for.
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

bool get_thread_interruption_enabled(thread_id_type const &id, error_code &ec = throws)

Returns whether the given thread can be interrupted at this point.

Return This function returns true if the given thread can be interrupted at this point in time. It will return false otherwise.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters
• id: [in] The thread id of the thread which should be queried.
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

bool set_thread_interruption_enabled(thread_id_type const &id, bool enable, error_code &ec = throws)

Set whether the given thread can be interrupted at this point.
Return This function returns the previous value of whether the given thread could have been interrupted.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters
• id: [in] The thread id of the thread which should receive the new value.
• enable: [in] This value will determine the new interruption enabled status for the given thread.
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

```cpp
bool get_thread_interruption_requested(thread_id_type const &id, error_code &ec = throws)
```

Returns whether the given thread has been flagged for interruption.

Return This function returns true if the given thread was flagged for interruption. It will return false otherwise.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters
• id: [in] The thread id of the thread which should be queried.
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

```cpp
void interrupt_thread(thread_id_type const &id, bool flag, error_code &ec = throws)
```

Flag the given thread for interruption.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters
• id: [in] The thread id of the thread which should be interrupted.
• flag: [in] The flag encodes whether the thread should be interrupted (if it is true), or ‘uninterrupted’ (if it is false).
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

```cpp
void interrupt_thread(thread_id_type const &id, error_code &ec = throws)
```

```cpp
void interruption_point(thread_id_type const &id, error_code &ec = throws)
```

Interrupt the current thread at this point if it was canceled. This will throw a thread_interrupted exception, which will cancel the thread.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters
• id: [in] The thread id of the thread which should be interrupted.
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

```cpp
threads::thread_priority get_thread_priority(thread_id_type const &id, error_code &ec = throws)
```

Return priority of the given thread
Note As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Parameters**
- `id`: [in] The thread id of the thread whose priority is queried.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
std::ptrdiff_t get_stack_size(thread_id_type const &id, error_code &ec = throws)
```
Return stack size of the given thread

**Parameters**
- `id`: [in] The thread id of the thread whose priority is queried.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
threads::thread_pool_base * get_pool(thread_id_type const &id, error_code &ec = throws)
```
Returns a pointer to the pool that was used to run the current thread

**Exceptions**
- If: &ec != &throws, never throws, but will set `ec` to an appropriate value when an error occurs. Otherwise, this function will throw an `hpx::exception` with an error code of `hpx::yield_aborted` if it is signaled with `wait_aborted`. If called outside of a HPX-thread, this function will throw an `hpx::exception` with an error code of `hpx::null_thread_id`. If this function is called while the thread-manager is not running, it will throw an `hpx::exception` with an error code of `hpx::invalid_status`.

Functions

std::size_t get_worker_thread_num()
Return the number of the current OS-thread running in the runtime instance the current HPX-thread is executed with.

This function returns the zero based index of the OS-thread which executes the current HPX-thread.

Note The returned value is zero based and its maximum value is smaller than the overall number of OS-threads executed (as returned by get_os_thread_count()).

Note This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

std::size_t get_worker_thread_num(error_code &ec)
Return the number of the current OS-thread running in the runtime instance the current HPX-thread is executed with.

This function returns the zero based index of the OS-thread which executes the current HPX-thread.

Note The returned value is zero based and its maximum value is smaller than the overall number of OS-threads executed (as returned by get_os_thread_count()). It will return -1 if the current thread is not a known thread or if the runtime is not in running state.

Note This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

Parameters

• ec: [in,out] this represents the error status on exit.

std::size_t get_local_worker_thread_num()
Return the number of the current OS-thread running in the current thread pool the current HPX-thread is executed with.

This function returns the zero based index of the OS-thread on the current thread pool which executes the current HPX-thread.

Note The returned value is zero based and its maximum value is smaller than the number of OS-threads executed on the current thread pool. It will return -1 if the current thread is not a known thread or if the runtime is not in running state.
Note This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

`std::size_t get_local_worker_thread_num(error_code &ec)`

Return the number of the current OS-thread running in the current thread pool the current HPX-thread is executed with.

This function returns the zero based index of the OS-thread on the current thread pool which executes the current HPX-thread.

Note The returned value is zero based and its maximum value is smaller than the number of OS-threads executed on the current thread pool. It will return -1 if the current thread is not a known thread or if the runtime is not in running state.

Note This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

Parameters

- `ec`: [in,out] this represents the error status on exit.

`std::size_t get_thread_pool_num()`

Return the number of the current thread pool the current HPX-thread is executed with.

This function returns the zero based index of the thread pool which executes the current HPX-thread.

Note The returned value is zero based and its maximum value is smaller than the number of thread pools started by the runtime. It will return -1 if the current thread pool is not a known thread pool or if the runtime is not in running state.

Note This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

`std::size_t get_thread_pool_num(error_code &ec)`

Return the number of the current thread pool the current HPX-thread is executed with.

This function returns the zero based index of the thread pool which executes the current HPX-thread.

Note The returned value is zero based and its maximum value is smaller than the number of thread pools started by the runtime. It will return -1 if the current thread pool is not a known thread pool or if the runtime is not in running state.

Note This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

Parameters

- `ec`: [in,out] this represents the error status on exit.

```

Suspends the given processing unit. Blocks until the processing unit has been suspended.

**Parameters**

- `virt_core`: [in] The processing unit on the the pool to be suspended. The processing units are indexed starting from 0.

```cpp
virtual void resume_processing_unit_direct (std::size_t virt_core, error_code &ec = throws) = 0
```

Resumes the given processing unit. Blocks until the processing unit has been resumed.

**Parameters**

- `virt_core`: [in] The processing unit on the the pool to be resumed. The processing units are indexed starting from 0.

```cpp
virtual void resume_direct (error_code &ec = throws) = 0
```

Resumes the thread pool. Blocks until all OS threads on the thread pool have been resumed.

**Parameters**

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
virtual void suspend_direct (error_code &ec = throws) = 0
```

Suspends the thread pool. Blocks until all OS threads on the thread pool have been suspended.

**Note** A thread pool cannot be suspended from an HPX thread running on the pool itself.
Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

Exceptions

- `hpx::exception`: if called from an HPX thread which is running on the pool itself.

```cpp
struct thread_pool_init_parameters
```

`struct topology`

Public Functions

`topology()`

`~topology()`

`std::size_t get_socket_number (std::size_t num_thread, error_code & = throws) const`

Return the Socket number of the processing unit the given thread is running on.

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

`std::size_t get_numa_node_number (std::size_t num_thread, error_code & = throws) const`

Return the NUMA node number of the processing unit the given thread is running on.
Parameters

• ec: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
mask_cref_type get_machine_affinity_mask (error_code &ec = throws) const
```

Return a bit mask where each set bit corresponds to a processing unit available to the application.

Parameters

• ec: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
mask_type get_service_affinity_mask (mask_cref_type used_processing_units, error_code &ec = throws) const
```

Return a bit mask where each set bit corresponds to a processing unit available to the service threads in the application.

Parameters

• `used_processing_units`: [in] This is the mask of processing units which are not available for service threads.
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
mask_cref_type get_socket_affinity_mask (std::size_t num_thread, error_code &ec = throws) const
```

Return a bit mask where each set bit corresponds to a processing unit available to the given thread inside the socket it is running on.

Parameters

• ec: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
mask_cref_type get_numa_node_affinity_mask (std::size_t num_thread, error_code &ec = throws) const
```

Return a bit mask where each set bit corresponds to a processing unit available to the given thread inside the NUMA domain it is running on.

Parameters

• ec: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
mask_type get_numa_node_affinity_mask_from_numa_node (std::size_t num_node) const
```

Return a bit mask where each set bit corresponds to a processing unit associated with the given NUMA node.

Parameters

• ec: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
mask_cref_type get_core_affinity_mask (std::size_t num_thread, error_code &ec = throws) const
```

Return a bit mask where each set bit corresponds to a processing unit available to the given thread inside the core it is running on.
Parameters
• \texttt{ec}: [in,out] this represents the error status on exit, if this is pre-initialized to \texttt{hpx::throws} the function will throw on error instead.

\begin{verbatim}
mask_cref_type get_thread_affinity_mask (std::size_t num_thread, error_code &ec = throws) const
\end{verbatim}

Return a bit mask where each set bit corresponds to a processing unit available to the given thread.

Parameters
• \texttt{ec}: [in,out] this represents the error status on exit, if this is pre-initialized to \texttt{hpx::throws} the function will throw on error instead.

\begin{verbatim}
void set_thread_affinity_mask (mask_cref_type mask, error_code &ec = throws) const
\end{verbatim}

Use the given bit mask to set the affinity of the given thread. Each set bit corresponds to a processing unit the thread will be allowed to run on.

Note Use this function on systems where the affinity must be set from inside the thread itself.

Parameters
• \texttt{ec}: [in,out] this represents the error status on exit, if this is pre-initialized to \texttt{hpx::throws} the function will throw on error instead.

\begin{verbatim}
mask_type get_thread_affinity_mask_from_lva (void const *lva, error_code &ec = throws) const
\end{verbatim}

Return a bit mask where each set bit corresponds to a processing unit co-located with the memory the given address is currently allocated on.

Parameters
• \texttt{ec}: [in,out] this represents the error status on exit, if this is pre-initialized to \texttt{hpx::throws} the function will throw on error instead.

\begin{verbatim}
void print_affinity_mask (std::ostream &os, std::size_t num_thread, mask_cref_type m,
                       const std::string &pool_name) const
\end{verbatim}

Prints the.

Parameters
• \texttt{m}: to \texttt{os} in a human readable form

\begin{verbatim}
bool reduce_thread_priority (error_code &ec = throws) const
\end{verbatim}

Reduce thread priority of the current thread.

Parameters
• \texttt{ec}: [in,out] this represents the error status on exit, if this is pre-initialized to \texttt{hpx::throws} the function will throw on error instead.

\begin{verbatim}
std::size_t get_number_of_sockets () const
\end{verbatim}

Return the number of available NUMA domains.

\begin{verbatim}
std::size_t get_number_of_numa_nodes () const
\end{verbatim}

Return the number of available NUMA domains.

\begin{verbatim}
std::size_t get_number_of_cores () const
\end{verbatim}

Return the number of available cores.
HPX Documentation, master

`std::size_t get_number_of_pus() const`
Return the number of available hardware processing units.

`std::size_t get_number_of_numa_node_cores(std::size_t numa) const`
Return number of cores in given numa domain.

`std::size_t get_number_of_numa_node_pus(std::size_t numa) const`
Return number of processing units in a given numa domain.

`std::size_t get_number_of_socket_pus(std::size_t socket) const`
Return number of processing units in a given socket.

`std::size_t get_number_of_core_pus(std::size_t core) const`
Return number of processing units in given core.

`std::size_t get_number_of_socket_cores(std::size_t socket) const`
Return number of cores units in given socket.

`std::size_t get_core_number(std::size_t num_thread, error_code& = throws) const`

`std::size_t get_pu_number(std::size_t num_core, std::size_t num_pu, error_code &ec = throws) const`

`mask_type get_cpubind_mask(error_code &ec = throws) const`

`mask_type get_cpubind_mask(std::thread &handle, error_code &ec = throws) const`

`hwloc_bitmap_ptr cpuset_to_nodeset(mask_cref_type cpuset) const`
convert a cpu mask into a numa node mask in hwloc bitmap form

`void write_to_log() const`

`void *allocate(std::size_t len) const`
This is equivalent to malloc(), except that it tries to allocate page-aligned memory from the OS.

`void *allocate_membind(std::size_t len, hwloc_bitmap_ptr bitmap, hpx_hwloc_membind_policy policy, int flags) const`
allocation memory with binding to a numa node set as specified by the policy and flags (see hwloc docs)

`threads::mask_type get_area_membind_nodeset(const void *addr, std::size_t len) const`

`bool set_area_membind_nodeset(const void *addr, std::size_t len, void *nodeset) const`

`int get_numa_domain(const void *addr) const`

`void deallocate(void *addr, std::size_t len) const`
Free memory that was previously allocated by allocate.

`void print_vector(std::ostream &os, std::vector<std::size_t> const &v) const`

`void print_mask_vector(std::ostream &os, std::vector<mask_type> const &v) const`

`void print_hwloc(std::ostream&) const`

`mask_type init_socket_affinity_mask_from_socket(std::size_t num_socket) const`
mask_type \texttt{init numa node affinity mask from numa node} (std::size_t num numa node) const

The contents of this module can be included with the header `hpx/modules/util.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/util.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

```cpp
namespace hpx
```

```cpp
namespace util
```
Functions

`std::size_t calculate_fanout (std::size_t size, std::size_t local_fanout)`

namespace hpx

namespace util

Functions

`std::uint64_t get_and_reset_value (std::uint64_t &value, bool reset)`

`std::int64_t get_and_reset_value (std::int64_t &value, bool reset)`

template<typename T>
`T get_and_reset_value (std::atomic<T> &value, bool reset)`

`std::vector<std::int64_t> get_and_reset_value (std::vector<std::int64_t> &value, bool reset)`

namespace hpx

namespace util

Functions

template<typename DestType, typename Config, typename std::enable_if<!std::is_same<DestType, std::string>::value, bool>::type = false>
`DestType get_entry_as (Config const &config, std::string const &key, DestType const &dflt)`

namespace hpx

namespace util

Functions

template<typename Iterator>
`bool insert_checked (std::pair<Iterator, bool> const &r)`

Helper function for writing predicates that test whether an std::map insertion succeeded. This inline template function negates the need to explicitly write the sometimes lengthy std::pair<Iterator, bool> type.

**Return** This function returns r.second.

**Parameters**

- `r`: [in] The return value of a std::map insert operation.

template<typename Iterator>
`bool insert_checked (std::pair<Iterator, bool> const &r, Iterator &it)`

Helper function for writing predicates that test whether an std::map insertion succeeded. This inline template function negates the need to explicitly write the sometimes lengthy std::pair<Iterator, bool> type.
Return  This function returns \texttt{r.second}.

Parameters
- \( r \): [in] The return value of a \texttt{std::map} insert operation.
- \( r \): [out] A reference to an Iterator, which is set to \texttt{r.first}.

Functions

`bool parse_sed_expression(std::string const &input, std::string &search, std::string &replace)`

Parse a sed command.

Return true if the parsing was successful, false otherwise.

Note Currently, only supports search and replace syntax (s/search/replace/)

Parameters

- input: [in] The content to parse.
- search: [out] If the parsing is successful, this string is set to the search expression.
- search: [out] If the parsing is successful, this string is set to the replace expression.

struct sed_transform

#include <sed_transform.hpp> An unary function object which applies a sed command to its subject and returns the resulting string.

Note Currently, only supports search and replace syntax (s/search/replace/)
Public Functions

\texttt{sed_transform (std::string const &search, std::string const &replace)}

{

  Functions

  bool is_pre_startup()
}
```

### actions_base

The contents of this module can be included with the header `hpx/modules/actions_base.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/actions_base.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

```cpp
namespace hpx
{

  namespace actions

    Functions

      template<typename Action>
      threads::thread_priority action_priority()

    Defines

    HPX_REGISTER_ACTION_DECLARATION(...)  
    Declare the necessary component action boilerplate code.
    
    The macro `HPX_REGISTER_ACTION_DECLARATION` can be used to declare all the boilerplate code which is required for proper functioning of component actions in the context of HPX.
    
    The parameter `action` is the type of the action to declare the boilerplate for.
    
    This macro can be invoked with an optional second parameter. This parameter specifies a unique name of the action to be used for serialization purposes. The second parameter has to be specified if the first parameter is not usable as a plain (non-qualified) C++ identifier, i.e. the first parameter contains special characters which cannot be part of a C++ identifier, such as '<', '>', or ':'.
```
namespace app
{
    // Define a simple component exposing one action 'print_greeting'
    class HPX_COMPONENT_EXPORT server
    : public hpx::components::component_base<server>
    {
        void print_greeting()
        {
            hpx::cout << "Hey, how are you?\n" << hpx::flush;
        }

        // Component actions need to be declared, this also defines the
        // type 'print_greeting_action' representing the action.
        HPX_DEFINE_COMPONENT_ACTION(server, print_greeting, print_greeting_action);
    }
}

// Declare boilerplate code required for each of the component actions.
HPX_REGISTER_ACTION_DECLARATION(app::server::print_greeting_action);

Example:

Note This macro has to be used once for each of the component actions defined using one of the
HPX_DEFINE_COMPONENT_ACTION macros. It has to be visible in all translation units using the
action, thus it is recommended to place it into the header file defining the component.

HPX_REGISTER_ACTION_DECLARATION(...)  
HPX_REGISTER_ACTION_DECLARATION_1(action)  
HPX_REGISTER_ACTION(...)  
    Define the necessary component action boilerplate code.
    
    The macro HPX_REGISTER_ACTION can be used to define all the boilerplate code which is required for proper
functioning of component actions in the context of HPX.
    
    The parameter action is the type of the action to define the boilerplate for.
    
    This macro can be invoked with an optional second parameter. This parameter specifies a unique name of the
action to be used for serialization purposes. The second parameter has to be specified if the first parameter is not
usable as a plain (non-qualified) C++ identifier, i.e. the first parameter contains special characters which cannot
be part of a C++ identifier, such as '<', '>', or ':'.

Note This macro has to be used once for each of the component actions defined using one of the
HPX_DEFINE_COMPONENT_ACTION or HPX_DEFINE_PLAIN_ACTION macros. It has to occur ex-
actly once for each of the actions, thus it is recommended to place it into the source file defining the
component.

Note Only one of the forms of this macro HPX_REGISTER_ACTION or HPX_REGISTER_ACTION_ID should
be used for a particular action, never both.

HPX_REGISTER_ACTION_ID(action, actionname, actionid)  
    Define the necessary component action boilerplate code and assign a predefined unique id to the action.
The macro `HPX_REGISTER_ACTION` can be used to define all the boilerplate code which is required for proper functioning of component actions in the context of HPX.

The parameter `action` is the type of the action to define the boilerplate for.

The parameter `actionname` specifies an unique name of the action to be used for serialization purposes. The second parameter has to be usable as a plain (non-qualified) C++ identifier, it should not contain special characters which cannot be part of a C++ identifier, such as '<', '>', or ':'.

The parameter `actionid` specifies an unique integer value which will be used to represent the action during serialization.

Note This macro has to be used once for each of the component actions defined using one of the `HPX_DEFINE_COMPONENT_ACTION` or global actions `HPX_DEFINE_PLAIN_ACTION` macros. It has to occur exactly once for each of the actions, thus it is recommended to place it into the source file defining the component.

Note Only one of the forms of this macro `HPX_REGISTER_ACTION` or `HPX_REGISTER_ACTION_ID` should be used for a particular action, never both.

```cpp
namespace hpx

namespace actions

#include <basic_action_fwd.hpp>

template<typename Component, typename Signature, typename Derived>
struct basic_action

namespace app
{
    // Define a simple component exposing one action 'print_greeting'
    class HPX_COMPONENT_EXPORT server
    : public hpx::components::component_base<server>
    {
        void print_greeting() const
            {
                hpx::cout << "Hey, how are you?\n" << hpx::flush;
            }

(continues on next page)
```
Component actions need to be declared, this also defines the type `print_greeting_action` representing the action.

```cpp
HPX_DEFINE_COMPONENT_ACTION(server, print_greeting, print_greeting_action);
```

Example:

The first argument must provide the type name of the component the action is defined for.
The second argument must provide the member function name the action should wrap.

The default value for the third argument (the typename of the defined action) is derived from the name of the function (as passed as the second argument) by appending `_action`. The third argument can be omitted only if the second argument with an appended suffix `_action` resolves to a valid, unqualified C++ type name.

**Note** The macro `HPX_DEFINE_COMPONENT_ACTION` can be used with 2 or 3 arguments. The third argument is optional.

**Defines**

`HPX_DEFINE_PLAIN_ACTION(...)`

Defines a plain action type.

```cpp
namespace app {
    void some_global_function(double d) {
        cout << d;
    }
    // This will define the action type 'app::some_global_action' which
    // represents the function 'app::some_global_function'.
    HPX_DEFINE_PLAIN_ACTION(some_global_function, some_global_action);
}
```

Example:

**Note** Usually this macro will not be used in user code unless the intent is to avoid defining the action_type in global namespace. Normally, the use of the macro `HPX.PLAIN_ACTION` is recommended.

**Note** The macro `HPX_DEFINE_PLAIN_ACTION` can be used with 1 or 2 arguments. The second argument is optional. The default value for the second argument (the typename of the defined action) is derived from the name of the function (as passed as the first argument) by appending `_action`. The second argument can be omitted only if the first argument with an appended suffix `_action` resolves to a valid, unqualified C++ type name.
HPX_DECLARE_PLAIN_ACTION(...)  
Declares a plain action type.

HPX_PLAIN_ACTION(...)  
Defines a plain action type based on the given function func and registers it with HPX.

The macro HPX_PLAIN_ACTION can be used to define a plain action (e.g. an action encapsulating a global or free function) based on the given function func. It defines the action type name representing the given function. This macro additionally registers the newly define action type with HPX.

The parameter func is a global or free (non-member) function which should be encapsulated into a plain action. The parameter name is the name of the action type defined by this macro.

```cpp
namespace app {
    void some_global_function(double d) {
        cout << d;
    }
}

// This will define the action type 'some_global_action' which represents
// the function 'app::some_global_function'.
HPX_PLAIN_ACTION(app::some_global_function, some_global_action);
```

Example:

Note The macro HPX_PLAIN_ACTION has to be used at global namespace even if the wrapped function is located in some other namespace. The newly defined action type is placed into the global namespace as well.

Note The macro HPXPLAIN_ACTION_ID can be used with 1, 2, or 3 arguments. The second and third arguments are optional. The default value for the second argument (the typename of the defined action) is derived from the name of the function (as passed as the first argument) by appending '_action'. The second argument can be omitted only if the first argument with an appended suffix '_action' resolves to a valid, unqualified C++ type name. The default value for the third argument is hpx::components::factory_check.

Note Only one of the forms of this macro HPXPLAIN_ACTION or HPXPLAIN_ACTION_ID should be used for a particular action, never both.

HPXPLAIN_ACTION_ID(func, name, id)  
Defines a plain action type based on the given function func and registers it with HPX.

The macro HPXPLAIN_ACTION_ID can be used to define a plain action (e.g. an action encapsulating a global or free function) based on the given function func. It defines the action type actionname representing the given function. The parameter actionid

The parameter actionid specifies an unique integer value which will be used to represent the action during serialization.

The parameter func is a global or free (non-member) function which should be encapsulated into a plain action. The parameter name is the name of the action type defined by this macro.

The second parameter has to be usable as a plain (non-qualified) C++ identifier, it should not contain special characters which cannot be part of a C++ identifier, such as ‘<’, ‘>’, or ‘:’.
namespace app
{
    void some_global_function(double d)
    {
        cout << d;
    }
}

// This will define the action type 'some_global_action' which represents
// the function 'app::some_global_function'.
HPX_PLAIN_ACTION_ID(app::some_global_function, some_global_action,
                        some_unique_id);

Example:

Note The macro HPX_PLAIN_ACTION_ID has to be used at global namespace even if the wrapped function
is located in some other namespace. The newly defined action type is placed into the global namespace as
well.

Note Only one of the forms of this macro HPX_PLAIN_ACTION or HPX_PLAIN_ACTION_ID should be used
for a particular action, never both.

bool register_locality (parcelset::endpoints_type const &endpoints, naming::gid_type &prefix, std::uint32_t num_threads, error_code &ec = throws)
   Add a locality to the runtime.

parcelset::endpoints_type const &resolve_locality (naming::gid_type const &gid, error_code &ec = throws)
   Resolve a locality to its prefix.

Return Returns an empty vector if the locality is not registered.

bool has_resolved_locality (naming::gid_type const &gid)

bool unregister_locality (naming::gid_type const &gid, error_code &ec = throws)
   Remove a locality from the runtime.

void remove_resolved_locality (naming::gid_type const &gid)
   remove given locality from locality cache

bool get_console_locality (naming::gid_type &locality, error_code &ec = throws)
   Get locality locality_id of the console locality.

Return This function returns true if a console locality_id exists and returns false otherwise.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters
• locality_id: [out] The locality_id value uniquely identifying the console locality. This is valid only, if the return value of this function is true.
• try_cache: [in] If this is set to true the console is first tried to be found in the local cache. Otherwise this function will always query AGAS, even if the console locality_id is already known locally.
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

bool get_localities (std::vector<naming::gid_type> &locality_ids, components::component_type type, error_code &ec = throws)
Query for the locality_ids of all known localities.

This function returns the locality_ids of all localities known to the AGAS server or all localities having a registered factory for a given component type.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters
• locality_ids: [out] The vector will contain the prefixes of all localities registered with the AGAS server. The returned vector holds the prefixes representing the runtime_support components of these localities.
• type: [in] The component type will be used to determine the set of prefixes having a registered factory for this component. The default value for this parameter is components::component_invalid, which will return prefixes of all localities.
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.
bool get_localities(std::vector<naming::gid_type> &locality_ids, error_code &ec = throws)

lcos::future<std::uint32_t> get_num_localities_async(components::component_type type = components::component_invalid) const

Query for the number of all known localities.

This function returns the number of localities known to the AGAS server or the number of localities having a registered factory for a given component type.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Parameters**
- **type**: [in] The component type will be used to determine the set of prefixes having a registered factory for this component. The default value for this parameter is `components::component_invalid`, which will return prefixes of all localities.
- **ec**: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Parameters**
- **name**: [in] The component name (string) to get the component type for.
- **ec**: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

Register a factory for a specific component type.
This function allows to register a component factory for a given locality and component type.

**Return** The function returns the currently associated component type. Any error results in an exception thrown from this function. The returned component type is the same as if the function `get_component_id` was called using the same component name.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Parameters**
- `locality_id`: [in] The locality value uniquely identifying the given locality the factory needs to be registered for.
- `name`: [in] The component name (string) to register a factory for the given component type for.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
components::component_type register_factory (std::uint32_t locality_id, std::string const &name, error_code &ec = throws)
```

**get_id_range**

Get unique range of freely assignable global ids.

Every locality needs to be able to assign global ids to different components without having to consult the AGAS server for every id to generate. This function can be called to preallocate a range of ids usable for this purpose.

**Return** This function returns `true` if a new range has been generated (it has been called for the first time for the given locality) and returns `false` if this locality already got a range assigned in an earlier call. Any error results in an exception thrown from this function.

**Note** This function assigns a range of global ids usable by the given locality for newly created components. Any of the returned global ids still has to be bound to a local address, either by calling `bind` or `bind_range`.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Parameters**
- `l`: [in] The locality the locality id needs to be generated for. Repeating calls using the same locality results in identical locality_id values.
- `count`: [in] The number of global ids to be generated.
- `lower_bound`: [out] The lower bound of the assigned id range. The returned value can be used as the first id to assign. This is valid only, if the return value of this function is true.
- `upper_bound`: [out] The upper bound of the assigned id range. The returned value can be used as the last id to assign. This is valid only, if the return value of this function is true.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
bool get_id_range (std::uint64_t count, naming::gid_type &lower_bound, naming::gid_type &upper_bound, error_code &ec = throws)
```

**bind_local**

Bind a global address to a local address.

Every element in the HPX namespace has a unique global address (global id). This global address has to be associated with a concrete local address to be able to address an instance of a component using its global address.
Return This function returns true, if this global id got associated with an local address. It returns false otherwise.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Note Binding a gid to a local address sets its global reference count to one.

Parameters

• id: [in] The global address which has to be bound to the local address.
• addr: [in] The local address to be bound to the global address.
• ec: [in,out] This represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

hpx::future<bool> bind_async(naming::gid_type const &id, naming::address const &addr, std::uint32_t locality_id)

hpx::future<bool> bind_async(naming::gid_type const &id, naming::address const &addr, naming::gid_type const &locality)

bool bind_range_local(naming::gid_type const &lower_id, std::uint64_t count, naming::address const &baseaddr, std::uint64_t offset, error_code &ec = throws)

Bind unique range of global ids to given base address.

Every locality needs to be able to bind global ids to different components without having to consult the AGAS server for every id to bind. This function can be called to bind a range of consecutive global ids to a range of consecutive local addresses (separated by a given offset).

Return This function returns true, if the given range was successfully bound. It returns false otherwise.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Note Binding a gid to a local address sets its global reference count to one.

Parameters

• lower_id: [in] The lower bound of the assigned id range. The value can be used as the first id to assign.
• count: [in] The number of consecutive global ids to bind starting at lower_id.
• baseaddr: [in] The local address to bind to the global id given by lower_id. This is the base address for all additional local addresses to bind to the remaining global ids.
• offset: [in] The offset to use to calculate the local addresses to be bound to the range of global ids.
• ec: [in,out] This represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

hpx::future<bool> bind_range_async(naming::gid_type const &lower_id, std::uint64_t count, naming::address const &baseaddr, std::uint64_t offset, naming::gid_type const &locality)

hpx::future<bool> bind_range_async(naming::gid_type const &lower_id, std::uint64_t count, naming::address const &baseaddr, std::uint32_t locality_id)

bool unbind_local(naming::gid_type const &id, error_code &ec = throws)

Unbind a global address.

Remove the association of the given global address with any local address, which was bound to this global address. Additionally it returns the local address which was bound at the time of this call.
**Return** The function returns *true* if the association has been removed, and it returns *false* if no association existed. Any error results in an exception thrown from this function.

**Note** You can unbind only global ids bound using the function `bind`. Do not use this function to unbind any of the global ids bound using `bind_range`.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Note** This function will raise an error if the global reference count of the given gid is not zero!

**TODO:** confirm that this happens.

**Parameters**
- `id`: [in] The global address (id) for which the association has to be removed.
- `addr`: [out] The local address which was associated with the given global address (id). This is valid only if the return value of this function is true.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
bool unbind_local (name::gid_type const &id, name::address &addr, error_code &ec = throws)
```

Unbind a global address.

Remove the association of the given global address with any local address, which was bound to this global address. Additionally it returns the local address which was bound at the time of this call.

**Return** The function returns *true* if the association has been removed, and it returns *false* if no association existed. Any error results in an exception thrown from this function.

**Note** You can unbind only global ids bound using the function `bind`. Do not use this function to unbind any of the global ids bound using `bind_range`.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Note** This function will raise an error if the global reference count of the given gid is not zero!

**TODO:** confirm that this happens.

**Parameters**
- `lower_id`: [in] The lower bound of the assigned id range. The value must be the first id of the range as specified to the corresponding call to `bind_range`.
- `count`: [in] The number of consecutive global ids to unbind starting at `lower_id`. This number must be identical to the number of global ids bound by the corresponding call to...
bind_range

- ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

bool unbind_range_local (naming::gid_type const &lower_id, std::uint64_t count, naming::address &addr, error_code &ec = throws)

Unbind the given range of global ids.

Return This function returns true if a new range has been generated (it has been called for the first time for the given locality) and returns false if this locality already got a range assigned in an earlier call.

Note You can unbind only global ids bound using the function bind_range. Do not use this function to unbind any of the global ids bound using bind.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Note This function will raise an error if the global reference count of the given gid is not zero!

Parameters

- lower_id: [in] The lower bound of the assigned id range. The value must the first id of the range as specified to the corresponding call to bind_range.
- count: [in] The number of consecutive global ids to unbind starting at lower_id. This number must be identical to the number of global ids bound by the corresponding call to bind_range.
- addr: [out] The local address which was associated with the given global address (id). This is valid only if the return value of this function is true.
- ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

hpx::future<naming::address> unbind_range_async (naming::gid_type const &lower_id, std::uint64_t count = 1)

bool is_local_address_cached (naming::gid_type const &id, error_code &ec = throws)

Test whether the given address refers to a local object.

This function will test whether the given address refers to an object living on the locality of the caller.

Return This function returns true if the passed address refers to an object which lives on the locality of the caller.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters

- addr: [in] The address to test.
- ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

bool is_local_address_cached (naming::gid_type const &id, naming::address &addr, error_code &ec = throws)

bool is_local_lva_encoded_address (std::uint64_t msb)

bool resolve_local (naming::gid_type const &id, naming::address &addr, error_code &ec = throws)

Resolve a given global address (id) to its associated local address.
This function returns the local address which is currently associated with the given global address (id).

**Return** This function returns true if the global address has been resolved successfully (there exists an association to a local address) and the associated local address has been returned. The function returns false if no association exists for the given global address. Any error results in an exception thrown from this function.

**Note** As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

**Parameters**
- id: [in] The global address (id) for which the associated local address should be returned.
- addr: [out] The local address which currently is associated with the given global address (id), this is valid only if the return value of this function is true.
- ec: [in, out] This represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

```cpp
bool resolve_local (naming::id_type const &id, naming::address &addr, error_code &ec = throws)

naming::address resolve_local (naming::gid_type const &id, error_code &ec = throws)

naming::address resolve_local (naming::id_type const &id, error_code &ec = throws)

hpx::future<naming::address> resolve_async (naming::gid_type const &id)

hpx::future<naming::address> resolve_async (naming::id_type const &id)

hpx::future<naming::id_type> get_colocation_id_async (naming::id_type const &id)

bool resolve_full_local (naming::gid_type const &id, naming::address &addr, error_code &ec = throws)

bool resolve_full_local (naming::id_type const &id, naming::address &addr, error_code &ec = throws)

naming::address resolve_full_local (naming::gid_type const &id, error_code &ec = throws)

naming::address resolve_full_local (naming::id_type const &id, error_code &ec = throws)

hpx::future<naming::address> resolve_full_async (naming::gid_type const &id)

hpx::future<naming::address> resolve_full_async (naming::id_type const &id)

bool resolve_cached (naming::gid_type const &id, naming::address &addr, error_code &ec = throws)

bool resolve_cached (naming::id_type const &id, naming::address &addr, error_code &ec = throws)

bool resolve_local (naming::gid_type const *gids, naming::address *addrs, std::size_t size, boost::dynamic_bitset<> &locals, error_code &ec = throws)

bool resolve_full_local (naming::gid_type const *gids, naming::address *addrs, std::size_t size, boost::dynamic_bitset<> &locals, error_code &ec = throws)

bool resolve_cached (naming::gid_type const *gids, naming::address *addrs, std::size_t size, boost::dynamic_bitset<> &locals, error_code &ec = throws)
```
lcos::future< std::int64_t > 

**incref_async** (naming:: gid_type const & gid, std::int64_t credits = 1, naming:: id_type const & keep_alive = naming::invalid_id)

Increment the global reference count for the given id.

**Return**  Whether the operation was successful.

**Note**  As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

**Parameters**

- **id**: [in] The global address (id) for which the global reference count has to be incremented.
- **credits**: [in] The number of reference counts to add for the given id.
- **ec**: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

**std::int64_t incref** (naming:: gid_type const & gid, std::int64_t credits = 1, error_code & ec = throws)

Decrement the global reference count for the given id.

**Return**  The global reference count after the decrement.

**Note**  As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

**Parameters**

- **id**: [in] The global address (id) for which the global reference count has to be decremented.
- **t**: [out] If this was the last outstanding global reference for the given gid (the return value of this function is zero), t will be set to the component type of the corresponding element. Otherwise t will not be modified.
- **credits**: [in] The number of reference counts to add for the given id.
- **ec**: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

**hpx::future< iterate_names_return_type > iterate_ids** (std::string const & pattern)

Invoke the supplied hpx::function for every registered global name.

This function iterates over all registered global ids and returns every found entry matching the given name pattern. Any error results in an exception thrown (or reported) from this function.

**Parameters**

- **pattern**: [in] pattern (poosibly using wildcards) to match all existing entries against

**bool register_name** (std::string const & name, naming:: gid_type const & id, error_code & ec = throws)

Register a global name with a global address (id)

This function registers an association between a global name (string) and a global address (id) usable with one of the functions above (bind, unbind, and resolve).

**Return**  The function returns true if the global name was registered. It returns false if the global name is not registered.

**Note**  As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

**Parameters**

- **name**: [in] The global name (string) to be associated with the global address.
- **id**: [in] The global address (id) to be associated with the global address.
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to \texttt{hpx::throws} the function will throw on error instead.

\texttt{lcos::future<bool> register_name_async (std::string const &name, naming::id_type const &id)}

bool \texttt{register_name (std::string const &name, naming::id_type const &id, error_code &ec = throws)}

\texttt{lcos::future<naming::id_type> unregister_name_async (std::string const &name)}

Unregister a global name (release any existing association)

This function releases any existing association of the given global name with a global address (id).

**Return** The function returns \texttt{true} if an association of this global name has been released, and it returns \texttt{false}, if no association existed. Any error results in an exception thrown from this function.

**Note** As long as \texttt{ec} is not pre-initialized to \texttt{hpx::throws} this function doesn’t throw but returns the result code using the parameter \texttt{ec}. Otherwise it throws an instance of \texttt{hpx::exception}.

**Parameters**

- \texttt{name: [in]} The global name (string) for which any association with a global address (id) has to be released.
- \texttt{ec: [in,out]} this represents the error status on exit, if this is pre-initialized to \texttt{hpx::throws} the function will throw on error instead.

\texttt{naming::id_type unregister_name (std::string const &name, error_code &ec = throws)}

\texttt{lcos::future<naming::id_type> resolve_name_async (std::string const &name)}

Query for the global address associated with a given global name.

This function returns the global address associated with the given global name.

This function returns true if it returned global address (id), which is currently associated with the given global name, and it returns false, if currently there is no association for this global name. Any error results in an exception thrown from this function.

**Return** [out] The id currently associated with the given global name (valid only if the return value is true).

**Parameters**

- \texttt{name: [in]} The global name (string) for which the currently associated global address has to be retrieved.
- \texttt{ec: [in,out]} this represents the error status on exit, if this is pre-initialized to \texttt{hpx::throws} the function will throw on error instead.

**Note** As long as \texttt{ec} is not pre-initialized to \texttt{hpx::throws} this function doesn’t throw but returns the result code using the parameter \texttt{ec}. Otherwise it throws an instance of \texttt{hpx::exception}.

\texttt{naming::id_type resolve_name (std::string const &name, error_code &ec = throws)}

\texttt{future<hpx::id_type> on_symbol_namespace_event (std::string const &name, bool call_for_past_events = false)}

Install a listener for a given symbol namespace event.

This function installs a listener for a given symbol namespace event. It returns a future which becomes ready as a result of the listener being triggered.
Return A future instance encapsulating the global id which is causing the registered listener to be triggered.

Note The only event type which is currently supported is symbol_ns_bind, i.e. the listener is triggered whenever a global id is registered with the given name.

Parameters
• name: [in] The global name (string) for which the given event should be triggered.
• evt: [in] The event for which a listener should be installed.
• call_for_past_events: [in, optional] Trigger the listener even if the given event has already happened in the past. The default for this parameter is false.

void update_cache_entry(naming::gid_type const &gid, gva const &gva, error_code &ec = throws)

Warning This function is for internal use only. It is dangerous and may break your code if you use it.

void update_cache_entry(naming::gid_type const &gid, naming::address const &addr, std::uint64_t count = 0, std::uint64_t offset = 0, error_code &ec = throws)

Warning This function is for internal use only. It is dangerous and may break your code if you use it.

bool get_cache_entry(naming::gid_type const &gid, gva &gva, naming::gid_type &id_base, error_code &ec = throws)

Warning This function is for internal use only. It is dangerous and may break your code if you use it.

void remove_cache_entry(naming::gid_type const &id, error_code &ec = throws)

Warning This function is for internal use only. It is dangerous and may break your code if you use it.

void clear_cache(error_code &ec = throws)

Warning This function is for internal use only. It is dangerous and may break your code if you use it.

void start_shutdown(error_code &ec = throws)

hpx::future<std::pair<naming::id_type, naming::address>> begin_migration(naming::id_type const &id)

start/stop migration of an object

Return Current locality and address of the object to migrate

bool end_migration(naming::id_type const &id)

std::pair<bool, components::pinned_ptr> was_object_migrated(naming::gid_type const &gid, util::unique_function_nonser<components::pinned_ptr>)

> &&/Maintain list of migrated objects.

hpx::future<void> mark_as_migrated(naming::gid_type const &gid, util::unique_function_nonser<hpx::future<void>>)>

> &&/bool expect_to_be_marked_as_migratingMark the given object as being migrated (if the object is unpinned). Delay migration until the object is unpinned otherwise.

void unmark_as_migrated(naming::gid_type const &gid)

Remove the given object from the table of migrated objects.
void `pre_cache_endpoints` (std::vector<parcelset::endpoints_type> const&)

The contents of this module can be included with the header hpx/modules/agas_base.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/agas_base.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.
namespace hpx
AGAS's primary namespace maps 128-bit global identifiers (GIDs) to resolved addresses.

The following is the canonical description of the partitioning of AGAS's primary namespace.

|-----MSB------||------LSB-----|
|BBBBBBBBBBBBBBBBBBBBBBBBBBBBBBBB|
|prefix||RC||----identifier----|

MSB - Most significant bits (bit 64 to bit 127)
LSB - Least significant bits (bit 0 to bit 63)
prefix - Highest 32 bits (bit 96 to bit 127) of the MSB. Each locality is assigned a prefix. This creates a 96-bit address space for each locality.
RC - Bit 88 to bit 92 of the MSB. This is the log2 of the number of reference counting credits on the GID.
Bit 93 is used by the locking scheme for gid_types.
Bit 94 is a flag which is set if the credit value is valid.
Bit 95 is a flag that is set if a GID's credit count is ever split (e.g. if the GID is ever passed to another locality).
- Bit 87 marks the gid such that it will not be stored in any of the AGAS caches. This is used mainly for ids which represent 'one-shot' objects (like promises).
identifier - Bit 64 to bit 86 of the MSB, and the entire LSB. The content of these bits depends on the component type of the underlying object. For all user-defined components, these bits contain a unique 88-bit number which is assigned sequentially for each locality. For \a hpx#components#component_runtime_support the high 24 bits are zeroed and the low 64 bits hold the LVA of the component.

Note The layout of the address space is implementation defined, and subject to change. Never write application code that relies on the internal layout of GIDs. AGAS only guarantees that all assigned GIDs will be unique.

The following address ranges are reserved. Some are either explicitly or implicitly protected by AGAS. The letter x represents a single-byte wild card.

00000000xxxxxxxxxxxxxxxxxxxxxxxxxxxx
Historically unused address space reserved for future use.
xxxxxxxxxxxxx0000xxxxxxxxxxxxxxxxxxxxx
Address space for LVA-encoded GIDs.
00000001xxxxxxxxxxxxxxxxxxxxxxxxxxxx
Prefix of the bootstrap AGAS locality.
000000010000000000000000000000001
Address of the primary_namespace component on the bootstrap AGAS locality.
000000010000000000000000000000002
Address of the component_namespace component on the bootstrap AGAS locality.
000000010000000000000000000000003
Address of the symbol_namespace component on the bootstrap AGAS locality.
000000010000000000000000000000004

```
|-----MSB------| |------LSB------|
BBBBBBBBBBBBBBBBBBBBBBBBBBBBBBBB
|prefix||RC||----identifier----|
```

- **MSB** - Most significant bits (bit 64 to bit 127)
- **LSB** - Least significant bits (bit 0 to bit 63)
- **prefix** - Highest 32 bits (bit 96 to bit 127) of the MSB. Each locality is assigned a prefix. This creates a 96-bit address space for each locality.
- **RC** - Bit 88 to bit 92 of the MSB. This is the log2 of the number of reference counting credits on the GID.
Bit 93 is used by the locking scheme for gid_types.
Bit 94 is a flag which is set if the credit value is valid.
Bit 95 is a flag that is set if a GID's credit count is ever split (e.g. if the GID is ever passed to another locality).
- Bit 87 marks the gid such that it will not be stored in any of the AGAS caches. This is used mainly for ids which represent 'one-shot' objects (like promises).

**identifier** - Bit 64 to bit 86 of the MSB, and the entire LSB. The content of these bits depends on the component type of the underlying object. For all user-defined components, these bits contain a unique 88-bit number which is assigned sequentially for each locality. For `hpx#components#component_runtime_support` the high 24 bits are zeroed and the low 64 bits hold the LVA of the component.

### Note
The layout of the address space is implementation defined, and subject to change. Never write application code that relies on the internal layout of GIDs. AGAS only guarantees that all assigned GIDs will be unique.

The following address ranges are reserved. Some are either explicitly or implicitly protected by AGAS. The letter x represents a single-byte wild card.

```
00000000xxxxxxxxxxxxxxxxxxxxxxxxxxxx
   Historically unused address space reserved for future use.
xxxxxxxxxxxxx0000xxxxxxxxxxxxxxxxxxxx
   Address space for LVA-encoded GIDs.
00000001xxxxxxxxxxxxxxxxxxxxxxxxxxxx
   Prefix of the bootstrap AGAS locality.
00000001000000000000000000000001
   Address of the primary_namespace component on the bootstrap AGAS locality.
00000001000000000000000000000002
   Address of the component_namespace component on the bootstrap AGAS locality.
00000001000000000000000000000003
   Address of the symbol_namespace component on the bootstrap AGAS locality.
00000001000000000000000000000004
   Address of the locality_namespace component on the bootstrap AGAS locality.
```

AGAS’s primary namespace maps 128-bit global identifiers (GIDs) to resolved addresses.

The following is the canonical description of the partitioning of AGAS’s primary namespace.
|-----MSB------|------LSB------|
BBBBBBBBBBBBBBBBBBBBBBBBBBBBBBBB
|prefix||RC||----identifier----|

**MSB** - Most significant bits (bit 64 to bit 127)

**LSB** - Least significant bits (bit 0 to bit 63)

**prefix** - Highest 32 bits (bit 96 to bit 127) of the MSB. Each locality is assigned a prefix. This creates a 96-bit address space for each locality.

**RC** - Bit 88 to bit 92 of the MSB. This is the log2 of the number of reference counting credits on the GID.

Bit 93 is used by the locking scheme for gid_types.

Bit 94 is a flag which is set if the credit value is valid.

Bit 95 is a flag that is set if a GID's credit count is ever split (e.g. if the GID is ever passed to another locality).

- Bit 87 marks the gid such that it will not be stored in any of the AGAS caches. This is used mainly for ids which represent 'one-shot' objects (like promises).

**identifier** - Bit 64 to bit 86 of the MSB, and the entire LSB. The content of these bits depends on the component type of the underlying object. For all user-defined components, these bits contain a unique 88-bit number which is assigned sequentially for each locality. For \a hpx#components#component_runtime_support the high 24 bits are zeroed and the low 64 bits hold the LVA of the component.

**Note** The layout of the address space is implementation defined, and subject to change. Never write application code that relies on the internal layout of GIDs. AGAS only guarantees that all assigned GIDs will be unique.

The following address ranges are reserved. Some are either explicitly or implicitly protected by AGAS. The letter x represents a single-byte wild card.

```
00000000xxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
Historically unused address space reserved for future use.
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
Address space for LVA-encoded GIDs.
00000001xxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
Prefix of the bootstrap AGAS locality.
00000010000000000000000000000001
Address of the primary_namespace component on the bootstrap AGAS locality.
00000001000000000000000000000002
Address of the component_namespace component on the bootstrap AGAS locality.
00000001000000000000000000000003
Address of the symbol_namespace component on the bootstrap AGAS locality.
00000001000000000000000000000004
Address of the locality_namespace component on the bootstrap AGAS locality.
```

namespace hpx

AGAS’s primary namespace maps 128-bit global identifiers (GIDs) to resolved addresses.

The following is the canonical description of the partitioning of AGAS’s primary namespace.

|-----MSB------|-----LSB------|
|BBBBBBBBBBBBBBBBBBBBBBBBBBBBBBBB|
|prefix||RC||----identifier----|

**MSB**
- Most significant bits (bit 64 to bit 127)

**LSB**
- Least significant bits (bit 0 to bit 63)

**prefix**
- Highest 32 bits (bit 96 to bit 127) of the MSB. Each locality is assigned a prefix. This creates a 96-bit address space for each locality.

**RC**
- Bit 88 to bit 92 of the MSB. This is the log2 of the number of reference counting credits on the GID. Bit 93 is used by the locking scheme for gid_types. Bit 94 is a flag which is set if the credit value is valid. Bit 95 is a flag that is set if a GID's credit count is ever split (e.g. if the GID is ever passed to another locality).

- Bit 87 marks the gid such that it will not be stored in any of the AGAS caches. This is used mainly for ids which represent 'one-shot' objects (like promises).

**identifier**
- Bit 64 to bit 86 of the MSB, and the entire LSB. The content of these bits depends on the component type of the underlying object. For all user-defined components, these bits contain a unique 88-bit number which is assigned sequentially for each locality. For `\a hpx#components#component_runtime_support` the high 24 bits are zeroed and the low 64 bits hold the LVA of the component.

**Note** The layout of the address space is implementation defined, and subject to change. Never write application code that relies on the internal layout of GIDs. AGAS only guarantees that all assigned GIDs will be unique.

The following address ranges are reserved. Some are either explicitly or implicitly protected by AGAS. The letter x represents a single-byte wild card.

```
0000000xxxxxxxxxxxxxxxxxxxxxxxxxxxx
    Historically unused address space reserved for future use.
xxxxxxxxxxxxx00000xxxxxxxxxxxxxxxxxxx
    Address space for LVA-encoded GIDs.
00000001xxxxxxxxxxxxxxxxxxxxxxxxxxxx
    Prefix of the bootstrap AGAS locality.
0000000100000001000000000000000001
    Address of the primary_namespace component on the bootstrap AGAS locality.
0000000100000001000000000000000002
    Address of the component_namespace component on the bootstrap AGAS locality.
```

async_colocated

The contents of this module can be included with the header hpx/modules/async_colocated.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/async_colocated.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

Defines

HPX_REGISTER_ASYNC_COLOCATED_DECLARATION (Action, Name)
HPX_REGISTER_ASYNC_COLOCATED (Action, Name)

namespace hpx

Functions

naming::id_type get_colocation_id(launch::sync_policy, naming::id_type const &id, error_code &ec = throws)

Return the id of the locality where the object referenced by the given id is currently located on.

The function hpx::get_colocation_id() returns the id of the locality where the given object is currently located.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.
See `hpx::get_colocation_id()`

Parameters

- `id`: [in] The id of the object to locate.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```
lcos::future<naming::id_type> get_colocation_id(naming::id_type const &id)
```

Asynchronously return the id of the locality where the object referenced by the given id is currently located on.

See `hpx::get_colocation_id(launch::sync_policy)`

Parameters

- `id`: [in] The id of the object to locate.

Defines

async_distributed

The contents of this module can be included with the header `hpx/modules/async_distributed.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/async_distributed.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

Public Static Functions

static lcos::base_lco const *call (naming::address_type lva)

namespace lcos

class base_lco
#include <base_lco.hpp>
The base_lco class is the common base class for all LCO’s implementing a simple set_event action

Subclassed by hpx::lcos::base_lco_with_value< Result, RemoteResult, ComponentTag >, hpx::lcos::base_lco_with_value< void, void, ComponentTag >

Public Types

typedef components::managed_component<base_lco> wrapping_type

typedef base_lco base_type_holder

Public Functions

virtual void set_event () = 0

virtual void set_exception (std::exception_ptr const &e)

virtual void connect (naming::id_type const&)

virtual void disconnect (naming::id_type const&)

virtual ~base_lco ()
Destructor, needs to be virtual to allow for clean destruction of derived objects

virtual void finalize ()
finalze() will be called just before the instance gets destructed

Chapter 2. What’s so special about HPX?
void **set_event_nonvirt** ()

The function `set_event_nonvirt` is called whenever a `set_event_action` is applied on a instance of a LCO. This function just forwards to the virtual function `set_event`, which is overloaded by the derived concrete LCO.

void **set_exception_nonvirt** (std::exception_ptr const &e)

The function `set_exception` is called whenever a `set_exception_action` is applied on a instance of a LCO. This function just forwards to the virtual function `set_exception`, which is overloaded by the derived concrete LCO.

**Parameters**

- e: [in] The exception encapsulating the error to report to this LCO instance.

void **connect_nonvirt** (naming::id_type const &id)

The function `connect_nonvirt` is called whenever a `connect_action` is applied on a instance of a LCO. This function just forwards to the virtual function `connect`, which is overloaded by the derived concrete LCO.

**Parameters**

- id: [in] target id

void **disconnect_nonvirt** (naming::id_type const &id)

The function `disconnect_nonvirt` is called whenever a `disconnect_action` is applied on a instance of a LCO. This function just forwards to the virtual function `disconnect`, which is overloaded by the derived concrete LCO.

**Parameters**

- id: [in] target id

**HPX_DEFINE_COMPONENT_DIRECT_ACTION** (base_lco, **set_event_nonvirt**, set_event_action)

Each of the exposed functions needs to be encapsulated into an action type, allowing to generate all required boilerplate code for threads, serialization, etc.

The `set_event_action` may be used to unconditionally trigger any LCO instances, it carries no additional parameters.

**HPX_DEFINE_COMPONENT_DIRECT_ACTION** (base_lco, **set_exception_nonvirt**, set_exception_action)

The `set_exception_action` may be used to transfer arbitrary error information from the remote site to the LCO instance specified as a continuation. This action carries 2 parameters:

**Parameters**

- std::exception_ptr: [in] The exception encapsulating the error to report to this LCO instance.

**HPX_DEFINE_COMPONENT_DIRECT_ACTION** (base_lco, **connect_nonvirt**, connect_action)

The `connect_action` may be used to.

**HPX_DEFINE_COMPONENT_DIRECT_ACTION** (base_lco, **disconnect_nonvirt**, disconnect_action)

The `disconnect_action` may be used to.

namespace hpx

namespace lcos
template<typename Result, typename RemoteResult, typename ComponentTag>
class base_lco_with_value: public hpx::lcos::base_lco, public ComponentTag
#include <base_lco_with_value.hpp> The base_lco_with_value class is the common base class for all LCO’s synchronizing on a value. The RemoteResult template argument should be set to the type of the argument expected for the set_value action.

Template Parameters
• RemoteResult: The type of the result value to be carried back to the LCO instance.
• ComponentTag: The tag type representing the type of the component (either component_tag or managed_component_tag).
Public Types

template<>
using wrapping_type = typename detail::base_lco_wrapping_type<ComponentTag, base_lco_with_value>::type

template<>
using base_type_holder = base_lco_with_value

Public Functions

void set_value_nonvirt (RemoteResult &&result)
The function set_value_nonvirt is called whenever a set_value_action is applied on this LCO instance. This function just forwards to the virtual function set_value, which is overloaded by the derived concrete LCO.

Parameters
• result: [in] The result value to be transferred from the remote operation back to this LCO instance.

Result get_value_nonvirt ()
The function get_result_nonvirt is called whenever a get_result_action is applied on this LCO instance. This function just forwards to the virtual function get_result, which is overloaded by the derived concrete LCO.

HPX_DEFINE_COMPONENT_DIRECT_ACTION (base_lco_with_value, set_value_nonvirt, set_value_action)
The set_value_action may be used to trigger any LCO instances while carrying an additional parameter of any type.

RemoteResult is taken by rvalue ref. This allows for perfect forwarding. When the action thread function is created, the values are moved into the called function. If we took it by const lvalue reference, we would disable the possibility to further move the result to the designated destination.

Parameters
• RemoteResult: [in] The type of the result to be transferred back to this LCO instance.

HPX_DEFINE_COMPONENT_DIRECT_ACTION (base_lco_with_value, get_value_nonvirt, get_value_action)
The get_value_action may be used to query the value this LCO instance exposes as its ‘result’ value.

Public Static Functions

static components::component_type get_component_type ()

static void set_component_type (components::component_type type)
Protected Types

typedef std::conditional<
    std::is_void<Result>::value,
    util::unused_type,
    Result>::type result_type

Protected Functions

~base_lco_with_value()
    Destructor, needs to be virtual to allow for clean destruction of derived objects

void set_event()

void set_event_nonvirt (std::false_type)

void set_event_nonvirt (std::true_type)

virtual void set_value(RemoteResult &&result) = 0

virtual result_type get_value() = 0

virtual result_type get_value(error_code&)

Template Parameters
• void: This specialization expects no result value and is almost completely equivalent to the plain base_lco.

Public Types

template<
    typename ComponentTag>
class base_lco_with_value<
    void, void, ComponentTag>
    : public hpx::lcos::base_lco, public ComponentTag
{
    #include <base_lco_with_value.hpp> The base_lco<void> specialization is used whenever the set_event action for a particular LCO doesn’t carry any argument.

2.8. API reference
class packaged_action
#include <packaged_action.hpp> A packaged_action can be used by a single thread to invoke a (remote) action and wait for the result. The result is expected to be sent back to the packaged_action using the LCO’s set_event action

A packaged_action is one of the simplest synchronization primitives provided by HPX. It allows to synchronize on a eager evaluated remote operation returning a result of the type Result.

**Note** The action executed using the packaged_action as a continuation must return a value of a type convertible to the type as specified by the template parameter Result.

**Template Parameters**
- **Action**: The template parameter Action defines the action to be executed by this packaged_action instance. The arguments arg0, ..., argN are used as parameters for this action.
- **Result**: The template parameter Result defines the type this packaged_action is expected to return from its associated future packaged_action::get_future.
- **DirectExecute**: The template parameter DirectExecute is an optimization aid allowing to execute the action directly if the target is local (without spawning a new thread for this). This template does not have to be supplied explicitly as it is derived from the template parameter Action.

template<
typename Action, typename Result>
class packaged_action<Action, Result, false>
: public promise<Result, hpx::traits::extract_action<Action>::remote_result_type>

Subclassed by hpx::lcos::packaged_action<Action, Result, true>

```
namespace hpx

Functions

void trigger_lco_event (naming::id_type const &id, naming::address &&addr, bool move_credits = true)
Trigger the LCO referenced by the given id.

Parameters

- id: [in] This represents the id of the LCO which should be triggered.
- addr: [in] This represents the addr of the LCO which should be triggered.
- move_credits: [in] If this is set to true then it is ok to send all credits in id along with the generated message. The default value is true.
```

void trigger_lco_event (naming::id_type const &id, bool move_credits = true)
Trigger the LCO referenced by the given id.

Parameters

- id: [in] This represents the id of the LCO which should be triggered.
- move_credits: [in] If this is set to true then it is ok to send all credits in id along with the generated message. The default value is true.
```

void trigger_lco_event (naming::id_type const &id, naming::address &addr, naming::id_type const &cont, bool move_credits = true)
Trigger the LCO referenced by the given id.

Parameters

- id: [in] This represents the id of the LCO which should be triggered.
- addr: [in] This represents the addr of the LCO which should be triggered.
- cont: [in] This represents the LCO to trigger after completion.
- move_credits: [in] If this is set to true then it is ok to send all credits in id along with the generated message. The default value is true.
```

void trigger_lco_event (naming::id_type const &id, naming::id_type const &cont, bool move_credits = true)
Trigger the LCO referenced by the given id.

Parameters
• id: [in] This represents the id of the LCO which should be triggered.
• cont: [in] This represents the LCO to trigger after completion.
• move_credits: [in] If this is set to true then it is ok to send all credits in id along with the generated message. The default value is true.

template<typename Result>
void set_lco_value(naming::id_type const &id, naming::address &addr, Result &t, bool move_credits = true)
Set the result value for the LCO referenced by the given id.

Parameters

• id: [in] This represents the id of the LCO which should receive the given value.
• addr: [in] This represents the addr of the LCO which should be triggered.
• t: [in] This is the value which should be sent to the LCO.
• move_credits: [in] If this is set to true then it is ok to send all credits in id along with the generated message. The default value is true.

template<typename Result>
std::enable_if<!std::is_same<typename std::decay<Result>::type, naming::address>::value>::type set_lco_value(naming::id_type const &id, Result &t, bool move_credits = true)
Set the result value for the (managed) LCO referenced by the given id.

Parameters

• id: [in] This represents the id of the LCO which should receive the given value.
• t: [in] This is the value which should be sent to the LCO.
• move_credits: [in] If this is set to true then it is ok to send all credits in id along with the generated message. The default value is true.

template<typename Result>
std::enable_if<!std::is_same<typename std::decay<Result>::type, naming::address>::value>::type set_lco_value_unmanaged(naming::id_type const &id, Result &t, bool move_credits = true)
Set the result value for the (unmanaged) LCO referenced by the given id.
Parameters

- id: [in] This represents the id of the LCO which should receive the given value.
- t: [in] This is the value which should be sent to the LCO.
- move_credits: [in] If this is set to true then it is ok to send all credits in id along with the generated message. The default value is true.

```
template<
    typename Result>
void set_lco_value (naming::id_type const &id, naming::address &&addr, Result &&t, naming::id_type const &cont, bool move_credits = true)
```

Set the result value for the LCO referenced by the given id.

Parameters

- id: [in] This represents the id of the LCO which should receive the given value.
- addr: [in] This represents the addr of the LCO which should be triggered.
- t: [in] This is the value which should be sent to the LCO.
- cont: [in] This represents the LCO to trigger after completion.
- move_credits: [in] If this is set to true then it is ok to send all credits in id along with the generated message. The default value is true.

```
template<
    typename Result>
std::enable_if<!std::is_same<typename std::decay<Result>::type, naming::address>::value>::type set_lco_value (naming::id_type const &id, Result &&t, naming::id_type const &cont, bool move_credits = true)
```

Set the result value for the (managed) LCO referenced by the given id.

Parameters

- id: [in] This represents the id of the LCO which should receive the given value.
- t: [in] This is the value which should be sent to the LCO.
- cont: [in] This represents the LCO to trigger after completion.
- move_credits: [in] If this is set to true then it is ok to send all credits in id along with the generated message. The default value is true.

```
template<
    typename Result>
```
```cpp
std::enable_if<!std::is_same<typename std::decay<Result>::type, naming::address>::value>::type
set_lco_value_unmanaged(naming::id_type const &id, Result &&t, naming::id_type const &cont, bool move_credits = true)
```

Set the result value for the (unmanaged) LCO referenced by the given id.

**Parameters**
- **id**: [in] This represents the id of the LCO which should receive the given value.
- **t**: [in] This is the value which should be sent to the LCO.
- **cont**: [in] This represents the LCO to trigger after completion.
- **move_credits**: [in] If this is set to true then it is ok to send all credits in id along with the generated message. The default value is true.

```cpp
void set_lco_error(naming::id_type const &id, naming::address &&addr, std::exception_ptr const &e, bool move_credits = true)
```

Set the error state for the LCO referenced by the given id.

**Parameters**
- **id**: [in] This represents the id of the LCO which should receive the error value.
- **addr**: [in] This represents the addr of the LCO which should be triggered.
- **e**: [in] This is the error value which should be sent to the LCO.
- **move_credits**: [in] If this is set to true then it is ok to send all credits in id along with the generated message. The default value is true.
void **set_lco_error** (naming::id_type const &id, std::exception_ptr const &e, bool move_credits = true)

Set the error state for the LCO referenced by the given id.

**Parameters**

- **id**: [in] This represents the id of the LCO which should receive the error value.
- **e**: [in] This is the error value which should be sent to the LCO.
- **move_credits**: [in] If this is set to `true` then it is ok to send all credits in `id` along with the generated message. The default value is `true`.

void **set_lco_error** (naming::id_type const &id, std::exception_ptr &&e, bool move_credits = true)

Set the error state for the LCO referenced by the given id.

**Parameters**

- **id**: [in] This represents the id of the LCO which should receive the error value.
- **e**: [in] This is the error value which should be sent to the LCO.
- **move_credits**: [in] If this is set to `true` then it is ok to send all credits in `id` along with the generated message. The default value is `true`.

void **set_lco_error** (naming::id_type const &id, naming::address &&addr, std::exception_ptr const &e, naming::id_type const &cont, bool move_credits = true)

Set the error state for the LCO referenced by the given id.

**Parameters**

- **id**: [in] This represents the id of the LCO which should receive the error value.
- **addr**: [in] This represents the addr of the LCO which should be triggered.
- **e**: [in] This is the error value which should be sent to the LCO.
- **cont**: [in] This represents the LCO to trigger after completion.
- **move_credits**: [in] If this is set to `true` then it is ok to send all credits in `id` along with the generated message. The default value is `true`.

void **set_lco_error** (naming::id_type const &id, naming::address &&addr, std::exception_ptr &&e, naming::id_type const &cont, bool move_credits = true)

Set the error state for the LCO referenced by the given id.

**Parameters**

- **id**: [in] This represents the id of the LCO which should receive the error value.
- **addr**: [in] This represents the addr of the LCO which should be triggered.
- **e**: [in] This is the error value which should be sent to the LCO.
- **cont**: [in] This represents the LCO to trigger after completion.
- **move_credits**: [in] If this is set to `true` then it is ok to send all credits in `id` along with the generated message. The default value is `true`.
void `set_lco_error` (naming::id_type const &id, std::exception_ptr const &e, naming::id_type const &cont, bool move_credits = true)

Set the error state for the LCO referenced by the given id.

Parameters

- `id`: [in] This represents the id of the LCO which should receive the error value.
- `e`: [in] This is the error value which should be sent to the LCO.
- `cont`: [in] This represents the LCO to trigger after completion.
- `move_credits`: [in] If this is set to `true` then it is ok to send all credits in `id` along with the generated message. The default value is `true`.

checkpoint

The contents of this module can be included with the header hpx/modules/checkpoint.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/checkpoint.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

This header defines the save_checkpoint and restore_checkpoint functions. These functions are designed to help HPX application developer’s checkpoint their applications. Save_checkpoint serializes one or more objects and saves them as a byte stream. Restore_checkpoint converts the byte stream back into instances of the objects.

namespace hpx

namespace util

Functions

std::ostream &operator<<(std::ostream &ost, checkpoint const &ckp)
Operator<< Overload

This overload is the main way to write data from a checkpoint to an object such as a file. Inside the function, the size of the checkpoint will be written to the stream before the checkpoint’s data. The operator>> overload uses this to read the correct number of bytes. Be mindful of this additional write and read when you use different facilities to write out or read in data to a checkpoint!

Parameters
- ost: Output stream to write to.
- ckp: Checkpoint to copy from.

Return Operator<< returns the ostream object.
std::istream &operator>>(std::istream &ist, checkpoint &ckp)

Operator>> Overload

This overload is the main way to read in data from an object such as a file to a checkpoint. It is important to note that inside the function, the first variable to be read is the size of the checkpoint. This size variable is written to the stream before the checkpoint’s data in the operator<< overload. Be mindful of this additional read and write when you use different facilities to read in or write out data from a checkpoint!

Parameters
- **ist**: Input stream to write from.
- **ckp**: Checkpoint to write to.

Return Operator>> returns the ostream object.

template<typename T, typename ...Ts, typename U = typename std::enable_if<!hpx::traits::is_launch_policy<T>::value & hpx::future<checkpoint>> save_checkpoint (T &&t, Ts&&... ts)

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component’s client instance to save_checkpoint. Additionally the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

Template Parameters
- **T**: Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- **Ts**: More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- **U**: This parameter is used to make sure that T is not a launch policy or a checkpoint. This forces the compiler to choose the correct overload.

Parameters
- **t**: A container to restore.
- **ts**: Other containers to restore Containers must be in the same order that they were inserted into the checkpoint.

Return Save_checkpoint returns a future to a checkpoint with one exception: if you pass hpx::launch::sync as the first argument. In this case save_checkpoint will simply return a checkpoint.

template<typename T, typename ...Ts>

hpx::future<checkpoint> save_checkpoint (checkpoint &&c, T &&t, Ts&&... ts)

Save_checkpoint - Take a pre-initialized checkpoint

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component’s client instance to save_checkpoint. Additionally the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

Template Parameters
- **T**: Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- **Ts**: More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
Parameters
- c: Takes a pre-initialized checkpoint to copy data into.
- t: A container to restore.
- t:s: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

Return Save_checkpoint returns a future to a checkpoint with one exception: if you pass hpx::launch::sync as the first argument. In this case save_checkpoint will simply return a checkpoint.

template<typename T, typename ...Ts>, typename U = typename std::enable_if<!std::is_same<typename std::decay<T>::type, checkpoint>::value>::type>

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component's client instance to save_checkpoint. Additionally the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint.

Template Parameters
- T: Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- Ts: More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.

Parameters
- p: Takes an HPX launch policy. Allows the user to change the way the function is launched i.e. async, sync, etc.
- t: A container to restore.
- t:s: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

Return Save_checkpoint returns a future to a checkpoint with one exception: if you pass hpx::launch::sync as the first argument. In this case save_checkpoint will simply return a checkpoint.

template<typename T, typename ...Ts>

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component's client instance to save_checkpoint. Additionally the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

Template Parameters
- T: Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- Ts: More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.

Parameters
- p: Takes an HPX launch policy. Allows the user to change the way the function is launched i.e. async, sync, etc.
- c: Takes a pre-initialized checkpoint to copy data into.
- t: A container to restore.
• ts: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

**Return** Save_checkpoint returns a future to a checkpoint with one exception: if you pass hpx::launch::sync as the first argument. In this case save_checkpoint will simply return a checkpoint.

```cpp
template<typename T, typename ...Ts
checkpoint save_checkpoint (hpx::launch::sync_policy sync_p, T &t, Ts &... ts)
```

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component’s client instance to save_checkpoint. Additionally the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

**Template Parameters**
- T: Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- Ts: More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- U: This parameter is used to make sure that T is not a checkpoint. This forces the compiler to choose the correct overload.

**Parameters**
- sync_p: hpx::launch::sync_policy
- t: A container to restore.
- ts: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

**Return** Save_checkpoint which is passed hpx::launch::sync_policy will return a checkpoint which contains the serialized values checkpoint.

```cpp
template<typename T, typename ...
 checkpoint save_checkpoint (hpx::launch::sync_policy sync_p, checkpoint &c, T &&t,
 Ts&... ts)
```

Save_checkpoint takes any number of objects which a user may wish to store and returns a future to a checkpoint object. This function can also store a component either by passing a shared_ptr to the component or by passing a component’s client instance to save_checkpoint. Additionally the function can take a policy as a first object which changes its behavior depending on the policy passed to it. Most notably, if a sync policy is used save_checkpoint will simply return a checkpoint object.

**Template Parameters**
- T: Containers passed to save_checkpoint to be serialized and placed into a checkpoint object.
- Ts: More containers passed to save_checkpoint to be serialized and placed into a checkpoint object.

**Parameters**
- sync_p: hpx::launch::sync_policy
- c: Takes a pre-initialized checkpoint to copy data into.
- t: A container to restore.
- ts: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.
Return  Save_checkpoint which is passed hpx::launch::sync_policy will return a checkpoint which
contains the serialized values checkpoint.

```cpp
template<typename T, typename ... Ts, typename U = typename std::enable_if<!hpx::traits::is_launch_policy<T>::value &&
hpx::future<checkpoint> prepare_checkpoint (T const &t, Ts const &... ts)

prepare_checkpoint

prepare_checkpoint takes the containers which have to be filled from the byte stream by a subsequent
restore_checkpoint invocation. prepare_checkpoint will calculate the necessary buffer size and will
return an appropriately sized checkpoint object.

Return  prepare_checkpoint returns a properly resized checkpoint object that can be used for a sub-
sequent restore_checkpoint operation.

Template Parameters
• T: A container to restore.
• Ts: Other containers to restore. Containers must be in the same order that they were inserted
into the checkpoint.

Parameters
• t: A container to restore.
• ts: Other containers to restore Containers must be in the same order that they were inserted
into the checkpoint.
```

```cpp
template<typename T, typename ... Ts>
hpx::future<checkpoint> prepare_checkpoint (checkpoint &c, T const &t, Ts const &... ts)

prepare_checkpoint

prepare_checkpoint takes the containers which have to be filled from the byte stream by a subsequent
restore_checkpoint invocation. prepare_checkpoint will calculate the necessary buffer size and will
return an appropriately sized checkpoint object.

Return  prepare_checkpoint returns a properly resized checkpoint object that can be used for a sub-
sequent restore_checkpoint operation.

Template Parameters
• T: A container to restore.
• Ts: Other containers to restore. Containers must be in the same order that they were inserted
into the checkpoint.

Parameters
• c: Takes a pre-initialized checkpoint to prepare
• t: A container to restore.
• ts: Other containers to restore Containers must be in the same order that they were inserted
into the checkpoint.
```

```cpp
template<typename T, typename ... Ts, typename U = typename std::enable_if<!std::is_same<T, checkpoint>::value>::type>
hpx::future<checkpoint> prepare_checkpoint (hpx::launch p, T const &t, Ts const &... ts)

prepare_checkpoint

prepare_checkpoint takes the containers which have to be filled from the byte stream by a subsequent
restore_checkpoint invocation. prepare_checkpoint will calculate the necessary buffer size and will
return an appropriately sized checkpoint object.

Return  prepare_checkpoint returns a properly resized checkpoint object that can be used for a sub-
sequent restore_checkpoint operation.

Template Parameters
• T: A container to restore.
• **Ts**: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

**Parameters**
- **p**: Takes an HPX launch policy. Allows the user to change the way the function is launched i.e. async, sync, etc.
- **t**: A container to restore.
- **ts**: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

```cpp
template<typename T, typename ...Ts>
hpx::future<checkpoint> prepare_checkpoint (hpx::launch p, checkpoint &c, T const &t,
                                       Ts const &... ts)
```

*prepare_checkpoint* takes the containers which have to be filled from the byte stream by a subsequent *restore_checkpoint* invocation. *prepare_checkpoint* will calculate the necessary buffer size and will return an appropriately sized checkpoint object.

**Return** *prepare_checkpoint* returns a properly resized checkpoint object that can be used for a subsequent *restore_checkpoint* operation.

**Template Parameters**
- **T**: A container to restore.
- **Ts**: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

**Parameters**
- **p**: Takes an HPX launch policy. Allows the user to change the way the function is launched i.e. async, sync, etc.
- **c**: Takes a pre-initialized checkpoint to prepare
- **t**: A container to restore.
- **ts**: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

```cpp
template<typename T, typename ...Ts>
void restore_checkpoint (checkpoint const &c, T &t, Ts &... ts)
```

*Restore_checkpoint* takes a checkpoint object as a first argument and the containers which will be filled from the byte stream (in the same order as they were placed in *save_checkpoint*). *Restore_checkpoint* can resurrect a stored component in two ways: by passing in an instance of a component’s shared_ptr or by passing in an instance of the component’s client.

**Return** *Restore_checkpoint* returns void.

**Template Parameters**
- **T**: A container to restore.
- **Ts**: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

**Parameters**
- **c**: The checkpoint to restore.
- **t**: A container to restore.
- **ts**: Other containers to restore. Containers must be in the same order that they were inserted into the checkpoint.

**class checkpoint**

```cpp
#include <checkpoint.hpp> Checkpoint Object
```
Checkpoint is the container object which is produced by save_checkpoint and is consumed by a re-
store_checkpoint. A checkpoint may be moved into the save_checkpoint object to write the byte
stream to the pre-created checkpoint object.

Checkpoints are able to store all containers which are able to be serialized including components.

Public Types

```cpp
using const_iterator = std::vector::const_iterator
```

Public Functions

```cpp

```
Friends

friend hpx::util::hpx::serialization::access

std::ostream &operator<<(std::ostream &ost, checkpoint const &ckp)
            Operator<< Overload

This overload is the main way to write data from a checkpoint to an object such as a file. Inside the
function, the size of the checkpoint will be written to the stream before the checkpoint’s data. The
operator>> overload uses this to read the correct number of bytes. Be mindful of this additional
write and read when you use different facilities to write out or read in data to a checkpoint!

Parameters
  • ost: Output stream to write to.
  • ckp: Checkpoint to copy from.

Return  Operator<< returns the ostream object.

std::istream &operator>>(std::istream &ist, checkpoint &ckp)
            Operator>> Overload

This overload is the main way to read in data from an object such as a file to a checkpoint. It is
important to note that inside the function, the first variable to be read is the size of the checkpoint.
This size variable is written to the stream before the checkpoint’s data in the operator<< overload.
Be mindful of this additional read and write when you use different facilities to read in or write
out data from a checkpoint!

Parameters
  • ist: Input stream to read from.
  • ckp: Checkpoint to write to.

Return  Operator>> returns the ostream object.

template<typename T, typename ...Ts>
void restore_checkpoint (checkpoint const &c, T &t, Ts&... ts)
            Restore_checkpoint

Restore_checkpoint takes a checkpoint object as a first argument and the containers which will
be filled from the byte stream (in the same order as they were placed in save_checkpoint). Re-
store_checkpoint can resurrect a stored component in two ways: by passing in an instance of a
component’s shared_ptr or by passing in an instance of the component’s client.

Return  Restore_checkpoint returns void.

Template Parameters
  • T: A container to restore.
  • Ts: Other containers to restore. Containers must be in the same order that they were inserted
    into the checkpoint.

Parameters
  • c: The checkpoint to restore.
  • t: A container to restore.
  • ts: Other containers to restore Containers must be in the same order that they were inserted
    into the checkpoint.

bool operator==(checkpoint const &lhs, checkpoint const &rhs)
bool operator!=(checkpoint const &lhs, checkpoint const &rhs)

**checkpoint_base**

The contents of this module can be included with the header `hpx/modules/checkpoint_base.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/checkpoint_base.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

```cpp
namespace hpx

namespace util

Functions

```cpp
template<typename Container, typename ...Ts>
void save_checkpoint_data(Container &data, Ts&&... ts)
```

Save_checkpoint_data takes any number of objects which a user may wish to store in the given container.

**Template Parameters**
- Container: Container used to store the check-pointed data.
- Ts: Types of variables to checkpoint

**Parameters**
- cont: Container instance used to store the checkpoint data
- ts: Variable instances to be inserted into the checkpoint.

```cpp
template<typename ...Ts>
std::size_t prepare_checkpoint_data(Ts const&&... ts)
```

Prepare_checkpoint_data takes any number of objects which a user may wish to store in a subsequent save_checkpoint_data operation. The function will return the number of bytes necessary to store the data that will be produced.

**Template Parameters**
- Ts: Types of variables to checkpoint

**Parameters**
- ts: Variable instances to be inserted into the checkpoint.

```cpp
template<typename Container, typename ...Ts>
void restore_checkpoint_data(Container const &cont, Ts&&... ts)
```

Restore_checkpoint_data takes any number of objects which a user may wish to restore from the given container. The sequence of objects has to correspond to the sequence of objects for the corresponding call to save_checkpoint_data that had used the given container instance.

**Template Parameters**
- Container: Container used to restore the check-pointed data.
Ts: Types of variables to restore

**Parameters**
- **cont**: Container instance used to restore the checkpoint data
- **ts**: Variable instances to be restored from the container

### collectives

The contents of this module can be included with the header `hpx/modules/collectives.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/collectives.hpp`, not the particular header in which the functionality you would like to use is defined. See *Public API* for a list of names that are part of the public HPX API.

```cpp
namespace hpx

namespace collectives

### Functions

**template<typename T>**

```cpp
hpx::future<std::vector<std::decay_t<T>>> all_gather(char const *basename, T &&result, num_sites_arg num_sites = num_sites_arg(), this_site_arg this_site = this_site_arg(), generation_arg generation = generation_arg(), root_site_arg root_site = root_site_arg())
```

AllGather a set of values from different call sites

This function receives a set of values from all participating sites operating on the given base name.

**Return**
This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all_gather operation has been completed.

**Parameters**
- **basename**: The base name identifying the all_gather operation
- **local_result**: The value to transmit to all participating sites from this call site.
- **num_sites**: The number of participating sites (default: all localities).
- **generation**: The generational counter identifying the sequence number of the all_gather operation performed on the given base name. This is optional and needs to be supplied only if the all_gather operation on the given base name has to be performed more than once.
- **this_site**: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns. 
- **params root_site** The site that is responsible for creating the all_gather support object. This value is optional and defaults to '0' (zero).

**template<typename T>**

```cpp
hpx::future<std::vector<std::decay_t<T>>> all_gather(communicator comm, T &&result, this_site_arg this_site = this_site_arg())
```

AllGather a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.
Return This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all_gather operation has been completed.

Parameters
- **comm**: A communicator object returned from `create_reducer`
- **local_result**: The value to transmit to all participating sites from this call site.
- **this_site**: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

namespace hpx

namespace collectives

Functions

template<typename T, typename F>
`hpx::future<std::decay_t<T>> all_reduce(char const *basename, T &&result, F &&op, num_sites_arg num_sites = num_sites_arg(),
this_site_arg this_site = this_site_arg(),
generation_arg generation = generation_arg(),
root_site_arg root_site = root_site_arg())`

AllReduce a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Return This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all_reduce operation has been completed.

Parameters
- **basename**: The base name identifying the all_reduce operation
- **local_result**: The value to transmit to all participating sites from this call site.
- **op**: Reduction operation to apply to all values supplied from all participating sites
- **num_sites**: The number of participating sites (default: all localities).
- **generation**: The generational counter identifying the sequence number of the all_reduce operation performed on the given base name. This is optional and needs to be supplied only if the all_reduce operation on the given base name has to be performed more than once.
- **this_site**: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns. 

params root_site The site that is responsible for creating the all_reduce support object. This value is optional and defaults to ‘0’ (zero).

template<typename T, typename F>
`hpx::future<std::decay_t<T>> all_reduce(communicator comm, T &&result, F &&op,
this_site_arg this_site = this_site_arg())`

AllReduce a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Return This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all_reduce operation has been completed.

Parameters
- **comm**: A communicator object returned from `create_reducer`
- **local_result**: The value to transmit to all participating sites from this call site.
- **op**: Reduction operation to apply to all values supplied from all participating sites
- **this_site**: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

hpx::future<std::vector<std::decay_t<T>>> all_to_all(char const *basename, T &&result, num_sites_arg num_sites = num_sites_arg(), this_site_arg this_site = this_site_arg(), generation_arg generation = generation_arg(), root_site_arg root_site = root_site_arg())

AllToAll a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Return This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all_to_all operation has been completed.

Parameters
- basename: The base name identifying the all_to_all operation
- local_result: The value to transmit to all participating sites from this call site.
- num_sites: The number of participating sites (default: all localities).
- generation: The generational counter identifying the sequence number of the all_to_all operation performed on the given base name. This is optional and needs to be supplied only if the all_to_all operation on the given base name has to be performed more than once.
- this_site: The sequence number of this invocation (usually the locality id). This value is optional and defaults to ‘0’ (zero).

template<typename T>
hpx::future<std::vector<std::decay_t<T>>> all_to_all(communicator comm, T &&result, this_site_arg this_site = this_site_arg())

AllToAll a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

Return This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all_to_all operation has been completed.

Parameters
- comm: A communicator object returned from create_reducer
- local_result: The value to transmit to all participating sites from this call site.
- this_site: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

namespace hpx

namespace lcos

class barrier

\#include \texttt{<barrier.hpp>} The barrier is an implementation performing a barrier over a number of participating threads. The different threads don’t have to be on the same locality. This barrier can be invoked in a distributed application.

For a local only barrier
See \texttt{hpx::lcos::local::barrier}.

Public Functions

\texttt{barrier (std::string const &base_name)}

Creates a barrier, rank is locality id, size is number of localities

A barrier \texttt{base_name} is created. It expects that \texttt{hpx::get_num_localities()} participate and the local rank is \texttt{hpx::get_locality_id()}.

Parameters

- \texttt{base_name}: The name of the barrier

\texttt{barrier (std::string const &base_name, std::size_t num)}

Creates a barrier with a given size, rank is locality id

A barrier \texttt{base_name} is created. It expects that \texttt{num} participate and the local rank is \texttt{hpx::get_locality_id()}.

Parameters

- \texttt{base_name}: The name of the barrier
- \texttt{num}: The number of participating threads
barrier (std::string const &base_name, std::size_t num, std::size_t rank)
  Creates a barrier with a given size and rank

A barrier base_name is created. It expects that num participate and the local rank is rank.

Parameters
  • base_name: The name of the barrier
  • num: The number of participating threads
  • rank: The rank of the calling site for this invocation

barrier (std::string const &base_name, std::vector<std::size_t> const &ranks, std::size_t rank)
  Creates a barrier with a vector of ranks

A barrier base_name is created. It expects that ranks.size() and the local rank is rank (must be contained in ranks).

Parameters
  • base_name: The name of the barrier
  • ranks: Gives a list of participating ranks (this could be derived from a list of locality ids
  • rank: The rank of the calling site for this invocation

void wait()
  Wait until each participant entered the barrier. Must be called by all participants

Return  This function returns once all participants have entered the barrier (have called wait).

hpx::future<void> wait (hpx::launch::async_policy)
  Wait until each participant entered the barrier. Must be called by all participants

Return  a future that becomes ready once all participants have entered the barrier (have called wait).

Public Static Functions

static void synchronize()
  Perform a global synchronization using the default global barrier The barrier is created once at
time and can be reused throughout the lifetime of an HPX application.

Note  This function currently does not support dynamic connection and disconnection of locali-
ties.
Functions

```cpp
template<typename T>
hpx::future<void> broadcast_to(char const *basename, T &local_result, num_sites_arg
    num_sites = num_sites_arg(), this_site_arg this_site =
    this_site_arg(), generation_arg generation = genera-
    tion_arg())

Broadcast a value to different call sites
This function sends a set of values to all call sites operating on the given base name.

Return  This function returns a future that will become ready once the broadcast operation has been
completed.

Parameters
• basename: The base name identifying the broadcast operation
• local_result: A value to transmit to all participating sites from this call site.
• num_sites: The number of participating sites (default: all localities).
• generation: The generational counter identifying the sequence number of the broadcast
operation performed on the given base name. This is optional and needs to be supplied only if
the broadcast operation on the given base name has to be performed more than once.
• this_site: The sequence number of this invocation (usually the locality id). This value is
optional and defaults to whatever hpx::get_locality_id() returns.
```

```cpp
template<typename T>
hpx::future<void> broadcast_to(communicator comm, T &local_result, this_site_arg
    this_site = this_site_arg())

Broadcast a value to different call sites
This function sends a set of values to all call sites operating on the given base name.

Return  This function returns a future that will become ready once the broadcast operation has been
completed.

Parameters
• comm: A communicator object returned from create_reducer
• local_result: A value to transmit to all participating sites from this call site.
• this_site: The sequence number of this invocation (usually the locality id). This value is
optional and defaults to whatever hpx::get_locality_id() returns.
```

```cpp
template<typename T>
hpx::future<T> broadcast_from(char const *basename, this_site_arg this_site =
    this_site_arg(), generation_arg generation = genera-
    tion_arg())

Receive a value that was broadcast to different call sites
This function sends a set of values to all call sites operating on the given base name.

Return  This function returns a future holding the value that was sent to all participating sites. It will
become ready once the broadcast operation has been completed.

Parameters
• basename: The base name identifying the broadcast operation
• generation: The generational counter identifying the sequence number of the broadcast
operation performed on the given base name. This is optional and needs to be supplied only if
the broadcast operation on the given base name has to be performed more than once.
• this_site: The sequence number of this invocation (usually the locality id). This value is
optional and defaults to whatever hpx::get_locality_id() returns.
```
template<typename T>
hp::future<T> broadcast_from (communicator comm, this_site_arg this_site = this_site_arg())

Receive a value that was broadcast to different call sites

This function sends a set of values to all call sites operating on the given base name.

**Return** This function returns a future holding the value that was sent to all participating sites. It will become ready once the broadcast operation has been completed.

**Parameters**
- `comm`: A communicator object returned from `create_reducer`
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hp::get_locality_id()` returns.

namespace hpx

namespace lcos

**Functions**

```cpp
template<typename Action, typename ArgN, ...>hp::future<std::vector<decltype(Action(hpx::id_type, ArgN, ...))> > hpx::lcos::broadcast(std::vector<hpx::id_type> const & ids, ArgN argN, ...)
```

Perform a distributed broadcast operation.

The function `hpx::lcos::broadcast` performs a distributed broadcast operation resulting in action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action.

The given action is invoked asynchronously on all given identifiers, and the arguments `ArgN` are passed along to those invocations.

**Return** This function returns a future representing the result of the overall reduction operation.

**Note** If `decltype(Action(...))` is `void`, then the result of this function is `future<void>`.  

**Parameters**
- `ids`: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- `argN`: [in] Any number of arbitrary arguments (passed by const reference) which will be forwarded to the action invocation.

```cpp
template<typename Action, typename ArgN, ...>void hpx::lcos::broadcast_apply(std::vector<hpx::id_type> const & ids, ArgN argN, ...)
```

Perform an asynchronous (fire&forget) distributed broadcast operation.

The function `hpx::lcos::broadcast_apply` performs an asynchronous (fire&forget) distributed broadcast operation resulting in action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action.

The given action is invoked asynchronously on all given identifiers, and the arguments `ArgN` are passed along to those invocations.

**Parameters**
- `ids`: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- `argN`: [in] Any number of arbitrary arguments (passed by const reference) which will be forwarded to the action invocation.
template<typename Action, typename ArgN, ...> hpx::future< std::vector< decltype(Action(hpx::id_type, ArgN, ..., std::size_t))>> hpx::lcos::broadcast_with_index(std::vector< hpx::id_type > const & ids, ArgN argN, ...)

Perform a distributed broadcast operation.

The function `hpx::lcos::broadcast_with_index` performs a distributed broadcast operation resulting in action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action.

The given action is invoked asynchronously on all given identifiers, and the arguments `ArgN` are passed along to those invocations.

The function passes the index of the global identifier in the given list of identifiers as the last argument to the action.

**Return**

This function returns a future representing the result of the overall reduction operation.

**Note**

If `decltype(Action(...))` is void, then the result of this function is `future<void>`.

**Parameters**

- `ids`: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- `argN`: [in] Any number of arbitrary arguments (passed by const reference) which will be forwarded to the action invocation.

---

template<typename Action, typename ArgN, ...> void hpx::lcos::broadcast_apply_with_index(std::vector< hpx::id_type > const & ids, ArgN argN, ...)

Perform an asynchronous (fire&forget) distributed broadcast operation.

The function `hpx::lcos::broadcast_apply_with_index` performs an asynchronous (fire&forget) distributed broadcast operation resulting in action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action.

The given action is invoked asynchronously on all given identifiers, and the arguments `ArgN` are passed along to those invocations.

The function passes the index of the global identifier in the given list of identifiers as the last argument to the action.

**Parameters**

- `ids`: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- `argN`: [in] Any number of arbitrary arguments (passed by const reference) which will be forwarded to the action invocation.

---

namespace hpx

namespace collectives
Functions

```
hpx::future<channel_communicator> create_channel_communicator(char const *basename, 
num_sites_arg num_sites = num_sites_arg(), 
this_site_arg this_site = this_site_arg())
```

Create a new communicator object usable with peer-to-peer channel-based operations

This function creates a new communicator object that can be called in order to pre-allocate a communicator object usable with multiple invocations of channel-based peer-to-peer operations.

Return This function returns a future to a new communicator object usable with the collective operation.

Parameters

- `basename`: The base name identifying the collective operation
- `num_sites`: The number of participating sites (default: all localities).
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

```
channel_communicator create_channel_communicator(hpx::launch::sync_policy, 
char const *basename, 
num_sites_arg num_sites = num_sites_arg(), 
this_site_arg this_site = this_site_arg())
```

Create a new communicator object usable with peer-to-peer channel-based operations

This function creates a new communicator object that can be called in order to pre-allocate a communicator object usable with multiple invocations of channel-based peer-to-peer operations.

Return This function returns a new communicator object usable with the collective operation.

Parameters

- `basename`: The base name identifying the collective operation
- `num_sites`: The number of participating sites (default: all localities).
- `this_site`: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

```
template<typename T>
hpx::future<void> set(channel_communicator comm, that_site_arg site, T &&value)
```

Send a value to the given site

This function sends a value to the given site based on the given communicator.

Return This function returns a future<void> that becomes ready once the data transfer operation has finished.

Parameters

- `comm`: The channel communicator object to use for the data transfer
- `site`: The destination site
- `value`: The value to send

```
template<typename T>
```
**namespace hpx**

**namespace lcos**

**Functions**

- **hpx::future<hpx::id_type> create_communication_set**
  
  ```cpp
  hpx::future<hpx::id_type> create_communication_set (char const *basename, std::size_t num_sites = std::size_t(-1), 
                                                        std::size_t this_site = std::size_t(-1), 
                                                        std::size_t arity = std::size_t(-1))
  ```

  The function `create_communication_set` sets up a (distributed) tree-like communication structure that can be used with any of the collective APIs (such like `all_to_all` and similar).

  **Return** This function returns a future holding an `id_type` of the communicator object to be used on the current locality.

  **Parameters**
  
  - **basename**: The base name identifying the `all_to_all` operation
  - **num_sites**: The number of participating sites (default: all localities).
  - **this_site**: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.
  - **arity**: The number of children each of the communication nodes is connected to (default: picked based on num_sites)

**namespace hpx**

**namespace collectives**

**Functions**

- **communicator create_communicator**
  
  ```cpp
  communicator create_communicator (char const *basename, num_sites_arg num_sites
                                     = num_sites_arg(), this_site_arg this_site = this_site_arg(),
                                     generation_arg generation = generation_arg(), root_site_arg root_site = root_site_arg())
  ```

  Create a new communicator object usable with any collective operation.

  This function creates a new communicator object that can be called in order to pre-allocate a communicator object usable with multiple invocations of any of the collective operations (such as `all_gather`, `all_reduce`, `all_to_all`, `broadcast`, etc.).

  **Return** This function returns a new communicator object usable with the collective operation.
Parameters

- **basename**: The base name identifying the collective operation
- **num_sites**: The number of participating sites (default: all localities)
- **generation**: The generational counter identifying the sequence number of the collective operation performed on the given base name. This is optional and needs to be supplied only if the collective operation on the given base name has to be performed more than once.
- **this_site**: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.
- **root_site**: The site that is responsible for creating the collective support object. This value is optional and defaults to '0' (zero).

```cpp
namespace hpx
namespace collectives

Functions

template<typename T, typename F>
hp::future<std::decay_t<T>> exclusive_scan (char const *basename, T &&result, F &&op,
num_sites_arg num_sites = num_sites_arg(),
this_site_arg this_site = this_site_arg(),
generation_arg generation = generation_arg(),
root_site_arg root_site = root_site_arg())
```

Exclusive scan a set of values from different call sites
This function receives a set of values from all call sites operating on the given base name.

**Note** The result returned on the root_site is always the same as the result returned on thus_site == 1 and is the same as the value provided by the thje root_site.

**Return** This function returns a future holding a vector with all values send by all participating sites. It will become ready once the exclusive_scan operation has been completed.

Parameters

- **basename**: The base name identifying the exclusive_scan operation
- **local_result**: The value to transmit to all participating sites from this call site.
- **op**: Reduction operation to apply to all values supplied from all participating sites
- **num_sites**: The number of participating sites (default: all localities).
- **generation**: The generational counter identifying the sequence number of the exclusive_scan operation performed on the given base name. This is optional and needs to be supplied only if the exclusive_scan operation on the given base name has to be performed more than once.
- **this_site**: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.
- **root_site**: The site that is responsible for creating the exclusive_scan support object. This value is optional and defaults to '0' (zero).

```cpp
template<typename T, typename F>
hp::future<std::decay_t<T>> exclusive_scan (communicator comm, T &&result, F &&op,
this_site_arg this_site = this_site_arg())
```

Exclusive scan a set of values from different call sites
This function receives a set of values from all call sites operating on the given base name.

**Note** The result returned on the root_site is always the same as the result returned on thus_site == 1 and is the same as the value provided by the thje root_site.
Return  This function returns a future holding a vector with all values send by all participating sites. It will become ready once the exclusive_scan operation has been completed.

Parameters
- comm: A communicator object returned from create_reducer
- local_result: The value to transmit to all participating sites from this call site.
- op: Reduction operation to apply to all values supplied from all participating sites
- this_site: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

namespace hpx

namespace lcos

Functions

template<typename Action, typename FoldOp, typename Init, typename ArgN, ...>hpx::future<decltype(Action(hpx::id_type, ArgN, ...))> hpx::lcos::fold(std::vector<hpx::id_type> const & ids, FoldOp && fold_op, Init && init, ArgN argN, ...)
Perform a distributed fold operation.

The function hpx::lcos::fold performs a distributed folding operation over results returned from action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).

Note  The type of the initial value must be convertible to the result type returned from the invoked action.

Return  This function returns a future representing the result of the overall folding operation.

Parameters
- ids: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
- fold_op: [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the folding operation performed on its arguments.
- init: [in] The initial value to be used for the folding operation
- argN: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the action invocation.

template<typename Action, typename FoldOp, typename Init, typename ArgN, ...>hpx::future<decltype(hpx::lcos::fold_with_index(std::vector<hpx::id_type> const & ids, FoldOp && fold_op, Init && init, ArgN argN, ...))> hpx::lcos::fold_with_index(std::vector<hpx::id_type> const & ids, FoldOp && fold_op, Init && init, ArgN argN, ...)
Perform a distributed folding operation.

The function hpx::lcos::fold_with_index performs a distributed folding operation over results returned from action invocations on a given set of global identifiers. The action can be either plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action).

The function passes the index of the global identifier in the given list of identifiers as the last argument to the action.

Note  The type of the initial value must be convertible to the result type returned from the invoked action.

Return  This function returns a future representing the result of the overall folding operation.

Parameters
- ids: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.
• `fold_op`: [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the folding operation performed on its arguments.

• `init`: [in] The initial value to be used for the folding operation

• `argN`: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the action invocation.

```cpp
template<typename Action, typename FoldOp, typename Init, typename ArgN, ...>
    hpx::future<decltype(Action(hpx::id_type, ArgN, ...))> hpx::lcos::inverse_fold
        (std::vector<hpx::id_type> const & ids, FoldOp && fold_op, Init && init, ArgN argN, ...)
```

Perform a distributed inverse folding operation.

The function `hpx::lcos::inverse_fold` performs an inverse distributed folding operation over results returned from action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action.

**Note** The type of the initial value must be convertible to the result type returned from the invoked action.

**Return** This function returns a future representing the result of the overall folding operation.

**Parameters**

• `ids`: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.

• `fold_op`: [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the folding operation performed on its arguments.

• `init`: [in] The initial value to be used for the folding operation

• `argN`: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the action invocation.

```cpp
template<typename Action, typename FoldOp, typename Init, typename ArgN, ...>
    hpx::future<decltype(Action(hpx::id_type, ArgN, ...))> hpx::lcos::inverse_fold_with_index
        (std::vector<hpx::id_type> const & ids, FoldOp && fold_op, Init && init, ArgN argN, ...)
```

Perform a distributed inverse folding operation.

The function `hpx::lcos::inverse_fold_with_index` performs an inverse distributed folding operation over results returned from action invocations on a given set of global identifiers. The action can be either plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action.

The function passes the index of the global identifier in the given list of identifiers as the last argument to the action.

**Note** The type of the initial value must be convertible to the result type returned from the invoked action.

**Return** This function returns a future representing the result of the overall folding operation.

**Parameters**

• `ids`: [in] A list of global identifiers identifying the target objects for which the given action will be invoked.

• `fold_op`: [in] A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the folding operation performed on its arguments.

• `init`: [in] The initial value to be used for the folding operation

• `argN`: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the action invocation.

char const *basename,
T &&result,
num_sites_arg num_sites =
num_sites_arg(),
this_site_arg this_site =
this_site_arg(),
generation_arg generation =
generation_arg())

Gather a set of values from different call sites
This function receives a set of values from all call sites operating on the given base name.

Return  This function returns a future holding a vector with all gathered values. It will become ready once the gather operation has been completed.

Parameters

•  basename: The base name identifying the gather operation
•  result: The value to transmit to the central gather point from this call site.
•  num_sites: The number of participating sites (default: all localities).
•  generation: The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once.
•  this_site: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hp::get_locality_id() returns.

template<typename T>
hp::future<
std::vector<
decay_t<T>>>
gather_here(
communicator comm,
T &&result,
this_site_arg this_site =
this_site_arg())

Gather a set of values from different call sites
This function receives a set of values from all call sites operating on the given base name.

Return  This function returns a future holding a vector with all gathered values. It will become ready once the gather operation has been completed.

Parameters

•  comm: A communicator object returned from create_reducer
•  result: The value to transmit to the central gather point from this call site.
•  this_site: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hp::get_locality_id() returns.

template<typename T>

char const *basename,
T &&result,
this_site_arg this_site =
this_site_arg(),
generation_arg generation =
generation_arg(),
root_site_arg root_site =
root_site_arg())

Gather a given value at the given call site
This function transmits the value given by result to a central gather site (where the corresponding gather_here is executed)

Return  This function returns a future holding a vector with all gathered values. It will become ready once the gather operation has been completed.
Parameters
- **basename**: The base name identifying the gather operation
- **result**: The value to transmit to the central gather point from this call site.
- **generation**: The generational counter identifying the sequence number of the gather operation performed on the given base name. This is optional and needs to be supplied only if the gather operation on the given base name has to be performed more than once.
- **this_site**: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.
- **root_site**: The sequence number of the central gather point (usually the locality id). This value is optional and defaults to 0.

```cpp
template<typename T>
hpx::future<std::vector<decay_t<T>>> gather_there (communicator comm, T &&result,
this_site_arg this_site = this_site_arg())
```

Gather a given value at the given call site

This function transmits the value given by `result` to a central gather site (where the corresponding `gather_here` is executed)

**Return** This function returns a future holding a vector with all gathered values. It will become ready once the gather operation has been completed.

**Parameters**
- **comm**: A communicator object returned from `create_reducer`
- **result**: The value to transmit to the central gather point from this call site.
- **this_site**: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

```cpp
namespace hpx

namespace collectives

Functions

```cpp
template<typename T, typename F>
hpx::future<std::decay_t<T>> inclusive_scan (char const *basename, T &&result, F &&op,
num_sites_arg num_sites = num_sites_arg(),
this_site_arg this_site = this_site_arg(),
generation_arg generation = generation_arg(),
root_site_arg root_site = root_site_arg())
```

Inclusive inclusive_scan a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

**Return** This function returns a future holding a vector with all values send by all participating sites. It will become ready once the inclusive_scan operation has been completed.

**Parameters**
- **basename**: The base name identifying the inclusive_scan operation
- **local_result**: The value to transmit to all participating sites from this call site.
- **op**: Reduction operation to apply to all values supplied from all participating sites
- **num_sites**: The number of participating sites (default: all localities).
- **generation**: The generational counter identifying the sequence number of the inclusive_scan operation performed on the given base name. This is optional and needs to be supplied only if the inclusive_scan operation on the given base name has to be performed more than once.
**this_site**: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns. 

**root_site**: The site that is responsible for creating the inclusive_scan support object. This value is optional and defaults to '0' (zero).

```cpp
template<typename T, typename F>
hpx::future<std::decay_t<T>> inclusive_scan (communicator comm, T &&result, F &&op,
        this_site_arg this_site = this_site_arg())
```

Inclusive inclusive_scan a set of values from different call sites

This function receives a set of values from all call sites operating on the given base name.

**Return** This function returns a future holding a vector with all values send by all participating sites. It will become ready once the inclusive_scan operation has been completed.

**Parameters**
- **comm**: A communicator object returned from `create_reducer`
- **local_result**: The value to transmit to all participating sites from this call site.
- **op**: Reduction operation to apply to all values supplied from all participating sites
- **this_site**: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever `hpx::get_locality_id()` returns.

```cpp
namespace hpx
namespace lcos

class latch : public components::client_base<latch, lcos::server::latch>

Public Functions

latch ()
latch (std::ptrdiff_t count)
    Initialize the latch
    Requires: count >= 0. Synchronization: None Postconditions: counter_ == count.
latch (naming::id_type const &id)
    Extension: Create a client side representation for the existing server::latch instance with the given global id id.
latch (hpx::future<naming::id_type> &&f)
    Extension: Create a client side representation for the existing server::latch instance with the given global id id.
latch (hpx::shared_future<naming::id_type> const &id)
    Extension: Create a client side representation for the existing server::latch instance with the given global id id.
latch (hpx::shared_future<naming::id_type> &&id)
    void count_down_and_wait ()
        Decrements counter_ by 1 . Blocks at the synchronization point until counter_ reaches 0.
        Requires: counter_ > 0.
```

2.8. API reference
Synchronization: Synchronizes with all calls that block on this latch and with all is_ready calls on this latch that return true.

Exceptions
• Nothing.

void count_down (std::ptrdiff_t n)
Decrements counter_ by n. Does not block.
Requires: counter_ >= n and n >= 0.
Synchronization: Synchronizes with all calls that block on this latch and with all is_ready calls on this latch that return true.

Exceptions
• Nothing.

bool is_ready () const
Returns: counter_ == 0. Does not block.

Exceptions
• Nothing.

void wait () const
If counter_ is 0, returns immediately. Otherwise, blocks the calling thread at the synchronization point until counter_ reaches 0.

Exceptions
• Nothing.

Functions

template<typename T, typename F>
hp::future<std::decay_t<T>> reduce_here (char const *basename, T &&result, F &&op,
num_sites_arg num_sites = num_sites_arg(),
this_site_arg this_site = this_site_arg(),
generation_arg generation = generation_arg())

Reduce a set of values from different call sites
This function receives a set of values from all call sites operating on the given base name.

Return This function returns a future holding a vector with all values send by all participating sites. It will become ready once the all_reduce operation has been completed.

Parameters
• **basename**: The base name identifying the all_reduce operation
• **local_result**: A value to reduce on the central reduction point from this call site.
• **op**: Reduction operation to apply to all values supplied from all participating sites
• **num_sites**: The number of participating sites (default: all localities).
• **generation**: The generational counter identifying the sequence number of the all_reduce operation performed on the given base name. This is optional and needs to be supplied only if the all_reduce operation on the given base name has to be performed more than once.
• **this_site**: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

```cpp
template<typename T, typename F>
hx::future<decay_t<T>> reduce_here (communicator comm, T &&local_result, F &&op,
this_site_arg this_site = this_site_arg())
```

Reduce a set of values from different call sites

This function receives a set of values that are the result of applying a given operator on values supplied from all call sites operating on the given base name.

**Return** This function returns a future holding a value calculated based on the values send by all participating sites. It will become ready once the all_reduce operation has been completed.

**Parameters**
• **comm**: A communicator object returned from create_communicator
• **local_result**: A value to reduce on the root_site from this call site.
• **op**: Reduction operation to apply to all values supplied from all participating sites
• **this_site**: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

```cpp
template<typename T, typename F>
hx::future<void> reduce_there (char const *basename, T &&result, this_site_arg this_site =
this_site_arg(), generation_arg generation = generation_arg(),
root_site_arg root_site = root_site_arg())
```

Reduce a given value at the given call site

This function transmits the value given by result to a central reduce site (where the corresponding reduce_here is executed)

**Return** This function returns a future<void>. It will become ready once the reduction operation has been completed.

**Parameters**
• **basename**: The base name identifying the reduction operation
• **result**: A future referring to the value to transmit to the central reduction point from this call site.
• **generation**: The generational counter identifying the sequence number of the reduction operation performed on the given base name. This is optional and needs to be supplied only if the reduction operation on the given base name has to be performed more than once.
• **this_site**: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.
• **root_site**: The sequence number of the central reduction point (usually the locality id). This value is optional and defaults to 0.

```cpp
template<typename T>
hx::future<void> reduce_there (communicator comm, T &&local_result, this_site_arg
this_site = this_site_arg())
```

Reduce a given value at the given call site
This function transmits the value given by \textit{result} to a central reduce site (where the corresponding \textit{reduce\_here} is executed)

\textbf{Return}   This function returns a future holding a value calculated based on the values send by all participating sites. It will become ready once the all\_reduce operation has been completed.

\textbf{Parameters}
\begin{itemize}
  \item \texttt{comm}: A communicator object returned from \textit{create\_communicator}
  \item \texttt{local\_result}: A value to reduce on the central reduction point from this call site.
  \item \texttt{this\_site}: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever \texttt{hpx\::get\_locality\_id()} returns.
\end{itemize}

Functions

\begin{verbatim}
template<typename Action, typename ReduceOp, typename ArgN, ...>hpx::future<decltype(Action(hpx::id_type, ArgN, ...))> hpx::lcos::reduce(std::vector<hpx::id_type> const & ids, ReduceOp && reduce_op, ArgN argN, ...)
Perform a distributed reduction operation.

The function hpx::lcos::reduce performs a distributed reduction operation over results returned from action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action.

\textbf{Return}   This function returns a future representing the result of the overall reduction operation.

\textbf{Parameters}
\begin{itemize}
  \item \texttt{ids}: \texttt{[in]} A list of global identifiers identifying the target objects for which the given action will be invoked.
  \item \texttt{reduce\_op}: \texttt{[in]} A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the reduction operation performed on its arguments.
  \item \texttt{argN}: \texttt{[in]} Any number of arbitrary arguments (passed by by const reference) which will be forwarded to the action invocation.
\end{itemize}
\end{verbatim}
\end{verbatim}

\begin{verbatim}
template<typename Action, typename ReduceOp, typename ArgN, ...>hpx::future<decltype(Action(hpx::id_type, ArgN, ..., std::size_t))> hpx::lcos::reduce_with_index(std::vector<hpx::id_type> const & ids, ReduceOp && reduce_op, ArgN argN, ...)
Perform a distributed reduction operation.

The function hpx::lcos::reduce_with_index performs a distributed reduction operation over results returned from action invocations on a given set of global identifiers. The action can be either a plain action (in which case the global identifiers have to refer to localities) or a component action (in which case the global identifiers have to refer to instances of a component type which exposes the action.

The function passes the index of the global identifier in the given list of identifiers as the last argument to the action.

\textbf{Return}   This function returns a future representing the result of the overall reduction operation.

\textbf{Parameters}
\begin{itemize}
  \item \texttt{ids}: \texttt{[in]} A list of global identifiers identifying the target objects for which the given action will be invoked.
  \item \texttt{reduce\_op}: \texttt{[in]} A binary function expecting two results as returned from the action invocations. The function (or function object) is expected to return the result of the reduction operation performed on its arguments.
\end{itemize}
\end{verbatim}

\end{verbatim}
• \texttt{argN}: [in] Any number of arbitrary arguments (passed by by const reference) which will be forwarded to the action invocation.

namespace hpx

namespace collectives

Functions

template<typename T>
hpx::future<T> scatter_from(char const *basename, this_site_arg this_site = this_site_arg(),
                             generation_arg generation = generation_arg(), root_site_arg root_site = root_site_arg())
Scatter (receive) a set of values to different call sites
This function receives an element of a set of values operating on the given base name.

Return This function returns a future holding a the scattered value. It will become ready once the scatter operation has been completed.

Parameters
• basename: The base name identifying the scatter operation
• generation: The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once.
• this_site: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.
• root_site: The sequence number of the central scatter point (usually the locality id). This value is optional and defaults to 0.

template<typename T>
hpx::future<T> scatter_from(communicator comm, this_site_arg this_site = this_site_arg())
Scatter (receive) a set of values to different call sites
This function receives an element of a set of values operating on the given base name.

Return This function returns a future holding a the scattered value. It will become ready once the scatter operation has been completed.

Parameters
• comm: A communicator object returned from create_reducer
• this_site: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

template<typename T>
hpx::future<T> scatter_to(char const *basename, std::vector<T> &&result, num_sites_arg num_sites = num_sites_arg(),
                          this_site_arg this_site = this_site_arg(), generation_arg generation = generation_arg())
Scatter (send) a part of the value set at the given call site
This function transmits the value given by result to a central scatter site (where the corresponding scatter_from is executed)

Return This function returns a future holding a the scattered value. It will become ready once the scatter operation has been completed.

Parameters
\end{verbatim}
• basename: The base name identifying the scatter operation
• result: The value to transmit to the central scatter point from this call site.
• num_sites: The number of participating sites (default: all localities).
• generation: The generational counter identifying the sequence number of the scatter operation performed on the given base name. This is optional and needs to be supplied only if the scatter operation on the given base name has to be performed more than once.
• this_site: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

```cpp
template<typename T>
hpx::future<T> scatter_to(communicator comm, std::vector<T> &&result, this_site_arg this_site = this_site_arg())
```

Scatter (send) a part of the value set at the given call site

This function transmits the value given by result to a central scatter site (where the corresponding scatter_from is executed)

**Return** This function returns a future holding a the scattered value. It will become ready once the scatter operation has been completed.

**Parameters**
- comm: A communicator object returned from create_reducer
- num_sites: The number of participating sites (default: all localities).
- this_site: The sequence number of this invocation (usually the locality id). This value is optional and defaults to whatever hpx::get_locality_id() returns.

```cpp
namespace hpx

namespace lcos

Functions

template<typename F, typename ...Args>
hpx::future<void> define_spmd_block(std::string &&name, std::size_t images_per_locality, F&&, Args&&... args)

struct spmd_block
```

#include <spmd_block.hpp> The class spmd_block defines an interface for launching multiple images while giving handles to each image to interact with the remaining images. The define_spmd_block function templates create multiple images of a user-defined action and launches them in a possibly separate thread. A temporary spmd block object is created and diffused to each image. The constraint for the action given to the define_spmd_block function is to accept a spmd_block as first parameter.

**Public Functions**

```cpp
spmd_block()

spmd_block(std::string const &name, std::size_t images_per_locality, std::size_t num_images, std::size_t image_id)
```

namespace hpx

Functions

```cpp
template<typename Client>
std::vector<Client> find_all_from_basename (std::string base_name, std::size_t num_ids)

Return all registered clients from all localities from the given base name. This function locates all ids which were registered with the given base name. It returns a list of futures representing those ids.

Return all registered ids from all localities from the given base name.

Return A list of futures representing the ids which were registered using the given base name.

Note The futures embedded in the returned client objects will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.
```

Template Parameters
• **Client**: The client type to return

**Parameters**

• **base_name**: [in] The base name for which to retrieve the registered ids.

• **num_ids**: [in] The number of registered ids to expect.

This function locates all ids which were registered with the given base name. It returns a list of futures representing those ids.

**Return** A list of futures representing the ids which were registered using the given base name.

**Note** The futures will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

**Parameters**

• **base_name**: [in] The base name for which to retrieve the registered ids.

• **num_ids**: [in] The number of registered ids to expect.

```cpp
template<typename Client>
std::vector<Client> find_from_basename (std::string base_name, std::vector<std::size_t> const &ids)
```

Return registered clients from the given base name and sequence numbers.

This function locates the ids which were registered with the given base name and the given sequence numbers. It returns a list of futures representing those ids.

Return registered ids from the given base name and sequence numbers.

**Return** A list of futures representing the ids which were registered using the given base name and sequence numbers.

**Note** The futures embedded in the returned client objects will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

**Template Parameters**

• **Client**: The client type to return

**Parameters**

• **base_name**: [in] The base name for which to retrieve the registered ids.

• **ids**: [in] The sequence numbers of the registered ids.

This function locates the ids which were registered with the given base name and the given sequence numbers. It returns a list of futures representing those ids.

**Return** A list of futures representing the ids which were registered using the given base name and sequence numbers.

**Note** The futures will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

**Parameters**
• base_name: [in] The base name for which to retrieve the registered ids.
• ids: [in] The sequence numbers of the registered ids.

template<typename Client>
Client find_from_basename (std::string base_name, std::size_t sequence_nr)

Return registered id from the given base name and sequence number.
This function locates the id which was registered with the given base name and the given sequence number. It returns a future representing those id.

This function locates the id which was registered with the given base name and the given sequence number. It returns a future representing those id.

Return A representing the id which was registered using the given base name and sequence numbers.

Note The future embedded in the returned client object will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

Template Parameters
• Client: The client type to return

Parameters
• base_name: [in] The base name for which to retrieve the registered ids.
• sequence_nr: [in] The sequence number of the registered id.

Return A representing the id which was registered using the given base name and sequence numbers.

Note The future will become ready even if the event (for instance, binding the name to an id) has already happened in the past. This is important in order to reliably retrieve ids from a name, even if the name was already registered.

Parameters
• base_name: [in] The base name for which to retrieve the registered ids.
• sequence_nr: [in] The sequence number of the registered id.

template<typename Client, typename Stub>
hpx::future<bool> register_with_basename (std::string base_name, components::client_base<Client, Stub> &client, std::size_t sequence_nr)

Register the id wrapped in the given client using the given base name.
The function registers the object the given client refers to using the provided base name.

Return A future representing the result of the registration operation itself.

Note The operation will fail if the given sequence number is not unique.

Template Parameters
• Client: The client type to register

Parameters
• base_name: [in] The base name for which to retrieve the registered ids.
• **client**: [in] The client which should be registered using the given base name.

• **sequence_nr**: [in, optional] The sequential number to use for the registration of the id. This number has to be unique system wide for each registration using the same base name. The default is the current locality identifier. Also, the sequence numbers have to be consecutive starting from zero.

```cpp
template<typename Client>
Client unregister_with_basename(std::string base_name, std::size_t sequence_nr)
```

Unregister the given id using the given base name.

The function unregisters the given ids using the provided base name.

**Return** A future representing the result of the un-registration operation itself.

**Template Parameters**

• **Client**: The client type to return

**Parameters**

• **base_name**: [in] The base name for which to retrieve the registered ids.

• **sequence_nr**: [in, optional] The sequential number to use for the un-registration. This number has to be the same as has been used with `register_with_basename` before.

**Return** A future representing the result of the un-registration operation itself.

**Parameters**

• **base_name**: [in] The base name for which to retrieve the registered ids.

• **sequence_nr**: [in, optional] The sequential number to use for the un-registration. This number has to be the same as has been used with `register_with_basename` before.

```cpp
namespace hpx

Functions

hpx::future<bool> register_with_basename(std::string base_name, hpx::id_type id, std::size_t sequence_nr = ~static_cast<std::size_t>(0))
```

Register the given id using the given base name.

The function registers the given ids using the provided base name.

**Return** A future representing the result of the registration operation itself.

**Note** The operation will fail if the given sequence number is not unique.

**Parameters**

• **base_name**: [in] The base name for which to retrieve the registered ids.

• **id**: [in] The id to register using the given base name.
sequence_nr: [in, optional] The sequential number to use for the registration of the id. This number has to be unique system wide for each registration using the same base name. The default is the current locality identifier. Also, the sequence numbers have to be consecutive starting from zero.

```cpp
hpx::future<bool> register_with_basename(std::string base_name, hpx::future<hpx::id_type> f, std::size_t sequence_nr = ~static_cast<std::size_t>(0))
```

Register the id wrapped in the given future using the given base name.

The function registers the object the given future refers to using the provided base name.

Return A future representing the result of the registration operation itself.

Note The operation will fail if the given sequence number is not unique.

Parameters

- `base_name`: [in] The base name for which to retrieve the registered ids.
- `f`: [in] The future which should be registered using the given base name.
- `sequence_nr`: [in, optional] The sequential number to use for the registration of the id. This number has to be unique system wide for each registration using the same base name. The default is the current locality identifier. Also, the sequence numbers have to be consecutive starting from zero.

namespace hpx
Functions

template<typename Component>
hpx::future<std::shared_ptr<Component>> get_ptr (naming::id_type const &id)

Returns a future referring to the pointer to the underlying memory of a component.

The function hpx::get_ptr can be used to extract a future referring to the pointer to the underlying memory of a given component.

Return  This function returns a future representing the pointer to the underlying memory for the component instance with the given id.

Note  This function will successfully return the requested result only if the given component is currently located on the calling locality. Otherwise the function will raise an error.

Note  The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned shared_ptr alive.

Parameters

  * id: [in] The global id of the component for which the pointer to the underlying memory should be retrieved.

Template Parameters

  * The: only template parameter has to be the type of the server side component.

template<typename Derived, typename Stub>
hpx::future<std::shared_ptr<components::client_base<Derived, Stub>::server_component_type>> get_ptr (components::client_base<Derived, Stub> const &c)

Returns a future referring to the pointer to the underlying memory of a component.

The function hpx::get_ptr can be used to extract a future referring to the pointer to the underlying memory of a given component.

Return  This function returns a future representing the pointer to the underlying memory for the component instance with the given id.

Note  This function will successfully return the requested result only if the given component is currently located on the calling locality. Otherwise the function will raise an error.

Note  The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned shared_ptr alive.

Parameters

  * c: [in] A client side representation of the component for which the pointer to the underlying memory should be retrieved.

template<typename Component>
std::shared_ptr<Component> get_ptr (launch::sync_policy p, naming::id_type const &id, error_code &ec = throws)

Returns the pointer to the underlying memory of a component.

The function hpx::get_ptr_sync can be used to extract the pointer to the underlying memory of a given component.
Return This function returns the pointer to the underlying memory for the component instance with the given id.

Note This function will successfully return the requested result only if the given component is currently located on the requesting locality. Otherwise the function will raise and error.

Note The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned shared_ptr alive.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters

• p: [in] The parameter p represents a placeholder type to turn make the call synchronous.

• id: [in] The global id of the component for which the pointer to the underlying memory should be retrieved.

• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

Template Parameters

• The: only template parameter has to be the type of the server side component.

```cpp
template<typename Derived, typename Stub>
std::shared_ptr<
components::client_base<
Derived, Stub>::server_component_type>
get_ptr (launch::sync_policy p,
components::client_base<
Stub>
const &c,
error_code &ec
= throws)
```

Returns the pointer to the underlying memory of a component.

The function hpx::get_ptr_sync can be used to extract the pointer to the underlying memory of a given component.

Return This function returns the pointer to the underlying memory for the component instance with the given id.

Note This function will successfully return the requested result only if the given component is currently located on the requesting locality. Otherwise the function will raise and error.

Note The component instance the returned pointer refers to can not be migrated as long as there is at least one copy of the returned shared_ptr alive.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Parameters

• p: [in] The parameter p represents a placeholder type to turn make the call synchronous.
• c: [in] A client side representation of the component for which the pointer to the underlying memory should be retrieved.
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

**components_base**

The contents of this module can be included with the header `hpx/modules/components_base.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/components_base.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

namespace hpx

namespace components

struct component_commandline: public component_commandline_base

#include <component_commandline.hpp> The component_startup_shutdown provides a minimal implementation of a component’s startup/shutdown function provider.

Public Functions

hpx::program_options::options_description add_commandline_options()

Return The module is expected to fill a options_description object with any additional command line options this component will handle.

Note This function will be executed by the runtime system during system startup.

namespace commandline_options_provider

    bool(*)(shutdown_function_type &, bool &)> Shutdown>
    hpx::components::component_startup_shutdown : public component_startup_shutdown_base
    {

#include <component_startup_shutdown.hpp>

The component_startup_shutdown class provides a
minimal implementation of a component’s startup/shutdown function provider.

Public Functions

bool get_startup_function(startup_function_type &startup, bool &pre_startup)
    Return any startup function for this component.

    Return  Returns true if the parameter startup has been successfully initialized with the startup
    function.

    Parameters
    •  startup: [in, out] The module is expected to fill this function object with a reference to a
        startup function. This function will be executed by the runtime system during system startup.

bool get_shutdown_function(shutdown_function_type &shutdown, bool &pre_shutdown)
    Return any startup function for this component.

    Return  Returns true if the parameter shutdown has been successfully initialized with the shut-
    down function.

    Parameters
    •  shutdown: [in, out] The module is expected to fill this function object with a reference
        to a startup function. This function will be executed by the runtime system during system
        startup.

template<typename Component>
using abstract_simple_component_base = abstract_component_base<Component>

template<typename Component, typename Derived>
class managed_component
    #include <managed_component_base.hpp> The managed_component template is used as a indirection layer for components allowing to gracefully handle the access to non-existing components.
    Additionally it provides memory management capabilities for the wrapping instances, and it integrates the memory management with the AGAS service. Every instance of a managed_component gets assigned a global id. The provided memory management allocates the managed_component instances from a special heap, ensuring fast allocation and avoids a full network round trip to the AGAS service for each of the allocated instances.

    The range of available ids for components.

naming::gid_type upper_

template<typename Component>
struct get_lva<Component, typename std::enable_if<!traits::is_managed_component<Component>::value>::type>
The get_lva template is a helper structure allowing to convert a local virtual address as stored in a local address (returned from the function `resolver_client::resolve`) to the address of the component implementing the action.

The default implementation uses the template argument `Component` to deduce the type wrapping the component implementing the action. This is used to get the needed address.

**Template Parameters**

- `Component`: This is the type of the component implementing the action to execute.

```cpp
namespace hpx

template<typename Component, typename Enable = void>
struct get_lva
#include <get_lva.hpp> The get_lva template is a helper structure allowing to convert a local virtual address as stored in a local address (returned from the function `resolver_client::resolve`) to the address of the component implementing the action.

The default implementation uses the template argument `Component` to deduce the type wrapping the component implementing the action. This is used to get the needed address.

compute

The contents of this module can be included with the header `hpx/modules/compute.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/compute.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

```cpp
namespace hpx
```

```cpp
namespace compute
```

Functions

```cpp
template<typename T, typename Allocator>
void swap (vector<T, Allocator> &x, vector<T, Allocator> &y)
    Effects: x.swap(y);
```

template<typename T, typename Allocator = std::allocator<T> >
```cpp
class vector
```
### Public Types

```cpp
typedef T value_type
  Member types (FIXME: add reference to std.

typedef Allocator allocator_type

typedef alloc_traits::access_target access_target

typedef std::size_t size_type

typedef std::ptrdiff_t difference_type

typedef alloc_traits::reference reference

typedef alloc_traits::const_reference const_reference

typedef alloc_traits::pointer pointer

typedef alloc_traits::const_pointer const_pointer

typedef detail::iterator<T, Allocator> iterator

typedef detail::const_iterator<T const, Allocator> const_iterator

typedef detail::reverse_iterator<T, Allocator> reverse_iterator

typedef detail::const_reverse_iterator<T, Allocator> const_reverse_iterator
```

### Public Functions

```cpp
vector (Allocator const &alloc = Allocator())

vector (size_type count, T const &value, Allocator const &alloc = Allocator())

vector (size_type count, Allocator const &alloc = Allocator())

template<typename InIter, typename Enable = typename std::enable_if<hpx::traits::is_input_iterator<InIter>>::value>
vector (InIter first, InIter last, Allocator const &alloc)

vector (vector const &other)

vector (vector const &other, Allocator const &alloc)

vector (vector &&other)

vector (vector &&&other, Allocator const &alloc)

vector (std::initializer_list<T> init, Allocator const &alloc)

~vector ()

vector &operator= (vector const &other)

vector &operator= (vector &&other)

allocator_type get_allocator () const
  Returns the allocator associated with the container.

typedef reference operator[] (size_type pos)

typedef const_reference operator[] (size_type pos) const
```
pointer data()
Returns pointer to the underlying array serving as element storage. The pointer is such that range [data(); data() + size()) is always a valid range, even if the container is empty (data() is not dereferenceable in that case).

const_pointer data() const
Returns pointer to the underlying array serving as element storage. The pointer is such that range [data(); data() + size()) is always a valid range, even if the container is empty (data() is not dereferenceable in that case).

T *device_data() const
Returns a raw pointer corresponding to the address of the data allocated on the device.

std::size_t size() const

std::size_t capacity() const

bool empty() const
Returns: size() == 0.

void resize(size_type)
Effects: If size <= size(), equivalent to calling pop_back() size() - size times. If size() < size, appends size - size() default-inserted elements to the sequence.
Requires: T shall be MoveInsertable and DefaultInsertable into *this.
Remarks: If an exception is thrown other than by the move constructor of a non-CopyInsertable T there are no effects.

void resize(size_type, T const&)
Effects: If size <= size(), equivalent to calling pop_back() size() - size times. If size() < size, appends size - size() copies of val to the sequence.
Requires: T shall be CopyInsertable into *this.
Remarks: If an exception is thrown there are no effects.

iterator begin()

iterator end()

const_iterator cbegin() const

const_iterator cend() const

const_iterator begin() const

const_iterator end() const

void swap(vector &other)
Effects: Exchanges the contents and capacity() of *this with that of x.
Complexity: Constant time.

void clear()
Effects: Erases all elements in the range [begin(),end()). Destroys all elements in a. Invalidates all references, pointers, and iterators referring to the elements of a and may invalidate the past-the-end iterator.
Post: a.empty() returns true.
Complexity: Linear.

compute_cuda

The contents of this module can be included with the header `hpx/modules/compute_cuda.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/compute_cuda.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

distribution_policies

The contents of this module can be included with the header `hpx/modules/distribution_policies.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/distribution_policies.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

```cpp
namespace hpx
```

```cpp
namespace components
```

Variables

```cpp
HPX_INLINE_CONSTEXPR_VARIABLE char const* const hpx::components::default_binpacking_counter_name = "/runtime{locality/total}/count/component@`

```cpp
const binpacking_distribution_policy binpacked = {};
```

A predefined instance of the binpacking distribution policy. It will represent the local locality and will place all items to create here.

```cpp
struct binpacking_distribution_policy
```

```
#include <binpacking_distribution_policy.hpp>
```

This class specifies the parameters for a binpacking distribution policy to use for creating a given number of items on a given set of localities. The binpacking policy will distribute the new objects in a way such that each of the localities will equalize the number of overall objects of this type based on a given criteria (by default this criteria is the overall number of objects of this type).
Public Functions

**binpacking_distribution_policy()**
Default-construct a new instance of a binpacking_distribution_policy. This policy will represent one locality (the local locality).

**binpacking_distribution_policy operator() (std::vector<id_type> const &locs, char const *perf_counter_name = default_binpacking_counter_name) const**
Create a new default_distribution policy representing the given set of localities.

**Parameters**
- `locs`: [in] The list of localities the new instance should represent
- `perf_counter_name`: [in] The name of the performance counter which should be used as the distribution criteria (by default the overall number of existing instances of the given component type will be used).

**binpacking_distribution_policy operator() (std::vector<id_type> &&locs, char const *perf_counter_name = default_binpacking_counter_name) const**
Create a new default_distribution policy representing the given set of localities.

**Parameters**
- `locs`: [in] The list of localities the new instance should represent
- `perf_counter_name`: [in] The name of the performance counter which should be used as the distribution criteria (by default the overall number of existing instances of the given component type will be used).

**binpacking_distribution_policy operator() (id_type const &loc, char const *perf_counter_name = default_binpacking_counter_name) const**
Create a new default_distribution policy representing the given locality

**Parameters**
- `loc`: [in] The locality the new instance should represent
- `perf_counter_name`: [in] The name of the performance counter that should be used as the distribution criteria (by default the overall number of existing instances of the given component type will be used).

**template<typename Component, typename... Ts> hpx::future<hpx::id_type> create(Ts&&... vs) const**
Create one object on one of the localities associated by this policy instance

**Return** A future holding the global address which represents the newly created object

**Parameters**
- `vs`: [in] The arguments which will be forwarded to the constructor of the new object.

**template<typename Component, typename... Ts> hpx::future<std::vector<bulk_locality_result>> bulk_create(std::size_t count, Ts&&... vs) const**
Create multiple objects on the localities associated by this policy instance

**Return** A future holding the list of global addresses which represent the newly created objects
Parameters
- **count**: [in] The number of objects to create
- **vs**: [in] The arguments which will be forwarded to the constructors of the new objects.

```cpp
std::string const & get_counter_name() const
```
Returns the name of the performance counter associated with this policy instance.

```cpp
std::size_t get_num_localities() const
```
Returns the number of associated localities for this distribution policy.

**Note** This function is part of the creation policy implemented by this class

```cpp
namespace hpx
```

```cpp
namespace components
```

## Variables

```cpp
const colocating_distribution_policy colocated = {}
```
A predefined instance of the co-locating distribution_policy. It will represent the local locality and will place all items to create here.

```cpp
struct colocating_distribution_policy
#include <colocating_distribution_policy.hpp> This class specifies the parameters for a distribution policy to use for creating a given number of items on the locality where a given object is currently placed.
```

## Public Functions

```cpp
colocating_distribution_policy() 
```
Default-construct a new instance of a colocating_distribution_policy. This policy will represent the local locality.

```cpp
colocating_distribution_policy operator() (id_type const & id) const
```
Create a new colocating_distribution_policy representing the locality where the given object is current located

**Parameters**
- **id**: [in] The global address of the object with which the new instances should be colocated on

```cpp
template<typename Client, typename Stub>
colocating_distribution_policy operator() (client_base<Client, Stub> const & client) const
```
Create a new colocating_distribution_policy representing the locality where the given object is current located

**Parameters**
- **client**: [in] The client side representation of the object with which the new instances should be colocated on

```cpp
template<typename Component, typename ... Ts>
```
**create** (Ts&&... vs) const

Create one object on the locality of the object this distribution policy instance is associated with.

**Note** This function is part of the placement policy implemented by this class.

**Return** A future holding the global address which represents the newly created object.

**Parameters**

- **vs**: [in] The arguments which will be forwarded to the constructor of the new object.

**bulk_create** (std::size_t count, Ts&&... vs) const

Create multiple objects colocated with the object represented by this policy instance.

**Note** This function is part of the placement policy implemented by this class.

**Return** A future holding the list of global addresses which represent the newly created objects.

**Parameters**

- **count**: [in] The number of objects to create.
- **vs**: [in] The arguments which will be forwarded to the constructors of the new objects.

**async_result**<Action>::type async<launch policy, Ts&&... vs> const

**async_result**<Action>::type async_cb<launch policy, Callback&& cb, Ts&&... vs> const

**apply** (Continuation&& c, threads::thread_priority priority, Ts&&... vs) const

**apply_cb** (Continuation&& c, threads::thread_priority priority, Callback&& cb, Ts&&... vs) const

**get_num_localities** () const

Returns the number of associated localities for this distribution policy.

**get_next_target** () const

Returns the locality which is anticipated to be used for the next async operation.

**async_result** struct

**Note** This function is part of the invocation policy implemented by this class.

Variables

\texttt{const target_distribution_policy target = {}}
A predefined instance of the \texttt{target_distribution_policy}. It will represent the local locality and will
place all items to create here.

\texttt{struct target_distribution_policy}

\texttt{#include <target_distribution_policy.hpp>} This class specifies the parameters for a simple distribu-
tion policy to use for creating (and evenly distributing) a given number of items on a given set of
localities.

Public Functions

\texttt{target_distribution_policy()} Default-construct a new instance of a \texttt{target_distribution_policy}. This policy will represent one
locality (the local locality).

\texttt{target_distribution_policy operator() (id_type const &id) const}
Create a new \texttt{target_distribution_policy} representing the given locality

Parameters

- \texttt{loc}: [in] The locality the new instance should represent

template<typename Component, typename ...Ts>
\texttt{hpx::future<hpx::id_type> create (Ts&&... vs) const}
Create one object on one of the localities associated by this policy instance

Note This function is part of the placement policy implemented by this class

Return A future holding the global address which represents the newly created object
Parameters

- \texttt{vs}: [in] The arguments which will be forwarded to the constructor of the new object.

```cpp
template<typename Component, typename ...Ts>
hpx::future<std::vector<bulk_locality_result>> bulk_create (std::size_t count, Ts&... vs)
const
```

Create multiple objects on the localities associated by this policy instance.

**Note** This function is part of the placement policy implemented by this class

**Return** A future holding the list of global addresses which represent the newly created objects

**Parameters**

- \texttt{count}: [in] The number of objects to create
- \texttt{vs}: [in] The arguments which will be forwarded to the constructors of the new objects.

namespace hpx

Functions

int finalize (double shutdown_timeout, double localwait = -1.0, error_code &ec = throws)

Main function to gracefully terminate the HPX runtime system.

The function hpx::finalize is the main way to (gracefully) exit any HPX application. It should be called from one locality only (usually the console) and it will notify all connected localities to finish execution. Only after all other localities have exited this function will return, allowing to exit the console locality as well.

During the execution of this function the runtime system will invoke all registered shutdown functions (see hpx::init) on all localities.

The default value (-1.0) will try to find a globally set timeout value (can be set as the configuration parameter hpx.shutdown_timeout), and if that is not set or -1.0 as well, it will disable any timeout, each connected locality will wait for all existing HPX-threads to terminate.

Parameters

- shutdown_timeout: This parameter allows to specify a timeout (in microseconds), specifying how long any of the connected localities should wait for pending tasks to be executed. After this timeout, all suspended HPX-threads will be aborted. Note, that this function will not abort any running HPX-threads. In any case the shutdown will not proceed as long as there is at least one pending/running HPX-thread.

The default value (-1.0) will try to find a globally set wait time value (can be set as the configuration parameter “hpx.finalize_wait_time”), and if this is not set or -1.0 as well, it will disable any addition local wait time before proceeding.

Parameters
- **localwait**: This parameter allows to specify a local wait time (in microseconds) before the connected localities will be notified and the overall shutdown process starts.

This function will block and wait for all connected localities to exit before returning to the caller. It should be the last HPX-function called by any application.

**Return** This function will always return zero.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Parameters**

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

Using this function is an alternative to `hpx::disconnect`, these functions do not need to be called both.

```c
int finalize (error_code &ec = throws)
```

Main function to gracefully terminate the HPX runtime system.

The function `hpx::finalize` is the main way to (gracefully) exit any HPX application. It should be called from one locality only (usually the console) and it will notify all connected localities to finish execution. Only after all other localities have exited this function will return, allowing to exit the console locality as well.

During the execution of this function the runtime system will invoke all registered shutdown functions (see `hpx::init`) on all localities.

This function will block and wait for all connected localities to exit before returning to the caller. It should be the last HPX-function called by any application.

**Return** This function will always return zero.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Parameters**

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

Using this function is an alternative to `hpx::disconnect`, these functions do not need to be called both.

```c
HPX_NORETURN void hpx::terminate()
```

Terminate any application non-gracefully.

The function `hpx::terminate` is the non-graceful way to exit any application immediately. It can be called from any locality and will terminate all localities currently used by the application.

**Note** This function will cause HPX to call `std::terminate()` on all localities associated with this application. If the function is called not from an HPX thread it will fail and return an error using the argument `ec`.

```c
int disconnect (double shutdown_timeout, double localwait = -1.0, error_code &ec = throws)
```

Disconnect this locality from the application.

The function `hpx::disconnect` can be used to disconnect a locality from a running HPX application.
During the execution of this function the runtime system will invoke all registered shutdown functions (see `hpx::init`) on this locality. The default value (-1.0) will try to find a globally set timeout value (can be set as the configuration parameter “hpx.shutdown_timeout”), and if that is not set or -1.0 as well, it will disable any timeout, each connected locality will wait for all existing HPX-threads to terminate.

**Parameters**

- `shutdown_timeout`: This parameter allows to specify a timeout (in microseconds), specifying how long this locality should wait for pending tasks to be executed. After this timeout, all suspended HPX-threads will be aborted. Note, that this function will not abort any running HPX-threads. In any case the shutdown will not proceed as long as there is at least one pending/running HPX-thread.

The default value (-1.0) will try to find a globally set wait time value (can be set as the configuration parameter `hpx.finalize_wait_time`), and if this is not set or -1.0 as well, it will disable any addition local wait time before proceeding.

**Parameters**

- `localwait`: This parameter allows to specify a local wait time (in microseconds) before the connected localities will be notified and the overall shutdown process starts.

This function will block and wait for this locality to finish executing before returning to the caller. It should be the last HPX-function called by any locality being disconnected.

**Return**  This function will always return zero.

**Note**  As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Parameters**

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
int disconnect (error_code &ec = throws)
```

Disconnect this locality from the application.

The function `hpx::disconnect` can be used to disconnect a locality from a running HPX application.

During the execution of this function the runtime system will invoke all registered shutdown functions (see `hpx::init`) on this locality.

This function will block and wait for this locality to finish executing before returning to the caller. It should be the last HPX-function called by any locality being disconnected.

**Return**  This function will always return zero.

**Note**  As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Parameters**

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
int stop (error_code &ec = throws)
```

Stop the runtime system.
This function will block and wait for this locality to finish executing before returning to the caller. It should be the last HPX-function called on every locality. This function should be used only if the runtime system was started using `hpx::start`.

**Return** The function returns the value, which has been returned from the user supplied main HPX function (usually `hpx_main`).

```cpp
namespace hpx {

Functions

int init (std::function<int(hpx::program_options::variables_map&)>
  > f, int argc, char **argv, init_params const & params = init_params())
Main entry point for launching the HPX runtime system.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. This overload will not call `hpx_main`.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread.

**Return** The function returns the value, which has been returned from the user supplied `f`.

**Note** If the parameter `mode` is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc/argv`. Otherwise it will be executed as specified by the parameter `mode`.

**Parameters**

- `f`: [in] The function to be scheduled as an HPX thread. Usually this function represents the main entry point of any HPX application. If `f` is `nullptr` the HPX runtime environment will be started without invoking `f`.
- `argc`: [in] The number of command line arguments passed in `argv`. This is usually the unchanged value as passed by the operating system (to `main()`).
- `argv`: [in] The command line arguments for this application, usually that is the value as passed by the operating system (to `main()`).
- `params`: [in] The parameters to the `hpx::init` function (See documentation of `hpx::init_params`)

```cpp
int init (std::function<int(int, char**)>
  > f, int argc, char **argv, init_params const & params = init_params())
Main entry point for launching the HPX runtime system.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. This overload will not call `hpx_main`.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread.

**Return** The function returns the value, which has been returned from the user supplied `f`.

---

Chapter 2. What’s so special about **HPX**?
**Note** If the parameter `mode` is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc/argv`. Otherwise it will be executed as specified by the parameter `mode`.

**Parameters**

- `f`: [in] The function to be scheduled as an HPX thread. Usually this function represents the main entry point of any HPX application. If `f` is `nullptr` the HPX runtime environment will be started without invoking `f`.
- `argc`: [in] The number of command line arguments passed in `argv`. This is usually the unchanged value as passed by the operating system (to `main()`).
- `argv`: [in] The command line arguments for this application, usually that is the value as passed by the operating system (to `main()`).
- `params`: [in] The parameters to the `hpx::init` function (See documentation of `hpx::init_params`)

```cpp
int init (int argc, char **argv, init_params const &params = init_params())
```

Main entry point for launching the HPX runtime system.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. This overload will not call `hpx_main`.

**Return** The function returns the value, which has been returned from the user supplied `f`.

**Note** If the parameter `mode` is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in `argc/argv`. Otherwise it will be executed as specified by the parameter `mode`.

**Parameters**

- `argc`: [in] The number of command line arguments passed in `argv`. This is usually the unchanged value as passed by the operating system (to `main()`).
- `argv`: [in] The command line arguments for this application, usually that is the value as passed by the operating system (to `main()`).
- `params`: [in] The parameters to the `hpx::init` function (See documentation of `hpx::init_params`)

```cpp
int init (std::nullptr_t f, int argc, char **argv, init_params const &params = init_params())
```

Main entry point for launching the HPX runtime system.

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. This overload will not call `hpx_main`.

**Return** The function returns the value, which has been returned from the user supplied `f`. 

This is the main entry point for any HPX application. This function (or one of its overloads below) should be called from the users `main()` function. It will set up the HPX runtime environment and schedule the function given by `f` as a HPX thread. 

**Return** The function returns the value, which has been returned from the user supplied `f`. 

2.8. API reference 827
Note If the parameter mode is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in \texttt{argc/argv}. Otherwise it will be executed as specified by the parameter \texttt{mode}.

Parameters

- \texttt{f}: \texttt{[in]} The function to be scheduled as an HPX thread. Usually this function represents the main entry point of any HPX application. If \texttt{f} is \texttt{nullptr} the HPX runtime environment will be started without invoking \texttt{f}.
- \texttt{argc}: \texttt{[in]} The number of command line arguments passed in \texttt{argv}. This is usually the unchanged value as passed by the operating system (to \texttt{main}()).
- \texttt{argv}: \texttt{[in]} The command line arguments for this application, usually that is the value as passed by the operating system (to \texttt{main}()).
- \texttt{params}: \texttt{[in]} The parameters to the \texttt{hpx::init} function (See documentation of \texttt{hpx::init_params})

```cpp
int \texttt{init} (\texttt{init_params const \&params = init_params()})
```

Main entry point for launching the HPX runtime system.

This is a simplified main entry point, which can be used to set up the runtime for an HPX application (the runtime system will be set up in console mode or worker mode depending on the command line settings).

This is a simplified main entry point, which can be used to set up the runtime for an HPX application (the runtime system will be set up in console mode or worker mode depending on the command line settings).

**Return** The function returns the value, which has been returned from \texttt{hpx_main} (or 0 when executed in worker mode).

**Note** The created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in \texttt{argc/argv}. If not command line arguments are passed, console mode is assumed.

**Note** If no command line arguments are passed the HPX runtime system will not support any of the default command line options as described in the section ‘HPX Command Line Options’.

Parameters

- \texttt{params}: \texttt{[in]} The parameters to the \texttt{hpx::init} function (See documentation of \texttt{hpx::init_params})

```cpp
namespace \texttt{hpx}
```

```cpp
struct \texttt{init_params}
```

```cpp
#include \texttt{<hpx_init_params.hpp>} Parameters used to initialize the HPX runtime through \texttt{hpx::init} and \texttt{hpx::start}.
```

**Public Members**

```cpp
std::reference_wrapper<\texttt{hpx::program_options::options_description const}> \texttt{desc_cmdline} = detail::default_desc
std::vector<\texttt{std::string}> \texttt{cfg}
startup_function_type \texttt{startup}
shutdown_function_type \texttt{shutdown}
\texttt{hpx::runtime_mode mode = ::hpx::runtime_mode::default_}
\texttt{hpx::resource::partitioner_mode rp_mode = ::hpx::resource::mode_default}
```

Chapter 2. What’s so special about \texttt{HPX}?
namespace hpx

Functions

bool start (std::function<int (int, char **)> f, int argc, char **argv, init_params const &params = init_params())
Main non-blocking entry point for launching the HPX runtime system.

This is the main, non-blocking entry point for any HPX application. This function (or one of its overloads below) should be called from the users main() function. It will set up the HPX runtime environment and schedule the function given by f as a HPX thread. It will return immediately after that. Use hpx::wait and hpx::stop to synchronize with the runtime system’s execution. This overload will not call hpx_main.

Return The function returns true if command line processing succeeded and the runtime system was started successfully. It will return false otherwise.

Note If the parameter mode is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in argc/argv. Otherwise it will be executed as specified by the parameter mode.

Parameters

• f: [in] The function to be scheduled as an HPX thread. Usually this function represents the main entry point of any HPX application. If f is nullptr the HPX runtime environment will be started without invoking f.

• argc: [in] The number of command line arguments passed in argv. This is usually the unchanged value as passed by the operating system (to main()).

• argv: [in] The command line arguments for this application, usually that is the value as passed by the operating system (to main()).

• params: [in] The parameters to the hpx::start function (See documentation of hpx::init_params)
The function returns \textit{true} if command line processing succeeded and the runtime system was started successfully. It will return \textit{false} otherwise.

\textbf{Note} If the parameter \texttt{mode} is not given (defaulted), the created runtime system instance will be executed in console or worker mode depending on the command line arguments passed in \texttt{argc/argv}. Otherwise it will be executed as specified by the parameter\texttt{mode}.

\textbf{Parameters}

- \texttt{f: }[in] The function to be scheduled as an HPX thread. Usually this function represents the main entry point of any HPX application. If \texttt{f} is \texttt{nullptr} the HPX runtime environment will be started without invoking \texttt{f}.
- \texttt{argc: }[in] The number of command line arguments passed in \texttt{argv}. This is usually the unchanged value as passed by the operating system (to \texttt{main()}).
- \texttt{argv: }[in] The command line arguments for this application, usually that is the value as passed by the operating system (to \texttt{main()}).
- \texttt{params: }[in] The parameters to the \texttt{hpx::start} function (See documentation of \texttt{hpx::init_params})

\begin{verbatim}
bool start (int argc, char **argv, init_params const &params = init_params())
\end{verbatim}

Main non-blocking entry point for launching the HPX runtime system.

This is the main, non-blocking entry point for any HPX application. This function (or one of its overloads below) should be called from the users \texttt{main()} function. It will set up the HPX runtime environment and schedule the function given by \texttt{f} as a HPX thread. It will return immediately after that. Use \texttt{hpx::wait} and \texttt{hpx::stop} to synchronize with the runtime system’s execution. This overload will not call \texttt{hpx_main}.

Note If no command line arguments are passed the HPX runtime system will not support any of the default command line options as described in the section ‘HPX Command Line Options’.

Parameters

- params: [in] The parameters to the hpx::start function (See documentation of hpx::init_params)
Functions

```cpp
int suspend (error_code &ec = throws)
    Suspend the runtime system.

    The function hpx::suspend is used to suspend the HPX runtime system. It can only be used when running HPX on a single locality. It will block waiting for all thread pools to be empty. This function only be called when the runtime is running, or already suspended in which case this function will do nothing.

    Return This function will always return zero.

    Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

    Parameters
    • ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.
```

```cpp
int resume (error_code &ec = throws)
    Resume the HPX runtime system.

    The function hpx::resume is used to resume the HPX runtime system. It can only be used when running HPX on a single locality. It will block waiting for all thread pools to be resumed. This function only be called when the runtime suspended, or already running in which case this function will do nothing.

    Return This function will always return zero.

    Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

    Parameters
    • ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.
```

namespace hpx_startup

Functions

Functions

\texttt{id\_type unmanaged(id\_type const &id)}

The helper function \texttt{hpx::unmanaged} can be used to generate a global identifier which does not participate in the automatic garbage collection.

\textbf{Return} This function returns a new global id referencing the same object as the parameter \texttt{id}. The only difference is that the returned global identifier does not participate in the automatic garbage collection.

\textbf{Note} This function allows to apply certain optimizations to the process of memory management in HPX. It however requires the user to take full responsibility for keeping the referenced objects alive long enough.

\textbf{Parameters}

- \texttt{id}: [in] The id to generated the unmanaged global id from This parameter can be itself a managed or a unmanaged global id.

\textbf{performance\_counters}

The contents of this module can be included with the header \texttt{hpx/modules/performance\_counters.hpp}. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header \texttt{hpx/modules/performance\_counters.hpp}, not the particular header in which the functionality you would like to use is defined. See \textit{Public API} for a list of names that are part of the public HPX API.

Functions

bool default_counter_discoverer(counter_info const&, discover_counter_func const&, discover_counters_mode, error_code&)

Default discovery function for performance counters; to be registered with the counter types. It will pass the counter_info and the error_code to the supplied function.

bool locality_counter_discoverer(counter_info const&, discover_counter_func const&, discover_counters_mode, error_code&)

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

/ (<objectname>)(locality#<locality_id>/total)/<instancename>

bool locality_pool_counter_discoverer(counter_info const&, discover_counter_func const&, discover_counters_mode, error_code&)

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

/ (<objectname>)(locality#<locality_id>/pool#<pool_name>/total)/<instancename>

bool locality0_counter_discoverer(counter_info const&, discover_counter_func const&, discover_counters_mode, error_code&)

Default discoverer function for AGAS performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

/ (<objectname>){locality#0/total}/<instancename>

bool locality_thread_counter_discoverer(counter_info const&, discover_counter_func const&, discover_counters_mode, error_code&)

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

/ (<objectname>)(locality#<locality_id>/worker-thread#<threadnum>)/<instancename>
bool locality_pool_thread_counter_discoverer(counter_info const &info, discover_counter_func const &f, discover_counters_mode mode, error_code &ec)

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

/\<objectname>\{ locality#<locality_id>/pool#<poolname>/thread#<threadnum> \}/<instancename>

bool locality_pool_thread_no_total_counter_discoverer(counter_info const &info, discover_counter_func const &f, discover_counters_mode mode, error_code &ec)

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

/\<objectname>\{ locality#<locality_id>/pool#<poolname>/thread#<threadnum> \}/<instancename>

This is essentially the same as above just that locality#*/total is not supported.

bool locality_numa_counter_discoverer(counter_info const &info, discover_counter_func const &f, discover_counters_mode mode, error_code &ec)

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

/\<objectname>\{ locality#<locality_id>/numa-node#<threadnum> \}/<instancename>

naming::gid_type locality_raw_counter_creator(counter_info const &info, hpx::util::function_nonser<\&std::int64_t> bool > const &error_code &)

Creation function for raw counters. The passed function is encapsulating the actual value to monitor. This function checks the validity of the supplied counter name, it has to follow the scheme:

/\<objectname>\{ locality#<locality_id>/total \}/<instancename>

naming::gid_type locality_raw_values_counter_creator(counter_info const &info, hpx::util::function_nonser<\&std::vector<\&std::int64_t> bool > const &error_code &)

naming::gid_type agas_raw_counter_creator(counter_info const &info, error_code & error_code & const &)

Creation function for raw counters. The passed function is encapsulating the actual value to monitor. This function checks the validity of the supplied counter name, it has to follow the scheme:

/agas\(<objectinstance>/total)/<instancename>

bool agas_counter_discoverer(counter_info const &info, discover_counter_func const &f, discover_counters_mode mode, error_code &ec)

Default discoverer function for performance counters; to be registered with the counter types. It is suitable to be used for all counters following the naming scheme:

/agas\(<objectinstance>/total)/<instancename>

naming::gid_type local_action_invocation_counter_creator(counter_info const &info, error_code & error_code &)

```hpx
namespace hpx

namespace performance_counters

Typedefs

```c++
typedef hpx::util::function_nonser<naming::gid_type (counter_info const&, error_code&)>
create_counter_func
```
This declares the type of a function, which will be called by HPX whenever a new performance counter instance of a particular type needs to be created.

```c++
typedef hpx::util::function_nonser<bool (counter_info const&, error_code&)>
discover_counter_func
```
This declares a type of a function, which will be passed to a `discover_counters_func` in order to be called for each discovered performance counter instance.

```c++
typedef hpx::util::function_nonser<bool (counter_info const&, discover_counter_func const&, discover_counters_mode, error_code&)>
discover_counters_func
```
This declares the type of a function, which will be called by HPX whenever it needs to discover all performance counter instances of a particular type.

 Enums

```c++
enum counter_type
```
Values:

```c++
counter_text
counter_text shows a variable-length text string. It does not deliver calculated values.

Formula: None Average: None Type: Text
```

```c++
counter_raw
counter_raw shows the last observed value only. It does not deliver an average.

Formula: None. Shows raw data as collected. Average: None Type: Instantaneous
```

```c++
counter_monotonically_increasing
```

```c++
counter_average_base
counter_average_base is used as the base data (denominator) in the computation of time or count averages for the `counter_average_count` and `counter_average_timer` counter types. This counter type collects the last observed value only.

Formula: None. This counter uses raw data in factional calculations without delivering an output. Average: SUM (N) / x Type: Instantaneous
```

```c++
counter_average_count
counter_average_count shows how many items are processed, on average, during an operation.
```
Counters of this type display a ratio of the items processed (such as bytes sent) to the number of operations completed. The ratio is calculated by comparing the number of items processed during the last interval to the number of operations completed during the last interval.

Formula: \((N_1 - N_0) / (D_1 - D_0)\), where the numerator \((N)\) represents the number of items processed during the last sample interval, and the denominator \((D)\) represents the number of operations completed during the last two sample intervals. Average: \((N_x - N_0) / (D_x - D_0)\) Type: Average

counter_aggregating

\textit{counter_aggregating} applies a function to an embedded counter instance. The embedded counter is usually evaluated repeatedly after a fixed (but configurable) time interval.

Formula: \(F(N_x)\)

counter_average_timer

\textit{counter_average_timer} measures the average time it takes to complete a process or operation. Counters of this type display a ratio of the total elapsed time of the sample interval to the number of processes or operations completed during that time. This counter type measures time in ticks of the system clock. The variable \(F\) represents the number of ticks per second. The value of \(F\) is factored into the equation so that the result is displayed in seconds.

Formula: \(((N_1 - N_0) / F) / (D_1 - D_0)\), where the numerator \((N)\) represents the number of ticks counted during the last sample interval, the variable \(F\) represents the frequency of the ticks, and the denominator \((D)\) represents the number of operations completed during the last sample interval. Average: \(((N_x - N_0) / F) / (D_x - D_0)\) Type: Average

counter_elapsed_time

\textit{counter_elapsed_time} shows the total time between when the component or process started and the time when this value is calculated. The variable \(F\) represents the number of time units that elapse in one second. The value of \(F\) is factored into the equation so that the result is displayed in seconds.

Formula: \((D_0 - N_0) / F\), where the nominator \((D)\) represents the current time, the numerator \((N)\) represents the time the object was started, and the variable \(F\) represents the number of time units that elapse in one second. Average: \((D_x - N_0) / F\) Type: Difference

counter_histogram

\textit{counter_histogram} exposes a histogram of the measured values instead of a single value as many of the other counter types. Counters of this type expose a \textit{counter_value_array} instead of a \textit{counter_value}. Those will also not implement the get\_counter\_value() functionality. The results are exposed through a separate get\_counter\_values\_array() function.

The first three values in the returned array represent the lower and upper boundaries, and the size of the histogram buckets. All remaining values in the returned array represent the number of measurements for each of the buckets in the histogram.

counter_raw_values

\textit{counter_raw_values} exposes an array of measured values instead of a single value as many of the other counter types. Counters of this type expose a \textit{counter_value_array} instead of a \textit{counter_value}. Those will also not implement the get\_counter\_value() functionality. The results are exposed through a separate get\_counter\_values\_array() function.

counter_text

\textit{counter_text} shows a variable-length text string. It does not deliver calculated values.

Formula: None Average: None Type: Text

counter_raw

\textit{counter_raw} shows the last observed value only. It does not deliver an average.
counter_monotonically_increasing

counter_average_base

counter_average_base is used as the base data (denominator) in the computation of time or count averages for the counter_average_count and counter_average_timer counter types. This counter type collects the last observed value only.

Formula: None. This counter uses raw data in factional calculations without delivering an output. Average: SUM (N) / x Type: Instantaneous

counter_average_count

counter_average_count shows how many items are processed, on average, during an operation. Counters of this type display a ratio of the items processed (such as bytes sent) to the number of operations completed. The ratio is calculated by comparing the number of items processed during the last interval to the number of operations completed during the last interval.

Formula: (N1 - N0) / (D1 - D0), where the numerator (N) represents the number of items processed during the last sample interval, and the denominator (D) represents the number of operations completed during the last two sample intervals. Average: (Nx - N0) / (Dx - D0) Type: Average

counter_aggregating

counter_aggregating applies a function to an embedded counter instance. The embedded counter is usually evaluated repeatedly after a fixed (but configurable) time interval.

Formula: F(Nx)

counter_average_timer

counter_average_timer measures the average time it takes to complete a process or operation. Counters of this type display a ratio of the total elapsed time of the sample interval to the number of processes or operations completed during that time. This counter type measures time in ticks of the system clock. The variable F represents the number of ticks per second. The value of F is factored into the equation so that the result is displayed in seconds.

Formula: ((N1 - N0) / F) / (D1 - D0), where the numerator (N) represents the number of ticks counted during the last sample interval, the variable F represents the frequency of the ticks, and the denominator (D) represents the number of operations completed during the last sample interval. Average: ((Nx - N0) / F) / (Dx - D0) Type: Average

counter_elapsed_time

counter_elapsed_time shows the total time between when the component or process started and the time when this value is calculated. The variable F represents the number of time units that elapse in one second. The value of F is factored into the equation so that the result is displayed in seconds.

Formula: (D0 - N0) / F, where the nominator (D) represents the current time, the numerator (N) represents the time the object was started, and the variable F represents the number of time units that elapse in one second. Average: (Dx - N0) / F Type: Difference

counter_histogram

counter_histogram exposes a histogram of the measured values instead of a single value as many of the other counter types. Counters of this type expose a counter_value_array instead of a counter_value. Those will also not implement the get_counter_value() functionality. The results are exposed through a separate get_counter_values_array() function.

The first three values in the returned array represent the lower and upper boundaries, and the size of the histogram buckets. All remaining values in the returned array represent the number of measurements for each of the buckets in the histogram.
counter_raw_values

*counter_raw_values* exposes an array of measured values instead of a single value as many of the other counter types. Counters of this type expose a *counter_value_array* instead of a *counter_value*. Those will also not implement the *get_counter_value()* functionality. The results are exposed through a separate *get_counter_values_array()* function.

**enum counter_status**

Status and error codes used by the functions related to performance counters.

*Values:*

**status_valid_data**

No error occurred, data is valid.

**status_new_data**

Data is valid and different from last call.

**status_invalid_data**

Some error occurred, data is not value.

**status_already_defined**

The type or instance already has been defined.

**status_counter_unknown**

The counter instance is unknown.

**status_counter_type_unknown**

The counter type is unknown.

**status_generic_error**

A unknown error occurred.

**status_valid_data**

No error occurred, data is valid.

**status_new_data**

Data is valid and different from last call.

**status_invalid_data**

Some error occurred, data is not value.

**status_already_defined**

The type or instance already has been defined.

**status_counter_unknown**

The counter instance is unknown.

**status_counter_type_unknown**

The counter type is unknown.

**status_generic_error**

A unknown error occurred.
Functions

std::string &ensure_counter_prefix (std::string &name)

text

enum counter_type

Values:

counter_text
counter_text shows a variable-length text string. It does not deliver calculated values.

Formula: None Average: None Type: Text
counter_raw
counter_raw shows the last observed value only. It does not deliver an average.

Formula: None. Shows raw data as collected. Average: None Type: Instantaneous
counter_monotonically_increasing
counter_average_base
counter_average_base is used as the base data (denominator) in the computation of time or count averages for the counter_average_count and counter_average_timer counter types. This counter type collects the last observed value only.

Formula: None. This counter uses raw data in factional calculations without delivering an output. Average: SUM (N) / x Type: Instantaneous
counter_average_count
counter_average_count shows how many items are processed, on average, during an operation. Counters of this type display a ratio of the items processed (such as bytes sent) to the number of operations completed. The ratio is calculated by comparing the number of items processed during the last interval to the number of operations completed during the last interval.

Formula: (N1 - N0) / (D1 - D0), where the numerator (N) represents the number of items processed during the last sample interval, and the denominator (D) represents the number of operations completed during the last two sample intervals. Average: (Nx - N0) / (Dx - D0) Type: Average
```
counter_aggregating

counter_aggregating applies a function to an embedded counter instance. The embedded counter is usually evaluated repeatedly after a fixed (but configurable) time interval.

Formula: F(Nx)

counter_average_timer

counter_average_timer measures the average time it takes to complete a process or operation. Counters of this type display a ratio of the total elapsed time of the sample interval to the number of processes or operations completed during that time. This counter type measures time in ticks of the system clock. The variable F represents the number of ticks per second. The value of F is factored into the equation so that the result is displayed in seconds.

Formula: ((N1 - N0) / F) / (D1 - D0), where the numerator (N) represents the number of ticks counted during the last sample interval, the variable F represents the frequency of the ticks, and the denominator (D) represents the number of operations completed during the last sample interval. Average: ((Nx - N0) / F) / (Dx - D0) Type: Average

counter_elapsed_time

counter_elapsed_time shows the total time between when the component or process started and the time when this value is calculated. The variable F represents the number of time units that elapse in one second. The value of F is factored into the equation so that the result is displayed in seconds.

Formula: (D0 - N0) / F, where the nominator (D) represents the current time, the numerator (N) represents the time the object was started, and the variable F represents the number of time units that elapse in one second. Average: (Dx - N0) / F Type: Difference

counter_histogram

counter_histogram exposes a histogram of the measured values instead of a single value as many of the other counter types. Counters of this type expose a counter_value_array instead of a counter_value. Those will also not implement the get_counter_value() functionality. The results are exposed through a separate get_counter_values_array() function.

The first three values in the returned array represent the lower and upper boundaries, and the size of the histogram buckets. All remaining values in the returned array represent the number of measurements for each of the buckets in the histogram.

counter_raw_values

counter_raw_values exposes an array of measured values instead of a single value as many of the other counter types. Counters of this type expose a counter_value_array instead of a counter_value. Those will also not implement the get_counter_value() functionality. The results are exposed through a separate get_counter_values_array() function.

counter_text

counter_text shows a variable-length text string. It does not deliver calculated values.

Formula: None Average: None Type: Text

counter_raw

counter_raw shows the last observed value only. It does not deliver an average.

Formula: None. Shows raw data as collected. Average: None Type: Instantaneous

counter_monotonically_increasing

counter_average_base

counter_average_base is used as the base data (denominator) in the computation of time or count averages for the counter_average_count and counter_average_timer counter types. This counter type collects the last observed value only.
Formula: None. This counter uses raw data in factional calculations without delivering an output.
Average: $\frac{\text{SUM}(N)}{x}$ Type: Instantaneous

**counter_average_count**

`counter_average_count` shows how many items are processed, on average, during an operation. Counters of this type display a ratio of the items processed (such as bytes sent) to the number of operations completed. The ratio is calculated by comparing the number of items processed during the last interval to the number of operations completed during the last interval.

Formula: $(N_1 - N_0) / (D_1 - D_0)$, where the numerator $(N)$ represents the number of items processed during the last sample interval, and the denominator $(D)$ represents the number of operations completed during the last two sample intervals. Average: $(N_x - N_0) / (D_x - D_0)$ Type: Average

**counter_aggregating**

`counter_aggregating` applies a function to an embedded counter instance. The embedded counter is usually evaluated repeatedly after a fixed (but configurable) time interval.

Formula: $F(N_x)$

**counter_average_timer**

`counter_average_timer` measures the average time it takes to complete a process or operation. Counters of this type display a ratio of the total elapsed time of the sample interval to the number of processes or operations completed during that time. This counter type measures time in ticks of the system clock. The variable $F$ represents the number of ticks per second. The value of $F$ is factored into the equation so that the result is displayed in seconds.

Formula: $\frac{(N_1 - N_0) / F}{(D_1 - D_0)}$, where the numerator $(N)$ represents the number of ticks counted during the last sample interval, the variable $F$ represents the frequency of the ticks, and the denominator $(D)$ represents the number of operations completed during the last sample interval. Average: $\frac{(N_x - N_0) / F}{(D_x - D_0)}$ Type: Average

**counter_elapsed_time**

`counter_elapsed_time` shows the total time between when the component or process started and the time when this value is calculated. The variable $F$ represents the number of time units that elapse in one second. The value of $F$ is factored into the equation so that the result is displayed in seconds.

Formula: $\frac{D_0 - N_0}{F}$, where the nominator $(D)$ represents the current time, the numerator $(N)$ represents the time the object was started, and the variable $F$ represents the number of time units that elapse in one second. Average: $\frac{D_x - N_0}{F}$ Type: Difference

**counter_histogram**

`counter_histogram` exposes a histogram of the measured values instead of a single value as many of the other counter types. Counters of this type expose a `counter_value_array` instead of a `counter_value`. Those will also not implement the `get_counter_value()` functionality. The results are exposed through a separate `get_counter_values_array()` function.

The first three values in the returned array represent the lower and upper boundaries, and the size of the histogram buckets. All remaining values in the returned array represent the number of measurements for each of the buckets in the histogram.

**counter_raw_values**

`counter_raw_values` exposes an array of measured values instead of a single value as many of the other counter types. Counters of this type expose a `counter_value_array` instead of a `counter_value`. Those will also not implement the `get_counter_value()` functionality. The results are exposed through a separate `get_counter_values_array()` function.

```cpp
class enum counter_status {
  Values:
```
status_valid_data
No error occurred, data is valid.

status_new_data
Data is valid and different from last call.

status_invalid_data
Some error occurred, data is not value.

status_already_defined
The type or instance already has been defined.

status_counter_unknown
The counter instance is unknown.

status_counter_type_unknown
The counter type is unknown.

status_generic_error
A unknown error occurred.

status_valid_data
No error occurred, data is valid.

status_new_data
Data is valid and different from last call.

status_invalid_data
Some error occurred, data is not value.

status_already_defined
The type or instance already has been defined.

status_counter_unknown
The counter instance is unknown.

status_counter_type_unknown
The counter type is unknown.

status_generic_error
A unknown error occurred.

enum discover_counters_mode
Values:

discover_counters_minimal

discover_counters_full

Functions

counter_status get_counter_type_name(counter_type_path_elements const &path,
        std::string &result, error_code &ec = throws)
Create a full name of a counter type from the contents of the given counter_type_path_elements instance. The generated counter type name will not contain any parameters.

counter_status get_full_counter_type_name(counter_type_path_elements const &path,
        std::string &result, error_code &ec = throws)
Create a full name of a counter type from the contents of the given counter_type_path_elements instance. The generated counter type name will contain all parameters.
**counter_status** get_counter_name (counter_path_elements const &path, std::string &result, error_code &ec = throws)

Create a full name of a counter from the contents of the given counter_path_elements instance.

**counter_status** get_counter_instance_name (counter_path_elements const &path, std::string &result, error_code &ec = throws)

Create a name of a counter instance from the contents of the given counter_path_elements instance.

**counter_status** get_counter_type_path_elements (std::string const &name, counter_type_path_elements &path, error_code &ec = throws)

Fill the given counter_type_path_elements instance from the given full name of a counter type.

**counter_status** get_counter_path_elements (std::string const &name, counter_path_elements &path, error_code &ec = throws)

Fill the given counter_path_elements instance from the given full name of a counter.

**counter_status** get_counter_name (std::string const &name, std::string &countername, error_code &ec = throws)

Return the canonical counter instance name from a given full instance name.

**counter_status** get_counter_type_name (std::string const &name, std::string &type_name, error_code &ec = throws)

Return the canonical counter type name from a given (full) instance name.

**counter_status** complement_counter_info (counter_info &info, counter_info const &type_info, error_code &ec = throws)

Complement the counter info if parent instance name is missing.

**counter_status** complement_counter_info (counter_info &info, error_code &ec = throws)

**counter_status** add_counter_type (counter_info const &info, create_counter_func const &create_counter, discover_counters_func const &discover_counters, error_code &ec = throws)

**counter_status** discover_counter_types (discover_counter_func const &discover_counter, discover_counters_mode mode = discover_counters_minimal, error_code &ec = throws)

Call the supplied function for each registered counter type.

**counter_status** discover_counter_types (std::vector<counter_info> &counters, discover_counters_mode mode = discover_counters_minimal, error_code &ec = throws)

Return a list of all available counter descriptions.

**counter_status** discover_counter_type (std::string const &name, discover_counter_func const &discover_counter, discover_counters_mode mode = discover_counters_minimal, error_code &ec = throws)

Call the supplied function for the given registered counter type.

**counter_status** discover_counter_type (counter_info const &info, discover_counter_func const &discover_counter, discover_counters_mode mode = discover_counters_minimal, error_code &ec = throws)
counter_status **discover_counter_type** (std::string const &name, std::vector<counter_info> &counters, discover_counters_mode mode = discover_counters_minimal, error_code &ec = throws)

Return a list of matching counter descriptions for the given registered counter type.

**counter_status discover_counter_type** (counter_info const &info, std::vector<counter_info> &counters, discover_counters_mode mode = discover_counters_minimal, error_code &ec = throws)

bool **expand_counter_info** (counter_info const&, discover_counter_func const&, error_code&)

call the supplied function will all expanded versions of the supplied counter info.

This function expands all locality#* and worker-thread#* wild cards only.

**counter_status remove_counter_type** (counter_info const &info, error_code &ec = throws)

Remove an existing counter type from the (local) registry.

**Note** This doesn’t remove existing counters of this type, it just inhibits defining new counters using this type.

**counter_status get_counter_type** (std::string const &name, counter_info &info, error_code &ec = throws)

Retrieve the counter type for the given counter name from the (local) registry.

lcos::future<naming::id_type> **get_counter_async** (std::string name, error_code &ec = throws)

Get the global id of an existing performance counter, if the counter does not exist yet, the function attempts to create the counter based on the given counter name.

lcos::future<naming::id_type> **get_counter_async** (counter_info const &info, error_code &ec = throws)

Get the global id of an existing performance counter, if the counter does not exist yet, the function attempts to create the counter based on the given counter info.

void **get_counter_infos** (counter_info const &info, counter_type &type, std::string &help_text, std::uint32_t &version, error_code &ec = throws)

Retrieve the meta data specific for the given counter instance.

void **get_counter_infos** (std::string name, counter_type &type, std::string &help_text, std::uint32_t &version, error_code &ec = throws)

Retrieve the meta data specific for the given counter instance.

**struct counter_value**

2.8. API reference 873
Public Members

`std::uint64_t time_`  
The local time when data was collected.

`std::uint64_t count_`  
The invocation counter for the data.

`std::vector<std::int64_t> values_`  
The current counter values.

`std::int64_t scaling_`  
The scaling of the current counter values.

`counter_status status_`  
The status of the counter value.

`bool scale_inverse_`  
If true, value_ needs to be divided by scaling_, otherwise it has to be multiplied.

Private Functions

void `serialize (serialization::output_archive &ar, const unsigned int)`

void `serialize (serialization::input_archive &ar, const unsigned int)`

Friends

`friend hpx::performance_counters::hpx::serialization::access
namespace hpx
namespace agas
Functions

void locality_namespace_register_counter_types (error_code &ec = throws)`

namespace hpx

namespace performance_counters

Functions

void `install_counter (naming::id_type const &id, counter_info const &info, error_code &ec = throws)`  
Install a new performance counter in a way, which will uninstall it automatically during shutdown.

namespace hpx

namespace performance_counters
Functions

`counter_status install_counter_type (std::string const &name,
   hpx::util::function_nonser<std::int64_t> bool
   > const &counter_value, std::string const &helptext = "",
   std::string const &uom = "", counter_type_type = counter_raw, error_code &ec = throws)'

Install a new generic performance counter type in a way, which will uninstall it automatically during shutdown.

The function `install_counter_type` will register a new generic counter type based on the provided function. The counter type will be automatically unregistered during system shutdown. Any consumer querying any instance of this this counter type will cause the provided function to be called and the returned value to be exposed as the counter value.

The counter type is registered such that there can be one counter instance per locality. The expected naming scheme for the counter instances is: `/objectname{locality#<*>/total}/countername` where `<*>` is a zero based integer identifying the locality the counter is created on.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Return** If successful, this function returns `status_valid_data`, otherwise it will either throw an exception or return an error_code from the enum `counter_status` (also, see note related to parameter `ec`).

**Note** The counter type registry is a locality based service. You will have to register each counter type on every locality where a corresponding performance counter will be created.

**Parameters**

- **name**: [in] The global virtual name of the counter type. This name is expected to have the format `objectname/countername`.
- **counter_value**: [in] The function to call whenever the counter value is requested by a consumer.
- **helptext**: [in, optional] A longer descriptive text shown to the user to explain the nature of the counters created from this type.
- **uom**: [in] The unit of measure for the new performance counter type.
- **type**: [in] Type for the new performance counter type.
- **ec**: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

`counter_status install_counter_type (std::string const &name,
   hpx::util::function_nonser<std::vector<std::int64_t>> bool
   > const &counter_value, std::string const &helptext = "",
   std::string const &uom = "", error_code &ec = throws)'

Install a new generic performance counter type returning an array of values in a way, that will uninstall it automatically during shutdown.

The function `install_counter_type` will register a new generic counter type that returns an array of values based on the provided function. The counter type will be automatically unregistered during system shutdown. Any consumer querying any instance of this this counter type will cause the provided function to be called and the returned array value to be exposed as the counter value.

The counter type is registered such that there can be one counter instance per locality. The expected naming scheme for the counter instances is: `/objectname{locality#<*>/total}/countername` where `<*>` is a zero based integer identifying the locality the counter is created on.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`. 
Return If successful, this function returns `status_valid_data`, otherwise it will either throw an exception or return an `error_code` from the enum `counter_status` (also, see note related to parameter `ec`).

Note The counter type registry is a locality based service. You will have to register each counter type on every locality where a corresponding performance counter will be created.

Parameters
- `name`: [in] The global virtual name of the counter type. This name is expected to have the format `/objectname/countername`.
- `counter_value`: [in] The function to call whenever the counter value (array of values) is requested by a consumer.
- `helptext`: [in, optional] A longer descriptive text shown to the user to explain the nature of the counters created from this type.
- `uom`: [in] The unit of measure for the new performance counter type.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
void install_counter_type(const std::string& name, counter_type type, error_code& ec = throws);
```

Install a new performance counter type in a way, which will uninstall it automatically during shutdown.

The function `install_counter_type` will register a new counter type based on the provided `counter_type_info`. The counter type will be automatically unregistered during system shutdown.

Return If successful, this function returns `status_valid_data`, otherwise it will either throw an exception or return an `error_code` from the enum `counter_status` (also, see note related to parameter `ec`).

Note The counter type registry is a locality based service. You will have to register each counter type on every locality where a corresponding performance counter will be created.

Note As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

Parameters
- `name`: [in] The global virtual name of the counter type. This name is expected to have the format `/objectname/countername`.
- `type`: [in] The type of the counters of this counter_type.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
counter_status install_counter_type(const std::string& name, counter_type type, const std::string& helptext, const std::string& uom = "", std::uint32_t version = HPX_PERFORMANCE_COUNTER_V1, error_code& ec = throws);
```

Install a new performance counter type in a way, which will uninstall it automatically during shutdown.

The function `install_counter_type` will register a new counter type based on the provided `counter_type_info`. The counter type will be automatically unregistered during system shutdown.

Return If successful, this function returns `status_valid_data`, otherwise it will either throw an exception or return an `error_code` from the enum `counter_status` (also, see note related to parameter `ec`).

Note The counter type registry is a locality based service. You will have to register each counter type on every locality where a corresponding performance counter will be created.
Note As long as \texttt{ec} is not pre-initialized to \texttt{hpx::throws} this function doesn’t throw but returns the result code using the parameter \texttt{ec}. Otherwise it throws an instance of \texttt{hpx::exception}.

Parameters

- \texttt{name}: [in] The global virtual name of the counter type. This name is expected to have the format /objectname/countername.
- \texttt{type}: [in] The type of the counters of this counter\_type.
- \texttt{helptext}: [in] A longer descriptive text shown to the user to explain the nature of the counters created from this type.
- \texttt{uom}: [in] The unit of measure for the new performance counter type.
- \texttt{version}: [in] The version of the counter type. This is currently expected to be set to \texttt{HPX\_PERFORMANCE\_COUNTER\_V1}.
- \texttt{ec}: [in,out] this represents the error status on exit, if this is pre-initialized to \texttt{hpx::throws} the function will throw on error instead.

\begin{verbatim}
counter_status install_counter_type(const std::string &name, counter_type type, const std::string &helptext, create_counter_func const &create_counter, discover_counters_func const &discover_counters, std::uint32_t version = HPX\_PERFORMANCE\_COUNTER\_V1, std::string const &uom = "", error_code &ec = throws)
\end{verbatim}

Install a new generic performance counter type in a way, which will uninstall it automatically during shutdown.

The function \texttt{install_counter_type} will register a new generic counter type based on the provided \texttt{counter_type\_info}. The counter type will be automatically unregistered during system shutdown.

Note As long as \texttt{ec} is not pre-initialized to \texttt{hpx::throws} this function doesn’t throw but returns the result code using the parameter \texttt{ec}. Otherwise it throws an instance of \texttt{hpx::exception}.

Return If successful, this function returns \texttt{status\_valid\_data}, otherwise it will either throw an exception or return an \texttt{error\_code} from the enum \texttt{counter\_status} (also, see note related to parameter \texttt{ec}).

Note The counter type registry is a locality based service. You will have to register each counter type on every locality where a corresponding performance counter will be created.

Parameters

- \texttt{name}: [in] The global virtual name of the counter type. This name is expected to have the format /objectname/countername.
- \texttt{type}: [in] The type of the counters of this counter\_type.
- \texttt{helptext}: [in] A longer descriptive text shown to the user to explain the nature of the counters created from this type.
- \texttt{version}: [in] The version of the counter type. This is currently expected to be set to \texttt{HPX\_PERFORMANCE\_COUNTER\_V1}.
- \texttt{create_counter}: [in] The function which will be called to create a new instance of this counter type.
- \texttt{discover_counters}: [in] The function will be called to discover counter instances which can be created.
- \texttt{uom}: [in] The unit of measure of the counter type (default: "")
- \texttt{ec}: [in,out] this represents the error status on exit, if this is pre-initialized to \texttt{hpx::throws} the function will throw on error instead.

namespace hpx

namespace performance_counters

class performance_counter_set

Public Functions

performance_counter_set (bool print_counters_locally = false)
Create an empty set of performance counters.

performance_counter_set (std::string const &names, bool reset = false)
Create a set of performance counters from a name, possibly containing wild-card characters

performance_counter_set (std::vector<std::string> const &names, bool reset = false)
void add_counters (std::string const &names, bool reset = false, error_code &ec = throws)
    Add more performance counters to the set based on the given name, possibly containing wild-card characters

void add_counters (std::vector<std::string> const &names, bool reset = false, error_code &ec = throws)
std::vector<counter_info> get_counter_infos () const
    Retrieve the counter infos for all counters in this set.

std::vector<hpx::future<counter_value>> get_counter_values (bool reset = false) const
    Retrieve the values for all counters in this set supporting this operation

std::vector<hpx::future<counter_value>> get_counter_values (launch::sync_policy, bool reset = false, error_code &ec = throws) const

std::vector<hpx::future<counter_values_array>> get_counter_values_array (bool reset = false) const
    Retrieve the array-values for all counters in this set supporting this operation

std::vector<hpx::future<counter_values_array>> get_counter_values_array (launch::sync_policy, bool reset = false, error_code &ec = throws) const

std::vector<hpx::future<void>> reset ()
    Reset all counters in this set.

void reset (launch::sync_policy, error_code &ec = throws)

std::vector<hpx::future<bool>> start ()
    Start all counters in this set.

bool start (launch::sync_policy, error_code &ec = throws)

std::vector<hpx::future<bool>> stop ()
    Stop all counters in this set.
bool stop(launch::sync_policy, error_code &ec = throws)

std::vector<hpx::future<void>> reinit (bool reset = true)
   Re-initialize all counters in this set.

void reinit (launch::sync_policy, bool reset = true, error_code &ec = throws)

void release ()
   Release all references to counters in the set.

std::size_t size() const
   Return the number of counters in this set.

template<typename T>
    hpx::future<std::vector<T>> get_values (bool reset = false) const

template<typename T>
    std::vector<T> get_values (launch::sync_policy, bool reset = false, error_code &ec =

namespace hpx

namespace performance_counters

class registry

Public Functions

registry()

void clear()
    Reset registry by deleting all stored counter types.

counter_status add_counter_type(counter_info const &info, create_counter_func const &create_counter, discover_counters_func const &discover_counters, error_code &ec = throws)
    Add a new performance counter type to the (local) registry.

counter_status discover_counter_types(discover_counter_func discover_counter, discover_counters_mode mode, error_code &ec = throws)
    Call the supplied function for all registered counter types.

counter_status discover_counter_type(std::string const &fullname, discover_counter_func discover_counter, discover_counters_mode mode, error_code &ec = throws)
    Call the supplied function for the given registered counter type.

counter_status discover_counter_type(counter_info const &info, discover_counter_func const &f, discover_counters_mode mode, error_code &ec = throws)

counter_status get_counter_create_function(counter_info const &info, create_counter_func &create_counter, error_code &ec = throws) const
    Retrieve the counter creation function which is associated with a given counter type.

counter_status get_counter_discovery_function(counter_info const &info, discover_counters_func &func, error_code &ec) const
    Retrieve the counter discovery function which is associated with a given counter type.

counter_status remove_counter_type(counter_info const &info, error_code &ec = throws)
    Remove an existing counter type from the (local) registry.

Note This doesn’t remove existing counters of this type, it just inhibits defining new counters using this type.

counter_status create_raw_counter_value(counter_info const &info, std::int64_t *countervalue, naming::gid_type &id, error_code &ec = throws)
    Create a new performance counter instance of type raw_counter based on given counter value.
counter_status create_raw_counter (counter_info const &info, hpx::util::function_nonser<std::int64_t> &f, naming::gid_type &id, error_code &ec = throws)

Create a new performance counter instance of type raw_counter based on given function returning the counter value.

counter_status create_raw_counter (counter_info const &info, hpx::util::function_nonser<std::vector<std::int64_t>> &f, naming::gid_type &id, error_code &ec = throws)

Create a new performance counter instance of type raw_counter based on given function returning the counter value.

counter_status create_raw_counter (counter_info const &info, hpx::util::function_nonser<std::vector<std::int64_t>> &f, bool &ec)

Create a new performance counter instance of type raw_counter based on given function returning the counter value.

counter_status create_raw_counter (counter_info const &info, hpx::util::function_nonser<std::vector<std::int64_t>> &f)

Create a new performance counter instance of type raw_counter based on given function returning the counter value.

counter_status create_counter (counter_info const &info, naming::gid_type &id, error_code &ec = throws)

Create a new performance counter instance based on given counter info.

counter_status create_statistics_counter (counter_info const &info, std::string const &base_counter_name, std::vector<std::size_t> const &parameters, naming::gid_type &id, error_code &ec = throws)

Create a new statistics performance counter instance based on given base counter name and given base time interval (milliseconds).

counter_status create_arithmetics_counter (counter_info const &info, std::vector<std::string> const &base_counter_names, naming::gid_type &id, error_code &ec = throws)

Create a new arithmetics performance counter instance based on given base counter names.

counter_status create_arithmetics_counter_extended (counter_info const &info, std::vector<std::string> const &base_counter_names, naming::gid_type &id, error_code &ec = throws)

Create a new extended arithmetics performance counter instance based on given base counter names.

counter_status add_counter (naming::id_type const &id, counter_info const &info, error_code &ec = throws)

Add an existing performance counter instance to the registry.

counter_status remove_counter (counter_info const &info, naming::id_type const &id, error_code &ec = throws)

Remove the existing performance counter from the registry.

counter_status get_counter_type (std::string const &name, counter_info &info, error_code &ec = throws)

Retrieve counter type information for given counter name.

HPX_DEFINE_COMPONENT_ACTION (base_performance_counter,

get_counter_info_nonvirt,

get_counter_info_action)

Each of the exposed functions needs to be encapsulated into an action type, allowing to generate all required boilerplate code for threads, serialization, etc. The get_counter_info_action retrieves a performance counters information.
HPX_DEFINE_COMPONENT_ACTION (base_performance_counter,
get_counter_value_nonvirt,
get_counter_value_action)
The get_counter_value_action queries the value of a performance counter.

HPX_DEFINE_COMPONENT_ACTION (base_performance_counter,
get_counter_values_array_nonvirt,
get_counter_values_array_action)
The get_counter_value_action queries the value of a performance counter.

HPX_DEFINE_COMPONENT_ACTION (base_performance_counter,
set_counter_value_nonvirt,
set_counter_value_action)
The set_counter_value_action.

HPX_DEFINE_COMPONENT_ACTION (base_performance_counter,
set_counter_value_nonvirt,
set_counter_value_action)
The reset_counter_value_action.

HPX_DEFINE_COMPONENT_ACTION (base_performance_counter,

The contents of this module can be included with the header `hpx/modules/program_options.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/program_options.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

```cpp
namespace hpx
{
  namespace program_options
  {
    namespace command_line_style
    {
      Enums
      {
        enum style_t
        {
          allow_long = 1,
          allow_short = allow_long << 1,
          allow_dash_for_short = allow_short << 1,
          allow_slash_for_short = allow_dash_for_short << 1,
          long_allow_adjacent = allow_slash_for_short << 1,
          long_allow_next = long_allow_adjacent << 1,
          short_allow_adjacent = long_allow_next << 1,
          short_allow_next = short_allow_adjacent << 1,
        }
      }
    }
  }
}
```

Values:
- `allow_long` = 1
  
  Allow “–long_name” style.
- `allow_short` = `allow_long` << 1
  
  Allow “-<single character” style.
- `allow_dash_for_short` = `allow_short` << 1
  
  Allow “." in short options.
- `allow_slash_for_short` = `allow_dash_for_short` << 1
  
  Allow “/” in short options.
- `long_allow_adjacent` = `allow_slash_for_short` << 1
  
  Allow option parameter in the same token for long option, like in
  ```
  --foo=10
  ```
- `long_allow_next` = `long_allow_adjacent` << 1
  
  Allow option parameter in the next token for long options.
- `short_allow_adjacent` = `long_allow_next` << 1
  
  Allow option parameter in the same token for short options.
- `short_allow_next` = `short_allow_adjacent` << 1
  
  Allow option parameter in the next token for short options.
allow_sticky = short_allow_next << 1
Allow to merge several short options together, so that "-s -k" become "-sk". All of the options
but last should accept no parameter. For example, if "-s" accept a parameter, then "k" will be
taken as parameter, not another short option. Dos-style short options cannot be sticky.

allow_guessing = allow_sticky << 1
Allow abbreviated spellings for long options, if they unambiguously identify long option. No
long option name should be prefix of other long option name if guessing is in effect.

long_case_insensitive = allow_guessing << 1
Ignore the difference in case for long options.

short_case_insensitive = long_case_insensitive << 1
Ignore the difference in case for short options.

case_insensitive = (long_case_insensitive | short_case_insensitive)
Ignore the difference in case for all options.

allow_long_disguise = short_case_insensitive << 1
Allow long options with single option starting character, e.g. -foo=10

unix_style = (allow_short | short_allow_adjacent | short_allow_next | allow_long | long_allow_adjacent | long_allow_next | allow_sticky | allow_guessing | allow_dash_for_short)
The more-or-less traditional unix style.

default_style = unix_style
The default style.

environment_iterator ()

void get ()
namespace hpx

namespace program_options

template<class Derived, class ValueType>
class eof_iterator : public util::iterator_facade<Derived, ValueType const, std::forward_iterator_tag>
#include <eof_iterator.hpp> The ‘eof_iterator’ class is useful for constructing forward iterators in cases where iterator extract data from some source and it’s easy to detect ‘eof’ – i.e. the situation where there’s no data. One apparent example is reading lines from a file.

Implementing such iterators using ‘iterator_facade’ directly would require to create class with three core operation, a couple of constructors. When using ‘eof_iterator’, the derived class should define only one method to get new value, plus a couple of constructors.

The basic idea is that iterator has ‘eof’ bit. Two iterators are equal only if both have their ‘eof’ bits set. The ‘get’ method either obtains the new value or sets the ‘eof’ bit.

Specifically, derived class should define:

1. A default constructor, which creates iterator with ‘eof’ bit set. The constructor body should call ‘found_eof’ method defined here.
2. Some other constructor. It should initialize some ‘data pointer’ used in iterator operation and then call ‘get’.
3. The ‘get’ method. It should operate this way:
   • look at some ‘data pointer’ to see if new element is available; if not, it should call ‘found_eof’.
   • extract new element and store it at location returned by the ‘value’ method.
   • advance the data pointer.

Essentially, the ‘get’ method has the functionality of both ‘increment’ and ‘dereference’. It’s very good for the cases where data extraction implicitly moves data pointer, like for stream operation.

Public Functions

eof_iterator ()

Protected Functions

ValueType &value ()
   Returns the reference which should be used by derived class to store the next value.

void found_eof ()
   Should be called by derived class to indicate that it can’t produce next element.

Makes all substitutions using the template
Private Members

`std::vector<std::string> m_alternatives`

class error: public logic_error

#include <errors.hpp> Base class for all errors in the library.

Subclassed by `hpx::program_options::duplicate_option_error`, `hpx::program_options::error_with_option_name`, `hpx::program_options::invalid_command_line_style`, `hpx::program_options::reading_file`, `hpx::program_options::too_many_positional_options_error`

Public Functions

error (const std::string &xwhat)

class error_with_no_option_name: public hpx::program_options::error_with_option_name

#include <errors.hpp> Base class of un-parsable options, when the desired option cannot be identified.

It makes no sense to have an option name, when we can’t match an option to the parameter

Having this a part of the error_with_option_name hierarchy makes error handling a lot easier, even if the name indicates some sort of conceptual dissonance!

Subclassed by `hpx::program_options::ambiguous_option`, `hpx::program_options::unknown_option`

Public Functions

error_with_no_option_name (const std::string &template_, const std::string &original_token = "")

void set_option_name (const std::string&)

   Does NOT set option name, because no option name makes sense

~error_with_no_option_name()

class error_with_option_name: public hpx::program_options::error

#include <errors.hpp> Base class for most exceptions in the library.

Substitutes the values for the parameter name placeholders in the template to create the human readable error message

Placeholders are surrounded by % signs: example% Poor man’s version of boost::format

If a parameter name is absent, perform default substitutions instead so ugly placeholders are never left in-place.

Options are displayed in “canonical” form This is the most unambiguous form of the parsed option name and would correspond to option_description::format_name() i.e. what is shown by print_usage()

The “canonical” form depends on whether the option is specified in short or long form, using dashes or slashes or without a prefix (from a configuration file)

Subclassed by `hpx::program_options::error_with_no_option_name`, `hpx::program_options::multiple_occurrences`, `hpx::program_options::required_option`, `hpx::program_options::invalid_syntax`, `hpx::program_options::multiple_values`, `hpx::program_options::validation_error`

namespace hpx

namespace program_options

Typedefs

using option = basic_option<char>
using woption = basic_option<wchar_t>

template<class Char>
class basic_option
#include <option.hpp>
Option found in input source. Contains a key and a value. The key, in turn, can be a string (name of an option), or an integer (position in input source) — in case no name is specified. The latter is only possible for command line. The template parameter specifies the type of char used for storing the option’s value.

Public Functions

basic_option()

basic_option(const std::string &xstring_key, const std::vector<std::string> &xvalue)

Public Members

std::string string_key
String key of this option. Intentionally independent of the template parameter.

int position_key
Position key of this option. All options without an explicit name are sequentially numbered starting from 0. If an option has explicit name, ‘position_key’ is equal to -1. It is possible that both position_key and string_key is specified, in case name is implicitly added.

std::vector<std::basic_string<Char>> value
Option’s value

std::vector<std::basic_string<Char>> original_tokens
The original unchanged tokens this option was created from.

bool unregistered
True if option was not recognized. In that case, ‘string_key’ and ‘value’ are results of purely syntactic parsing of source. The original tokens can be recovered from the “original_tokens” member.

bool case_insensitive
True if string_key has to be handled case insensitive.
class duplicate_option_error : public hpx::program_options::error
#include <options_description.hpp> Class thrown when duplicate option description is found.

Public Functions

duplicate_option_error (const std::string &xwhat)

class option_description
#include <options_description.hpp> Describes one possible command line/config file option. There
are two kinds of properties of an option. First describe it syntactically and are used only to validate
input. Second affect interpretation of the option, for example default value for it or function that
should be called when the value is finally known. Routines which perform parsing never use second
kind of properties – they are side effect free.
See option_description

Public Types

enum match_result
Values:
  no_match
  full_match
  approximate_match

Public Functions

option_description()

option_description (const char *name, const value_semantic *s)
  Initializes the object with the passed data.
  Note: it would be nice to make the second parameter auto_ptr, to explicitly pass owner-
ship. Unfortunately, it’s often needed to create objects of types derived from ‘value_semantic’:
  options_description d: d.add_options()("a", parameter<int>("n")->default_value(1)); Here, the
static type returned by ‘parameter’ should be derived from value_semantic.
  Alas, derived->base conversion for auto_ptr does not really work, see http://www.open-std.org/
defects.html#84
  So, we have to use plain old pointers. Besides, users are not expected to use the constructor
directly.
  The ‘name’ parameter is interpreted by the following rules:
  • if there’s no ‘,” character in ‘name’, it specifies long name
  • otherwise, the part before ‘,” specifies long name and the part after – short name.

option_description (const char *name, const value_semantic *s, const char *de-
scription)
  Initializes the class with the passed data.

virtual ~option_description()
match_result match(const std::string &option, bool approx, bool long_ignore_case, bool short_ignore_case) const
Given ‘option’, specified in the input source, returns ‘true’ if ‘option’ specifies ‘this.

const std::string &key(const std::string &option) const
Returns the key that should identify the option, in particular in the variables_map class. The
‘option’ parameter is the option spelling from the input source. If option name contains ‘*’,
returns ‘option’. If long name was specified, it’s the long name, otherwise it’s a short name with
pre-pended ‘-‘.

std::string canonical_display_name(int canonical_option_style = 0) const
Returns the canonical name for the option description to enable the user to recognized a matching
option. 1) For short options (‘-‘, ‘!’), returns the short name prefixed. 2) For long options (‘’ / ‘-‘)
returns the first long name prefixed 3) All other cases, returns the first long name (if present) or
the short name, un-prefixed.

const std::string &long_name() const

const std::pair<const std::string*, std::size_t> long_names() const

const std::string &description() const
Explanation of this option.

std::shared_ptr<const value_semantic> semantic() const
Semantic of option’s value.

std::string format_name() const
Returns the option name, formatted suitably for usage message.

std::string format_parameter() const
Returns the parameter name and properties, formatted suitably for usage message.

Private Functions

option_description &set_names(const char *name)

Private Members

std::string m_short_name
a one-character “switch” name - with its prefix, so that this is either empty or has length 2 (e.g.
“-c”

std::vector<std::string> m_long_names
one or more names by which this option may be specified on a command-line or in a config file,
which are not a single-letter switch. The names here are without any prefix.

std::string m_description

std::shared_ptr<const value_semantic> m_value_semantic

class options_description
#include <options_description.hpp> A set of option descriptions. This provides convenient interface
for adding new option (the add_options) method, and facilities to search for options by name.

See here for option adding interface discussion.
See option_description
Public Functions

options_description(unsigned line_length = m_default_line_length, unsigned min_description_length = m_default_line_length / 2)

Creates the instance.

options_description(const std::string &caption, unsigned line_length = m_default_line_length, unsigned min_description_length = m_default_line_length / 2)

Creates the instance. The 'caption' parameter gives the name of this 'options_description' instance. Primarily useful for output. The 'description_length' specifies the number of columns that should be reserved for the description text; if the option text encroaches into this, then the description will start on the next line.

void add (std::shared_ptr<option_description> desc)

Adds new variable description. Throws duplicate_variable_error if either short or long name matches that of already present one.

options_description &add(const options_description &desc)

Adds a group of option description. This has the same effect as adding all option_descriptions in 'desc' individually, except that output operator will show a separate group. Returns *this.

std::size_t get_option_column_width() const

Find the maximum width of the option column, including options in groups.

options_description_easy_init add_options ()

Returns an object of implementation-defined type suitable for adding options to options_description. The returned object will have overloaded operator() with parameter type matching 'option_description' constructors. Calling the operator will create new option_description instance and add it.

const option_description &find(const std::string &name, bool approx, bool long_ignore_case = false, bool short_ignore_case = false)

const option_description *findnothrow(const std::string &name, bool approx, bool long_ignore_case = false, bool short_ignore_case = false)

const std::vector<std::shared_ptr<option_description>> &options () const

void print (std::ostream &os, std::size_t width = 0) const

Outputs 'desc' to the specified stream, calling 'f' to output each option_description element.

Public Static Attributes

Friends

std::ostream &operator<<(std::ostream &os, const options_description &desc)
    Produces a human readable output of ‘desc’, listing options, their descriptions and allowed pa-
rameters. Other options_description instances previously passed to add will be output separately.

class options_description_easy_init
    #include <options_description.hpp> Class which provides convenient creation syntax to option_description.

Public Functions

options_description_easy_init (options_description *owner)  
options_description_easy_init &operator() (const char *name, const char *description)  
options_description_easy_init &operator() (const char *name, const value_semantic *s)  
options_description_easy_init &operator() (const char *name, const value_semantic *s,  
const char *description)  

Private Members

options_description *owner

namespace hpx

namespace program_options
**Typedefs**

```cpp
using parsed_options = basic_parsed_options<char>
using wparsed_options = basic_parsed_options<wchar_t>

using ext_parser = std::function<std::pair<std::string, std::string>(const std::string&)>  
    Augments basic_parsed_options<wchar_t> with conversion from 'parsed_options'

using command_line_parser = basic_command_line_parser<char>
using wcommand_line_parser = basic_command_line_parser<wchar_t>
```

**Enums**

```cpp
class collect_unrecognized_mode

Controls if the ‘collect_unregistered’ function should include positional options, or not.

Values:

- include_positional
- exclude_positional
```

**Functions**

```cpp
template<class Char>  
basic_parsed_options<Char> parse_command_line(int argc, const Char *const argv[],  
    const options_description&, int style = 0, std::function<std::pair<std::string,  
    std::string> > ext = ext_parser())  
    Creates instance of ‘command_line_parser’, passes parameters to it, and returns  
    the result of calling the ‘run’ method.

template<class Char>  
basic_parsed_options<Char> parse_config_file(std::basic_istream<Char>&,  
    const options_description&, bool allow_unregistered = false)

Parse a config file.

Read from given stream.

template<class Char> = char>  
basic_parsed_options<Char> parse_config_file(const char *filename, const  
    options_description&, bool allow_unregistered = false)

Parse a config file.

Read from file with the given name. The character type is passed to the file stream.

template<class Char>  
std::vector<std::basic_string<Char>> collect_unrecognized(const  
    std::vector<basic_option<Char>> &options, enum collect_unrecognized_mode  
    mode)

Collects the original tokens for all named options with ‘unregistered’ flag set. If ‘mode’ is ‘include_positional’ also collects all positional options. Returns the vector of original tokens for all collected options.
```
parsed_options parse_environment (const options_description&, const std::function<std::string()> &name_mapper)

> Parse environment.

For each environment variable, the ‘name_mapper’ function is called to obtain the option name. If it returns empty string, the variable is ignored.

This is done since naming of environment variables is typically different from the naming of command line options.

parsed_options parse_environment (const options_description&, const std::string &prefix)

Parse environment.

Takes all environment variables which start with ‘prefix’. The option name is obtained from variable name by removing the prefix and converting the remaining string into lower case.

parsed_options parse_environment (const options_description&, const char *prefix)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts. This function exists to resolve ambiguity between the two above functions when second argument is of ‘char*’ type. There’s implicit conversion to both std::function and string.

std::vector<std::string> split_unix (const std::string &cmdline, const std::string &separator = " 	", const std::string &quote = "'", const std::string &escape = \\)

Splits a given string to a collection of single strings which can be passed to command_line_parser. The second parameter is used to specify a collection of possible separator chars used for splitting. The separator is defaulted to space “ ”. Splitting is done in a unix style way, with respect to quotes “'” and escape characters ‘\’

std::vector<std::wstring> hpx::program_options::split_unix(const std::wstring &cmdline, const std::wstring &separator = L" 	", const std::wstring &quote = L"'", const std::wstring &escape = L\\)

This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

template<class Char>

class basic_command_line_parser : private cmdline

#include <parsers.hpp> Command line parser.

The class allows one to specify all the information needed for parsing and to parse the command line. It is primarily needed to emulate named function parameters – a regular function with 5 parameters will be hard to use and creating overloads with a smaller number of parameters will be confusing.

For the most common case, the function parse_command_line is a better alternative.

There are two typedefs – command_line_parser and wcommand_line_parser, for charT == char and charT == wchar_t cases.

Public Functions

basic_command_line_parser (const std::vector<std::basic_string<Char>> &args)

Creates a command line parser for the specified arguments list. The ‘args’ parameter should not include program name.

basic_command_line_parser (int argc, const Char *const argv[])

Creates a command line parser for the specified arguments list. The parameters should be the same as passed to ‘main’.
basic_command_line_parser &options(const options_description &desc)
Sets options descriptions to use.

basic_command_line_parser &positional(const positional_options_description &desc)
Sets positional options description to use.

basic_command_line_parser &style(int)
Sets the command line style.

basic_command_line_parser &extra_parser(ext_parser)
Sets the extra parsers.

basic_parsed_options<Char> run()
Parses the options and returns the result of parsing. Throws on error.

basic_command_line_parser &allow_unregistered()
Specifies that unregistered options are allowed and should be passed through. For each command
like token that looks like an option but does not contain a recognized name, an instance of ba-
sic_option<charT> will be added to result, with ‘unrecognized’ field set to ‘true’. It’s possible to
collect all unrecognized options with the ‘collect_unrecognized’ function.

bias_command_line_parser &extra_style_parser(style_parser s)

Private Members

const options_description *m_desc

template<class Char>
class basic_parsed_options
#include <parsers.hpp> Results of parsing an input source. The primary use of this class is passing
information from parsers component to value storage component. This class does not makes much
sense itself.

Public Functions

basic_parsed_options(const options_description *xdescription, int options_prefix = 0)

Public Members

std::vector<basic_option<Char>> options
Options found in the source.

const options_description *description
Options description that was used for parsing. Parsers should return pointer to the instance of
option_description passed to them, and issues of lifetime are up to the caller. Can be NULL.

int m_options_prefix
Mainly used for the diagnostic messages in exceptions. The canonical option prefix for the parser
which generated these results, depending on the settings for basic_command_line_parser::style() or
cmdline::style(). In order of precedence of command_line_style enums: allow_long al-
allow_long_disguise allow_dash_for_short allow_slash_for_short

template<>
class basic_parsed_options<wchar_t>
#include <parsers.hpp> Specialization of basic_parsed_options which:
• provides convenient conversion from basic_parsed_options<char>
• stores the passed char-based options for later use.

Public Functions

basic_parsed_options(const basic_parsed_options<char> &po)
Constructs wrapped options from options in UTF8 encoding.

Public Members

std::vector<basic_option<wchar_t>> options
const options_description *description
basic_parsed_options<char> utf8_encoded_options
Stores UTF8 encoded options that were passed to constructor, to avoid reverse conversion in some cases.

int m_options_prefix
Mainly used for the diagnostic messages in exceptions. The canonical option prefix for the parser which generated these results, depending on the settings for basic_command_line_parser::style() or cmdline::style(). In order of precedence of command_line_style enums: allow_long allow_long_disguise allow_dash_for_short allow_slash_for_short

class positional_options_description
#include <positional_options.hpp> Describes positional options.

The class allows to guess option names for positional options, which are specified on the command line and are identified by the position. The class uses the information provided by the user to associate a name with every positional option, or tell that no name is known.

The primary assumption is that only the relative order of the positional options themselves matters, and that any interleaving ordinary options don’t affect interpretation of positional options.

The user initializes the class by specifying that first N positional options should be given the name X1, following M options should be given the name X2 and so on.

Public Functions

positional_options_description() positional_options_description &add(const char *name, int max_count)
Species that up to ‘max_count’ next positional options should be given the ‘name’. The value of ‘-1’ means ‘unlimited’. No calls to ‘add’ can be made after call with ‘max_value’ equal to ‘-1’.

unsigned max_total_count() const
Returns the maximum number of positional options that can be present. Can return (numeric_limits<unsigned>::max)() to indicate unlimited number.

const std::string &name_for_position(unsigned position) const
Returns the name that should be associated with positional options at 'position'. Precondition: position < max_total_count()
Public Functions

**typed_value**(T *store_to)

Ctor. The 'store_to' parameter tells where to store the value when it’s known. The parameter can be NULL.

**typed_value** *(default_value(const T &v))

Specifies default value, which will be used if none is explicitly specified. The type ‘T’ should provide `operator<<` for `ostream`.

**typed_value** *(default_value(const T &v, const std::string &textual))

Specifies default value, which will be used if none is explicitly specified. Unlike the above overload, the type ‘T’ need not provide `operator<<` for `ostream`, but textual representation of default value must be provided by the user.

**typed_value** *(implicit_value(const T &v))

Specifies an implicit value, which will be used if the option is given, but without an adjacent value. Using this implies that an explicit value is optional,

**typed_value** *(implicit_value(const T &v, const std::string &textual))

Specifies an implicit value, which will be used if the option is given, but without an adjacent value. Using this implies that an implicit value is optional, but if given, must be strictly adjacent to the option, i.e., ‘-ovalue’ or ‘option=value’. Giving ‘-o’ or ‘option’ will cause the implicit value to be applied. Unlike the above overload, the type ‘T’ need not provide `operator<<` for `ostream`, but textual representation of default value must be provided by the user.

**typed_value** *(notifier(std::function<void(T&)> f))

Specifies a function to be called when the final value is determined.

**typed_value** *(composing())

Specifies that the value is composing. See the ‘is_composing’ method for explanation.

**typed_value** *(multitoken())

Specifies that the value can span multiple tokens.

**typed_value** *(zero_tokens())

Specifies that no tokens may be provided as the value of this option, which means that only presence of the option is significant. For such option to be useful, either the ‘validate’ function should be specialized, or the ‘implicit_value’ method should be also used. In most cases, you can use the ‘bool_switch’ function instead of using this method.

**typed_value** *(required())

Specifies that the value must occur.

**std::string** *(name() const)

Returns the name of the option. The name is only meaningful for automatic help message.

**bool** *(is_composing() const)

Returns true if values from different sources should be composed. Otherwise, value from the first source is used and values from other sources are discarded.

**unsigned** *(min_tokens() const)

The minimum number of tokens for this option that should be present on the command line.
unsigned max_tokens() const
The maximum number of tokens for this option that should be present on the command line.

bool is_required() const
Returns true if value must be given. Non-optional value

void xparse(hpx::any_nonser &value_store, const std::vector<std::basic_string<Char>> &new_tokens) const
Creates an instance of the 'validator' class and calls its operator() to perform the actual conversion.

virtual bool apply_default(hpx::any_nonser &value_store) const
If default value was specified via previous call to 'default_value', stores that value into
'value_store'. Returns true if default value was stored.

void notify(const hpx::any_nonser &value_store) const
If an address of variable to store value was specified when creating *this, stores the value there.
Otherwise, does nothing.

const std::type_info &value_type() const

Private Members

bool m_composing
bool m_implicit
bool m_multitoken
bool m_zero_tokens
bool m_required
std::function<void (const T&)> m_notifier

class typed_value_base
#include <value_semantic.hpp> Base class for all option that have a fixed type, and are willing to
announce this type to the outside world. Any 'value_semantics' for which you want to find out the
type can be dynamic_cast-ed to typed_value_base. If conversion succeeds, the ‘type’ method can be
called.
Subclassed by hpx::program_options::typed_value<T, Char>
Public Functions

```cpp
virtual const std::type_info & value_type() const = 0
virtual ~typed_value_base()
```

class untyped_value : public hpx::program_options::value_semantic_codecvt_helper<char>
#include <value_semantic.hpp> Class which specifies a simple handling of a value: the value will have string type and only one token is allowed.

Public Functions

```cpp
untyped_value(bool zero_tokens = false)
std::string name() const
    Returns the name of the option. The name is only meaningful for automatic help message.
unsigned min_tokens() const
    The minimum number of tokens for this option that should be present on the command line.
unsigned max_tokens() const
    The maximum number of tokens for this option that should be present on the command line.
bool is_composing() const
    Returns true if values from different sources should be composed. Otherwise, value from the first source is used and values from other sources are discarded.
bool is_required() const
    Returns true if value must be given. Non-optional value
void xparse(hpx::any_nonser &value_store, const std::vector<std::string> &new_tokens)
    const
    If ‘value_store’ is already initialized, or new_tokens has more than one elements, throws. Otherwise, assigns the first string from ‘new_tokens’ to ‘value_store’, without any modifications.
bool apply_default(hpx::any_nonser&) const
    Does nothing.
void notify(const hpx::any_nonser&) const
    Does nothing.
```

Private Members

```cpp
bool m_zero_tokens

class value_semantic
#include <value_semantic.hpp> Class which specifies how the option’s value is to be parsed and converted into C++ types.
Subclass by hpx::program_options::value_semantic_codecvt_helper<char>, hpx::program_options::value_semantic_codecvt_helper<wchar_t>
```
Public Functions

```cpp
virtual std::string name() const = 0

Returns the name of the option. The name is only meaningful for automatic help message.

virtual unsigned min_tokens() const = 0

The minimum number of tokens for this option that should be present on the command line.

virtual unsigned max_tokens() const = 0

The maximum number of tokens for this option that should be present on the command line.

virtual bool is_composing() const = 0

Returns true if values from different sources should be composed. Otherwise, value from the first source is used and values from other sources are discarded.

virtual bool is_required() const = 0

Returns true if value must be given. Non-optional value

virtual void parse(hpx::any_nonser &value_store, const std::vector<std::string> &new_tokens, bool utf8) const = 0

Parses a group of tokens that specify a value of option. Stores the result in ‘value_store’, using whatever representation is desired. May be be called several times if value of the same option is specified more than once.

virtual bool apply_default(hpx::any_nonser &value_store) const = 0

Called to assign default value to ‘value_store’. Returns true if default value is assigned, and false if no default value exists.

virtual void notify(const hpx::any_nonser &value_store) const = 0

Called when final value of an option is determined.

virtual ~value_semantic()
```

```cpp
template<class Char>

class value_semantic_codecvt_helper

#include <value_semantic.hpp> Helper class which perform necessary character conversions in the ‘parse’ method and forwards the data further.

```

```cpp
template<>

class value_semantic_codecvt_helper<char> : public hpx::program_options::value_semantic

#include <value_semantic.hpp> Helper conversion class for values that accept ascii strings as input. Overrides the ‘parse’ method and defines new ‘xparse’ method taking std::string. Depending on whether input to parse is ascii or UTF8, will pass it to xparse unmodified, or with UTF8->ascii conversion.

Subclassed by hpx::program_options::typed_value< T, Char >, hpx::program_options::untyped_value
Protected Functions

```cpp
virtual void xpars(e hpx::any_nonser &value_store, const std::vector<std::string> &new_tokens) const = 0
```

Private Functions

```cpp
void parse(hpx::any_nonser &value_store, const std::vector<std::string> &new_tokens, bool utf8) const
Parses a group of tokens that specify a value of option. Stores the result in 'value_store', using whatever representation is desired. May be be called several times if value of the same option is specified more than once.
```

```cpp
namespace hpx
namespace program_options

Functions

void store(const basic_parsed_options<char> &options, variables_map &m, bool utf8 = false)
Stores in 'm' all options that are defined in 'options'. If 'm' already has a non-defaulted value of an option, that value is not changed, even if 'options' specify some value.

void store(const basic_parsed_options<wchar_t> &options, variables_map &m)
Stores in 'm' all options that are defined in 'options'. If 'm' already has a non-defaulted value of an option, that value is not changed, even if 'options' specify some value. This is wide character variant.

void notify(variables_map &m)
Runs all 'notify' function for options in 'm'.
```
class abstract_variables_map
    #include <variables_map.hpp> Implements string->string mapping with convenient value casting facilities.

Subclassed by hpx::program_options::variables_map

**Public Functions**

abstract_variables_map()

abstract_variables_map(const abstract_variables_map *next)

virtual ~abstract_variables_map()

const variable_value &operator[](const std::string &name) const

Obtains the value of variable 'name', from *this and possibly from the chain of variable maps.

- if there’s no value in *this.
  - if there’s next variable map, returns value from it
  - otherwise, returns empty value
- if there’s defaulted value
  - if there’s next variable map, which has a non-defaulted value, return that
  - otherwise, return value from *this
- if there’s a non-defaulted value, returns it.

void next (abstract_variables_map *next)

Sets next variable map, which will be used to find variables not found in *this.

**Private Functions**

virtual const variable_value &get (const std::string &name) const = 0

Returns value of variable ‘name’ stored in *this, or empty value otherwise.

**Private Members**

const abstract_variables_map *m_next

class variable_value
    #include <variables_map.hpp> Class holding value of option. Contains details about how the value is set and allows to conveniently obtain the value.

**Public Functions**

variable_value()

variable_value(const hpx::any_nonser &xv, bool xdefaulted)

template<class T>
const T &as () const

If stored value if of type T, returns that value. Otherwise, throws boost::bad_any_cast exception.

template<class T>
This is an overloaded member function, provided for convenience. It differs from the above function only in what argument(s) it accepts.

bool empty() const
Returns true if no value is stored.

bool defaulted() const
Returns true if the value was not explicitly given, but has default value.

bool empty() const
Returns true if no value is stored.

bool defaulted() const
Returns true if the value was not explicitly given, but has default value.

Public Functions

void clear()
void notify()
Private Functions

**const variable_value &get (const std::string &name) const**

Implementation of abstract_variables_map::get which does 'find' in *this.

Private Members

*std::set<std::string>* m_final

Names of option with ‘final’ values – which should not be changed by subsequence assignments.

*std::map<std::string, std::string>* m_required

Names of required options, filled by parser which has access to options_description. The map values are the “canonical” names for each corresponding option. This is useful in creating diagnostic messages when the option is absent.

Friends

void *store* (const basic_parsed_options<char> &options, variables_map &xm, bool utf8)

Stores in ‘m’ all options that are defined in ‘options’. If ‘m’ already has a non-defaulted value of an option, that value is not changed, even if ‘options’ specify some value.

Defines

**HPX_PROGRAM_OPTIONS_VERSION**

The version of the source interface. The value will be incremented whenever a change is made which might cause compilation errors for existing code.

**HPX_PROGRAM_OPTIONS_IMPLICIT_VALUE_NEXT_TOKEN**

Enums

definition of enum partitioner_mode
This enumeration describes the modes available when creating a resource partitioner.

Values:
- mode_default = 0
  Default mode.
- mode_allow_oversubscription = 1
  Allow processing units to be oversubscribed, i.e. multiple worker threads to share a single processing unit.
- mode_allow_dynamic_pools = 2
  Allow worker threads to be added and removed from thread pools.

definition of enum scheduling_policy
This enumeration lists the available scheduling policies (or schedulers) when creating thread pools.

Values:
- user_defined = -2
- unspecified = -1

Functions

detail::partitioner & get_partitioner()
May be used anywhere in code and returns a reference to the single, global resource partitioner.

bool is_partitioner_valid()
Returns true if the resource partitioner has been initialized. Returns false otherwise.
The contents of this module can be included with the header `hpx/modules/runtime_components.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we *strongly* suggest only including the module header `hpx/modules/runtime_components.hpp`, not the particular header in which the functionality you would like to use is defined. See *Public API* for a list of names that are part of the public *HPX* API.

### Defines

**HPX\_REGISTER\_COMPONENT**(*type, name, mode*)

Define a component factory for a component type.

This macro is used create and to register a minimal component factory for a component type which allows it to be remotely created using the `hpx::new<>` function.

This macro can be invoked with one, two or three arguments

**Parameters**

- **type**: The *type* parameter is a (fully decorated) type of the component type for which a factory should be defined.
- **name**: The *name* parameter specifies the name to use to register the factory. This should uniquely (system-wide) identify the component type. The *name* parameter must conform to the C++ identifier rules (without any namespace). If this parameter is not given, the first parameter is used.
- **mode**: The *mode* parameter has to be one of the defined enumeration values of the enumeration `hpx::components::factory_state_enum`. The default for this parameter is `hpx::components::factory_enabled`.

### Defines

**HPX\_REGISTER\_MINIMAL\_COMPONENT\_REGISTRY**(*...)**

This macro is used create and to register a minimal component registry with Hpx.Plugin.

**HPX\_REGISTER\_MINIMAL\_COMPONENT\_REGISTRY\_2**(*ComponentType, componentname*)

**HPX\_REGISTER\_MINIMAL\_COMPONENT\_REGISTRY\_3**(*ComponentType, componentname, state*)

**HPX\_REGISTER\_MINIMAL\_COMPONENT\_REGISTRY\_DYNAMIC**(*...)**

**HPX\_REGISTER\_MINIMAL\_COMPONENT\_REGISTRY\_DYNAMIC\_2**(*ComponentType, componentname*)

**HPX\_REGISTER\_MINIMAL\_COMPONENT\_REGISTRY\_DYNAMIC\_3**(*ComponentType, componentname, state*)

namespace hpx

    namespace components

        template<typename Component, factory_state_enum state>
The component_registry provides a minimal implementation of a component’s registry. If no additional functionality is required this type can be used to implement the full set of minimally required functions to be exposed by a component’s registry instance.

Template Parameters
• Component: The component type this registry should be responsible for.

Public Functions

bool get_component_info (std::vector<std::string> &fillini, std::string const &filepath, bool is_static = false)
Return the ini-information for all contained components.

Return Returns true if the parameter fillini has been successfully initialized with the registry data of all implemented in this module.

Parameters
• fillini: [in] The module is expected to fill this vector with the ini-information (one line per vector element) for all components implemented in this module.

void register_component_type ()
Return the unique identifier of the component type this factory is responsible for.

Return Returns the unique identifier of the component type this factory instance is responsible for. This function throws on any error.

Parameters
• locality: [in] The id of the locality this factory is responsible for.
• agas_client: [in] The AGAS client to use for component id registration (if needed).
Functions

```cpp
void console_logging(logging_destination dest, std::size_t level, std::string const &msg)
void cleanup_logging()
void activate_logging()
```

namespace hpx

namespace components

Functions

```cpp
template<typename Component, typename ...Ts>
future<naming::id_type> create_async(naming::id_type const &gid, Ts&&... vs)
    Asynchronously create a new instance of a component.

template<typename Component, typename ...Ts>
future<std::vector<naming::id_type>> bulk_create_async(naming::id_type const &gid, std::size_t count, Ts&&... vs)

template<typename Component, typename ...Ts>
naming::id_type create(naming::id_type const &gid, Ts&&... vs)

template<typename Component, typename ...Ts>
std::vector<naming::id_type> bulk_create(naming::id_type const &gid, std::size_t count, Ts&&... vs)

template<typename Component, typename ...Ts>
future<naming::id_type> create_colocated_async(naming::id_type const &gid, Ts&&... vs)

template<typename Component, typename ...Ts>
static naming::id_type create_colocated(naming::id_type const &gid, Ts&&... vs)

static future<std::vector<naming::id_type>> bulk_create_colocated_async(naming::id_type const &gid, std::size_t count, Ts&&... vs)

static future<std::vector<naming::id_type>> bulk_create_colocated(name::id_type const &gid, std::size_t count, Ts&&... vs)
```

namespace hpx

namespace components

932 Chapter 2. What's so special about HPX?
Variables

```cpp
const default_distribution_policy default_layout = {}
```
A predefined instance of the default `distribution_policy`. It will represent the local locality and will place all items to create here.

```cpp
struct default_distribution_policy
```
This class specifies the parameters for a simple distribution policy to use for creating (and evenly distributing) a given number of items on a given set of localities.

### Public Functions

```cpp
constexpr default_distribution_policy()
```
Default-construct a new instance of a `default_distribution_policy`. This policy will represent one locality (the local locality).

```cpp
default_distribution_policy operator() (std::vector<id_type> const &locs) const
```
Create a new `default_distribution_policy` representing the given set of localities.

#### Parameters
- `locs`: [in] The list of localities the new instance should represent

```cpp
default_distribution_policy operator() (std::vector<id_type> &&locs) const
```
Create a new `default_distribution_policy` representing the given set of localities.

#### Parameters
- `locs`: [in] The list of localities the new instance should represent

```cpp
default_distribution_policy operator() (id_type const &loc) const
```
Create a new `default_distribution_policy` representing the given locality

#### Parameters
- `loc`: [in] The locality the new instance should represent

```cpp
template<typename Component, typename ...Ts>
hpx::future<hpx::id_type> create (Ts&& ... vs) const
```
Create one object on one of the localities associated by this policy instance

#### Note
This function is part of the placement policy implemented by this class

#### Return
A future holding the global address which represents the newly created object

#### Parameters
- `vs`: [in] The arguments which will be forwarded to the constructor of the new object.

```cpp
template<typename Component, typename ...Ts>
hpx::future<std::vector<bulk_locality_result>> bulk_create (std::size_t count, Ts&& ... vs)
```
Create multiple objects on the localities associated by this policy instance

#### Note
This function is part of the placement policy implemented by this class

#### Return
A future holding the list of global addresses which represent the newly created objects

#### Parameters
• count: [in] The number of objects to create
• vs: [in] The arguments which will be forwarded to the constructors of the new objects.

```cpp
template<typename Action, typename ...Ts>
async_result<Action>::type async (launch policy, Ts&&... vs) const
```

```cpp
template<typename Action, typename Callback, typename ...Ts>
async_result<Action>::type async_cb (launch policy, Callback &&cb, Ts&&... vs) const
```

Note This function is part of the invocation policy implemented by this class

```cpp
template<typename Action, typename Continuation, typename ...Ts>
bool apply (Continuation &c, threads::thread_priority priority, Ts&&... vs) const
```

Note This function is part of the invocation policy implemented by this class

```cpp
template<typename Action, typename ...Ts>
bool apply (threads::thread_priority priority, Ts&&... vs) const
```

```cpp
template<typename Action, typename Continuation, typename Callback, typename ...Ts>
bool apply_cb (Continuation &c, threads::thread_priority priority, Callback &&cb, Ts&&... vs) const
```

Note This function is part of the invocation policy implemented by this class

```cpp
template<typename Action, typename Callback, typename ...Ts>
bool apply_cb (threads::thread_priority priority, Callback &&cb, Ts&&... vs) const
```

```cpp
std::size_t get_num_localities () const
```

Returns the number of associated localities for this distribution policy

Note This function is part of the creation policy implemented by this class

```cpp
hpx::id_type get_next_target () const
```

Returns the locality which is anticipated to be used for the next async operation

```cpp
template<typename Action>
struct async_result
```

```cpp
#include <default_distribution_policy.hpp>
```

Note This function is part of the invocation policy implemented by this class

**Public Types**

```cpp
template<>
using type = hpx::future<typename traits::promise_local_result typename hpx::traits::extract_action<<Action>
```

**Defines**

HPX_REGISTER_DERIVED_COMPONENT_FACTORY (...)

This macro is used create and to register a minimal component factory with Hpx.Plugin. This macro may be used if the registered component factory is the only factory to be exposed from a particular module. If more than one factory needs to be exposed the HPX_REGISTER_COMPONENT_FACTORY and HPX_REGISTER_COMPONENT_MODULE macros should be used instead.

HPX_REGISTER_DERIVED_COMPONENT_FACTORY_ (...)

namespace hpx

Functions

template<typename Component, typename... Ts><unspecified> hpx::new_(id_type const & locality, Ts &&... vs)
Create one or more new instances of the given Component type on the specified locality.

This function creates one or more new instances of the given Component type on the specified locality and returns a future object for the global address which can be used to reference the new component instance.

Note This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```cpp
hpx::future<hpx::id_type> f =
    hpx::new_<some_component>(hpx::find_here(), ...);
```

hpx::id_type id = f.get();

Return The function returns different types depending on its use:

- If the explicit template argument Component represents a component type (traits::is_component<Component>::value evaluates to true), the function will return an hpx::future object instance which can be used to retrieve the global address of the newly created component.
- If the explicit template argument Component represents a client side object (traits::is_client<Component>::value evaluates to true), the function will return a new instance of that type which can be used to refer to the newly created component instance.

Parameters

- locality: [in] The global address of the locality where the new instance should be created on.
- vs: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

Note This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```cpp
hpx::future<hpx::id_type> f =
    hpx::local_new<some_component>(...);
```

hpx::id_type id = f.get();

Return The function returns different types depending on its use:

- If the explicit template argument Component represents a component type (traits::is_component<Component>::value evaluates to true), the function
will return an \texttt{hpx::future} object instance which can be used to retrieve the global address of the newly created component. If the first argument is \texttt{hpx::launch::sync} the function will directly return an \texttt{hpx::id\_type}.

- If the explicit template argument \texttt{Component} represents a client side object (\texttt{traits::is\_client\_type<\texttt{Component}>\_value} evaluates to true), the function will return a new instance of that type which can be used to refer to the newly created component instance.

\textbf{Note} The difference of this function to \texttt{hpx::new\_} is that it can be used in cases where the supplied arguments are non-copyable and non-movable. All operations are guaranteed to be local only.

\textbf{Parameters}

- \texttt{vs}: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

```
template<typename Component, typename... Ts><\texttt{unspecified}> \texttt{hpx::new\_\(id\_type\texttt{\ const & locality, std::size\_t count, Ts &&\ ...}\)}} \texttt{Create multiple new instances of the given Component type on the specified locality.}
```

This function creates multiple new instances of the given Component type on the specified locality and returns a future object for the global address which can be used to reference the new component instance.

\textbf{Note} This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```cpp
\texttt{hpx::future<\texttt{std::vector<hpx::id\_type>}> f =}
\texttt{hpx::new\_<\texttt{some\_component[]}}\texttt{(hpx::find\_here(), 10, ...);}
\texttt{hpx::id\_type id = f.get();}
```

\textbf{Return} The function returns different types depending on its use:

- If the explicit template argument \texttt{Component} represents an array of a component type (i.e. \texttt{Component[]}[], where \texttt{traits::is\_component<\texttt{Component}>\_value} evaluates to true), the function will return an \texttt{hpx::future} object instance which holds a \texttt{std::vector<hpx::id\_type>}, where each of the items in this vector is a global address of one of the newly created components.

- If the explicit template argument \texttt{Component} represents an array of a client side object type (i.e. \texttt{Component[]}[], where \texttt{traits::is\_client<\texttt{Component}>\_value} evaluates to true), the function will return an \texttt{hpx::future} object instance which holds a \texttt{std::vector<hpx::id\_type>}, where each of the items in this vector is a client side instance of the given type, each representing one of the newly created components.

\textbf{Parameters}

- \texttt{locality}: [in] The global address of the locality where the new instance should be created on.
- \texttt{count}: [in] The number of component instances to create
- \texttt{vs}: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

```
template<typename Component, typename DistPolicy, typename... Ts><\texttt{unspecified}> \texttt{hpx::new\_\(id\_type\texttt{\ const & policy, Ts &&\ ...}\)}} \texttt{Create one or more new instances of the given Component type based on the given distribution policy.}
```

This function creates one or more new instances of the given Component type on the localities defined by the given distribution policy and returns a future object for global address which can be used to reference the new component instance(s).
Note This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```cpp
hpx::future<hpx::id_type> f =
    hpx::new_<some_component>(hpx::default_layout, ...);
hpx::id_type id = f.get();
```

**Return** The function returns different types depending on its use:

- If the explicit template argument `Component` represents a component type (traits::is_component<Component>::value evaluates to true), the function will return an `hpx::future` object instance which can be used to retrieve the global address of the newly created component.
- If the explicit template argument `Component` represents a client side object (traits::is_client<Component>::value evaluates to true), the function will return a new instance of that type which can be used to refer to the newly created component instance.

**Parameters**

- `policy`: [in] The distribution policy used to decide where to place the newly created.
- `vs`: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

```cpp
template<typename Component, typename DistPolicy, typename... Ts><unspecified> hpx::new_(DistPolicy const & policy, std::size_t count, Ts &&... vs)
```

Create multiple new instances of the given Component type on the localities as defined by the given distribution policy.

This function creates multiple new instances of the given Component type on the localities defined by the given distribution policy and returns a future object for the global address which can be used to reference the new component instance.

Note This function requires to specify an explicit template argument which will define what type of component(s) to create, for instance:

```cpp
hpx::future<std::vector<hpx::id_type> > f =
    hpx::new_<some_component[]>(hpx::default_layout, 10, ...);
hpx::id_type id = f.get();
```

**Return** The function returns different types depending on its use:

- If the explicit template argument `Component` represents an array of a component type (i.e. Component[], where traits::is_component<Component>::value evaluates to true), the function will return an `hpx::future` object instance which holds a std::vector<hpx::id_type>, where each of the items in this vector is a global address of one of the newly created components.
- If the explicit template argument `Component` represents an array of a client side object type (i.e. Component[], where traits::is_client<Component>::value evaluates to true), the function will return an `hpx::future` object instance which holds a std::vector<hpx::id_type>, where each of the items in this vector is a client side instance of the given type, each representing one of the newly created components.

**Parameters**

- `policy`: [in] The distribution policy used to decide where to place the newly created.
- `count`: [in] The number of component instances to create
• vs: [in] Any number of arbitrary arguments (passed by value, by const reference or by rvalue reference) which will be forwarded to the constructor of the created component instance.

namespace hpx

Enums

enum runtime_mode
A HPX runtime can be executed in two different modes: console mode and worker mode.

Values:
  invalid = -1
  console = 0
    The runtime is the console locality.
  worker = 1
    The runtime is a worker locality.
  connect = 2
    The runtime is a worker locality connecting late
  local = 3
    The runtime is fully local.
  default_ = 4
    The runtime mode will be determined based on the command line arguments
  last
Functions

char const *get_runtime_mode_name(runtime_mode state)
Get the readable string representing the name of the given runtime_mode constant.

runtime_mode get_runtime_mode_from_name(std::string const &mode)
Returns the internal representation (runtime_mode constant) from the readable string representing the
name.
This represents the internal representation from the readable string representing the name.

Parameters

• mode: this represents the runtime mode

**runtime_distributed**

The contents of this module can be included with the header `hpx/modules/runtime_distributed.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/runtime_distributed.hpp`, not the particular header in which the functionality you would like to use is defined. See **Public API** for a list of names that are part of the public HPX API.

```cpp
namespace hpx {

Functions

bool tolerate_node_faults();

class runtime_distributed: public runtime {
    // The runtime class encapsulates the HPX runtime system in a simple to use way. It makes sure all required parts of the HPX runtime system are properly initialized.

Public Functions

hpx::runtime_distributed::runtime_distributed(util::runtime_configuration & rtcfg, int(*pre_main)(runtime_mode) = nullptr)
    Construct a new HPX runtime instance

Parameters

• locality_mode: [in] This is the mode the given runtime instance should be executed in.

~runtime_distributed()
    The destructor makes sure all HPX runtime services are properly shut down before exiting.

int start (util::function_nonser<hpx_main_function_type> const &func, bool blocking = false)
    Start the runtime system.

Return If a blocking is a true, this function will return the value as returned as the result of the invocation of the function object given by the parameter func. Otherwise it will return zero.

Parameters

• func: [in] This is the main function of an HPX application. It will be scheduled for execution by the thread manager as soon as the runtime has been initialized. This function is expected to expose an interface as defined by the typedef hpx_main_function_type.
• blocking: [in] This allows to control whether this call blocks until the runtime system has been stopped. If this parameter is true the function runtime::start will call runtime::wait internally.

int start (bool blocking = false)
    Start the runtime system.

Return If a blocking is a true, this function will return the value as returned as the result of the invocation of the function object given by the parameter func. Otherwise it will return zero.

Parameters

• blocking: [in] This allows to control whether this call blocks until the runtime system has been stopped. If this parameter is true the function runtime::start will call runtime::wait internally.
```
int wait()
    Wait for the shutdown action to be executed.

Return This function will return the value as returned as the result of the invocation of the function object given by the parameter func.

void stop (bool blocking = true)
    Initiate termination of the runtime system.

Parameters
    • blocking: [in] This allows to control whether this call blocks until the runtime system has been fully stopped. If this parameter is false then this call will initiate the stop action but will return immediately. Use a second call to stop with this parameter set to true to wait for all internal work to be completed.

int finalize (double shutdown_timeout)

void stop_helper (bool blocking, std::condition_variable &cond, std::mutex &mtx)
    Stop the runtime system, wait for termination.

Parameters
    • blocking: [in] This allows to control whether this call blocks until the runtime system has been fully stopped. If this parameter is false then this call will initiate the stop action but will return immediately. Use a second call to stop with this parameter set to true to wait for all internal work to be completed.

int suspend()
    Suspend the runtime system.

int resume()
    Resume the runtime system.

bool report_error (std::size_t num_thread, std::exception_ptr const &e, bool terminate_all = true)
    Report a non-recoverable error to the runtime system.

Parameters
    • num_thread: [in] The number of the operating system thread the error has been detected in.
    • e: [in] This is an instance encapsulating an exception which lead to this function call.
    • terminate_all: [in] Kill all localities attached to the currently running application (default: true)

bool report_error (std::exception_ptr const &e, bool terminate_all = true)
    Report a non-recoverable error to the runtime system.

Note This function will retrieve the number of the current shepherd thread and forward to the report_error function above.

Parameters
    • e: [in] This is an instance encapsulating an exception which lead to this function call.
    • terminate_all: [in] Kill all localities attached to the currently running application (default: true)
int run (util::function_nonser<hpx_main_function_type> const &func)
Run the HPX runtime system, use the given function for the main thread and block waiting for all threads to finish.

**Note**  The parameter `func` is optional. If no function is supplied, the runtime system will simply wait for the shutdown action without explicitly executing any main thread.

**Return**  This function will return the value as returned as the result of the invocation of the function object given by the parameter `func`.

**Parameters**
- `func`: [in] This is the main function of an HPX application. It will be scheduled for execution by the thread manager as soon as the runtime has been initialized. This function is expected to expose an interface as defined by the typedef `hpx_main_function_type`. This parameter is optional and defaults to none main thread function, in which case all threads have to be scheduled explicitly.

int run ()
Run the HPX runtime system, initially use the given number of (OS) threads in the thread-manager and block waiting for all threads to finish.

**Return**  This function will always return 0 (zero).

bool is_networking_enabled ()

```cpp
template<typename F>
components::server::console_error_dispatcher::sink_type set_error_sink (F &&sink)
```

**performance_counters::registry &get_counter_registry ()**
Allow access to the registry counter registry instance used by the HPX runtime.

```cpp
performance_counters::registry const &get_counter_registry () const
```
Allow access to the registry counter registry instance used by the HPX runtime.

void register_counter_types ()
Install all performance counters related to this runtime instance.

```cpp
void register_query_counters (std::shared_ptr<util::query_counters> const &active_counters)
```

```cpp
void start_active_counters (error_code &ec = throws)
```

```cpp
void stop_active_counters (error_code &ec = throws)
```

```cpp
void reset_active_counters (error_code &ec = throws)
```

```cpp
void reinit_active_counters (bool reset = true, error_code &ec = throws)
```

```cpp
void evaluate_active_counters (bool reset = false, char const *description = nullptr, error_code &ec = throws)
```

```cpp
void stop_evaluating_counters (bool terminate = false)
```

**naming::resolver_client &get_agas_client ()**
Allow access to the AGAS client instance used by the HPX runtime.

**hpx::threads::threadmanager &get_thread_manager ()**
Allow access to the thread manager instance used by the HPX runtime.
applier::applier &get_applier()
   Allow access to the applier instance used by the HPX runtime.

std::string here() const
   Returns a string of the locality endpoints (usable in debug output)

std::uint64_t get_runtime_support_lva() const

naming::gid_type get_next_id(std::size_t count = 1)

void init_id_pool_range()

void initialize_agas()
   Initialize AGAS operation.

void add_pre_start_up_function(startup_function_type f)
   Add a function to be executed inside a HPX thread before hpx_main but guaranteed to be executed before any startup function registered with add_startup_function.

   Note  The difference to a startup function is that all pre-startup functions will be (system-wide) executed before any startup function.

   Parameters
   • f: The function ‘f’ will be called from inside a HPX thread before hpx_main is executed. This is very useful to setup the runtime environment of the application (install performance counters, etc.)

void add_startup_function(startup_function_type f)
   Add a function to be executed inside a HPX thread before hpx_main

   Parameters
   • f: The function ‘f’ will be called from inside a HPX thread before hpx_main is executed. This is very useful to setup the runtime environment of the application (install performance counters, etc.)

void add_pre_shutdown_function(shutdown_function_type f)
   Add a function to be executed inside a HPX thread during hpx::finalize, but guaranteed before any of the shutdown functions is executed.

   Note  The difference to a shutdown function is that all pre-shutdown functions will be (system-wide) executed before any shutdown function.

   Parameters
   • f: The function ‘f’ will be called from inside a HPX thread while hpx::finalize is executed. This is very useful to tear down the runtime environment of the application (uninstall performance counters, etc.)

void add_shutdown_function(shutdown_function_type f)
   Add a function to be executed inside a HPX thread during hpx::finalize

   Parameters
   • f: The function ‘f’ will be called from inside a HPX thread while hpx::finalize is executed. This is very useful to tear down the runtime environment of the application (uninstall performance counters, etc.)
hpx::util::io_service_pool \*get_thread_pool (char const \*name)
Access one of the internal thread pools (io_service instances) HPX is using to perform specific tasks.
The three possible values for the argument name are “main_pool”, “io_pool”, “parcel_pool”, and “timer_pool”. For any other argument value the function will return zero.

bool register_thread (char const \*name, std::size_t num = 0, bool service_thread = true, error_code &ec = throws)
Register an external OS-thread with HPX.

notification_policy_type get_notification_policy (char const \*prefix, runtime_local::os_thread_type type)
Generate a new notification policy instance for the given thread name prefix

std::uint32_t get_locality_id (error_code &ec) const
std::size_t get_num_worker_threads () const
std::uint32_t get_num_localities (hpx::launch::sync_policy, error_code &ec) const

Private Static Functions

static void default_errorsink (std::string const &)
namespace hpx
namespace applier

Functions

applier &get_applier ()
The function get_applier returns a reference to the (thread specific) applier instance.
applier *get_applier_ptr ()
The function get_applier_ptr returns a pointer to the (thread specific) applier instance. The returned pointer is NULL if the current thread is not known to HPX or if the runtime system is not active.
namespace applier
The namespace applier contains all definitions needed for the class hpx::applier::applier and its related functionality. This namespace is part of the HPX core module.
namespace hpx

namespace components

Functions

template<typename Component>
future<naming::id_type> copy (naming::id_type const &to_copy)
Copy given component to the specified target locality.
The function copy<Component> will create a copy of the component referenced by to_copy on the locality specified with target_locality. It returns a future referring to the newly created component instance.

Return A future representing the global id of the newly (copied) component instance.
Note The new component instance is created on the locality of the component instance which is to be copied.

Parameters
- \texttt{to\_copy}: [in] The global id of the component to copy

Template Parameters
- \texttt{The}: only template argument specifies the component type to create.

\begin{Verbatim}
\texttt{template<typename Component>}
\end{Verbatim}

\begin{Verbatim}
\texttt{future<naming::id\_type> copy (naming::id\_type const &to\_copy, naming::id\_type const &target\_locality)}
\end{Verbatim}

Copy given component to the specified target locality.

The function \texttt{copy<Component>} will create a copy of the component referenced by \texttt{to\_copy} on the locality specified with \texttt{target\_locality}. It returns a future referring to the newly created component instance.

Return A future representing the global id of the newly (copied) component instance.

Parameters
- \texttt{to\_copy}: [in] The global id of the component to copy
- \texttt{target\_locality}: [in ] The locality where the copy should be created.

Template Parameters
- \texttt{The}: only template argument specifies the component type to create.

\begin{Verbatim}
\texttt{template<typename Derived, typename Stub>}
\end{Verbatim}

\begin{Verbatim}
\texttt{Derived copy (client\_base<Derived, Stub> const &to\_copy, naming::id\_type const &target\_locality = naming::invalid\_id)}
\end{Verbatim}

Copy given component to the specified target locality.

The function \texttt{copy} will create a copy of the component referenced by the client side object \texttt{to\_copy} on the locality specified with \texttt{target\_locality}. It returns a new client side object future referring to the newly created component instance.

Return A future representing the global id of the newly (copied) component instance.

Note If the second argument is omitted (or is invalid\_id) the new component instance is created on the locality of the component instance which is to be copied.

Parameters
- \texttt{to\_copy}: [in] The client side object representing the component to copy
- \texttt{target\_locality}: [in, optional] The locality where the copy should be created (default is same locality as source).

Template Parameters
- \texttt{The}: only template argument specifies the component type to create.

\begin{Verbatim}
namespace hpx
\end{Verbatim}

\textbf{Functions}

\begin{Verbatim}
naming::id\_type find\_root\_locality (error\_code &ec = throws)
\end{Verbatim}

Return the global id representing the root locality.

The function find\_root\_locality() can be used to retrieve the global id usable to refer to the root locality.
The root locality is the locality where the main AGAS service is hosted.

Note Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).
Return  The global id representing the root locality for this application.

Note  As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result
code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Note  This function will return meaningful results only if called from an HPX-thread. It will return
hpx::naming::invalid_id otherwise.

See  hpx::find_all_localities(), hpx::find_locality()

Parameters

- ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the
  function will throw on error instead.

```cpp
std::vector<naming::id_type> find_all_localities(error_code &ec = throws)
```

Return the list of global ids representing all localities available to this application.

The function find_all_localities() can be used to retrieve the global ids of all localities currently available
to this application.

Note  Generally, the id of a locality can be used for instance to create new instances of components and to
invoke plain actions (global functions).

Return  The global ids representing the localities currently available to this application.

Note  As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result
code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Note  This function will return meaningful results only if called from an HPX-thread. It will return an
empty vector otherwise.

See  hpx::find_here(), hpx::find_locality()

Parameters

- ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the
  function will throw on error instead.

```cpp
std::vector<naming::id_type> find_remote_localities(error_code &ec = throws)
```

Return the list of locality ids of remote localities supporting the given component type. By default this
function will return the list of all remote localities (all but the current locality).

The function find_remote_localities() can be used to retrieve the global ids of all remote localities currently
available to this application (i.e. all localities except the current one).

Note  Generally, the id of a locality can be used for instance to create new instances of components and to
invoke plain actions (global functions).

Return  The global ids representing the remote localities currently available to this application.

Note  As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result
code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Note  This function will return meaningful results only if called from an HPX-thread. It will return an
empty vector otherwise.

See  hpx::find_here(), hpx::find_locality()

Parameters
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

namespace hpx

Functions

naming::id_type find_here(error_code &ec = throws)
Return the global id representing this locality.

The function find_here() can be used to retrieve the global id usable to refer to the current locality.

Note Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

Return The global id representing the locality this function has been called on.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Note This function will return meaningful results only if called from an HPX-thread. It will return hpx::naming::invalid_id otherwise.

See hpx::find_here(), hpx::find_locality()

Parameters

• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

namespace hpx

Functions

std::vector<naming::id_type> find_all_localities(components::component_type type, error_code &ec = throws)
Return the list of global ids representing all localities available to this application which support the given component type.

The function find_all_localities() can be used to retrieve the global ids of all localities currently available to this application which support the creation of instances of the given component type.

Note Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).

Return The global ids representing the localities currently available to this application which support the creation of instances of the given component type. If no localities supporting the given component type are currently available, this function will return an empty vector.

Note As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Note This function will return meaningful results only if called from an HPX-thread. It will return an empty vector otherwise.

See hpx::find_here(), hpx::find_locality()

Parameters
\begin{itemize}
\item \textbf{type:} [in] The type of the components for which the function should return the available localities.
\item \textbf{ec:} [in,out] this represents the error status on exit, if this is pre-initialized to \texttt{hpx::throws} the function will throw on error instead.
\end{itemize}

\begin{verbatim}
std::vector<naming::id_type> find_remote_localities (components::component_type type, error_code &ec = throws)
\end{verbatim}

Return the list of locality ids of remote localities supporting the given component type. By default this function will return the list of all remote localities (all but the current locality).

The function \texttt{find_remote_localities()} can be used to retrieve the global ids of all remote localities currently available to this application (i.e. all localities except the current one) which support the creation of instances of the given component type.

\begin{itemize}
\item [Note] Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).
\item [Return] The global ids representing the remote localities currently available to this application.
\item [Note] As long as \texttt{ec} is not pre-initialized to \texttt{hpx::throws} this function doesn’t throw but returns the result code using the parameter \texttt{ec}. Otherwise it throws an instance of \texttt{hpx::exception}.
\item [Note] This function will return meaningful results only if called from an HPX-thread. It will return an empty vector otherwise.
\item [See] \texttt{hpx::find_here()}, \texttt{hpx::find_locality()}
\end{itemize}

\textbf{Parameters}

\begin{itemize}
\item \textbf{type:} [in] The type of the components for which the function should return the available remote localities.
\item \textbf{ec:} [in,out] this represents the error status on exit, if this is pre-initialized to \texttt{hpx::throws} the function will throw on error instead.
\end{itemize}

\begin{verbatim}
naming::id_type find_locality (components::component_type type, error_code &ec = throws)
\end{verbatim}

Return the global id representing an arbitrary locality which supports the given component type.

The function \texttt{find_locality()} can be used to retrieve the global id of an arbitrary locality currently available to this application which supports the creation of instances of the given component type.

\begin{itemize}
\item [Note] Generally, the id of a locality can be used for instance to create new instances of components and to invoke plain actions (global functions).
\item [Return] The global id representing an arbitrary locality currently available to this application which supports the creation of instances of the given component type. If no locality supporting the given component type is currently available, this function will return \texttt{hpx::naming::invalid_id}.
\item [Note] As long as \texttt{ec} is not pre-initialized to \texttt{hpx::throws} this function doesn’t throw but returns the result code using the parameter \texttt{ec}. Otherwise it throws an instance of \texttt{hpx::exception}.
\item [Note] This function will return meaningful results only if called from an HPX-thread. It will return \texttt{hpx::naming::invalid_id} otherwise.
\item [See] \texttt{hpx::find_here()}, \texttt{hpx::find_all_localities()}
\item [Parameters]
\begin{itemize}
\item \textbf{type:} [in] The type of the components for which the function should return any available locality.
\end{itemize}
\end{itemize}
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

namespace hpx

Functions

future<std::string> get_locality_name(naming::id_type const &id)
Return the name of the referenced locality.
This function returns a future referring to the name for the locality of the given id.

Return This function returns the name for the locality of the given id. The name is retrieved from the underlying networking layer and may be different for different parcel ports.

See std::string get_locality_name()

Parameters

• id: [in] The global id of the locality for which the name should be retrieved

namespace hpx

Functions

lcos::future<std::uint32_t> get_num_localities(components::component_type t)
Asynchronously return the number of localities which are currently registered for the running application.
The function get_num_localities asynchronously returns the number of localities currently connected to the console which support the creation of the given component type. The returned future represents the actual result.

Note This function will return meaningful results only if called from an HPX-thread. It will return 0 otherwise.

See hpx::find_all_localities, hpx::get_num_localities

Parameters

• t: The component type for which the number of connected localities should be retrieved.

std::uint32_t get_num_localities(launch::sync_policy, components::component_type t, error_code &ec = throws)
Synchronously return the number of localities which are currently registered for the running application.
The function get_num_localities returns the number of localities currently connected to the console which support the creation of the given component type. The returned future represents the actual result.

Note This function will return meaningful results only if called from an HPX-thread. It will return 0 otherwise.

See hpx::find_all_localities, hpx::get_num_localities

Parameters

• t: The component type for which the number of connected localities should be retrieved.
• ec: [in,out] this represents the error status on exit, if this is pre-initialized to \texttt{hpx::throws} the function will throw on error instead.

\begin{verbatim}
namespace hpx

namespace components

\end{verbatim}

\textbf{Functions}

\begin{verbatim}
template<typename Component, typename DistPolicy>
future<naming::id_type> migrate(naming::id_type const &to_migrate, DistPolicy const &policy)
    Migrate the given component to the specified target locality
    The function \texttt{migrate\langle Component\rangle} will migrate the component referenced by \texttt{to_migrate} to the locality specified with \texttt{target_locality}. It returns a future referring to the migrated component instance.

    \textbf{Return} A future representing the global id of the migrated component instance. This should be the same as \texttt{migrate\_to}.

    \textbf{Parameters}
    \begin{itemize}
        \item \texttt{to_migrate}: [in] The client side representation of the component to migrate.
        \item \texttt{policy}: [in] A distribution policy which will be used to determine the locality to migrate this object to.
    \end{itemize}

    \textbf{Template Parameters}
    \begin{itemize}
        \item Component: Specifies the component type of the component to migrate.
        \item DistPolicy: Specifies the distribution policy to use to determine the destination locality.
    \end{itemize}
\end{verbatim}

\begin{verbatim}
template<typename Derived, typename Stub, typename DistPolicy>
Derived migrate(client_base<Derived, Stub> const &to_migrate, DistPolicy const &policy)
    Migrate the given component to the specified target locality
    The function \texttt{migrate\langle Component\rangle} will migrate the component referenced by \texttt{to_migrate} to the locality specified with \texttt{target_locality}. It returns a future referring to the migrated component instance.

    \textbf{Return} A future representing the global id of the migrated component instance. This should be the same as \texttt{migrate\_to}.

    \textbf{Parameters}
    \begin{itemize}
        \item \texttt{to_migrate}: [in] The client side representation of the component to migrate.
        \item \texttt{policy}: [in] A distribution policy which will be used to determine the locality to migrate this object to.
    \end{itemize}

    \textbf{Template Parameters}
    \begin{itemize}
        \item Derived: Specifies the component type of the component to migrate.
        \item DistPolicy: Specifies the distribution policy to use to determine the destination locality.
    \end{itemize}
\end{verbatim}

\begin{verbatim}
template<typename Component>
future<naming::id_type> migrate(naming::id_type const &to_migrate, naming::id_type const &target_locality)
    Migrate the component with the given id to the specified target locality
    The function \texttt{migrate\langle Component\rangle} will migrate the component referenced by \texttt{to_migrate} to the locality specified with \texttt{target_locality}. It returns a future referring to the migrated component instance.

    \textbf{Return} A future representing the global id of the migrated component instance. This should be the same as \texttt{migrate\_to}.
\end{verbatim}
Parameters
- **to_migrate**: [in] The global id of the component to migrate.
- **target_locality**: [in] The locality where the component should be migrated to.

Template Parameters
- **Component**: Specifies the component type of the component to migrate.

```cpp
template<typename Derived, typename Stub>
Derived migrate(client_base<Derived, Stub> const &to_migrate, naming::id_type const &target_locality)
```

Migrate the given component to the specified target locality.

The function `migrate<Component>` will migrate the component referenced by `to_migrate` to the locality specified with `target_locality`. It returns a future referring to the migrated component instance.

Return A client side representation of representing of the migrated component instance. This should be the same as `migrate_to`.

Parameters
- **to_migrate**: [in] The client side representation of the component to migrate.
- **target_locality**: [in] The id of the locality to migrate this object to.

Template Parameters
- **Derived**: Specifies the component type of the component to migrate.

namespace hpx

namespace components

class runtime_support: public hpx::components::stubs::runtime_support
```
#include <runtime_support.hpp> The runtime_support class is the client side representation of a server::runtime_support component

Public Functions

runtime_support (naming::id_type const &gid = naming::invalid_id)
Create a client side representation for the existing server::runtime_support instance with the given global id `gid`.

```
template<typename Component, typename ...Ts>
  naming::id_type create_component (Ts&&... vs)
Create a new component type using the runtime_support.

```
template<typename Component, typename ...Ts>
  lcos::future<naming::id_type> create_component_async (Ts&&... vs)
Asynchronously create a new component using the runtime_support.

```
template<typename Component, typename ...Ts>
  std::vector<naming::id_type> bulk_create_component (std::size_t, Ts&&... vs)
Asynchronously create N new default constructed components using the runtime_support

```
template<typename Component, typename ...Ts>
  lcos::future<std::vector<naming::id_type>> bulk_create_components_async (std::size_t, Ts&&... vs)
Asynchronously create a new component using the runtime_support.
lcos::future<int> load_components_async()

int load_components()

lcos::future<void> call_startup_functions_async (bool pre_start)

void call_startup_functions (bool pre_start)

lcos::future<void> shutdown_async (double timeout = -1)

Shutdown the given runtime system.

void shutdown (double timeout = -1)

void shutdown_all (double timeout = -1)

Shutdown the runtime systems of all localities.

lcos::future<void> terminate_async()

Terminate the given runtime system.

void terminate()

void terminate_all()

Terminate the runtime systems of all localities.

void get_config (util::section &ini)

Retrieve configuration information.

void shutdown (double timeout, naming::id_type const &respond_to)
Gracefully shutdown this runtime system instance.

void shutdown_all (double timeout)
Gracefully shutdown runtime system instances on all localities.

HPX_NORETURN void hpx::components::server::runtime_support::terminate(naming::id_type const &respond_to)
Shutdown this runtime system instance.

void terminate_act (naming::id_type const &id)

HPX_NORETURN void hpx::components::server::runtime_support::terminate_all()
Shutdown runtime system instances on all localities.

void terminate_all_act ()

util::section get_config ()
Retrieve configuration information.

int load_components ()
Load all components on this locality.

void call_startup_functions (bool pre_startup)

void call_shutdown_functions (bool pre_shutdown)

void garbage_collect ()
Force a garbage collection operation in the AGAS layer.

naming::gid_type create_performance_counter (performance_counters::counter_info const &info)
Create the given performance counter instance.

void remove_from_connection_cache (naming::gid_type const &gid, parcelset::endpoints_type const &eps)
Remove the given locality from our connection cache.

HPX_DEFINE_COMPONENT_ACTION (runtime_support, load_components)
termination detection

HPX_DEFINE_COMPONENT_ACTION (runtime_support, call_startup_functions)

HPX_DEFINE_COMPONENT_ACTION (runtime_support, call_shutdown_functions)

HPX_DEFINE_COMPONENT_ACTION (runtime_support, shutdown)
`HPX_DEFINE_COMPONENT_ACTION` (runtime_support, shutdown_all)

`HPX_DEFINE_COMPONENT_ACTION` (runtime_support, garbage_collect)

`HPX_DEFINE_COMPONENT_ACTION` (runtime_support, create_performance_counter)

`HPX_DEFINE_COMPONENT_ACTION` (runtime_support, remove_from_connection_cache)

```cpp
void run()
    Start the runtime_support component.
```

```cpp
void wait()
    Wait for the runtime_support component to notify the calling thread.
```

This function will be called from the main thread, causing it to block while the HPX functionality is executed. The main thread will block until the shutdown_action is executed, which in turn notifies all waiting threads.

```cpp
void stop(double timeout, naming::id_type const &respond_to, bool remove_from_remote_caches)
    Notify all waiting (blocking) threads allowing the system to be properly stopped.
```

**Note** This function can be called from any thread.

```cpp
void stopped()
    called locally only
```

```cpp
void notify_waiting_main()

bool was_stopped() const
```

```cpp
void add_pre_startup_function(startup_function_type f)
void add_startup_function(startup_function_type f)
void add_pre_shutdown_function(shutdown_function_type f)
void add_shutdown_function(shutdown_function_type f)
void remove_here_from_connection_cache()
void remove_here_from_console_connection_cache()
```
Public Static Functions

static component_type get_component_type()

static void set_component_type(component_type t)

static constexpr void finalize()

finalize() will be called just before the instance gets destructed

Parameters

- self: [in] The HPX thread used to execute this function.
- appl: [in] The applier to be used for finalization of the component instance.

static bool is_target_valid(naming::id_type const &id)

Protected Functions

runtime_local

The contents of this module can be included with the header hpx/modules/runtime_local.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/runtime_local.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

Defines

HPX_REGISTER_STARTUP_SHUTDOWN_REGISTRY (RegistryType, componentname)

This macro is used to register the given component factory with Hpx.Plugin. This macro has to be used for each of the components.

HPX_REGISTER_STARTUP_SHUTDOWN_REGISTRY_DYNAMIC (RegistryType, componentname)

HPX_REGISTER_STARTUP_SHUTDOWN_FUNCTIONS ()

This macro is used to define the required Hpx.Plugin entry point for the startup/shutdown registry. This macro has to be used in not more than one compilation unit of a component module.

HPX_REGISTER_STARTUP_SHUTDOWN_FUNCTIONS_DYNAMIC ()
namespace hpx

namespace components

struct component_startup_shutdown_base
#include <component_startup_shutdown_base.hpp> The component_startup_shutdown_base has to
be used as a base class for all component startup/shutdown registries.

Public Functions

virtual ~component_startup_shutdown_base ()

virtual bool get_startup_function (startup_function_type &startup, bool &pre_startup) = 0

Return Returns true if the parameter startup has been successfully initialized with the startup
function.

Parameters

• startup: [in, out] The module is expected to fill this function object with a reference to a
startup function. This function will be executed by the runtime system during system startup.

virtual bool get_shutdown_function (shutdown_function_type &shutdown, bool &pre_shutdown) = 0

Return Returns true if the parameter shutdown has been successfully initialized with the shut-
down function.

Parameters

• shutdown: [in, out] The module is expected to fill this function object with a reference
to a startup function. This function will be executed by the runtime system during system
startup.

namespace hpx

Functions

std::string get_config_entry (std::string const &key, std::string const &dflt)
Retrieve the string value of a configuration entry given by key.

std::string get_config_entry (std::string const &key, std::size_t dflt)
Retrieve the integer value of a configuration entry given by key.

void set_config_entry (std::string const &key, std::string const &value)
Set the string value of a configuration entry given by key.

void set_config_entry (std::string const &key, std::size_t value)
Set the integer value of a configuration entry given by key.

void set_config_entry_callback (std::string const &key, util::function_nonser<void> std::string
const&, std::string const&
> const &callback) Set the string value of a configuration entry given by key.
namespace hpx

# Functions

```cpp
std::string diagnostic_information(exception_info const &xi)
```

Extract the diagnostic information embedded in the given exception and return a string holding a formatted message.

The function hpx::diagnostic_information can be used to extract all diagnostic information stored in the given exception instance as a formatted string. This simplifies debug output as it composes the diagnostics into one, easy to use function call. This includes the name of the source file and line number, the sequence number of the OS-thread and the HPX-thread id, the locality id and the stack backtrace of the point where the original exception was thrown.

**Return** The formatted string holding all of the available diagnostic information stored in the given exception instance.

**See** hpx::get_error_locality_id(), hpx::get_error_host_name(), hpx::get_error_process_id(), hpx::get_error_function_name(), hpx::get_error_file_name(), hpx::get_error_line_number(), hpx::get_error_os_thread(), hpx::get_error_thread_id(), hpx::get_error_thread_description(), hpx::get_error(), hpx::get_error_backtrace(), hpx::get_error_env(), hpx::get_error_what(), hpx::get_error_config(), hpx::get_error_state()

**Parameters**

- `xi`: The parameter `e` will be inspected for all diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: hpx::exception_info, hpx::error_code, std::exception, or std::exception_ptr.

**Exceptions**

- std::bad_alloc: (if any of the required allocation operations fail)

```cpp
std::uint32_t get_error_locality_id(exception_info const &xi)
```

Return the locality id where the exception was thrown.

The function hpx::get_error_locality_id can be used to extract the diagnostic information element representing the locality id as stored in the given exception instance.

**Return** The locality id of the locality where the exception was thrown. If the exception instance does not hold this information, the function will return hpx::naming::invalid_locality_id.

**See** hpx::diagnostic_information(), hpx::get_error_host_name(), hpx::get_error_process_id(), hpx::get_error_function_name(), hpx::get_error_file_name(), hpx::get_error_line_number(), hpx::get_error_os_thread(), hpx::get_error_thread_id(), hpx::get_error_thread_description(), hpx::get_error(), hpx::get_error_backtrace(), hpx::get_error_env(), hpx::get_error_what(), hpx::get_error_config(), hpx::get_error_state()

**Parameters**

- `xi`: The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: hpx::exception_info, hpx::error_code, std::exception, or std::exception_ptr.

**Exceptions**

- nothing:
Return the hostname of the locality where the exception was thrown.

The function `hpx::get_error_host_name` can be used to extract the diagnostic information element representing the host name as stored in the given exception instance.

```
std::string get_error_host_name (hpx::exception_info const &xi)
```

Return: The hostname of the locality where the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

See `hpx::diagnostic_information()`, `hpx::get_error_process_id()`, `hpx::get_error_host_name()`, `hpx::get_error_function_name()`, `hpx::get_error_file_name()`, `hpx::get_error_line_number()`, `hpx::get_error_os_thread()`, `hpx::get_error_thread_id()`, `hpx::get_error_thread_description()`, `hpx::get_error_backtrace()`, `hpx::get_error_env()`, `hpx::get_error_what()`, `hpx::get_error_config()`, `hpx::get_error_state()`

Parameters

- `xi`: The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

Exceptions

- `std::bad_alloc` (if one of the required allocations fails)

```
std::int64_t get_error_process_id (hpx::exception_info const &xi)
```

Return the (operating system) process id of the locality where the exception was thrown.

The function `hpx::get_error_process_id` can be used to extract the diagnostic information element representing the process id as stored in the given exception instance.

Return: The process id of the OS-process which threw the exception. If the exception instance does not hold this information, the function will return 0.

See `hpx::diagnostic_information()`, `hpx::get_error_host_name()`, `hpx::get_error_function_name()`, `hpx::get_error_file_name()`, `hpx::get_error_line_number()`, `hpx::get_error_os_thread()`, `hpx::get_error_thread_id()`, `hpx::get_error_thread_description()`, `hpx::get_error_backtrace()`, `hpx::get_error_env()`, `hpx::get_error_what()`, `hpx::get_error_config()`, `hpx::get_error_state()`

Parameters

- `xi`: The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

Exceptions

- `nothing`:

```
std::string get_error_env (hpx::exception_info const &xi)
```

Return the environment of the OS-process at the point the exception was thrown.

The function `hpx::get_error_env` can be used to extract the diagnostic information element representing the environment of the OS-process collected at the point the exception was thrown.

Return: The environment from the point the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.
See hpx::diagnostic_information(), hpx::get_error_host_name(), hpx::get_error_process_id(), hpx::get_error_function_name(), hpx::get_error_file_name(), hpx::get_error_line_number(), hpx::get_error_os_thread(), hpx::get_error_thread_id(), hpx::get_error_thread_description(), hpx::get_error(), hpx::get_error_backtrace(), hpx::get_error_what(), hpx::get_error_config(), hpx::get_error_state()

Parameters

• xi: The parameter e will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: hpx::exception_info, hpx::error_code, std::exception, or std::exception_ptr.

Exceptions

• std::bad_alloc: (if one of the required allocations fails)

std::string get_error_backtrace (hpx::exception_info const &xi)
Return the stack backtrace from the point the exception was thrown.

The function hpx::get_error_backtrace can be used to extract the diagnostic information element representing the stack backtrace collected at the point the exception was thrown.

Return The stack back trace from the point the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

See hpx::diagnostic_information(), hpx::get_error_host_name(), hpx::get_error_process_id(), hpx::get_error_function_name(), hpx::get_error_file_name(), hpx::get_error_line_number(), hpx::get_error_os_thread(), hpx::get_error_thread_id(), hpx::get_error_thread_description(), hpx::get_error(), hpx::get_error_backtrace(), hpx::get_error_what(), hpx::get_error_env(), hpx::get_error_config(), hpx::get_error_state()

Parameters

• xi: The parameter e will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: hpx::exception_info, hpx::error_code, std::exception, or std::exception_ptr.

Exceptions

• std::bad_alloc: (if one of the required allocations fails)

std::size_t get_error_os_thread (hpx::exception_info const &xi)
Return the sequence number of the OS-thread used to execute HPX-threads from which the exception was thrown.

The function hpx::get_error_os_thread can be used to extract the diagnostic information element representing the sequence number of the OS-thread as stored in the given exception instance.

Return The sequence number of the OS-thread used to execute the HPX-thread from which the exception was thrown. If the exception instance does not hold this information, the function will return std::size(-1).

See hpx::diagnostic_information(), hpx::get_error_host_name(), hpx::get_error_process_id(), hpx::get_error_function_name(), hpx::get_error_file_name(), hpx::get_error_line_number(), hpx::get_error_os_thread(), hpx::get_error_thread_id(), hpx::get_error_thread_description(), hpx::get_error(), hpx::get_error_backtrace(), hpx::get_error_env(), hpx::get_error_what(), hpx::get_error_config(), hpx::get_error_state()
• **xi**: The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Exceptions**

- **nothing**:

```cpp
class std::size_t get_error_thread_id(hpx::exception_info const &xi)
```

Return the unique thread id of the HPX-thread from which the exception was thrown.

The function `hpx::get_error_thread_id` can be used to extract the diagnostic information element representing the HPX-thread id as stored in the given exception instance.

**Return** The unique thread id of the HPX-thread from which the exception was thrown. If the exception instance does not hold this information, the function will return `std::size_t(0)`.

**See** `hpx::diagnostic_information()`, `hpx::get_error_host_name()`, `hpx::get_error_process_id()`, `hpx::get_error_function_name()`, `hpx::get_error_file_name()`, `hpx::get_error_line_number()`, `hpx::get_error_os_thread()`, `hpx::get_error_thread_description()`, `hpx::get_error_backtrace()`, `hpx::get_error_env()`, `hpx::get_error_what()`, `hpx::get_error_config()`, `hpx::get_error_state()`

**Parameters**

- **xi**: The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Exceptions**

- **nothing**:

```cpp
class std::string get_error_thread_description(hpx::exception_info const &xi)
```

Return any additionally available thread description of the HPX-thread from which the exception was thrown.

The function `hpx::get_error_thread_description` can be used to extract the diagnostic information element representing the additional thread description as stored in the given exception instance.

**Return** Any additionally available thread description of the HPX-thread from which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

**See** `hpx::diagnostic_information()`, `hpx::get_error_host_name()`, `hpx::get_error_process_id()`, `hpx::get_error_function_name()`, `hpx::get_error_file_name()`, `hpx::get_error_line_number()`, `hpx::get_error_os_thread()`, `hpx::get_error_thread_id()`, `hpx::get_error_backtrace()`, `hpx::get_error_env()`, `hpx::get_error_what()`, `hpx::get_error_config()`

**Parameters**

- **xi**: The parameter `e` will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: `hpx::exception_info`, `hpx::error_code`, `std::exception`, or `std::exception_ptr`.

**Exceptions**

- **std::bad_alloc**: (if one of the required allocations fails)
std::string get_error_config(hpx::exception_info const &xi)
Return the HPX configuration information point from which the exception was thrown.

The function hpx::get_error_config can be used to extract the HPX configuration information element representing the full HPX configuration information as stored in the given exception instance.

Return Any additionally available HPX configuration information the point from which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

See hpx::diagnostic_information(), hpx::get_error_host_name(), hpx::get_error_process_id(), hpx::get_error_function_name(), hpx::get_error_file_name(), hpx::get_error_line_number(), hpx::get_error_os_thread(), hpx::get_error_thread_id(), hpx::get_error_backtrace(), hpx::get_error_env(), hpx::get_error(), hpx::get_error_state(), hpx::get_error_what(), hpx::get_error_thread_description()

Parameters
• xi: The parameter e will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: hpx::exception_info, hpx::error_code, std::exception, or std::exception_ptr.

Exceptions
• std::bad_alloc: (if one of the required allocations fails)

std::string get_error_state(hpx::exception_info const &xi)
Return the HPX runtime state information at which the exception was thrown.

The function hpx::get_error_state can be used to extract the HPX runtime state information element representing the state the runtime system is currently in as stored in the given exception instance.

Return The point runtime state at the point at which the exception was thrown. If the exception instance does not hold this information, the function will return an empty string.

See hpx::diagnostic_information(), hpx::get_error_host_name(), hpx::get_error_process_id(), hpx::get_error_function_name(), hpx::get_error_file_name(), hpx::get_error_line_number(), hpx::get_error_os_thread(), hpx::get_error_thread_id(), hpx::get_error_backtrace(), hpx::get_error_env(), hpx::get_error(), hpx::get_error_state(), hpx::get_error_what(), hpx::get_error_thread_description()

Parameters
• xi: The parameter e will be inspected for the requested diagnostic information elements which have been stored at the point where the exception was thrown. This parameter can be one of the following types: hpx::exception_info, hpx::error_code, std::exception, or std::exception_ptr.

Exceptions
• std::bad_alloc: (if one of the required allocations fails)
Functions

```cpp
void may_attach_debugger (std::string const &category)
```

Attaches a debugger if `category` is equal to the configuration entry `hpx.attach-debugger`.

namespace hpx

```cpp
std::uint32_t get_locality_id (error_code &ec = throws)
```

Return the number of the locality this function is being called from.

This function returns the id of the current locality.

Note The returned value is zero based and its maximum value is smaller than the overall number of localities the current application is running on (as returned by `get_num_localities()`).

Note As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

Note This function needs to be executed on a HPX-thread. It will fail otherwise (it will return -1).

Parameters

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

namespace hpx

```cpp
std::string get_locality_name ()
```

Return the name of the locality this function is called on.

This function returns the name for the locality on which this function is called.

Return This function returns the name for the locality on which the function is called. The name is retrieved from the underlying networking layer and may be different for different parcelports.

See `future<std::string> get_locality_name(naming::id_type const& id)`

namespace hpx

```cpp
std::uint32_t get_initial_num_localities ()
```

Return the number of localities which were registered at startup for the running application.

The function `get_initial_num_localities` returns the number of localities which were connected to the console at application startup.

Note As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`. 
See `hpx::find_all_localities`, `hpx::get_num_localities`

```
lcos::future<std::uint32_t> get_num_localities()
```

Asynchronously return the number of localities which are currently registered for the running application.

The function `get_num_localities` asynchronously returns the number of localities currently connected to the console. The returned future represents the actual result.

**Note**
This function will return meaningful results only if called from an HPX-thread. It will return 0 otherwise.

See `hpx::find_all_localities`, `hpx::get_num_localities`

```
std::uint32_t get_num_localities(launch::sync_policy, error_code &ec = throws)
```

Return the number of localities which are currently registered for the running application.

The function `get_num_localities` returns the number of localities currently connected to the console.

**Note**
This function will return meaningful results only if called from an HPX-thread. It will return 0 otherwise.

**Note**
As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

See `hpx::find_all_localities`, `hpx::get_num_localities`

**Parameters**

- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**namespace hpx**

**Functions**

```
std::size_t get_os_thread_count()
```

Return the number of OS-threads running in the runtime instance the current HPX-thread is associated with.

```
std::size_t get_os_thread_count(threads::executor const &exec)
```

Return the number of worker OS-threads used by the given executor to execute HPX threads.

This function returns the number of cores used to execute HPX threads for the given executor. If the function is called while no HPX runtime system is active, it will return zero. If the executor is not valid, this function will fall back to retrieving the number of OS threads used by HPX.

**Parameters**

- `exec`: [in] The executor to be used.

**namespace hpx**
Functions

`std::string get_thread_name()`
Return the name of the calling thread.

This function returns the name of the calling thread. This name uniquely identifies the thread in the context of HPX. If the function is called while no HPX runtime system is active, the result will be "<unknown>".

namespace hpx

namespace hpx

namespace runtime_local

Enums

```cpp
eenum os_thread_type

Types of kernel threads registered with the runtime.

Values:

unknown = -1

main_thread = 0
    kernel thread represents main thread

worker_thread
    kernel thread is used to schedule HPX threads

io_thread
    kernel thread can be used for IO operations

timer_thread
    kernel is used by timer operations

parcel_thread
    kernel is used by networking operations

custom_thread
    kernel is registered by the application
```

Functions

```cpp
std::string get_os_thread_type_name(os_thread_type type)

Return a human-readable name representing one of the kernel thread types.
```

```cpp
struct os_thread_data

#include <os_thread_type.hpp> Registration data for kernel threads that is maintained by the runtime internally
```

Public Members

```cpp
std::string label_
    name used for thread registration

std::thread::id id_
    thread id of corresponding kernel thread

std::uint64_t native_handle_
    the threads native handle

os_thread_type type_
    HPX thread type.
```

hpx::future<typename util::invoke_result<F, Ts...>::type> run_as_os_thread(F &&f, Ts&&... vs)
```

namespace hpx

Functions

void set_error_handlers()

class runtime

Public Types

```cpp
using notification_policy_type = threads::policies::callback_notifier
```

Generate a new notification policy instance for the given thread name prefix.

```cpp
using hpx_main_function_type = int()
```

The `hpx_main_function_type` is the default function type usable as the main HPX thread function.

```cpp
using hpx_errorsink_function_type = void(std::uint32_t, std::string const &)
```

Public Functions

```cpp
virtual notification_policy_type get_notification_policy(char const *prefix, runtime_local::os_thread_type type)
```

```cpp
state get_state() const
```

void set_state(state s)

```cpp
runtime(hpx::util::runtime_configuration &rtcfg, bool initialize = true)
```

Construct a new HPX runtime instance.

```cpp
virtual ~runtime()
```

The destructor makes sure all HPX runtime services are properly shut down before exiting.

```cpp
void on_exit(util::function_nonser<void>) const
```

Manage list of functions to call on exit.

```cpp
void starting()
```

Manage runtime ‘stopped’ state.
void stopping()
    Call all registered on_exit functions.

bool stopped() const
    This accessor returns whether the runtime instance has been stopped.

hpx::util::runtime_configuration &get_config()
    access configuration information

hpx::util::runtime_configuration const &get_config() const

std::size_t get_instance_number() const

util::thread_mapper &get_thread_mapper()
    Return a reference to the internal PAPI thread manager.

threads::topology const &get_topology() const

virtual int run
    (util::function_nonser<hpx_main_function_type> const &func)
    Run the HPX runtime system, use the given function for the main thread and block waiting for all threads to finish.

    Note  The parameter func is optional. If no function is supplied, the runtime system will simply wait for the shutdown action without explicitly executing any main thread.

    Return  This function will return the value as returned as the result of the invocation of the function object given by the parameter func.

    Parameters
        •  func: [in] This is the main function of an HPX application. It will be scheduled for execution by the thread manager as soon as the runtime has been initialized. This function is expected to expose an interface as defined by the typedef hpx_main_function_type. This parameter is optional and defaults to none main thread function, in which case all threads have to be scheduled explicitly.

virtual int run()
    Run the HPX runtime system, initially use the given number of (OS) threads in the thread-manager and block waiting for all threads to finish.

    Return  This function will always return 0 (zero).

virtual void rethrow_exception()
    Rethrow any stored exception (to be called after stop())

virtual int start
    (util::function_nonser<hpx_main_function_type> const &func, bool blocking = false)
    Start the runtime system.

    Return  If a blocking is a true, this function will return the value as returned as the result of the invocation of the function object given by the parameter func. Otherwise it will return zero.

    Parameters
        •  func: [in] This is the main function of an HPX application. It will be scheduled for execution by the thread manager as soon as the runtime has been initialized. This function is expected to expose an interface as defined by the typedef hpx_main_function_type.
        •  blocking: [in] This allows to control whether this call blocks until the runtime system has been stopped. If this parameter is true the function runtime::start will call runtime::wait internally.
virtual int start (bool blocking = false)
Start the runtime system.

Return If a blocking is a true, this function will return the value as returned as the result of the
invocation of the function object given by the parameter func. Otherwise it will return zero.

Parameters
• blocking: [in] This allows to control whether this call blocks until the runtime system has
been stopped. If this parameter is true the function runtime::start will call runtime::wait inter-
nally.

virtual int wait()
Wait for the shutdown action to be executed.

Return This function will return the value as returned as the result of the invocation of the function
object given by the parameter func.

virtual void stop (bool blocking = true)
Initiate termination of the runtime system.

Parameters
• blocking: [in] This allows to control whether this call blocks until the runtime system has
been fully stopped. If this parameter is false then this call will initiate the stop action but will
return immediately. Use a second call to stop with this parameter set to true to wait for all
internal work to be completed.

virtual int suspend()
Suspend the runtime system.

virtual int resume()
Resume the runtime system.

virtual int finalize (double)

virtual bool is_networking_enabled()
Return true if networking is enabled.

virtual hpx::threads::threadmanager &get_thread_manager ()
Allow access to the thread manager instance used by the HPX runtime.

virtual std::string here () const
Returns a string of the locality endpoints (usable in debug output)

virtual bool report_error (std::size_t num_thread, std::exception_ptr const &e, bool terminate_all = true)
Report a non-recoverable error to the runtime system.

Parameters
• num_thread: [in] The number of the operating system thread the error has been detected in.
• e: [in] This is an instance encapsulating an exception which lead to this function call.

virtual bool report_error (std::exception_ptr const &e, bool terminate_all = true)
Report a non-recoverable error to the runtime system.

Note This function will retrieve the number of the current shepherd thread and forward to the re-
port_error function above.
Parameters

• e: [in] This is an instance encapsulating an exception which lead to this function call.

\textbf{virtual} \textbf{void} \textbf{add\_pre\_startup\_function} (\textit{startup\_function\_type f})

Add a function to be executed inside a HPX thread before \textit{hpx\_main} but guaranteed to be executed before any startup function registered with \textit{add\_startup\_function}.

\textbf{Note} The difference to a startup function is that all pre-startup functions will be (system-wide) executed before any startup function.

\textbf{Parameters}

• \textit{f}: The function ‘\textit{f}’ will be called from inside a HPX thread before \textit{hpx\_main} is executed. This is very useful to setup the runtime environment of the application (install performance counters, etc.)

\textbf{virtual} \textbf{void} \textbf{add\_startup\_function} (\textit{startup\_function\_type f})

Add a function to be executed inside a HPX thread before \textit{hpx\_main}

\textbf{Parameters}

• \textit{f}: The function ‘\textit{f}’ will be called from inside a HPX thread before \textit{hpx\_main} is executed. This is very useful to setup the runtime environment of the application (install performance counters, etc.)

\textbf{virtual} \textbf{void} \textbf{add\_pre\_shutdown\_function} (\textit{shutdown\_function\_type f})

Add a function to be executed inside a HPX thread during \textit{hpx\_finalize}, but guaranteed before any of the shutdown functions is executed.

\textbf{Note} The difference to a shutdown function is that all pre-shutdown functions will be (system-wide) executed before any shutdown function.

\textbf{Parameters}

• \textit{f}: The function ‘\textit{f}’ will be called from inside a HPX thread while \textit{hpx\_finalize} is executed. This is very useful to tear down the runtime environment of the application (uninstall performance counters, etc.)

\textbf{virtual} \textbf{void} \textbf{add\_shutdown\_function} (\textit{shutdown\_function\_type f})

Add a function to be executed inside a HPX thread during \textit{hpx\_finalize}

\textbf{Parameters}

• \textit{f}: The function ‘\textit{f}’ will be called from inside a HPX thread while \textit{hpx\_finalize} is executed. This is very useful to tear down the runtime environment of the application (uninstall performance counters, etc.)

\textbf{virtual} \textbf{hpx::util::io\_service\_pool* get\_thread\_pool} (\textit{char const *name})

Access one of the internal thread pools (io_service instances) HPX is using to perform specific tasks. The three possible values for the argument \textit{name} are “main\_pool”, “io\_pool”, “parcel\_pool”, and “timer\_pool”. For any other argument value the function will return zero.

\textbf{virtual} \textbf{bool register\_thread} (\textit{char const *name, std::size\_t num = 0, bool service\_thread = true, error\_code &ec = throws})

Register an external OS-thread with HPX.

This function should be called from any OS-thread which is external to HPX (not created by HPX), but which needs to access HPX functionality, such as setting a value on a promise or similar.

`main`, `io`, `timer`, `parcel`, `worker`
Note The function will compose a thread name of the form ‘<name>-thread#<num>’ which is used to register the thread. It is the user’s responsibility to ensure that each (composed) thread name is unique. HPX internally uses the following names for the threads it creates, do not reuse those:

Parameters
- name: [in] The name to use for thread registration.
- num: [in] The sequence number to use for thread registration. The default for this parameter is zero.
- service_thread: [in] The thread should be registered as a service thread. The default for this parameter is ‘true’. Any service threads will be pinned to cores not currently used by any of the HPX worker threads.

Note This function should be called for each thread exactly once. It will fail if it is called more than once.

Return This function will return whether the requested operation succeeded or not.

virtual bool unregister_thread()
Unregister an external OS-thread with HPX.

This function will unregister any external OS-thread from HPX.

Note This function should be called for each thread exactly once. It will fail if it is called more than once. It will fail as well if the thread has not been registered before (see register_thread).

Return This function will return whether the requested operation succeeded or not.

virtual runtime_local::os_thread_data get_os_thread_data (std::string const &label) const
Access data for a given OS thread that was previously registered by register_thread.

virtual bool enumerate_os_threads (util::function_nonser<bool>) runtime_local::os_thread_data const&>
Enumerate all OS threads that have registered with the runtime.

notification_policy_type::on_startstop_type on_start_func () const
notification_policy_type::on_startstop_type on_stop_func () const

Private Functions

```cpp
void stop_helper (bool blocking, std::condition_variable & cond, std::mutex & mtx)
    Helper function to stop the runtime.
```

**Parameters**

- `blocking`: [in] This allows to control whether this call blocks until the runtime system has been fully stopped. If this parameter is `false` then this call will initiate the stop action but will return immediately. Use a second call to stop with this parameter set to `true` to wait for all internal work to be completed.

```cpp
void deinit_tss_helper (char const * context, std::size_t num)
```

```cpp
void init_tss_ex (char const * context, runtime_local::os_thread_type type, std::size_t local_thread_num, std::size_t global_thread_num, char const * pool_name, char const * postfix, bool service_thread, error_code & ec)
```

```cpp
void init_tss_helper (char const * context, runtime_local::os_thread_type type, std::size_t local_thread_num, std::size_t global_thread_num, char const * pool_name, char const * postfix, bool service_thread)
```

namespace threads
Functions

char \texttt{const *}\texttt{get_stack_size_name} (std::ptrdiff_t \texttt{size})
Returns the stack size name.
Get the readable string representing the given stack size constant.

Parameters
• \texttt{size}: this represents the stack size

\texttt{std::ptrdiff_t get_default_stack_size} ()
Returns the default stack size.
Get the default stack size in bytes.

\texttt{std::ptrdiff_t get_stack_size} (\texttt{thread_stacksize})
Returns the stack size corresponding to the given stack size enumeration.
Get the stack size corresponding to the given stack size enumeration.

Parameters
• \texttt{size}: this represents the stack size

namespace \texttt{util}

Functions

bool \texttt{retrieve_commandline_arguments} (hpx::program_options::options_description \texttt{const} &\texttt{app_options},
hpx::program_options::variables_map &\texttt{vm})

bool \texttt{retrieve_commandline_arguments} (std::string \texttt{const} &\texttt{appname},
hpx::program_options::variables_map &\texttt{vm})

namespace \texttt{hpx}

Functions

bool \texttt{register_thread} (runtime *\texttt{rt}, char \texttt{const} *\texttt{name}, error_code &\texttt{ec} = throws)
Register the current kernel thread with HPX, this should be done once for each external OS-thread intended to invoke HPX functionality. Calling this function more than once will return false.

void \texttt{unregister_thread} (runtime *\texttt{rt})
Unregister the thread from HPX, this should be done once in the end before the external thread exists.

\texttt{runtime_local::os_thread_data get_os_thread_data} (std::string \texttt{const} &\texttt{label})
Access data for a given OS thread that was previously registered by \texttt{register_thread}. This function must be called from a thread that was previously registered with the runtime.

bool \texttt{enumerate_os_threads} (util::function_nonser<\texttt{bool}> os_thread_data \texttt{const} &
> \texttt{const} &/Enumerate all OS threads that have registered with the runtime.

\texttt{std::size_t get_runtime_instance_number} ()
Return the runtime instance number associated with the runtime instance the current thread is running in.
bool register_on_exit (util::function_nonser<void>)
    > const& Register a function to be called during system shutdown.

bool is_starting()
    Test whether the runtime system is currently being started.

    This function returns whether the runtime system is currently being started or not, e.g. whether the current
    state of the runtime system is hpx::state_startup

Note This function needs to be executed on a HPX-thread. It will return false otherwise.

bool tolerate_node_faults()
    Test if HPX runs in fault-tolerant mode.

    This function returns whether the runtime system is running in fault-tolerant mode

bool is_running()
    Test whether the runtime system is currently running.

    This function returns whether the runtime system is currently running or not, e.g. whether the current state
    of the runtime system is hpx::state_running

Note This function needs to be executed on a HPX-thread. It will return false otherwise.

bool is_stopped()
    Test whether the runtime system is currently stopped.

    This function returns whether the runtime system is currently stopped or not, e.g. whether the current state
    of the runtime system is hpx::state_stopped

Note This function needs to be executed on a HPX-thread. It will return false otherwise.

bool is_stopped_or_shutting_down()
    Test whether the runtime system is currently being shut down.

    This function returns whether the runtime system is currently being shut down or not, e.g. whether the current
    state of the runtime system is hpx::state_stopped or hpx::state_shutdown

Note This function needs to be executed on a HPX-thread. It will return false otherwise.

std::size_t get_num_worker_threads()
    Return the number of worker OS-threads used to execute HPX threads.

    This function returns the number of OS-threads used to execute HPX threads. If the function is called
    while no HPX runtime system is active, it will return zero.

std::uint64_t get_system_uptime()
    Return the system uptime measure on the thread executing this call.

    This function returns the system uptime measured in nanoseconds for the thread executing this call. If the
    function is called while no HPX runtime system is active, it will return zero.

namespace hpx

Typedefs

typedef util::unique_function_nonser<void()> shutdown_function_type  
The type of a function which is registered to be executed as a shutdown or pre-shutdown function.

Functions

void register_pre_shutdown_function(shutdown_function_type f)  
Add a function to be executed by a HPX thread during hpx::finalize() but guaranteed before any shutdown function is executed (system-wide)

Any of the functions registered with register_pre_shutdown_function are guaranteed to be executed by an HPX thread during the execution of hpx::finalize() before any of the registered shutdown functions are executed (see: hpx::register_shutdown_function()).

Note If this function is called while the pre-shutdown functions are being executed, or after that point, it will raise a invalid_status exception.

See hpx::register_shutdown_function()

Parameters

• f: [in] The function to be registered to run by an HPX thread as a pre-shutdown function.

void register_shutdown_function(shutdown_function_type f)  
Add a function to be executed by a HPX thread during hpx::finalize() but guaranteed after any pre-shutdown function is executed (system-wide)

Any of the functions registered with register_shutdown_function are guaranteed to be executed by an HPX thread during the execution of hpx::finalize() after any of the registered pre-shutdown functions are executed (see: hpx::register_pre_shutdown_function()).

Note If this function is called while the shutdown functions are being executed, or after that point, it will raise a invalid_status exception.

See hpx::register_pre_shutdown_function()

Parameters

• f: [in] The function to be registered to run by an HPX thread as a shutdown function.
Typedefs

typedef util::unique_function_nonser<void () > startup_function_type

The type of a function which is registered to be executed as a startup or pre-startup function.

Functions

void register_pre_startup_function (startup_function_type f)

Add a function to be executed by a HPX thread before hpx_main but guaranteed before any startup function is executed (system-wide).

Any of the functions registered with register_pre_startup_function are guaranteed to be executed by an HPX thread before any of the registered startup functions are executed (see hpx::register_startup_function()).

This function is one of the few API functions which can be called before the runtime system has been fully initialized. It will automatically stage the provided startup function to the runtime system during its initialization (if necessary).

Note If this function is called while the pre-startup functions are being executed or after that point, it will raise a invalid_status exception.

Parameters

• f: [in] The function to be registered to run by an HPX thread as a pre-startup function.

See hpx::register_startup_function()

void register_startup_function (startup_function_type f)

Add a function to be executed by a HPX thread before hpx_main but guaranteed after any pre-startup function is executed (system-wide).

Any of the functions registered with register_startup_function are guaranteed to be executed by an HPX thread after any of the registered pre-startup functions are executed (see: hpx::register_pre_startup_function()), but before hpx_main is being called.

This function is one of the few API functions which can be called before the runtime system has been fully initialized. It will automatically stage the provided startup function to the runtime system during its initialization (if necessary).

Note If this function is called while the startup functions are being executed or after that point, it will raise a invalid_status exception.

Parameters

• f: [in] The function to be registered to run by an HPX thread as a startup function.

See hpx::register_pre_startup_function()
### Functions

```cpp
bool threadmanager_is(state st)
bool threadmanager_is_at_least(state st)
```

#### namespace hpx

### Functions

```cpp
callback_notifier::on_startstop_type get_thread_on_start_func()
```
Retrieve the currently installed start handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered start function chains into the previous one (see `register_thread_on_start_func`).

**Return** The currently installed error handler function.

**Note** This function can be called before the HPX runtime is initialized.

```cpp
callback_notifier::on_startstop_type get_thread_on_stop_func()
```
Retrieve the currently installed stop handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered stop function chains into the previous one (see `register_thread_on_stop_func`).

**Return** The currently installed error handler function.

**Note** This function can be called before the HPX runtime is initialized.

```cpp
callback_notifier::on_error_type get_thread_on_error_func()
```
Retrieve the currently installed error handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered error function chains into the previous one (see `register_thread_on_error_func`).

**Return** The currently installed error handler function.

**Note** This function can be called before the HPX runtime is initialized.

```cpp
callback_notifier::on_startstop_type register_thread_on_start_func(threads::policies::callback_notifier::on_startstop_type f)
```
Set the currently installed start handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered start function chains into the previous one (see `get_thread_on_start_func`).

**Return** The previously registered function of this category. It is the user’s responsibility to call that function if the callback is invoked by HPX.

**Note** This function can be called before the HPX runtime is initialized.
• \texttt{f}: The function to install as the new start handler.

\begin{verbatim}
threads::policies::callback_notifier::on_startstop_type register_thread_on_stop_func (threads::policies::callback_notifier::on_startstop_type &&f)
\end{verbatim}

Set the currently installed stop handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered stop function chains into the previous one (see \texttt{get_thread_on_stop_func}).

**Return** The previously registered function of this category. It is the user’s responsibility to call that function if the callback is invoked by HPX.

**Note** This function can be called before the HPX runtime is initialized.

**Parameters**

• \texttt{f}: The function to install as the new stop handler.

\begin{verbatim}
threads::policies::callback_notifier::on_error_type register_thread_on_error_func (threads::policies::callback_notifier::on_error_type &&f)
\end{verbatim}

Set the currently installed error handler function. This is a function that will be called by HPX for each newly created thread that is made known to the runtime. HPX stores exactly one such function reference, thus the caller needs to make sure any newly registered error function chains into the previous one (see \texttt{get_thread_on_error_func}).

**Return** The previously registered function of this category. It is the user’s responsibility to call that function if the callback is invoked by HPX.

**Note** This function can be called before the HPX runtime is initialized.

**Parameters**

• \texttt{f}: The function to install as the new error handler.

namespace resource
Functions

`std::size_t get_num_thread_pools()`  
Return the number of thread pools currently managed by the `resource_partitioner`  

`std::size_t get_num_threads()`  
Return the number of threads in all thread pools currently managed by the `resource_partitioner`  

`std::size_t get_num_threads(std::string const &pool_name)`  
Return the number of threads in the given thread pool currently managed by the `resource_partitioner`  

`std::size_t get_num_threads(std::size_t pool_index)`  
Return the number of threads in the given thread pool currently managed by the `resource_partitioner`  

`std::size_t get_pool_index(std::string const &pool_name)`  
Return the internal index of the pool given its name.  

`std::string const &get_pool_name(std::size_t pool_index)`  
Return the name of the pool given its internal index.  

`threads::thread_pool_base &get_thread_pool(std::string const &pool_name)`  
Return the name of the pool given its name.  

`threads::thread_pool_base &get_thread_pool(std::size_t pool_index)`  
Return the thread pool given its internal index.  

`bool pool_exists(std::string const &pool_name)`  
Return true if the pool with the given name exists.  

`bool pool_exists(std::size_t pool_index)`  
Return true if the pool with the given index exists.

namespace threads

Functions

`std::int64_t get_thread_count(thread_schedule_state state = thread_schedule_state::unknown)`  
The function `get_thread_count` returns the number of currently known threads.  

**Note**  
If `state` == `unknown` this function will not only return the number of currently existing threads,  
but will add the number of registered task descriptions (which have not been converted into  
threads yet).  

**Parameters**  
- `state`: [in] This specifies the thread-state for which the number of threads should be retrieved.  

`std::int64_t get_thread_count(thread_priority priority, thread_schedule_state state = thread_schedule_state::unknown)`  
The function `get_thread_count` returns the number of currently known threads.  

**Note**  
If `state` == `unknown` this function will not only return the number of currently existing threads,  
but will add the number of registered task descriptions (which have not been converted into  
threads yet).  

**Parameters**
• **priority**: [in] This specifies the thread-priority for which the number of threads should be retrieved.
  • **state**: [in] This specifies the thread-state for which the number of threads should be retrieved.

```cpp
std::int64_t get_idle_core_count()
```

The function `get_idle_core_count` returns the number of currently idling threads (cores).

```cpp
mask_type get_idle_core_mask()
```

The function `get_idle_core_mask` returns a bit-mask representing the currently idling threads (cores).

```cpp
bool enumerate_threads (util::function_nonser<bool> thread_id_type
    > const &f, thread_schedule_state state = thread_schedule_state::unknown)
```

The function `enumerate_threads` will invoke the given function `f` for each thread with a matching thread state.

**Parameters**
  • **f**: [in] The function which should be called for each matching thread. Returning ‘false’ from this function will stop the enumeration process.
  • **state**: [in] This specifies the thread-state for which the threads should be enumerated.

```cpp
namespace hpx

namespace util

namespace debug

**Functions**

```cpp
std::vector<hpx::threads::thread_id_type> get_task_ids (hpx::threads::thread_schedule_state
    state
    = hpx::threads::thread_schedule_state::suspended)
```

```cpp
std::vector<hpx::threads::thread_data*> get_task_data (hpx::threads::thread_schedule_state
    state
    = hpx::threads::thread_schedule_state::suspended)
```

```cpp
std::string suspended_task_backtraces ()
```

**segmented_algorithms**

The contents of this module can be included with the header `hpx/modules/segmented_algorithms.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/segmented_algorithms.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

threadmanager

The contents of this module can be included with the header `hpx/modules/threadmanager.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/threadmanager.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

```cpp
namespace hpx

namespace threads

class threadmanager
#include <threadmanager.hpp> The thread-manager class is the central instance of management for all (non-depleted) threads
```
Public Types

typedef threads::policies::callback_notifier notification_policy_type

typedef std::unique_ptr<thread_pool_base> pool_type

typedef threads::policies::scheduler_base scheduler_type

typedef std::vector<pool_type> pool_vector

Public Functions

threadmanager (hpx::util::runtime_configuration &rtcfg, notification_policy_type &notifier, detail::network_background_callback_type network_background_callback = detail::network_background_callback_type())

~threadmanager ()

void init ()

void create_pools ()

void print_pools (std::ostream&)  
    FIXME move to private and add hpx:printpools cmd line option.

thread_pool_base &default_pool () const

scheduler_type &default_scheduler () const

thread_pool_base &get_pool (std::string const &pool_name) const

thread_pool_base &get_pool (pool_id_type const &pool_id) const

thread_pool_base &get_pool (std::size_t thread_index) const

bool pool_exists (std::string const &pool_name) const

bool pool_exists (std::size_t pool_index) const

void register_work (thread_init_data &data, error_code &ec = throws)
   The function register_work adds a new work item to the thread manager. It doesn’t immediately create a new thread, it just adds the task parameters (function, initial state and description) to the internal management data structures. The thread itself will be created when the number of existing threads drops below the number of threads specified by the constructor’s max_count parameter.

Parameters

• func: [in] The function or function object to execute as the thread’s function. This must have a signature as defined by thread_function_type.
• description: [in] The value of this parameter allows to specify a description of the thread to create. This information is used for logging purposes mainly, but might be useful for debugging as well. This parameter is optional and defaults to an empty string.

void register_thread (thread_init_data &data, thread_id_type &id, error_code &ec = throws)
   The function register_thread adds a new work item to the thread manager. It creates a new thread, adds it to the internal management data structures, and schedules the new thread, if appropriate.
Parameters

- **func**: [in] The function or function object to execute as the thread’s function. This must have a signature as defined by `thread_function_type`.
- **id**: [out] This parameter will hold the id of the created thread. This id is guaranteed to be validly initialized before the thread function is executed.
- **description**: [in] The value of this parameter allows to specify a description of the thread to create. This information is used for logging purposes mainly, but might be useful for debugging as well. This parameter is optional and defaults to an empty string.

```cpp
bool run()
Run the thread manager’s work queue. This function instantiates the specified number of OS threads in each pool. All OS threads are started to execute the function \( tfunc \).
```

**Return** The function returns `true` if the thread manager has been started successfully, otherwise it returns `false`.

```cpp
void stop(bool blocking = true)
Forcefully stop the thread-manager.
```

Parameters

- **blocking**:

```cpp
bool is_busy()

bool is_idle()

void wait()

void suspend()

void resume()

state status() const
Return whether the thread manager is still running This returns the “minimal state”, i.e. the state of the least advanced thread pool.
```

```cpp
std::int64_t get_thread_count(thread_schedule_state state =
  thread_schedule_state::unknown, thread_priority priority = thread_priority::default_,
  std::size_t num_thread = std::size_t(-1), bool reset = false)
return the number of HPX-threads with the given state
```

**Note** This function lock the internal OS lock in the thread manager

```cpp
std::int64_t get_idle_core_count()

mask_type get_idle_core_mask()

std::int64_t get_background_thread_count()

bool enumerate_threads(util::function_nonser<bool> thread_id_type
  > const &f, thread_schedule_state state = thread_schedule_state::unknown const

void abort_all_suspended_threads()

bool cleanup_terminated(bool delete_all)
```
std::size_t get_os_thread_count() const
Return the number of OS threads running in this thread-manager.
This function will return correct results only if the thread-manager is running.

std::thread &get_os_thread_handle(std::size_t num_thread) const
API functions forwarding to notification policy.
This notifies the thread manager that the passed exception has been raised. The exception will be
routed through the notifier and the scheduler (which will result in it being passed to the runtime
object, which in turn will report it to the console, etc.).

mask_type get_used_processing_units() const
Returns the mask identifying all processing units used by this thread manager.

hwloc_bitmap_ptr get_pool_numa_bitmap(const std::string &pool_name) const

void set_scheduler_mode(threads::policies::scheduler_mode mode)
void add_scheduler_mode(threads::policies::scheduler_mode mode)
void add_remove_scheduler_mode(threads::policies::scheduler_mode to_add_mode,
                             threads::policies::scheduler_mode to_remove_mode)
void remove_scheduler_mode(threads::policies::scheduler_mode mode)

void reset_thread_distribution()
void init_tss(std::size_t global_thread_num)
void deinit_tss()

std::int64_t get_queue_length(bool reset)
std::int64_t get_cumulative_duration(bool reset)
std::int64_t get_thread_count_unknown(bool reset)

namespace parallel
**Typedefs**

```cpp
using spmd_block = hpx::lcos::local::spmd_block
```

The class `spmd_block` defines an interface for launching multiple images while giving handles to each image to interact with the remaining images. The `define_spmd_block` function templates create multiple images of a user-defined function (or lambda) and launches them in a possibly separate thread. A temporary `spmd_block` object is created and diffused to each image. The constraint for the function (or lambda) given to the `define_spmd_block` function is to accept a `spmd_block` as first parameter.

**Functions**

```cpp
template<typename ExPolicy, typename F, typename ...Args, typename std::enable_if<hpx::parallel::execution::is_async_execution_policy<ExPolicy>::value>::type>
std::vector<hpx::future<void>> define_spmd_block(ExPolicy &&policy, std::size_t num_images, F &&f, Args&&... args)

template<typename ExPolicy, typename F, typename ...Args, typename std::enable_if<!hpx::is_async_execution_policy<ExPolicy>::value>::type>
void define_spmd_block(ExPolicy &&policy, std::size_t num_images, F &&f, Args&&... args)

template<typename F, typename ...Args>
void define_spmd_block(std::size_t num_images, F &&f, Args&&... args)
```

```cpp
namespace hpx

namespace parallel

Functions

```cpp
template<typename ExPolicy, typename F>
hp::future<void> define_task_block(ExPolicy &&policy, F &&f)
```

Constructs a `task_block`, `tr`, using the given execution policy `policy`, and invokes the expression `f(tr)` on the user-provided object, `f`.

Postcondition: All tasks spawned from `f` have finished execution. A call to `define_task_block` may return on a different thread than that on which it was called.

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the task block may be parallelized.
- `F`: The type of the user defined function to invoke inside the `define_task_block` (deduced). `F` shall be MoveConstructible.

**Parameters**
- `policy`: The execution policy to use for the scheduling of the iterations.
- `f`: The user defined function to invoke inside the task block. Given an lvalue `tr` of type `task_block`, the expression, `(void)f(tr)`, shall be well-formed.

**Note** It is expected (but not mandated) that `f` will (directly or indirectly) call `tr.run(callable_object)`.

**Exceptions**
- An `exception_list`, as specified in Exception Handling.

```cpp
template<typename ExPolicy, typename F>
void define_task_block(ExPolicy &&policy, F &&f)
```
template<typename F>
void define_task_block (F &&f)
    Constructs a task_block, tr, and invokes the expression f(tr) on the user-provided object, f. This version uses parallel_policy for task scheduling.

Postcondition: All tasks spawned from f have finished execution. A call to define_task_block may return on a different thread than that on which it was called.

Template Parameters
• F: The type of the user defined function to invoke inside the define_task_block (deduced). F shall be MoveConstructible.

Parameters
• f: The user defined function to invoke inside the task block. Given an lvalue tr of type task_block, the expression, (void)f(tr), shall be well-formed.

Note It is expected (but not mandated) that f will (directly or indirectly) call tr.run(callable_object).

Exceptions
• An: exception_list, as specified in Exception Handling.

template<typename ExPolicy, typename F>
util::detail::algorithm_result<ExPolicy>::type define_task_block_restore_thread (ExPolicy &&policy, F &&f)

Constructs a task_block, tr, and invokes the expression f(tr) on the user-provided object, f.

Postcondition: All tasks spawned from f have finished execution. A call to define_task_block_restore_thread always returns on the same thread as that on which it was called.

Template Parameters
• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the task block may be parallelized.
• F: The type of the user defined function to invoke inside the define_task_block (deduced). F shall be MoveConstructible.

Parameters
• policy: The execution policy to use for the scheduling of the iterations.
• f: The user defined function to invoke inside the define_task_block. Given an lvalue tr of type task_block, the expression, (void)f(tr), shall be well-formed.

Exceptions
• An: exception_list, as specified in Exception Handling.

Note It is expected (but not mandated) that f will (directly or indirectly) call tr.run(callable_object).

template<typename F>
void define_task_block_restore_thread (F &&f)
    Constructs a task_block, tr, and invokes the expression f(tr) on the user-provided object, f. This version uses parallel_policy for task scheduling.

Postcondition: All tasks spawned from f have finished execution. A call to define_task_block_restore_thread always returns on the same thread as that on which it was called.

Template Parameters
• F: The type of the user defined function to invoke inside the define_task_block (deduced). F shall be MoveConstructible.
Parameters

- \( f \): The user-defined function to invoke inside the `define_task_block`. Given an lvalue \( tr \) of type `task_block`, the expression, `(void)f(tr)`, shall be well-formed.

Exceptions

- \( An: \) `exception_list`, as specified in Exception Handling.

**Note** It is expected (but not mandated) that \( f \) will (directly or indirectly) call \( tr.run(callable_object) \).

```cpp
namespace v2

template<typename ExPolicy = hpx::execution::parallel_policy>
class task_block
#
```

The class `task_block` defines an interface for forking and joining parallel tasks. The `define_task_block` and `define_task_block_restore_thread` function templates create an object of type `task_block` and pass a reference to that object to a user-provided callable object.

An object of class `task_block` cannot be constructed, destroyed, copied, or moved except by the implementation of the task region library. Taking the address of a `task_block` object via `operator&` or `addressof` is ill formed. The result of obtaining its address by any other means is unspecified.

A `task_block` is active if it was created by the nearest enclosing `task_block`, where “task block” refers to an invocation of `define_task_block` or `define_task_block_restore_thread` and “nearest enclosing” means the most recent invocation that has not yet completed. Code designated for execution in another thread by means other than the facilities in this section (e.g., using `thread` or `async`) are not enclosed in the task region and a `task_block` passed to (or captured by) such code is not active within that code. Performing any operation on a `task_block` that is not active results in undefined behavior.

The `task_block` that is active before a specific call to the run member function is not active within the asynchronous function that invoked `run`. (The invoked function should not, therefore, capture the `task_block` from the surrounding block.)

```
Example:
    define_task_block([&](auto & tr) {
        tr.run([&] {
            tr.run([&] { f(); });
        }); // Error: tr is not active
        define_task_block([&](auto & tr) {
            tr.run(f);
            // Nested task block active
            define_task_block([&](auto & tr) {
                tr.run([&] { f(); });
            });
            // OK: inner tr is active
        });
    });
```

Template Parameters

- `ExPolicy`: The execution policy an instance of a `task_block` was created with. This defaults to `parallel_policy`. 

1020 Chapter 2. What’s so special about HPX?
Public Types

template<>
using execution_policy = ExPolicy

Refers to the type of the execution policy used to create the task_block.

Public Functions

execution_policy const & get_execution_policy () const

Return the execution policy instance used to create this task_block.

template<typename F, typename ...Ts>
void run (F &&f, Ts&&... ts)

Causes the expression f() to be invoked asynchronously. The invocation of f is permitted to
run on an unspecified thread in an unordered fashion relative to the sequence of operations
following the call to run(f) (the continuation), or indeterminately sequenced within the same
thread as the continuation.

The call to run synchronizes with the invocation of f. The completion of f() synchronizes with
the next invocation of wait on the same task_block or completion of the nearest enclosing task
block (i.e., the define_task_block or define_task_block_restore_thread that created this task
block).

Requires: F shall be MoveConstructible. The expression, (void)f(), shall be well-formed.
Precondition: this shall be the active task_block.
Postconditions: A call to run may return on a different thread than that on which it was called.

Note The call to run is sequenced before the continuation as if run returns on the same thread.
The invocation of the user-supplied callable object f may be immediate or may be delayed
until compute resources are available. run might or might not return before invocation of f
completes.

Exceptions
• This: function may throw task_canceled_exception, as described in Exception Handling.

template<typename Executor, typename F, typename ...Ts>
void run (Executor &&exec, F &&f, Ts&&... ts)

Causes the expression f() to be invoked asynchronously using the given executor. The invoca-
tion of f is permitted to run on an unspecified thread associated with the given executor and in
an unordered fashion relative to the sequence of operations following the call to run(exec, f)
(the continuation), or indeterminately sequenced within the same thread as the continuation.

The call to run synchronizes with the invocation of f. The completion of f() synchronizes with
the next invocation of wait on the same task_block or completion of the nearest enclosing task
block (i.e., the define_task_block or define_task_block_restore_thread that created this task
block).

Requires: Executor shall be a type modeling the Executor concept. F shall be MoveCon-
structible. The expression, (void)f(), shall be well-formed.
Precondition: this shall be the active task_block.
Postconditions: A call to run may return on a different thread than that on which it was called.
Note The call to \textit{run} is sequenced before the continuation as if \textit{run} returns on the same thread. The invocation of the user-supplied callable object \( f \) may be immediate or may be delayed until compute resources are available. \textit{run} might or might not return before invocation of \( f \) completes.

Exceptions

- This function may throw task\_canceled\_exception, as described in Exception Handling. The function will also throw a \textit{exception\_list} holding all exceptions that were caught while executing the tasks.

\begin{verbatim}
void \textit{wait}()
Blocks until the tasks spawned using this \textit{task\_block} have finished.

Precondition: this shall be the active \textit{task\_block}.

Postcondition: All tasks spawned by the nearest enclosing task region have finished. A call to \textit{wait} may return on a different thread than that on which it was called.
\end{verbatim}

Example:

\begin{verbatim}
define_task_block([\&] (auto & tr) {
  tr.run([\&] { process(a, w, x); }); // Process a[w] through a[x]
  if (y < x) tr.wait(); // Wait if overlap between [w, x)
    and [y, z)
  process(a, y, z); // Process a[y] through a[z]
});
\end{verbatim}

Note The call to \textit{wait} is sequenced before the continuation as if \textit{wait} returns on the same thread.

Exceptions

- This function may throw task\_canceled\_exception, as described in Exception Handling. The function will also throw a \textit{exception\_list} holding all exceptions that were caught while executing the tasks.

ExPolicy \&\textit{policy}()

Returns a reference to the execution policy used to construct this object.

Precondition: this shall be the active \textit{task\_block}.

ExPolicy \textit{const \&policy}() \textit{const}

Returns a reference to the execution policy used to construct this object.

Precondition: this shall be the active \textit{task\_block}.

Private Members

Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
std::enable_if<hpx::is_execution_policy<ExPolicy>::value, typename util::detail::algorithm_result<ExPolicy, FwdIter2>::type>::type
adjacent_difference(
    ExPolicy&& policy,
    FwdIter1 first,
    FwdIter1 last,
    FwdIter2 dest)

Assigns each value in the range given by result its corresponding element in the range [first, last] and the one preceding it except *result, which is assigned *first

The difference operations in the parallel adjacent_difference invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complex: Exactly (last - first) - 1 application of the binary operator and (last - first) assignments.

Template Parameters
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- FwdIter1: The type of the source iterators used for the input range (deduced). This iterator type must meet the requirements of an forward iterator.
- FwdIter2: The type of the source iterators used for the output range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters
- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- last: Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- dest: Refers to the beginning of the sequence of elements the results will be assigned to.

The difference operations in the parallel adjacent_difference invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of adjacent_find is available if the user decides to provide their algorithm their own binary predicate op.

Return The adjacent_difference algorithm returns a hpx::future<FwdIter2> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter2 otherwise. The adjacent_find algorithm returns an iterator to the last element in the output range.
Assigns each value in the range given by result its corresponding element in the range [first, last] and the one preceding it except *result, which is assigned *first

The difference operations in the parallel adjacent_difference invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Exactly (last - first) - 1 application of the binary operator and (last - first) assignments.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the source iterators used for the input range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the source iterators used for the output range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Op**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of adjacent_difference requires Op to meet the requirements of CopyConstructible.

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **dest**: Refers to the beginning of the sequence of elements the results will be assigned to.
- **op**: The binary operator which returns the difference of elements. The signature should be equivalent to the following:

```cpp
bool op(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 must be such that objects of type FwdIter1 can be dereferenced and then implicitly converted to the dereferenced type of dest.

The difference operations in the parallel adjacent_difference invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The adjacent_difference algorithm returns a hpx::future<FwdIter2> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter2 otherwise. The adjacent_find algorithm returns an iterator to the last element in the output range.
namespace hpx

Functions

```cpp
template<typename FwdIter, typename Pred = detail::equal_to>
FwdIter adjacent_find(FwdIter first, FwdIter last, Pred &&pred = Pred())
    Searches the range [first, last) for two consecutive identical elements.
```

**Note** Complexity: Exactly the smaller of (result - first) + 1 and (last - first) - 1 application of the predicate where result is the value returned

**Return** The `adjacent_find` algorithm returns an iterator to the first of the identical elements. If no such elements are found, `last` is returned.

**Template Parameters**

- `FwdIter`: The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- `Pred`: The type of an optional function/function object to use.

**Parameters**

- `first`: Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- `last`: Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- `pred`: The binary predicate which returns `true` if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const & , but the function must not modify the objects passed to it. The types `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

```cpp
template<typename ExPolicy, typename FwdIter, typename Pred = detail::equal_to>
std::enable_if<hpx::is_execution_policy<ExPolicy>::value, typename util::detail::algorithm_result<ExPolicy, FwdIter>::type>::type
adjacent_find(ExPolicy &&policy, FwdIter first, FwdIter last, Pred &&pred = Pred())
    Searches the range [first, last) for two consecutive identical elements. This version uses the given binary predicate `pred`
```

The comparison operations in the parallel `adjacent_find` invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.
**Note**  Complexity: Exactly the smaller of \((\text{result} - \text{first}) + 1\) and \((\text{last} - \text{first}) - 1\) application of the predicate where \(\text{result}\) is the value returned

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter**: The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.

- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.

- **first**: Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.

- **last**: Refers to the end of the sequence of elements of the range the algorithm will be applied to.

- **pred**: The binary predicate which returns `true` if the elements should be treated as equal. The signature should be equivalent to the following:

  ```cpp
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

  The comparison operations in the parallel `adjacent_find` invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

  This overload of `adjacent_find` is available if the user decides to provide their algorithm their own binary predicate `pred`.

**Return**  The `adjacent_find` algorithm returns a `hpx::future<InIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `InIter` otherwise. The `adjacent_find` algorithm returns an iterator to the first of the identical elements. If no such elements are found, `last` is returned.
Functions

```cpp
template<typename ExPolicy, typename FwdIter, typename F, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, bool>::type none_of(ExPolicy &&policy, FwdIter first, FwdIter last, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate \( f \) returns true for no elements in the range \([\text{first}, \text{last})\).

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: At most \( \text{last} - \text{first} \) applications of the predicate \( f \)

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `none_of` requires \( F \) to meet the requirements of `CopyConstructible`.
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\). The signature of this predicate should be equivalent to:

  ```cpp
  bool pred(const Type &a);
  ```

  The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate \( f \) is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `none_of` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `none_of` algorithm returns true if the unary predicate \( f \) returns true for no elements in the range, false otherwise. It returns true if the range is empty.
util::detail::algorithm_result<ExPolicy, bool>::type any_of (ExPolicy &&policy, FwdIter first, FwdIter last, F &&f, Proj &&proj = Proj())

Checks if unary predicate f returns true for at least one element in the range [first, last).

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: At most last - first applications of the predicate f

**Template Parameters**

- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- FwdIter: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- F: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `any_of` requires F to meet the requirements of `CopyConstructible`.
- Proj: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last: Refers to the end of the sequence of elements the algorithm will be applied to.
- f: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to Type.

- proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `any_of` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns bool otherwise. The `any_of` algorithm returns true if the unary predicate f returns true for at least one element in the range, false otherwise. It returns false if the range is empty.

```
template<typename ExPolicy, typename FwdIter, typename F, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, bool>::type all_of (ExPolicy &&policy, FwdIter first, FwdIter last, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate f returns true for all elements in the range [first, last).
The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: At most last - first applications of the predicate \( f \)

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `all_of` requires \( F \) to meet the requirements of `CopyConstructible`.
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\). The signature of this predicate should be equivalent to:

```cpp
def pred(const Type &a);```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `all_of` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `all_of` algorithm returns true if the unary predicate \( f \) returns true for all elements in the range, false otherwise. It returns true if the range is empty.

```cpp
namespace hpx
```

1030 Chapter 2. What’s so special about HPX?
Functions

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type copy
(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest)
```

Copies the elements in the range, defined by \([\text{first}, \text{last})\), to another range beginning at \(\text{dest}\).

The assignments in the parallel \(\text{copy}\) algorithm invoked with an execution policy object of type \(\text{sequenced\_policy}\) execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly \(\text{last - first}\) assignments.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.

The assignments in the parallel \(\text{copy}\) algorithm invoked with an execution policy object of type \(\text{parallel\_policy}\) or \(\text{parallel\_task\_policy}\) are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The \(\text{copy}\) algorithm returns a \(\text{hpx::future<FwdIter2>}\) if the execution policy is of type \(\text{sequenced\_task\_policy}\) or \(\text{parallel\_task\_policy}\) and returns \(\text{FwdIter2}\) otherwise. The \(\text{copy}\) algorithm returns the pair of the input iterator \(\text{last}\) and the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename Size, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type copy_n
(ExPolicy &&policy, FwdIter1 first, Size count, FwdIter2 dest)
```

Copies the elements in the range \([\text{first}, \text{first + count})\), starting from first and proceeding to \(\text{first + count - 1}\), to another range beginning at dest.

The assignments in the parallel \(\text{copy\_n}\) algorithm invoked with an execution policy object of type \(\text{sequenced\_policy}\) execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly \(\text{count}\) assignments, if \(\text{count} > 0\), no assignments otherwise.

**Template Parameters**
• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• FwdIter1: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

• Size: The type of the argument specifying the number of elements to apply \( f \) to.

• FwdIter2: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

• policy: The execution policy to use for the scheduling of the iterations.

• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.

• count: Refers to the number of elements starting at first the algorithm will be applied to.

• dest: Refers to the beginning of the destination range.

The assignments in the parallel \( \text{copy}\_n \) algorithm invoked with an execution policy object of type \( \text{parallel}\_\text{policy} \) or \( \text{parallel}\_\text{task}\_\text{policy} \) are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The \( \text{copy}\_n \) algorithm returns a \( \text{hpx}::\text{future}<\text{FwdIter2}> \) if the execution policy is of type \( \text{sequence}\_\text{task}\_\text{policy} \) or \( \text{parallel}\_\text{task}\_\text{policy} \) and returns \( \text{FwdIter2} \) otherwise. The \( \text{copy} \) algorithm returns the pair of the input iterator forwarded to the first element after the last in the input sequence and the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename F>
hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type copy_if(ExPolicy && policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest, F && pred)
```

Copies the elements in the range, defined by \([\text{first}, \text{last})\), to another range beginning at \( \text{dest} \). Copies only the elements for which the predicate \( f \) returns true. The order of the elements that are not removed is preserved.

The assignments in the parallel \( \text{copy}\_\text{if} \) algorithm invoked with an execution policy object of type \( \text{sequence}\_\text{policy} \) execute in sequential order in the calling thread.

Note Complexity: Performs not more than \( \text{last} - \text{first} \) assignments, exactly \( \text{last} - \text{first} \) applications of the predicate \( f \).

Template Parameters

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• FwdIter1: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

• FwdIter2: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
• **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `copy_if` requires `F` to meet the requirements of `CopyConstructible`.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`.

The assignments in the parallel `copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `copy_if` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `copy` algorithm returns the pair of the input iterator forwarded to the first element after the last in the input sequence and the output iterator to the element in the destination range, one past the last element copied.

```cpp
namespace hpx
{
    template<typename ExPolicy, typename FwdIterB, typename FwdIterE, typename T, typename Proj = util::projection_identity>
    util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<FwdIterB>::difference_type>::type count(ExPolicy &&policy, FwdIterB first, FwdIterE last, T const &value, Proj &&proj = Proj())
```

Returns the number of elements in the range `[first, last)` satisfying a specific criteria. This version counts the elements that are equal to the given `value`.

The comparisons in the parallel `count` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.
**Note** Complexity: Performs exactly \( last - first \) comparisons.

**Template Parameters**
- \texttt{ExPolicy}: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the comparisons.
- \texttt{FwdIterB}: The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- \texttt{FwdIterE}: The type of the source end iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- \texttt{T}: The type of the value to search for (deduced).
- \texttt{Proj}: The type of an optional projection function. This defaults to \texttt{util::projection\_identity}

**Parameters**
- \texttt{policy}: The execution policy to use for the scheduling of the iterations.
- \texttt{first}: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- \texttt{last}: Refers to the end of the sequence of elements the algorithm will be applied to.
- \texttt{value}: The value to search for.
- \texttt{proj}: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Note** The comparisons in the parallel \texttt{count} algorithm invoked with an execution policy object of type \texttt{parallel\_policy} or \texttt{parallel\_task\_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The \texttt{count} algorithm returns a \texttt{hpx::future<difference\_type>} if the execution policy is of type \texttt{sequenced\_task\_policy} or \texttt{parallel\_task\_policy} and returns \texttt{difference\_type} otherwise (where \texttt{difference\_type} is defined by \texttt{std::iterator\_traits<FwdIterB>::difference\_type}). The \texttt{count} algorithm returns the number of elements satisfying the given criteria.

```cpp
template<typename \texttt{ExPolicy}, typename \texttt{Iter}, typename \texttt{Sent}, typename \texttt{F}, typename \texttt{Proj} = \texttt{util::projection\_identity}>
util::detail::algorithm\_result<ExPolicy, \texttt{typename std::iterator\_traits<Iter>::difference\_type}>::type \texttt{count\_if} (ExPolicy \&\&policy, 
\texttt{Iter} \texttt{first}, 
\texttt{Sent} \texttt{last}, 
\texttt{F} \&\&f, 
\texttt{Proj} \&\&proj = \texttt{Proj}())
```

Returns the number of elements in the range \([\texttt{first}, \texttt{last})\) satisfying a specific criteria. This version counts elements for which predicate \( f \) returns true.

**Note** Complexity: Performs exactly \( last - first \) applications of the predicate.
**Note** The assignments in the parallel `count_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** The assignments in the parallel `count_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `count_if` algorithm returns `hpx::future<difference_type>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `difference_type` otherwise (where `difference_type` is defined by `std::iterator_traits<FwdIterB>::difference_type`). The `count` algorithm returns the number of elements satisfying the given criteria.

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the comparisons.
- `Iter`: The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- `Sent`: The type of the source end iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- `F`: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `count_if` requires `F` to meet the requirements of `CopyConstructible`.
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- `policy`: The execution policy to use for the scheduling of the iterations.
- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last`: Refers to the end of the sequence of elements the algorithm will be applied to.
- `f`: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

  ```cpp
  bool pred(const Type &a);
  ```

  The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIterB` can be dereferenced and then implicitly converted to `Type`.

- `proj`: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

```cpp
namespace hpx {

```
Functions

template<typename ExPolicy, typename FwdIter>
util::detail::algorithm_result<ExPolicy>::type destroy (ExPolicy &policy, FwdIter first, FwdIter last)
Destroys objects of type typename iterator_traits<ForwardIt>::value_type in the range [first, last).

The operations in the parallel destroy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Performs exactly last - first operations.

Template Parameters

- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- FwdIter: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last: Refers to the end of the sequence of elements the algorithm will be applied to.

The operations in the parallel destroy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The destroy algorithm returns a hpx::future<void>, if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns void otherwise.

template<typename ExPolicy, typename FwdIter, typename Size>
util::detail::algorithm_result<ExPolicy, FwdIter>::type destroy_n (ExPolicy &&policy, FwdIter first, Size count)
Destroys objects of type typename iterator_traits<ForwardIt>::value_type in the range [first, first + count).

The operations in the parallel destroy_n algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Performs exactly count operations, if count > 0, no assignments otherwise.

Template Parameters

- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- FwdIter: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- Size: The type of the argument specifying the number of elements to apply this algorithm to.

Parameters
• **policy**: The execution policy to use for the scheduling of the iterations.
• **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **count**: Refers to the number of elements starting at `first` the algorithm will be applied to.

The operations in the parallel `destroy_n` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `destroy_n` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `destroy_n` algorithm returns the iterator to the element in the source range, one past the last element constructed.

```cpp
namespace hpx
{

Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result<ExPolicy, bool>::type equal(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, Pred &&op = Pred())
{
    return boost::copy_range<std::equal_to>(first1, last1, first2, last2, op);
}
```

Returns true if the range `[first1, last1)` is equal to the range `[first2, last2)`, and false otherwise.

The comparison operations in the parallel `equal` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: At most `min(last1 - first1, last2 - first2)` applications of the predicate `f`.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2**: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
• **last2**: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

• **op**: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
def bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

The comparison operations in the parallel `equal` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note** The two ranges are considered equal if, for every iterator i in the range `[first1, last1)`, *i equals *(first2 + (i - first1)). This overload of `equal` uses `operator==` to determine if two elements are equal.

**Return** The `equal` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `equal` algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range `[first1, last1)` does not equal the length of the range `[first2, last2)`, it returns false.

```cpp
template<
    typename ExPolicy,
    typename FwdIter1,
    typename FwdIter2,
    typename Pred = detail::equal_to>
util::detail::algorithm_result<ExPolicy, bool>::type equal(
    ExPolicy &&policy,
    FwdIter1 first1,
    FwdIter1 last1, FwdIter2 first2, Pred &&op = Pred())
```

Returns true if the range `[first1, last1)` is equal to the range starting at `first2`, and false otherwise.

The comparison operations in the parallel `equal` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: At most `last1 - first1` applications of the predicate `f`.

**Template Parameters**

• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **FwdIter1**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

• **FwdIter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

• **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`.

**Parameters**

• **policy**: The execution policy to use for the scheduling of the iterations.

• **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
• last1: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
• first2: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
• op: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively.

The comparison operations in the parallel `equal` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note** The two ranges are considered equal if, for every iterator i in the range [first1,last1), *i equals *(first2 + (i - first1)). This overload of equal uses operator== to determine if two elements are equal.

**Return** The `equal` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `equal` algorithm returns true if the elements in the two ranges are equal, otherwise it returns false.

```cpp
namespace hpx

namespace parallel

Functions

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename T, typename Op>
std::enable_if<hpx::is_execution_policy<ExPolicy>::value, typename util::detail::algorithm_result<ExPolicy, FwdIter2>::type>
```

Assigns through each iterator i in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(binary_op, init, *first, ..., *(first + (i - result) - 1)).

The reduce operations in the parallel `exclusive_scan` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: O(last - first) applications of the predicate op.

**Template Parameters**
• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **FwdIter1**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

• **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

• **T**: The type of the value to be used as initial (and intermediate) values (deduced).

• **Op**: The type of the binary function object used for the reduction operation.

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **init**: The initial value for the generalized sum.
- **op**: Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```cpp
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types `Type1` and `Ret` must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

The reduce operations in the parallel `exclusive_scan` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `exclusive_scan` and `inclusive_scan` is that `inclusive_scan` includes the ith input element in the ith sum. If `op` is not mathematically associative, the behavior of `inclusive_scan` may be non-deterministic.

### Return

The `exclusive_scan` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `exclusive_scan` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

### Note

`GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN)` is defined as:

- `a1` when `N` is `1`
- `op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN))` where `1 <= K+1 = M <= N`.

Assigns through each iterator `i` in `[result, result + (last - first))` the value of `GENERALIZED_NONCOMMUTATIVE_SUM(+, init, *first, ..., *(first + (i - result) - 1))`
The reduce operations in the parallel `exclusive_scan` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: \( O(\text{last} - \text{first}) \) applications of the predicate `std::plus<T>`.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T**: The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **init**: The initial value for the generalized sum.

The reduce operations in the parallel `exclusive_scan` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `exclusive_scan` and `inclusive_scan` is that `inclusive_scan` includes the ith input element in the ith sum.

**Return** The `exclusive_scan` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `exclusive_scan` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

**Note** `GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, \ldots, aN)` is defined as:
- \( a1 \) when \( N = 1 \)
- \( GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, \ldots, aK) - GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, \ldots, aN) \) where \( 1 < K+1 = M <= N \).

namespace hpx

**Functions**

```cpp
template<typename ExPolicy, typename FwdIter, typename T>
util::detail::algorithm_result<ExPolicy>::type fill (ExPolicy &policy, FwdIter first, FwdIter last, T value)
```

Assigns the given value to the elements in the range \([\text{first}, \text{last})\).

The comparisons in the parallel `fill` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly \( \text{last} - \text{first} \) assignments.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

• **T**: The type of the value to be assigned (deduced).

### Parameters

• **policy**: The execution policy to use for the scheduling of the iterations.

• **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **last**: Refers to the end of the sequence of elements the algorithm will be applied to.

• **value**: The value to be assigned.

The comparisons in the parallel `fill` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `fill` algorithm returns a `hpx::future<void>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `difference_type` otherwise (where `difference_type` is defined by `void`).

```cpp
template<typename ExPolicy, typename FwdIter, typename Size, typename T>
util::detail::algorithm_result<ExPolicy, FwdIter>::type fill_n (ExPolicy&& policy, FwdIter first, Size count, T value)
```

Assigns the given value `value` to the first `count` elements in the range beginning at `first` if `count > 0`. Does nothing otherwise.

The comparisons in the parallel `fill_n` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `count` assignments, for `count > 0`.

### Template Parameters

• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an output iterator.

• **Size**: The type of the argument specifying the number of elements to apply `f` to.

• **T**: The type of the value to be assigned (deduced).

**Parameters**

• **policy**: The execution policy to use for the scheduling of the iterations.

• **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **count**: Refers to the number of elements starting at `first` the algorithm will be applied to.

• **value**: The value to be assigned.

The comparisons in the parallel `fill_n` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
Return The `fill_n` algorithm returns a `hpx::future<void>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `difference_type` otherwise (where `difference_type` is defined by `void`).

namespace hpx

Functions

template<typename ExPolicy, typename FwdIter, typename T>
util::detail::algorithm_result<ExPolicy, FwdIter>::type find(ExPolicy &&policy, FwdIter first, FwdIter last, T const &val)
Returns the first element in the range `[first, last)` that is equal to value.

The comparison operations in the parallel `find` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

Note Complexity: At most last - first applications of the operator `==`.

Template Parameters

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter`: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- `T`: The type of the value to find (deduced).

Parameters

- `policy`: The execution policy to use for the scheduling of the iterations.
- `first`: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- `last`: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- `val`: the value to compare the elements to

The comparison operations in the parallel `find` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The `find` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `find` algorithm returns the first element in the range `[first, last)` that is equal to `val`. If no such element in the range of `[first, last)` is equal to `val`, then the algorithm returns `last`.

template<typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result<ExPolicy, FwdIter>::type find_if(ExPolicy &&policy, FwdIter first, FwdIter last, F &&f)
Returns the first element in the range `[first, last)` for which predicate `f` returns true.

The comparison operations in the parallel `find_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.
Note  Complexity: At most last - first applications of the predicate.

Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `F` to meet the requirements of `CopyConstructible`.

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **f**: The unary predicate which returns true for the required element. The signature of the predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

  The comparison operations in the parallel `find_if` algorithm invoked with an execution policy object of type `sequenced_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return  The `find_if` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `find_if` algorithm returns the first element in the range `[first,last)` that satisfies the predicate `f`. If no such element exists that satisfies the predicate `f`, the algorithm returns `last`.

```
template<typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result<ExPolicy, FwdIter>::type find_if_not (ExPolicy &&policy, FwdIter first, FwdIter last, F &&f)
```

Returns the first element in the range `[first, last)` for which predicate `f` returns false.

The comparison operations in the parallel `find_if_not` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

Note  Complexity: At most last - first applications of the predicate.

Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
• F: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `F` to meet the requirements of `CopyConstructible`.

**Parameters**

- `policy`: The execution policy to use for the scheduling of the iterations.
- `first`: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- `last`: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- `f`: The unary predicate which returns false for the required element. The signature of the predicate should be equivalent to:

  ```cpp
def pred(const Type &a);
```  

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

The comparison operations in the parallel `find_if_not` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `find_if_not` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `find_if_not` algorithm returns the first element in the range `[first, last)` that does not satisfy the predicate `f`. If no such element exists that does not satisfy the predicate `f`, the algorithm returns `last`.

```cpp
template<
    typename ExPolicy,
    typename FwdIter1,
    typename FwdIter2,
    typename Pred = detail::equal_to>
util::detail::algorithm_result<ExPolicy, FwdIter1>::type find_end(
    ExPolicy &&policy,
    FwdIter1 first1,
    FwdIter1 last1,
    FwdIter2 first2,
    FwdIter2 last2,
    Pred &&op
    = Pred())
```

Returns the last subsequence of elements `[first2, last2)` found in the range `[first, last)` using the given predicate `f` to compare elements.

The comparison operations in the parallel `find_end` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: at most \( S \times (N-S+1) \) comparisons where \( S = \text{distance}(first2, last2) \) and \( N = \text{distance}(first1, last1) \).

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter1`: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- `FwdIter2`: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
• **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `replace` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`.

• **Proj**: The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements of type dereferenced `FwdIter1` and dereferenced `FwdIter2`.

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2**: Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **last2**: Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op**: The binary predicate which returns `true` if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

• **proj**: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `FwdIter1` and dereferenced `FwdIter2` as a projection operation before the function `f` is invoked.

The comparison operations in the parallel `find_end` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of `find_end` is available if the user decides to provide the algorithm their own predicate `f`.

### Return

The `find_end` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `find_end` algorithm returns an iterator to the beginning of the last subsequence `[first2, last2)` in range `[first1, last1)`. If the length of the subsequence `[first2, last2)` is greater than the length of the range `[first1, last1)`, `last1` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `last1` is also returned.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result<ExPolicy, FwdIter1>::type find_first_of(ExPolicy &&policy,
FwdIter1 first, FwdIter1 last, FwdIter2 s_first,
FwdIter2 s_last, Pred &&op = Pred())
```

Searches the range `[first, last)` for any elements in the range `[s_first, s_last)`. Uses binary predicate `p` to compare elements.
The comparison operations in the parallel `find_first_of` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: at most \((S*N)\) comparisons where \(S = \text{distance}(s\_first, s\_last)\) and \(N = \text{distance}(\text{first}, \text{last})\).

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`.
- **Proj1**: The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements of type dereferenced `FwdIter1`.
- **Proj2**: The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements of type dereferenced `FwdIter2`.

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s_first**: Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last**: Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op**: The binary predicate which returns `true` if the elements should be treated as equal. The signature should be equivalent to the following:

  ```cpp
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.
- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `FwdIter1` as a projection operation before the function `op` is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `FwdIter2` as a projection operation before the function `op` is invoked.

The comparison operations in the parallel `find_first_of` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
The `find_first_of` algorithm returns a `hpx::future<FwdIter1>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter1` otherwise. The `find_first_of` algorithm returns an iterator to the first element in the range `[first, last)` that is equal to an element from the range `[s_first, s_last)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, last)`, `last` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `last` is also returned. This overload of `find_end` is available if the user decides to provide the algorithm their own predicate `f`.

```cpp
namespace hpx

Functions

template<typename InIter, typename F>
F for_each (InIter first, InIter last, F &&f)
Applies f to the result of dereferencing every iterator in the range [first, last).

If f returns a result, the result is ignored.

Note  Complexity: Applies f exactly last - first times.

If the type of first satisfies the requirements of a mutable iterator, f may apply non-constant functions through the dereferenced iterator.

Return  f.

Template Parameters

• InIter: The type of the source begin and end iterator used (deduced). This iterator type must meet the requirements of an input iterator.

• F: The type of the function/function object to use (deduced). F must meet requirements of Move-Constructible.

Parameters

• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.

• last: Refers to the end of the sequence of elements the algorithm will be applied to.

• f: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

  ```cpp
  <ignored> pred(const Type &a);
  ```

  The signature does not need to have const&. The type Type must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to Type.

```cpp
template<typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result<ExPolicy, void>::type for_each (ExPolicy &&policy, FwdIter first,
  FwdIter last, F &&f)
Applies f to the result of dereferencing every iterator in the range [first, last).

If f returns a result, the result is ignored.

Note  Complexity: Applies f exactly last - first times.
```
If the type of \textit{first} satisfies the requirements of a mutable iterator, \textit{f} may apply non-constant functions through the dereferenced iterator.

Unlike its sequential form, the parallel overload of \texttt{for_each} does not return a copy of its \textit{Function} parameter, since parallelization may not permit efficient state accumulation.

The application of function objects in parallel algorithm invoked with an execution policy object of type \texttt{sequenced\_policy} execute in sequential order in the calling thread.

**Template Parameters**

- \texttt{ExPolicy}: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- \texttt{FwdIte}: The type of the source begin and end iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- \texttt{F}: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \texttt{for\_each} requires \texttt{F} to meet the requirements of \texttt{CopyConstructible}.

**Parameters**

- \texttt{policy}: The execution policy to use for the scheduling of the iterations.
- \texttt{first}: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- \texttt{last}: Refers to the end of the sequence of elements the algorithm will be applied to.
- \texttt{f}: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \texttt{[first, last)}. The signature of this predicate should be equivalent to:

\begin{verbatim}
<ignored> pred(const Type &a);
\end{verbatim}

The signature does not need to have \texttt{const\&}. The type \texttt{Type} must be such that an object of type \texttt{FwdIter} can be dereferenced and then implicitly converted to \texttt{Type}.

The application of function objects in parallel algorithm invoked with an execution policy object of type \texttt{parallel\_policy} or \texttt{parallel\_task\_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The \texttt{for\_each} algorithm returns a \texttt{hpx::future<void>} if the execution policy is of type \texttt{sequenced\_task\_policy} or \texttt{parallel\_task\_policy} and returns void otherwise.

\[ \text{template<typename InIter, typename Size, typename F> InIter for_each_n(InIter first, Size count, F &&f)} \]

Applies \texttt{f} to the result of dereferencing every iterator in the range \texttt{[first, first + count)}, starting from \texttt{first} and proceeding to \texttt{first + count - 1}.

If \texttt{f} returns a result, the result is ignored.

**Note** Complexity: Applies \texttt{f} exactly \texttt{count} times.

If the type of \texttt{first} satisfies the requirements of a mutable iterator, \texttt{f} may apply non-constant functions through the dereferenced iterator.

**Return** \texttt{first + count} for non-negative values of \texttt{count} and \texttt{first} for negative values.
Template Parameters

- **InIter**: The type of the source begin and end iterator used (deduced). This iterator type must meet the requirements of an input iterator.
- **Size**: The type of the argument specifying the number of elements to apply $f$ to.
- **F**: The type of the function/function object to use (deduced). $F$ must meet requirements of *Move-Constructible*.

Parameters

- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count**: Refers to the number of elements starting at *first* the algorithm will be applied to.
- **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by *[first, last)*. The signature of this predicate should be equivalent to:

  ```cpp
  <ignored> pred(const Type &a);
  ```

  The signature does not need to have const&. The type *Type* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to *Type*.

```
template<typename ExPolicy, typename FwdIter, typename Size, typename F>
util::detail::algorithm_result<ExPolicy, FwdIter>::type
for_each_n(ExPolicy&& policy, FwdIter first, Size count, F&& f)
```

Applies $f$ to the result of dereferencing every iterator in the range *[first, first + count)*, starting from first and proceeding to first + count - 1.

If $f$ returns a result, the result is ignored.

**Note** Complexity: Applies $f$ exactly *count* times.

If the type of *first* satisfies the requirements of a mutable iterator, $f$ may apply non-constant functions through the dereferenced iterator.

Unlike its sequential form, the parallel overload of *for_each* does not return a copy of its *Function* parameter, since parallelization may not permit efficient state accumulation.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size**: The type of the argument specifying the number of elements to apply $f$ to.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *for_each* requires $F$ to meet the requirements of *CopyConstructible*.

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• count: Refers to the number of elements starting at first the algorithm will be applied to.

• f: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

\[
\text{pred(const Type &a)};
\]

The signature does not need to have const&. The type Type must be such that an object of type FwdIter can be dereferenced and then implicitly converted to Type.

The application of function objects in parallel algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The for_each_n algorithm returns a hpx::future<FwdIter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter otherwise. It returns first + count for non-negative values of count and first for negative values.

namespace hpx

Functions

template<typename I, typename ...Args>
void for_loop (std::decay_t<I> first, I last, Args&&... args)

The for_loop implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of for_loop without specifying an execution policy is equivalent to specifying hpx::execution::seq as the execution policy.

Requires: I shall be an integral type or meet the requirements of an input iterator type. The args parameter pack shall have at least one element, comprising objects returned by invocations of reduction and/or induction function templates followed by exactly one element invocable element-access function, f. f shall meet the requirements of MoveConstructible.

Template Parameters

• I: The type of the iteration variable. This could be an (forward) iterator type or an integral type.

• Args: A parameter pack, it’s last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

Parameters

• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.

• last: Refers to the end of the sequence of elements the algorithm will be applied to.

• args: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

\[
\text{pred(I const% a, ...)};
\]
The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

Effects: Applies \( f \) to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the \( \text{args} \) parameter pack. The length of the input sequence is \( \text{last} - \text{first} \).

The first element in the input sequence is specified by \( \text{first} \). Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the \( \text{args} \) parameter pack excluding \( f \), an additional argument is passed to each application of \( f \) as follows:

**Note** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

**Note** The order of the elements of the input sequence is important for determining ordinal position of an application of \( f \), even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of \( f \) in the input sequence.

Complexity: Applies \( f \) exactly once for each element of the input sequence.

Remarks: If \( f \) returns a result, the result is ignored.

```cpp
template<typename ExPolicy, typename I, typename ...Args>
util::detail::algorithm_result<ExPolicy>::type for_loop(ExPolicy &&policy, std::decay_t<I> first, I last, Args&&... args)
```

The for_loop implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

Requires: \( I \) shall be an integral type or meet the requirements of an input iterator type. The \( \text{args} \) parameter pack shall have at least one element, comprising objects returned by invocations of reduction and/or induction function templates followed by exactly one element invocable element-access function, \( f \). \( f \) shall meet the requirements of MoveConstructible.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **I**: The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- **Args**: A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
• **args**: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

```cpp
<ignored> pred(I const & a, ...);
```

The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Effects**: Applies \( f \) to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the **args** parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by **first**. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the **args** parameter pack excluding \( f \), an additional argument is passed to each application of \( f \) as follows:

**Note** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

**Note** The order of the elements of the input sequence is important for determining ordinal position of an application of \( f \), even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of \( f \) in the input sequence.

**Complexity**: Applies \( f \) exactly once for each element of the input sequence.

**Remarks**: If \( f \) returns a result, the result is ignored.

**Return** The **for_loop** algorithm returns a **hpx::future<void>** if the execution policy is of type **hpx::execution::sequenced_task_policy** or **hpx::execution::parallel_task_policy** and returns **void** otherwise.

```cpp
template<typename I, typename S, typename ...Args>
void for_loop_strided(std::decay_t<I> first, I last, S stride, Args&... args)
```

The **for_loop_strided** implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble **for_each** from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of **for_loop** without specifying an execution policy is equivalent to specifying **hpx::execution::seq** as the execution policy.

**Requires**: \( I \) shall be an integral type or meet the requirements of an input iterator type. The **args** parameter pack shall have at least one element, comprising objects returned by invocations of **reduction** and/or **induction** function templates followed by exactly one element invocable element-access function, \( f \). \( f \) shall meet the requirements of MoveConstructible.

**Template Parameters**

- **I**: The type of the iteration variable. This could be an (forward) iterator type or an integral type.
• **S**: The type of the stride variable. This should be an integral type.
• **Args**: A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

### Parameters

• **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
• **stride**: Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if I has integral type or meets the requirements of a bidirectional iterator.
• **args**: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

```cpp
<ignored> pred(I const& a, ...);
```

The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Effects**: Applies \( f \) to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the \( \text{args} \) parameter pack. The length of the input sequence is \( \text{last} - \text{first} \).

The first element in the input sequence is specified by \( \text{first} \). Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the \( \text{args} \) parameter pack excluding \( f \), an additional argument is passed to each application of \( f \) as follows:

**Note** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

**Note** The order of the elements of the input sequence is important for determining ordinal position of an application of \( f \), even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of \( f \) in the input sequence.

**Complexity**: Applies \( f \) exactly once for each element of the input sequence.

**Remarks**: If \( f \) returns a result, the result is ignored.

```cpp
template<typename ExPolicy, typename I, typename S, typename ..Args>
util::detail::algorithm_result<ExPolicy>::type for_loop_strided(ExPolicy &&policy,
std::decay_t<I> first, I last, S stride, Args&&... args)
```

The \( \text{for\_loop\_strided} \) implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble \( \text{for\_each} \) from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

**Requires**: \( I \) shall be an integral type or meet the requirements of an input iterator type. The \( \text{args} \) parameter pack shall have at least one element, comprising objects returned by invocations of \( \text{reduction} \) and/or
induction function templates followed by exactly one element invocable element-access function, \( f \) shall meet the requirements of MoveConstructible.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **I**: The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- **S**: The type of the stride variable. This should be an integral type.
- **Args**: A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **stride**: Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if \( I \) has integral type or meets the requirements of a bidirectional iterator.
- **args**: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\) should expose a signature equivalent to:

  ```cpp
  <\text{ignored}> \text{pred}(I\ \text{const}\&\ a, \ldots);
  ```

  The signature does not need to have \text{const}\&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

  Effects: Applies \( f \) to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the \text{args} parameter pack. The length of the input sequence is \text{last} - \text{first}.

  The first element in the input sequence is specified by \text{first}. Each subsequent element is generated by incrementing the previous element.

  Along with an element from the input sequence, for each member of the \text{args} parameter pack excluding \( f \), an additional argument is passed to each application of \( f \) as follows:

  **Note** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

  **Note** The order of the elements of the input sequence is important for determining ordinal position of an application of \( f \), even though the applications themselves may be unordered.

  If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of \( f \) in the input sequence.

  Complexity: Applies \( f \) exactly once for each element of the input sequence.

  Remarks: If \( f \) returns a result, the result is ignored.
**Return** The `for_loop_strided` algorithm returns a `hpx::future<void>` if the execution policy is of type `hpx::execution::sequenced_task_policy` or `hpx::execution::parallel_task_policy` and returns `void` otherwise.

```cpp
template<typename I, typename Size, typename ...Args>
void for_loop_n(I first, Size size, Args&&... args)
```

The `for_loop_n` implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of `for_loop_n` without specifying an execution policy is equivalent to specifying `hpx::execution::seq` as the execution policy.

**Requires:** `I` shall be an integral type or meet the requirements of an input iterator type. The `args` parameter pack shall have at least one element, comprising objects returned by invocations of `reduction` and/or `induction` function templates followed by exactly one element invocable element-access function. `f` shall meet the requirements of `MoveConstructible`.

**Template Parameters**

- `I`: The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- `Size`: The type of a non-negative integral value specifying the number of items to iterate over.
- `Args`: A parameter pack, it’s last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**

- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `size`: Refers to the number of items the algorithm will be applied to.
- `args`: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)` should expose a signature equivalent to:

```cpp
<ignored> pred(I const & a, ...);
```

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Effects:** Applies `f` to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the `args` parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by `first`. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the `args` parameter pack excluding `f`, an additional argument is passed to each application of `f` as follows:

**Note** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

**Note** The order of the elements of the input sequence is important for determining ordinal position of an application of `f`, even though the applications themselves may be unordered.
If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of $f$ in the input sequence.

Complexity: Applies $f$ exactly once for each element of the input sequence.

Remarks: If $f$ returns a result, the result is ignored.

```cpp
template<typename ExPolicy, typename I, typename Size, typename ... Args>
util::detail::algorithm_result<ExPolicy>::type for_loop_n(ExPolicy &&policy, I first, Size size, Args&&... args)
```

The for_loop_n implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

Requires: $I$ shall be an integral type or meet the requirements of an input iterator type. The $args$ parameter pack shall have at least one element, comprising objects returned by invocations of reduction and/or induction function templates followed by exactly one element invocable element-access function, $f$. $f$ shall meet the requirements of MoveConstructible.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **I**: The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- **Size**: The type of a non-negative integral value specifying the number of items to iterate over.
- **Args**: A parameter pack, it's last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **size**: Refers to the number of items the algorithm will be applied to.
- **args**: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

```cpp
<ignored> pred(I const& a, ...);
```

The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Effects**: Applies $f$ to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the $args$ parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by $first$. Each subsequent element is generated by incrementing the previous element.
Along with an element from the input sequence, for each member of the \texttt{args} parameter pack excluding \texttt{f}, an additional argument is passed to each application of \texttt{f} as follows:

**Note** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

**Note** The order of the elements of the input sequence is important for determining ordinal position of an application of \texttt{f}, even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of \texttt{f} in the input sequence.

**Complexity:** Applies \texttt{f} exactly once for each element of the input sequence.

**Remarks:** If \texttt{f} returns a result, the result is ignored.

**Return** The \texttt{for\_loop\_n} algorithm returns a \texttt{hpx::future<void>} if the execution policy is of type \texttt{hpx::execution::sequenced\_task\_policy} or \texttt{hpx::execution::parallel\_task\_policy} and returns \texttt{void} otherwise.

```cpp
template<typename I, typename Size, typename S, typename ...Args>
void for_loop_n_strided(I first, Size size, S stride, Args&&... args)
```

The for\_loop\_n\_strided implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble for\_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of for\_loop without specifying an execution policy is equivalent to specifying \texttt{hpx::execution::seq} as the execution policy.

**Requires:** \texttt{I} shall be an integral type or meet the requirements of an input iterator type. The \texttt{args} parameter pack shall have at least one element, comprising objects returned by invocations of \texttt{reduction} and/or \texttt{induction} function templates followed by exactly one element invokeable element-access function, \texttt{f}. \texttt{f} shall meet the requirements of MoveConstructible.

**Template Parameters**

- \texttt{I}: The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- \texttt{Size}: The type of a non-negative integral value specifying the number of items to iterate over.
- \texttt{S}: The type of the stride variable. This should be an integral type.
- \texttt{Args}: A parameter pack, it’s last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**

- \texttt{first}: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- \texttt{size}: Refers to the number of items the algorithm will be applied to.
- \texttt{stride}: Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if \texttt{I} has integral type or meets the requirements of a bidirectional iterator.
- \texttt{args}: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by \texttt{[first, last]} should expose a signature equivalent to:
The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

Effects: Applies $f$ to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the $args$ parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by $first$. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the $args$ parameter pack excluding $f$, an additional argument is passed to each application of $f$ as follows:

**Note** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

**Note** The order of the elements of the input sequence is important for determining ordinal position of an application of $f$, even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of $f$ in the input sequence.

Complexity: Applies $f$ exactly once for each element of the input sequence.

Remarks: If $f$ returns a result, the result is ignored.

template<
  typename ExPolicy,
  typename I,
  typename Size,
  typename S,
  typename ... Args>
util::detail::algorithm_result<ExPolicy>::type for_loop_n_strided(
  ExPolicy && policy,
  I first,
  Size size,
  S stride,
  Args&&... args)

The for_loop_n_strided implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

Requires: $I$ shall be an integral type or meet the requirements of an input iterator type. The $args$ parameter pack shall have at least one element, comprising objects returned by invocations of reduction and/or induction function templates followed by exactly one element invocable element-access function, $f$. $f$ shall meet the requirements of MoveConstructible.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **I**: The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- **Size**: The type of a non-negative integral value specifying the number of items to iterate over.
- **S**: The type of the stride variable. This should be an integral type.
- **Args**: A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **size**: Refers to the number of items the algorithm will be applied to.
- **stride**: Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if I has integral type or meets the requirements of a bidirectional iterator.
- **args**: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

  ```cpp
  <ignored> pred(I const& a, ...);
  ```

  The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

  **Effects**: Applies \( f \) to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the \( args \) parameter pack. The length of the input sequence is last - first.

  The first element in the input sequence is specified by \( \text{first} \). Each subsequent element is generated by incrementing the previous element.

  Along with an element from the input sequence, for each member of the \( args \) parameter pack excluding \( f \), an additional argument is passed to each application of \( f \) as follows:

  **Note** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

  **Note** The order of the elements of the input sequence is important for determining ordinal position of an application of \( f \), even though the applications themselves may be unordered.

  If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of \( f \) in the input sequence.

  **Complexity**: Applies \( f \) exactly once for each element of the input sequence.

  **Remarks**: If \( f \) returns a result, the result is ignored.

  **Return** The \texttt{for\_loop\_n\_strided} algorithm returns a \texttt{hpx::future<\texttt{void}>} if the execution policy is of type \texttt{hpx::execution::sequenced\_task\_policy} or \texttt{hpx::execution::parallel\_task\_policy} and returns \texttt{\text{void}} otherwise.

```cpp
namespace hpx
{

namespace parallel
{

```
Functions

\[
\text{template<typename } T \text{> constexpr detail::induction_stride_helper}<T> \text{ induction } (T \&\&\text{value}, \text{std}::\text{size} _{t} \text{ stride})
\]

The function template returns an induction object of unspecified type having a value type and encapsulating an initial value \text{value} of that type and, optionally, a stride.

For each element in the input range, a looping algorithm over input sequence \( S \) computes an induction value from an induction variable and ordinal position \( p \) within \( S \) by the formula \( i + p \times \text{stride} \) if a stride was specified or \( i + p \) otherwise. This induction value is passed to the element access function.

If the \text{value} argument to \text{induction} is a non-const lvalue, then that lvalue becomes the live-out object for the returned induction object. For each induction object that has a live-out object, the looping algorithm assigns the value of \( i + n \times \text{stride} \) to the live-out object upon return, where \( n \) is the number of elements in the input range.

Return This returns an induction object with value type \( T \), initial value \text{value}, and (if specified) stride \( \text{stride} \). If \( T \) is an lvalue of non-const type, \text{value} is used as the live-out object for the induction object; otherwise there is no live-out object.

Template Parameters
- \( T \): The value type to be used by the induction object.

Parameters
- \text{value} : [in] The initial value to use for the induction object
- \text{stride} : [in] The (optional) stride to use for the induction object (default: 1)

namespace hpx

namespace parallel

Functions

\[
\text{template<typename } T, \text{ typename } Op\text{> constexpr detail::reduction_helper}<T, \text{typename std}::\text{decay}<Op>\text{::type} \text{ reduction } (T \&\text{var}, \text{const } T \&\text{idem}\text{ntity}, Op \&\&\text{combiner})
\]

The function template returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, a combiner function object, and a live-out object from which the initial value is obtained and into which the final value is stored.

A parallel algorithm uses reduction objects by allocating an unspecified number of instances, called views, of the reduction’s value type. Each view is initialized with the reduction object’s identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function, ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.

Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the
reduction object's combiner operation until a single value remains, which is then assigned back to the live-out object.

T shall meet the requirements of CopyConstructible and MoveAssignable. The expression var = combiner(var, var) shall be well formed.

Template Parameters

- T: The value type to be used by the induction object.
- Op: The type of the binary function (object) used to perform the reduction operation.

Parameters

- var: [in,out] The life-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing.
- identity: [in] The identity value to use for the reduction operation.
- combiner: [in] The binary function (object) used to perform a pairwise reduction on the elements.

Note In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation. For example if the combiner is plus<T>, incrementing the view would be consistent with the combiner but doubling it or assigning to it would not.

Return This returns a reduction object of unspecified type having a value type of T. When the return value is used by an algorithm, the reference to var is used as the live-out object, new views are initialized to a copy of identity, and views are combined by invoking the copy of combiner, passing it the two views to be combined.

namespace hpx

Functions

template<typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result<ExPolicy, FwdIter>::type generate(ExPolicy &&policy, FwdIter first, FwdIter last, F &&f)

Assign each element in range [first, last) a value generated by the given function object f

The assignments in the parallel generate algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Exactly distance(first, last) invocations of f and assignments.

Template Parameters

- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- FwdIter: The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- F: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of equal requires F to meet the requirements of CopyConstructible.

Parameters

- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **last**: Refers to the end of the sequence of elements the algorithm will be applied to.

• **f**: generator function that will be called. signature of function should be equivalent to the following:

```cpp
Ret fun();
```

The type `Ret` must be such that an object of type `FwdIter` can be dereferenced and assigned a value of type `Ret`.

The assignments in the parallel `generate` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `replace_if` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. It returns `last`.

```cpp
template<typename ExPolicy, typename FwdIter, typename Size, typename F>
util::detail::algorithm_result<ExPolicy, FwdIter>::type generate_n(
    ExPolicy&& policy,
    FwdIter first,
    Size count,
    F&& f)
```

Assigns each element in range `[first, first+count)` a value generated by the given function object g.

The assignments in the parallel `generate_n` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Exactly `count` invocations of `f` and assignments, for `count > 0`.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `F` to meet the requirements of `CopyConstructible`.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.

- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **count**: Refers to the number of elements in the sequence the algorithm will be applied to.

- **f**: Refers to the generator function object that will be called. The signature of the function should be equivalent to

```cpp
Ret fun();
```

The type `Ret` must be such that an object of type `OutputIt` can be dereferenced and assigned a value of type `Ret`.

The assignments in the parallel `generate_n` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
Return: The replace_if algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. It returns `last`.

namespace hpx

Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::less>
util::detail::algorithm_result<ExPolicy, bool>::type::type includes(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, Pred &&op = Pred())

Returns true if every element from the sorted range `[first2, last2)` is found within the sorted range `[first1, last1)`. Also returns true if `[first2, last2)` is empty. The version expects both ranges to be sorted with the user supplied binary predicate f.

The comparison operations in the parallel includes algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

Note: At most \(2\times(N1+N2-1)\) comparisons, where \(N1 = \text{std::distance(first1, last1)}\) and \(N2 = \text{std::distance(first2, last2)}\).

Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of includes requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to std::less<>.

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2**: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2**: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op**: The binary predicate which returns true if the elements should be treated as includes. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```
The signature does not need to have const &, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

The comparison operations in the parallel `includes` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `includes` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `includes` algorithm returns true every element from the sorted range `[first2, last2)` is found within the sorted range `[first1, last1)`. Also returns true if `[first2, last2)` is empty.

```cpp
namespace hpx
{
    namespace parallel
    {

        Functions

        template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Op, typename T>
        util::detail::algorithm_result<ExPolicy, FwdIter2>::type inclusive_scan(
            ExPolicy &&policy,
            FwdIter1 first,
            FwdIter1 last,
            FwdIter2 dest,
            Op &&op,
            T init)
        {
            Assigns through each iterator `i` in `[result, result + (last - first))` the value of `GENERALIZED_NONCOMMUTATIVE_SUM(op, init, *first, ..., *(first + (i - result))).`
        }

        The reduce operations in the parallel `inclusive_scan` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

        **Note** Complexity: \(O(last - first)\) applications of the predicate `op`.

        **Template Parameters**
        • `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
        • `FwdIter1`: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
        • `FwdIter2`: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
        • `T`: The type of the value to be used as initial (and intermediate) values (deduced).
        • `Op`: The type of the binary function object used for the reduction operation.

        **Parameters**
        • `policy`: The execution policy to use for the scheduling of the iterations.
        • `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
        • `last`: Refers to the end of the sequence of elements the algorithm will be applied to.
        • `dest`: Refers to the beginning of the destination range.
        • `init`: The initial value for the generalized sum.
        • `op`: Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:
```
Ret fun(const Type1 &a, const Type1 &b);

The signature does not need to have const&, but the function must not modify the objects passed to it. The types Type1 and Ret must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

The reduce operations in the parallel inclusive_scan algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between exclusive_scan and inclusive_scan is that inclusive_scan includes the ith input element in the ith sum. If op is not mathematically associative, the behavior of inclusive_scan may be non-deterministic.

Return The inclusive_scan algorithm returns a hpx::future<FwdIter2> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter2 otherwise. The inclusive_scan algorithm returns the output iterator to the element in the destination range, one past the last element copied.

Note GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN) is defined as:
• a1 when N is 1
• op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN)) where 1 < K+1 = M <= N.

Note Complexities: O(last - first) applications of the predicate op.

Template Parameters
• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• FwdIter1: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
• FwdIter2: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
• Op: The type of the binary function object used for the reduction operation.

Parameters
• policy: The execution policy to use for the scheduling of the iterations.
• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• last: Refers to the end of the sequence of elements the algorithm will be applied to.
• dest: Refers to the beginning of the destination range.
• op: Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:
Ret fun(const Type1 &a, const Type1 &b);

The signature does not need to have const&, but the function must not modify the objects passed to it. The types Type1 and Ret must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

The reduce operations in the parallel `inclusive_scan` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `exclusive_scan` and `inclusive_scan` is that `inclusive_scan` includes the ith input element in the ith sum.

**Return** The `inclusive_scan` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `inclusive_scan` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

**Note** `GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ..., aN)` is defined as:
- \( a1 \) when \( N = 1 \)
- `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK) - GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, ..., aN)` where \( 1 < K+1 = M <= N \).

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
std::enable_if<hpx::is_execution_policy<ExPolicy>::value, typename util::detail::algorithm_result<ExPolicy, FwdIter2>::type>::type
inclusive_scan(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest)
```

Assigns through each iterator \( i \) in \([\text{result}, \text{result} + (\text{last} - \text{first}))\) the value of \( \text{GENERALIZED_NONCOMMUTATIVE_SUM}(+, \ast\text{first}, \ldots, \ast((\text{i} + 1) - \text{result})) \).

The reduce operations in the parallel `inclusive_scan` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: \( O(\text{last} - \text{first}) \) applications of the predicate \( \text{op} \).

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.

The reduce operations in the parallel `inclusive_scan` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
The difference between exclusive_scan and inclusive_scan is that inclusive_scan includes the ith input element in the ith sum.

Return The inclusive_scan algorithm returns a hpx::future<FwdIter2> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter2 otherwise. The inclusive_scan algorithm returns the output iterator to the element in the destination range, one past the last element copied.

Note GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ..., aN) is defined as:

- a1 when N is 1
- GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ..., aK)
- GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, ..., aN) where 1 < K+1 = M <= N.

namespace hpx

Functions

template<typename ExPolicy, typename RandIter, typename Comp = detail::less>
util::detail::algorithm_result<ExPolicy, bool>::type is_heap(
    ExPolicy &&policy,
    RandIter first,
    RandIter last,
    Comp &&comp = Comp())

Returns whether the range is max heap. That is, true if the range is max heap, false otherwise. The function uses the given comparison function object comp (defaults to using operator<()).

comp has to induce a strict weak ordering on the values.

Note Complexity: Performs at most N applications of the comparison comp, at most 2 \* N applications of the projection proj, where N = last - first.

Template Parameters

- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- RandIter: The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- Comp: The type of the function/function object to use (deduced).

Parameters

- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last: Refers to the end of the sequence of elements the algorithm will be applied to.
- comp: comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.

The application of function objects in parallel algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
The `is_heap` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `is_heap` algorithm returns whether the range is max heap. That is, true if the range is max heap, false otherwise.

```
template<typename ExPolicy, typename RandIter, typename Comp = detail::less>
util::detail::algorithm_result<ExPolicy, RandIter>::type is_heap_until((ExPolicy &&policy, RandIter first, RandIter last, Comp &&comp = Comp()))
```

Returns the upper bound of the largest range beginning at `first` which is a max heap. That is, the last iterator `it` for which range `[first, it)` is a max heap. The function uses the given comparison function object `comp` (defaults to using `operator<()`).

`comp` has to induce a strict weak ordering on the values.

**Note** Complexity: Performs at most N applications of the comparison `comp`, at most 2 * N applications of the projection `proj`, where N = last - first.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RandIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp**: The type of the function/function object to use (deduced).

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp**: `comp` is a callable object. The return value of the INVOKE operation applied to an object of type `Comp`, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `is_heap_until` algorithm returns a `hpx::future<RandIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `RandIter` otherwise. The `is_heap_until` algorithm returns the upper bound of the largest range beginning at first which is a max heap. That is, the last iterator `it` for which range `[first, it)` is a max heap.

```
namespace hpx
```
Functions

```cpp
template<typename FwdIter, typename Pred>
bool is_partitioned(FwdIter first, FwdIter last, Pred &&pred)
    Determines if the range [first, last) is partitioned.
```

**Note** Complexity: at most (N) predicate evaluations where N = distance(first, last).

**Return** The `is_partitioned` algorithm returns `bool`. The `is_partitioned` algorithm returns true if each element in the sequence for which `pred` returns true precedes those for which `pred` returns false. Otherwise, `is_partitioned` returns false. If the range [first, last) contains less than two elements, the function is always true.

**Template Parameters**
- `FwdIter`: The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- `Pred`: The type of the function/function object to use (deduced).

**Parameters**
- `first`: Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- `last`: Refers to the end of the sequence of elements of that the algorithm will be applied to.
- `pred`: Refers to the unary predicate which returns true for elements expected to be found in the beginning of the range. The signature of the function should be equivalent to
  ```cpp
  bool pred(const Type &a);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.

```cpp
template<typename ExPolicy, typename FwdIter, typename Pred>
util::detail::algorithm_result<ExPolicy, bool>::type is_partitioned(ExPolicy &&policy, FwdIter first, FwdIter last, Pred &&pred)
    Determines if the range [first, last) is partitioned.
```

The predicate operations in the parallel `is_partitioned` algorithm invoked with an execution policy object of type `sequenced_policy` executes in sequential order in the calling thread.

**Note** Complexity: at most (N) predicate evaluations where N = distance(first, last).

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter`: The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- `Pred`: The type of the function/function object to use (deduced). `Pred` must be `CopyConstructible` when using a parallel policy.
Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements that the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements that the algorithm will be applied to.
- **pred**: Refers to the unary predicate which returns true for elements expected to be found in the beginning of the range. The signature of the function should be equivalent to
  
  ```cpp
  bool pred(const Type &a);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type Type must be such that objects of types FwdIter can be dereferenced and then implicitly converted to Type.

  The comparison operations in the parallel is_partitioned algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The is_partitioned algorithm returns a hpx::future<bool> if the execution policy is of type task_execution_policy and returns bool otherwise. The is_partitioned algorithm returns true if each element in the sequence for which pred returns true precedes those for which pred returns false. Otherwise is_partitioned returns false. If the range [first, last) contains less than two elements, the function is always true.

namespace hpx

Functions

template<typename FwdIter, typename Pred = hpx::parallel::v1::detail::less>
bool is_sorted(FwdIter first, FwdIter last, Pred &&pred = Pred())

Determines if the range [first, last) is sorted. Uses pred to compare elements.

The comparison operations in the parallel is_sorted algorithm executes in sequential order in the calling thread.

Note Complexity: at most (N+S-1) comparisons where \( N = \text{distance(first, last)} \). \( S \) = number of partitions

Template Parameters

- **FwdIter**: The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred**: The type of an optional function/function object to use.

Parameters

- **first**: Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred**: Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to
The signature does not need to have const &, but the function must not modify the objects passed to it. The type Type must be such that objects of types FwdIter can be dereferenced and then implicitly converted to Type.

Return The is_sorted algorithm returns a bool. The is_sorted algorithm returns true if each element in the sequence [first, last) satisfies the predicate passed. If the range [first, last) contains less than two elements, the function always returns true.

determines if the range [first, last) is sorted. Uses pred to compare elements.

The comparison operations in the parallel is_sorted algorithm invoked with an execution policy object of type sequenced_policy executes in sequential order in the calling thread.

Note Complexity: at most (N+S-1) comparisons where N = distance(first, last). S = number of partitions

Template Parameters

- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- FwdIter: The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- Pred: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of is_sorted requires Pred to meet the requirements of CopyConstructible. This defaults to std::less<>

Parameters

- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- last: Refers to the end of the sequence of elements of that the algorithm will be applied to.
- pred: Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to
Return The `is_sorted` algorithm returns a `hpx::future<bool>` if the execution policy is of type `task_execution_policy` and returns `bool` otherwise. The `is_sorted` algorithm returns a bool if each element in the sequence [first, last) satisfies the predicate passed. If the range [first, last) contains less than two elements, the function always returns true.

```cpp
template<typename FwdIter, typename Pred = hpx::parallel::v1::detail::less>
FwdIter is_sorted_until (FwdIter first, FwdIter last, Pred &&pred = Pred())
```

Returns the first element in the range [first, last) that is not sorted. Uses a predicate to compare elements or the less than operator.

The comparison operations in the parallel `is_sorted_until` algorithm execute in sequential order in the calling thread.

Note Complexity: at most (N+S-1) comparisons where N = distance(first, last). S = number of partitions

Template Parameters
- **FwdIter**: The type of the source iterators used for the This iterator type must meet the require-
ments of a forward iterator.
- **Pred**: The type of an optional function/function object to use.

Parameters
- **first**: Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred**: Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a, const Type &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to Type.

Return The `is_sorted_until` algorithm returns a `FwdIter`. The `is_sorted_until` algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, last is returned.

```cpp
template<typename ExPolicy, typename FwdIter, typename Pred = hpx::parallel::v1::detail::less>
hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type is_sorted_until (ExPolicy &&policy,
FwdIter first,
FwdIter last, Pred &&pred = Pred())
```

Returns the first element in the range [first, last) that is not sorted. Uses a predicate to compare elements or the less than operator.

The comparison operations in the parallel `is_sorted_until` algorithm invoked with an execution policy object of type `sequenced_policy` executes in sequential order in the calling thread.
Note Complexity: at most \((N+S-1)\) comparisons where \(N = \text{distance}(\text{first}, \text{last})\). \(S = \text{number of partitions}\)

Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `is_sorted_until` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to std::less<>

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred**: Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a, const Type &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.

The comparison operations in the parallel `is_sorted_until` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The `is_sorted_until` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `is_sorted_until` algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, last is returned.

namespace hpx

### Functions

#### template<typename InIter1, typename InIter2, typename Pred>

```cpp
bool lexicographical_compare(InIter1 first1, InIter1 last1, InIter2 first2, InIter2 last2, Pred &&pred)
```

Checks if the first range \([\text{first1}, \text{last1})\) is lexicographically less than the second range \([\text{first2}, \text{last2})\). uses a provided predicate to compare elements.

The comparison operations in the parallel `lexicographical_compare` algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Note Complexity: At most \(2 \times \min(N1, N2)\) applications of the comparison operation, where \(N1 = \text{std::distance}(\text{first1}, \text{last})\) and \(N2 = \text{std::distance}(\text{first2}, \text{last2})\).
• **InIter1**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an input iterator.

• **InIter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an input iterator.

• **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `lexicographical_compare` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`

### Parameters

- **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

- **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

- **first2**: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

- **last2**: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

- **pred**: Refers to the comparison function that the first and second ranges will be applied to

### Note

Lexicographical comparison is an operation with the following properties:

- Two ranges are compared element by element

- The first mismatching element defines which range is lexicographically less or greater than the other

- If one range is a prefix of another, the shorter range is lexicographically less than the other

- If two ranges have equivalent elements and are of the same length, then the ranges are lexicographically equal

- An empty range is lexicographically less than any non-empty range

- Two empty ranges are lexicographically equal

### Return

The `lexicographical_compare` algorithm returns a returns `bool` if the execution policy object is not passed in. The `lexicographical_compare` algorithm returns true if the first range is lexicographically less, otherwise it returns false. range `{first2, last2}`, it returns false.

```cpp
template<typename FwdIter1, typename FwdIter2, typename Pred>
util::detail::algorithm_result<ExPolicy, bool>::type lexicographical_compare(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, Pred &&pred)
```

Checks if the first range `{first1, last1}` is lexicographically less than the second range `{first2, last2}`. uses a provided predicate to compare elements.

The comparison operations in the parallel `lexicographical_compare` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.
Note Complexity: At most 2 * min(N1, N2) applications of the comparison operation, where N1 = std::distance(first1, last) and N2 = std::distance(first2, last2).

**Template Parameters**

- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- FwdIter1: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- FwdIter2: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- Pred: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of lexicographical_compare requires Pred to meet the requirements of Copy-Constructible. This defaults to std::less<>

**Parameters**

- policy: The execution policy to use for the scheduling of the iterations.
- first1: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- last1: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- first2: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- last2: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- pred: Refers to the comparison function that the first and second ranges will be applied to.

The comparison operations in the parallel lexicographical_compare algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note** Lexicographical comparison is an operation with the following properties

- Two ranges are compared element by element
- The first mismatching element defines which range is lexicographically less or greater than the other
- If one range is a prefix of another, the shorter range is lexicographically less than the other
- If two ranges have equivalent elements and are of the same length, then the ranges are lexicographically equal
- An empty range is lexicographically less than any non-empty range
- Two empty ranges are lexicographically equal

**Return** The lexicographical_compare algorithm returns a hpx::future<bool> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns bool otherwise. The lexicographically_compare algorithm returns true if the first range is lexicographically less, otherwise it returns false. range [first2, last2), it returns false.
Functions

```cpp
template<typename ExPolicy, typename RndIter, typename Comp>
util::detail::algorithm_result<ExPolicy>::type make_heap(ExPolicy &&policy, RndIter first, RndIter last, Comp &&comp)
```

Constructs a `max heap` in the range `[first, last).

The predicate operations in the parallel `make_heap` algorithm invoked with an execution policy object of type `sequential_execution_policy` executes in sequential order in the calling thread.

**Note** Complexity: at most \((3*N)\) comparisons where \(N = \text{distance(first, last)}\).

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `RndIter`: The type of the source iterators used for algorithm. This iterator must meet the requirements for a random access iterator.

**Parameters**

- `first`: Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- `last`: Refers to the end of the sequence of elements of that the algorithm will be applied to.
- `comp`: Refers to the binary predicate which returns true if the first argument should be treated as less than the second. The signature of the function should be equivalent to

```cpp
bool comp(const Type &a, const Type &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `RndIter` can be dereferenced and then implicitly converted to `Type`.

The comparison operations in the parallel `make_heap` algorithm invoked with an execution policy object of type `parallel_execution_policy` or `parallel_task_execution_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `make_heap` algorithm returns a `hpx::future<void>` if the execution policy is of type `task_execution_policy` and returns `void` otherwise.

```cpp
template<typename ExPolicy, typename RndIter>
hpx::parallel::util::detail::algorithm_result<ExPolicy>::type make_heap(ExPolicy &&policy, RndIter first, RndIter last)
```

Constructs a `max heap` in the range `[first, last). Uses the operator `<` for comparisons.

The predicate operations in the parallel `make_heap` algorithm invoked with an execution policy object of type `sequential_execution_policy` executes in sequential order in the calling thread.

**Note** Complexity: at most \((3*N)\) comparisons where \(N = \text{distance(first, last)}\).

**Template Parameters**
• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• RndIter: The type of the source iterators used for algorithm. This iterator must meet the requirements for a random access iterator.

Parameters

• first: Refers to the beginning of the sequence of elements of that the algorithm will be applied to.

• last: Refers to the end of the sequence of elements of that the algorithm will be applied to.

The comparison operations in the parallel make_heap algorithm invoked with an execution policy object of type parallel_execution_policy or parallel_task_execution_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The make_heap algorithm returns a hpx::future<void> if the execution policy is of type task_execution_policy and returns void otherwise.

namespace hpx

Functions

template<typename ExPolicy, typename RandIter1, typename RandIter2, typename RandIter3, typename Comp = detail::less>
util::detail::algorithm_result<ExPolicy, RandIter3>::type merge(ExPolicy &&policy, RandIter1 first1, RandIter1 last1, RandIter2 first2, RandIter2 last2, RandIter3 dest, Comp &&comp = Comp())

Merges two sorted ranges [first1, last1) and [first2, last2) into one sorted range beginning at dest. The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. The destination range cannot overlap with either of the input ranges.

The assignments in the parallel merge algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Performs O(std::distance(first1, last1) + std::distance(first2, last2)) applications of the comparison comp and the each projection.

Template Parameters

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• RandIter1: The type of the source iterators used (deduced) representing the first sorted range. This iterator type must meet the requirements of an random access iterator.

• RandIter2: The type of the source iterators used (deduced) representing the second sorted range. This iterator type must meet the requirements of an random access iterator.

• RandIter3: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an random access iterator.
• **Comp**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `merge` requires `Comp` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`.

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the first range of elements the algorithm will be applied to.
- **last1**: Refers to the end of the first range of elements the algorithm will be applied to.
- **first2**: Refers to the beginning of the second range of elements the algorithm will be applied to.
- **last2**: Refers to the end of the second range of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **comp**: `comp` is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```cpp
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `RandIter1` and `RandIter2` can be dereferenced and then implicitly converted to both `Type1` and `Type2`.

The assignments in the parallel `merge` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

### Return

The `merge` algorithm returns a `hpx::future<RandIter3>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `tagged_tuple<RandIter3>` otherwise. The `merge` algorithm returns the destination iterator to the end of the `dest` range.

```cpp
template<typename ExPolicy, typename RandIter, typename Comp = detail::less>
tinterface::algorithm_result<ExPolicy>::type inplace_merge(ExPolicy &&policy, RandIter first, RandIter middle, RandIter last, Comp &&comp = Comp())
```

Merges two consecutive sorted ranges `[first, middle)` and `[middle, last)` into one sorted range `[first, last)`. The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range.

The assignments in the parallel `inplace_merge` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

### Note

Complexity: Performs O(std::distance(first, last)) applications of the comparison `comp` and the each projection.

### Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RandIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an random access iterator.
Comp: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `inplace_merge` requires `Comp` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`

**Parameters**

- `policy`: The execution policy to use for the scheduling of the iterations.
- `first`: Refers to the beginning of the first sorted range the algorithm will be applied to.
- `middle`: Refers to the end of the first sorted range and the beginning of the second sorted range the algorithm will be applied to.
- `last`: Refers to the end of the second sorted range the algorithm will be applied to.
- `comp`: `comp` is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```cpp
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `RandIter` can be dereferenced and then implicitly converted to both `Type1` and `Type2`.

The assignments in the parallel `inplace_merge` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `inplace_merge` algorithm returns a `hpx::future<void>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns void otherwise. The `inplace_merge` algorithm returns the source iterator `last`.

```cpp
default namespace hpx

default namespace parallel

**Functions**

```cpp
template<typename ExPolicy, typename FwdIter, typename Proj = util::projection_identity, typename F = detail::less>
util::detail::algorithm_result<ExPolicy, FwdIter>::type min_element (ExPolicy &&policy,
FwdIter first, FwdIter last,
F &&f = F(), Proj &&proj
= Proj())
```

Finds the smallest element in the range `[first, last)` using the given comparison function `f`.

The comparisons in the parallel `min_element` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Exactly \( \text{max}(N-1, 0) \) comparisons, where \( N = \text{std::distance}(first, last) \).

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter`: The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
• F: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `min_element` requires F to meet the requirements of `CopyConstructible.`

• Proj: The type of an optional projection function. This defaults to `util::projection_identity`.

Parameters

• policy: The execution policy to use for the scheduling of the iterations.
• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• last: Refers to the end of the sequence of elements the algorithm will be applied to.
• f: The binary predicate which returns true if the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);`
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

• proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The comparisons in the parallel `min_element` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return

The `min_element` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `min_element` algorithm returns the iterator to the smallest element in the range `[first, last)` if several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```cpp
template<typename ExPolicy, typename FwdIter, typename Proj = util::projection_identity, typename F = detail::less>
util::detail::algorithm_result<ExPolicy, FwdIter>::type max_element (ExPolicy &&policy,
    FwdIter first, FwdIter last,
    F &&f = F(), Proj &&proj = Proj())
```

Finds the greatest element in the range `[first, last)` using the given comparison function `f`.

The comparisons in the parallel `max_element` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

Note

Complexity: Exactly `max(N-1, 0)` comparisons, where `N = std::distance(first, last)`.

Template Parameters

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• FwdIter: The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
• F: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `max_element` requires F to meet the requirements of `CopyConstructible`.
• Proj: The type of an optional projection function. This defaults to `util::projection_identity`.

Parameters

• policy: The execution policy to use for the scheduling of the iterations.
• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• last: Refers to the end of the sequence of elements the algorithm will be applied to.
• f: The binary predicate which returns true if the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:
The signature does not need to have const &, but the function must not modify the objects passed to it. The type Type1 must be such that objects of type FwdIter can be dereferenced and then implicitly converted to Type1.

- proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The comparisons in the parallel max_element algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The max_element algorithm returns a hpx::future<FwdIter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter otherwise. The max_element algorithm returns the iterator to the smallest element in the range [first, last). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

The comparisons in the parallel minmax_element algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: At most max(floor(3/2*(N-1)), 0) applications of the predicate, where N = std::distance(first, last).

Template Parameters

- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- FwdIter: The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- F: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of minmax_element requires F to meet the requirements of CopyConstructible.
- Proj: The type of an optional projection function. This defaults to util::projection_identity.

Parameters

- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last: Refers to the end of the sequence of elements the algorithm will be applied to.
- f: The binary predicate which returns true if the the left argument is less than the right element. This argument is optional and defaults to std::less. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type Type1 must be such that objects of type FwdIter can be dereferenced and then implicitly converted to Type1.

- proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The comparisons in the parallel minmax_element algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in
unspecified threads, and indeterminately sequenced within each thread.

**Return** The `minmax_element` algorithm returns a `hpx::future<tagged_pair<tag::min(FwdIter), tag::max(FwdIter)>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `tagged_pair<tag::min(FwdIter), tag::max(FwdIter)>>` otherwise. The `minmax_element` algorithm returns a pair consisting of an iterator to the smallest element as the first element and an iterator to the greatest element as the second. Returns `std::make_pair(first, first)` if the range is empty. If several elements are equivalent to the smallest element, the iterator to the first such element is returned. If several elements are equivalent to the largest element, the iterator to the last such element is returned.

```cpp
namespace hpx

Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result<ExPolicy, std::pair<FwdIter1, FwdIter2>>::type mismatch(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, Pred &&op = Pred())
```

Returns true if the range `[first1, last1)` is mismatch to the range `[first2, last2)`, and false otherwise.

The comparison operations in the parallel `mismatch` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: At most `min(last1 - first1, last2 - first2)` applications of the predicate `f`. If `FwdIter1` and `FwdIter2` meet the requirements of `RandomAccessIterator` and `(last1 - first1) != (last2 - first2)` then no applications of the predicate `f` are made.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `mismatch` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
• first1: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
• last1: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
• first2: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
• last2: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
• op: The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively.

The comparison operations in the parallel mismatch algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note** The two ranges are considered mismatch if, for every iterator i in the range [first1,last1), *i mismatches *(first2 + (i - first1)). This overload of mismatch uses operator== to determine if two elements are mismatch.

**Return** The mismatch algorithm returns a hpx::future<bool> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns bool otherwise. The mismatch algorithm returns true if the elements in the two ranges are mismatch, otherwise it returns false. If the length of the range [first1, last1) does not mismatch the length of the range [first2, last2), it returns false.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result<ExPolicy, std::pair<FwdIter1, FwdIter2>>::type mismatch(ExPolicy &&policy,
FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, Pred &&op = Pred())
```

Returns std::pair with iterators to the first two non-equivalent elements.

The comparison operations in the parallel mismatch algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: At most last1 - first1 applications of the predicate f.

**Template Parameters**

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• **FwdIter1**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

• **FwdIter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

• **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `mismatch` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2**: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **op**: The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

  The comparison operations in the parallel `mismatch` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

### Return

The `mismatch` algorithm returns a `hpx::future<std::pair<FwdIter1, FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `std::pair<FwdIter1, FwdIter2>` otherwise. The `mismatch` algorithm returns the first mismatching pair of elements from two ranges: one defined by `[first1, last1)` and another defined by `[first2, last2)`.

```cpp
namespace hpx

Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
util::detail::algorithm_result<ExPolicy, FwdIter2>::type move(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest)

  Moves the elements in the range [first, last), to another range beginning at dest. After this operation the elements in the moved-from range will still contain valid values of the appropriate type, but not necessarily the same values as before the move.

  The move assignments in the parallel `move` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

  Note: Complexity: Performs exactly `last - first` move assignments.

Template Parameters
ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the move assignments.

FwdIter1: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

FwdIter2: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters
- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last: Refers to the end of the sequence of elements the algorithm will be applied to.
- dest: Refers to the beginning of the destination range.

The move assignments in the parallel move algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The move algorithm returns a hpx: :future<tagged_pair<tag::in(FwdIter1), tag::out(FwdIter2)>> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns tagged_pair<tag::in(FwdIter1), tag::out(FwdIter2)>> otherwise. The move algorithm returns the pair of the input iterator last and the output iterator to the element in the destination range, one past the last element moved.

namespace hpx

Functions

template<typename RandIter>
util::detail::algorithm_result<ExPolicy>::type partial_sort (ExPolicy &&policy, RandIter first, RandIter middle, RandIter last)

Places the first middle - first elements from the range [first, last) as sorted with respect to comp into the range [first, middle). The rest of the elements in the range [middle, last) are placed in an unspecified order.

Note Complexity: Approximately (last - first) * log(middle - first) comparisons.

Return The partial_sort algorithm returns a hpx: :future<void> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns void otherwise.

Template Parameters
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- RandIter: The type of the source begin, middle, and end iterators used (deduced). This iterator type must meet the requirements of a random access iterator.

Parameters
- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• *middle*: Refers to the middle of the sequence of elements the algorithm will be applied to.

• *last*: Refers to the end of the sequence of elements the algorithm will be applied to.

```cpp
namespace hpx

namespace parallel

Functions

template<typename ExPolicy, typename BidirIter, typename F, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, BidirIter>::type stable_partition(ExPolicy &&policy,
    BidirIter first, BidirIter last, F &&f, Proj &&proj = Proj())
```

Permutes the elements in the range [first, last) such that there exists an iterator i such that for every iterator j in the range [first, i) \( \text{INVOKE}(f, \text{INVOKE}(n, *j)) \neq \text{false} \), and for every iterator k in the range [i, last), \( \text{INVOKE}(f, \text{INVOKE}(n, *k)) = \text{false} \)

The invocations of \( f \) in the parallel \textit{stable_partition} algorithm invoked with an execution policy object of type \textit{sequenced_policy} executes in sequential order in the calling thread.

**Note** Complexity: At most \((\text{last} - \text{first}) * \log(\text{last} - \text{first})\) swaps, but only linear number of swaps if there is enough extra memory. Exactly last - first applications of the predicate and projection.

**Template Parameters**

• *ExPolicy*: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of \( f \).

• *BidirIter*: The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.

• *F*: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \textit{transform} requires \( F \) to meet the requirements of \textit{CopyConstructible}.

• *Proj*: The type of an optional projection function. This defaults to \textit{util::projection_identity}.

**Parameters**

• *policy*: The execution policy to use for the scheduling of the iterations.

• *first*: Refers to the beginning of the sequence of elements the algorithm will be applied to.

• *last*: Refers to the end of the sequence of elements the algorithm will be applied to.

• *f*: Unary predicate which returns true if the element should be ordered before other elements. Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last}]\). The signature of this predicate should be equivalent to:

```cpp
bool fun(const Type &a);
```

The signature does not need to have \textit{const}\. The type \textit{Type} must be such that an object of type \textit{BidirIter} can be dereferenced and then implicitly converted to \textit{Type}.

• *proj*: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate \( f \) is invoked.

The invocations of \( f \) in the parallel \textit{stable_partition} algorithm invoked with an execution policy object of type \textit{parallel_policy} or \textit{parallel_task_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
**Return** The *stable_partition* algorithm returns an iterator i such that for every iterator j in the range [first, i), \( f(*j) \neq \text{false} \) \( \text{INVOKE}(f, \text{INVOKE}(\text{proj}, *j)) \neq \text{false} \), and for every iterator k in the range [i, last), \( f(*k) = \text{false} \) \( \text{INVOKE}(f, \text{INVOKE}(\text{proj}, *k)) = \text{false} \). The relative order of the elements in both groups is preserved. If the execution policy is of type *parallel_task_policy* the algorithm returns a future<> referring to this iterator.

```cpp
template<typename ExPolicy, typename FwdIter, typename Pred, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, FwdIter>::type
partition(ExPolicy &&policy, FwdIter first, FwdIter last, Pred &&pred, Proj &&proj = Proj())
```

Reorders the elements in the range [first, last) in such a way that all elements for which the predicate *pred* returns true precede the elements for which the predicate *pred* returns false. Relative order of the elements is not preserved.

The assignments in the parallel *partition* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

**Note** Complexity: At most 2 * (last - first) swaps. Exactly last - first applications of the predicate and projection.

**Template Parameters**
- *ExPolicy*: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- *FwdIter*: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- *Pred*: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *partition* requires *Pred* to meet the requirements of *CopyConstructible*.
- *Proj*: The type of an optional projection function. This defaults to *util::projection_identity*

**Parameters**
- *policy*: The execution policy to use for the scheduling of the iterations.
- *first*: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- *last*: Refers to the end of the sequence of elements the algorithm will be applied to.
- *pred*: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *InIter* can be dereferenced and then implicitly converted to *Type*.
- *proj*: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel *partition* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The *partition* algorithm returns a *hpx::future<FwdIter>* if the execution policy is of type *parallel_task_policy* and returns *FwdIter* otherwise. The *partition* algorithm returns the iterator to the first element of the second group.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, hpx::util::tagged_tuple<tag::in(FwdIter1), tag::out2FwdIter1, tag::out2FwdIter2, tag::out1FwdIter3>>::type
partition_copy(ExPolicy &&policy, FwdIter1 first, FwdIter2 last, Pred &&pred, Proj &&proj = Proj())
```
FwdIter1 last, FwdIter2 dest_true, FwdIter3 dest_false, Pred && pred, Proj && proj = Proj() Copy the elements in the range, defined by [first, last), to two different ranges depending on the value returned by the predicate pred. The elements, that satisfy the predicate pred, are copied to the range beginning at dest_true. The rest of the elements are copied to the range beginning at dest_false. The order of the elements is preserved.

The assignments in the parallel partition_copy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than last - first assignments, exactly last - first applications of the predicate f.

**Template Parameters**
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- FwdIter1: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- FwdIter2: The type of the iterator representing the destination range for the elements that satisfy the predicate pred (deduced). This iterator type must meet the requirements of an forward iterator.
- FwdIter3: The type of the iterator representing the destination range for the elements that don’t satisfy the predicate pred (deduced). This iterator type must meet the requirements of an forward iterator.
- Pred: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of partition_copy requires Pred to meet the requirements of CopyConstructible.
- Proj: The type of an optional projection function. This defaults to util::projection_identity

**Parameters**
- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last: Refers to the end of the sequence of elements the algorithm will be applied to.
- dest_true: Refers to the beginning of the destination range for the elements that satisfy the predicate pred.
- dest_false: Refers to the beginning of the destination range for the elements that don’t satisfy the predicate pred.
- pred: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type FwdIter1 can be dereferenced and then implicitly converted to Type.
- proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel partition_copy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The partition_copy algorithm returns a hpx::future<tagged_tuple<tag::in(InIter), tag::out1(OutIter1), tag::out2(OutIter2)>> if the execution policy is of type parallel_task_policy and returns tagged_tuple<tag::in(InIter), tag::out1(OutIter1), tag::out2(OutIter2)>> otherwise. The partition_copy algorithm returns the tuple of the source iterator last, the destination iterator
to the end of the dest_true range, and the destination iterator to the end of the dest_false range.

namespace hpx

Functions

template<typename ExPolicy, typename FwdIter, typename T, typename F>
util::detail::algorithm_result<ExPolicy, T>::type reduce (ExPolicy &&policy, FwdIter first, FwdIter last, T init, F &&f)
Returns GENERALIZED_SUM(f, init, *first, ..., *(first + (last - first) - 1)).

The reduce operations in the parallel reduce algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: O(last - first) applications of the predicate f.

Template Parameters

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• FwdIter: The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

• F: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of copy_if requires F to meet the requirements of CopyConstructible.

• T: The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

• policy: The execution policy to use for the scheduling of the iterations.

• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.

• last: Refers to the end of the sequence of elements the algorithm will be applied to.

• f: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&. The types Type1 Ret must be such that an object of type FwdIter can be dereferenced and then implicitly converted to any of those types.

• init: The initial value for the generalized sum.

The reduce operations in the parallel copy_if algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between reduce and accumulate is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Return The reduce algorithm returns a hpx::future<T> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns T otherwise. The reduce algorithm returns the result of the generalized sum over the elements given by the input range [first, last).
**Note** GENERALIZED\_SUM(op, a1, \ldots, aN) is defined as follows:

- \( a1 \) when \( N = 1 \)
- \( \text{op}(\text{GENERALIZED\_SUM}(\text{op, } b1, \ldots, bK), \text{GENERALIZED\_SUM}(\text{op, } bM, \ldots, bN)) \), where:
  - \( b1, \ldots, bN \) may be any permutation of \( a1, \ldots, aN \) and
  - \( 1 < K+1 = M \leq N \).

\[
\text{template<typename } \text{ExPolicy, typename FwdIter, typename T}> \\
\text{util::detail::algorithm_result<ExPolicy, T>::type } \text{reduce (ExPolicy } \&\&\text{policy, FwdIter first, FwdIter last, T init)} \\
\text{Returns } \text{GENERALIZED\_SUM}(+, \text{init, } *\text{first, \ldots, } *\text{(first + (last - first) - 1)}).
\]

The reduce operations in the parallel \text{reduce} algorithm invoked with an execution policy object of type \text{sequenced\_policy} execute in sequential order in the calling thread.

**Note** Complexity: \( O(last - first) \) applications of the operator\(+\).

**Template Parameters**

- \text{ExPolicy}: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- \text{FwdIter}: The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- \text{T}: The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**

- \text{policy}: The execution policy to use for the scheduling of the iterations.
- \text{first}: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- \text{last}: Refers to the end of the sequence of elements the algorithm will be applied to.
- \text{init}: The initial value for the generalized sum.

The reduce operations in the parallel \text{copy\_if} algorithm invoked with an execution policy object of type \text{parallel\_policy} or \text{parallel\_task\_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between \text{reduce} and \text{accumulate} is that the behavior of \text{reduce} may be non-deterministic for non-associative or non-commutative binary predicate.

**Return** The \text{reduce} algorithm returns a \text{hpx::future<T>} if the execution policy is of type \text{sequenced\_task\_policy} or \text{parallel\_task\_policy} and returns \text{T} otherwise. The \text{reduce} algorithm returns the result of the generalized sum (applying operator\(+\)) over the elements given by the input range [first, last).
template<typename ExPolicy, typename FwdIter>
util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<FwdIter>::value_type>::type reduce(ExPolicy &&policy, FwdIter first, FwdIter last)

Returns GENERALIZED_SUM(+, T(), *first, . . . , *(first + (last - first) - 1)).

The reduce operations in the parallel reduce algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: O(last - first) applications of the operator+().

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.

The reduce operations in the parallel copy_if algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between reduce and accumulate is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

**Return** The reduce algorithm returns a hpx::future<T> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns T otherwise (where T is the value_type of FwdIter). The reduce algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

**Note** The type of the initial value (and the result type) T is determined from the value_type of the used FwdIter.

**Note** GENERALIZED_SUM(+, a1, . . . , aN) is defined as follows:
- a1 when N is 1
- op(GENERALIZED_SUM(+, b1, . . . , bK), GENERALIZED_SUM(+, bM, . . . , bN)), where:
  - b1, . . . , bN may be any permutation of a1, . . . , aN and
  - 1 < K+1 = M <= N.
Functions

```cpp
template<typename ExPolicy, typename RanIter, typename RanIter2, typename FwdIter1, typename FwdIter2, typename Compare = std::equal_to<typename std::iterator_traits<RanIter>::value_type>, typename Func = std::plus<typename std::iterator_traits<RanIter2>::value_type>>
util::detail::algorithm_result<ExPolicy, util::in_out_result<FwdIter1, FwdIter2>>::type reduce_by_key(ExPolicy &&policy, RanIter key_first, RanIter key_last, RanIter2 values_first, FwdIter1 keys_output, FwdIter2 values_output, Compare &&comp = Compare(), Func &&func = Func())
```

Reduce by Key performs an inclusive scan reduction operation on elements supplied in key/value pairs. The algorithm produces a single output value for each set of equal consecutive keys in [key_first, key_last). The value being the GENERALIZED_NONCOMMUTATIVE_SUM(op, init, *first, . . . , *(first + (i - result))). for the run of consecutive matching keys. The number of keys supplied must match the number of values.

`comp` has to induce a strict weak ordering on the values.

**Note** Complexity: $O(\text{last} - \text{first})$ applications of the predicate `op`.

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- `RanIter`: The type of the key iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- `RanIter2`: The type of the value iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- `FwdIter1`: The type of the iterator representing the destination key range (deduced). This iterator type must meet the requirements of an random access iterator.
- `FwdIter2`: The type of the iterator representing the destination value range (deduced). This iterator type must meet the requirements of an forward iterator.
- `Compare`: The type of the optional function/function object to use to compare keys (deduced). Assumed to be `std::equal_to` otherwise.
- `Func`: The type of the function/function object to use (deduced). Unlike its sequential form,
the parallel overload of *copy_if* requires \( F \) to meet the requirements of *CopyConstructible*.

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **key_first**: Refers to the beginning of the sequence of key elements the algorithm will be applied to.
- **key_last**: Refers to the end of the sequence of key elements the algorithm will be applied to.
- **values_first**: Refers to the beginning of the sequence of value elements the algorithm will be applied to.
- **keys_output**: Refers to the start output location for the keys produced by the algorithm.
- **values_output**: Refers to the start output location for the values produced by the algorithm.
- **comp**: comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.
- **func**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\). This is a binary predicate. The signature of this predicate should be equivalent to:

\[
\text{Ret fun(const Type1 &a, const Type1 &b);}
\]

The signature does not need to have const&. The types *Type1 Ret* must be such that an object of type *FwdIter* can be dereferenced and then implicitly converted to any of those types.

The application of function objects in parallel algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The *reduce_by_key* algorithm returns a hpx::future\(<\text{pair<Iter1,Iter2>>}\) if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns \(<\text{pair<Iter1,Iter2>>}\) otherwise.

```
namespace hpx {

Functions

template<typename FwdIter, typename T>
FwdIter remove(FwdIter first, FwdIter last, T const &value)

Removes all elements satisfying specific criteria from the range \([\text{first}, \text{last})\) and returns a past-the-end iterator for the new end of the range. This version removes all elements that are equal to *value*.

The assignments in the parallel *remove* algorithm execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than \(\text{last} - \text{first}\) assignments, exactly \(\text{last} - \text{first}\) applications of the operator==().

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T**: The type of the value to remove (deduced). This value type must meet the requirements of `CopyConstructible`.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **value**: Specifies the value of elements to remove.

**Return** The `remove` algorithm returns a `FwdIter`. The `remove` algorithm returns the iterator to the new end of the range.

```cpp
template<typename ExPolicy, typename FwdIter, typename T>
util::detail::algorithm_result<ExPolicy, FwdIter>::type remove(
    ExPolicy &&policy, FwdIter first,
    FwdIter last, T const &value)
```

Removes all elements satisfying specific criteria from the range `[first, last)` and returns a past-the-end iterator for the new end of the range. This version removes all elements that are equal to `value`.

The assignments in the parallel `remove` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than `last - first` assignments, exactly `last - first` applications of the operator `==`.

**Template Parameters**

- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T**: The type of the value to remove (deduced). This value type must meet the requirements of `CopyConstructible`.

**Parameters**

- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **value**: Specifies the value of elements to remove.

The assignments in the parallel `remove` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `remove` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `remove` algorithm returns the iterator to the new end of the range.

```cpp
template<typename FwdIter, typename Pred>
FwdIter remove_if (FwdIter first, FwdIter last, Pred &pred)
```

Removes all elements satisfying specific criteria from the range `[first, last)` and returns a past-the-end
iterator for the new end of the range. This version removes all elements for which predicate \( \text{pred} \) returns true.

The assignments in the parallel \texttt{remove\_if} algorithm execute in sequential order in the calling thread.

\textbf{Note} Complexity: Performs not more than \( \text{last} - \text{first} \) assignments, exactly \( \text{last} - \text{first} \) applications of the predicate \( \text{pred} \).

\textbf{Template Parameters}

- \( \text{FwdIter} \): The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

- \( \text{Pred} \): The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \texttt{remove\_if} requires \( \text{Pred} \) to meet the requirements of \texttt{CopyConstructible}.

\textbf{Parameters}

- \( \text{first} \): Refers to the beginning of the sequence of elements the algorithm will be applied to.

- \( \text{last} \): Refers to the end of the sequence of elements the algorithm will be applied to.

- \( \text{pred} \): Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last}]\). This is an unary predicate which returns \textit{true} for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have \texttt{const\&}, but the function must not modify the objects passed to it. The type \texttt{Type} must be such that an object of type \texttt{FwdIter} can be dereferenced and then implicitly converted to \texttt{Type}.

\textbf{Return} The \texttt{remove\_if} algorithm returns a \texttt{FwdIter}. The \texttt{remove\_if} algorithm returns the iterator to the new end of the range.

\texttt{template<typename ExPolicy, typename FwdIter, typename Pred> util::detail::algorithm_result<ExPolicy, FwdIter>::type remove\_if(ExPolicy &&policy, FwdIter first, FwdIter last, Pred &&pred)}

Removes all elements satisfying specific criteria from the range \([\text{first}, \text{last}]\) and returns a past-the-end iterator for the new end of the range. This version removes all elements for which predicate \( \text{pred} \) returns true.

The assignments in the parallel \texttt{remove\_if} algorithm invoked with an execution policy object of type \texttt{sequenced\_policy} execute in sequential order in the calling thread.

\textbf{Note} Complexity: Performs not more than \( \text{last} - \text{first} \) assignments, exactly \( \text{last} - \text{first} \) applications of the predicate \( \text{pred} \).

\textbf{Template Parameters}

- \( \text{ExPolicy} \): The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- \( \text{FwdIter} \): The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
• **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `remove_if` requires `Pred` to meet the requirements of `CopyConstructible`.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

  ```cpp
  bool pred(const Type &a);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

  The assignments in the parallel `remove_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `remove_if` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `remove_if` algorithm returns the iterator to the new end of the range.

```cpp
namespace hpx

Functions

template<typename InIter, typename OutIter, typename T>
FwdIter remove_copy(InIter first, InIter last, OutIter dest, T const &value)

Copies the elements in the range, defined by `[first, last)`, to another range beginning at `dest`. Copies only the elements for which the comparison operator returns false when compare to value. The order of the elements that are not removed is preserved.

Effects: Copies all the elements referred to by the iterator it in the range `[first,last)` for which the following corresponding conditions do not hold: `*it == value`

The assignments in the parallel `remove_copy` algorithm execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than `last - first` assignments, exactly `last - first` applications of the predicate `f`.

**Template Parameters**

- **InIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **T**: The type that the result of dereferencing `FwdIter1` is compared to.

**Parameters**
• **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
• **dest**: Refers to the beginning of the destination range.
• **val**: Value to be removed.

**Return**  The remove_copy algorithm returns an **OutIter**. The remove_copy algorithm returns the iterator to the element past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename T>
FwdIter remove_copy(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest, T const &val)
```

Copies the elements in the range, defined by \([first, last)\), to another range beginning at \(dest\). Copies only the elements for which the comparison operator returns false when compare to value. The order of the elements that are not removed is preserved.

**Effects**: Copies all the elements referred to by the iterator it in the range \([first,last)\) for which the following corresponding conditions do not hold: \(*it == value\)

The assignments in the parallel remove_copy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note**  Complexity: Performs not more than \(last - first\) assignments, exactly \(last - first\) applications of the predicate \(f\).

**Template Parameters**

• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• **FwdIter1**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
• **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
• **T**: The type that the result of dereferencing FwdIter1 is compared to.

**Parameters**

• **policy**: The execution policy to use for the scheduling of the iterations.
• **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
• **dest**: Refers to the beginning of the destination range.
• **val**: Value to be removed.

The assignments in the parallel remove_copy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return**  The remove_copy algorithm returns a **hpx::future<FwdIter2>** if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter2 otherwise. The remove_copy algorithm returns the iterator to the element past the last element copied.
template<typename InIter, typename OutIter, typename Pred>
FwdIter remove_copy_if(InIter first, InIter last, OutIter dest, Pred &&pred)

Copies the elements in the range, defined by [first, last), to another range beginning at dest. Copies only the elements for which the predicate f returns false. The order of the elements that are not removed is preserved.

Effects: Copies all the elements referred to by the iterator it in the range [first,last) for which the following corresponding conditions do not hold: INVOKE(pred, *it) != false.

The assignments in the parallel remove_copy_if algorithm execute in sequential order in the calling thread.

Note  Complexity: Performs not more than last - first assignments, exactly last - first applications of the predicate f.

Template Parameters

- **InIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter**: The type of the iterator representing the destination range (deduced).
- **Pred**: The type of the function/function object to use (deduced).

Parameters

- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns true for the elements to be removed. The signature of this predicate should be equivalent to:

  ```cpp
  bool pred(const Type &a);
  ```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type InIter can be dereferenced and then implicitly converted to Type.

Return  The remove_copy_if algorithm returns an OutIter. The remove_copy_if algorithm returns the iterator to the element past the last element copied.

The assignments in the parallel remove_copy_if algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

2.8. API reference 1099
Note Complexity: Performs not more than last - first assignments, exactly last - first applications of the predicate $f$.

Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `remove_copy_if` requires Pred to meet the requirements of `CopyConstructible`.

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the elements to be removed. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`.

The assignments in the parallel `remove_copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The `remove_copy_if` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `remove_copy_if` algorithm returns the iterator to the element past the last element copied.

namespace hpx

Functions

template<typename InIter, typename T>
void replace(InIter first, InIter last, T const &old_value, T const &new_value)
Replaces all elements satisfying specific criteria with `new_value` in the range `[first, last)`. Effects: Substitutes elements referred by the iterator `it` in the range `[first, last) with new_value, when the following corresponding conditions hold: `*it == old_value`
The assignments in the parallel `replace` algorithm execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `last - first` assignments.

**Template Parameters**

- `InIter`: The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- `T`: The type of the old and new values to replace (deduced).

**Parameters**

- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last`: Refers to the end of the sequence of elements the algorithm will be applied to.
- `old_value`: Refers to the old value of the elements to replace.
- `new_value`: Refers to the new value to use as the replacement.

**Return** The `replace` algorithm returns a `void`.

```cpp
template<typename ExPolicy, typename FwdIter, typename T>
parallel::util::detail::algorithm_result<ExPolicy, void>::type replace(ExPolicy &&policy, FwdIter first, FwdIter last, T const &old_value, T const &new_value);
```

Replaces all elements satisfying specific criteria with `new_value` in the range `[first, last)`. Effects: Substitutes elements referred by the iterator `it` in the range `[first, last)` with `new_value`, when the following corresponding conditions hold: `*it == old_value`

The assignments in the parallel `replace` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `last - first` assignments.

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter`: The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- `T`: The type of the old and new values to replace (deduced).

**Parameters**

- `policy`: The execution policy to use for the scheduling of the iterations.
- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last`: Refers to the end of the sequence of elements the algorithm will be applied to.
- `old_value`: Refers to the old value of the elements to replace.
- `new_value`: Refers to the new value to use as the replacement.
The assignments in the parallel replace algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The replace algorithm returns a hpx::future<void> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns void otherwise.

```cpp
template<typename Iter, typename Pred, typename T>
void replace_if(Iter first, Iter last, Pred &&pred, T const &new_value)

Replaces all elements satisfying specific criteria (for which predicate f returns true) with new_value in the range [first, last).

Effects: Substitutes elements referred by the iterator it in the range [first, last) with new_value, when the following corresponding conditions hold: INVOKE(f, *it) != false

The assignments in the parallel replace_if algorithm execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly last - first applications of the predicate.

**Template Parameters**

- Iter: The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- Pred: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of equal requires Pred to meet the requirements of CopyConstructible. (deduced).
- T: The type of the new values to replace (deduced).

**Parameters**

- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last: Refers to the end of the sequence of elements the algorithm will be applied to.
- pred: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns true for the elements which need to be replaced. The signature of this predicate should be equivalent to:

  ```cpp
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type InIter can be dereferenced and then implicitly converted to Type.

- new_value: Refers to the new value to use as the replacement.

**Return** The replace_if algorithm returns void.

```cpp
template<typename ExPolicy, typename FwdIter, typename Pred, typename T>
parallel::util::detail::algorithm_result<ExPolicy, void>::type replace_if(ExPolicy &&policy, FwdIter first, FwdIter last, Pred &&pred, T const &new_value)

Replaces all elements satisfying specific criteria (for which predicate f returns true) with new_value in the range [first, last).
Effects: Substitutes elements referred by the iterator it in the range [first, last) with new_value, when the following corresponding conditions hold: INVOKE(f, *it) != false

The assignments in the parallel `replace_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly last - first applications of the predicate.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible` (deduced).
- **T**: The type of the new values to replace (deduced).

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns `true` for the elements which need to replaced. The signature of this predicate should be equivalent to:

  ```cpp
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- **new_value**: Refers to the new value to use as the replacement.

The assignments in the parallel `replace_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `replace_if` algorithm returns a `hpx::future<void>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `void` otherwise.

```cpp
template<typename InIter, typename OutIter, typename T>
OutIter replace_copy(InIter first, InIter last, OutIter dest, T const &old_value, T const &new_value)
```

Copies the all elements from the range [first, last) to another range beginning at dest replacing all elements satisfying a specific criteria with new_value.

Effects: Assigns to every iterator it in the range [result, result + (last - first)) either new_value or *(first + (it - result)) depending on whether the following corresponding condition holds: *(first + (i - result)) == old_value
The assignments in the parallel `replace_copy` algorithm execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `last - first` applications of the predicate. Of the algorithm may be parallelized and the manner in which it executes the assignments.

**Template Parameters**
- `InIter`: The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- `OutIter`: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- `T`: The type of the old and new values (deduced).

**Parameters**
- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last`: Refers to the end of the sequence of elements the algorithm will be applied to.
- `dest`: Refers to the beginning of the destination range.
- `old_value`: Refers to the old value of the elements to replace.
- `new_value`: Refers to the new value to use as the replacement.

**Return** The `replace_copy` algorithm returns an `OutIter`. The `replace_copy` algorithm returns the Iterator to the element past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename T>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type replace_copy(
    ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest,
    T const &old_value, T const &new_value)
```

Copies the all elements from the range `[first, last)` to another range beginning at `dest` replacing all elements satisfying a specific criteria with `new_value`.

Effects: Assigns to every iterator it in the range `[result, result + (last - first))` either `new_value` or *(first + (it - result)) depending on whether the following corresponding condition holds: *(first + (i - result)) == old_value

The assignments in the parallel `replace_copy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `last - first` applications of the predicate.

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter1`: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
• **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

• **T**: The type of the old and new values (deduced).

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **old_value**: Refers to the old value of the elements to replace.
- **new_value**: Refers to the new value to use as the replacement.

The assignments in the parallel `replace_copy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

### Return

The `replace_copy` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `replace_copy` algorithm returns the Iterator to the element past the last element copied.

```cpp
template<typename InIter, typename OutIter, typename Pred, typename T>
OutIter replace_copy_if(InIter first, InIter last, OutIter dest, Pred &&pred, T const &new_value)
```

Copies the all elements from the range `[first, last)` to another range beginning at `dest` replacing all elements satisfying a specific criteria with `new_value`.

Effects: Assigns to every iterator `it` in the range `[result, result + (last - first))` either `new_value` or `*(first + (i - result))` depending on whether the following corresponding condition holds: `INVOKE(f, *(first + (i - result))) != false`

The assignments in the parallel `replace_copy_if` algorithm execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `last - first` applications of the predicate.

### Template Parameters

- **InIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.

- **OutIter**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

- **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible`. (deduced).

- **T**: The type of the new values to replace (deduced).

### Parameters

- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.

- **dest**: Refers to the beginning of the destination range.
• **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the elements which need to be replaced. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `InIter` can be dereferenced and then implicitly converted to `Type`.

• **new_value**: Refers to the new value to use as the replacement.

**Return** The `replace_copy_if` algorithm returns an `OutIter`. The `replace_copy_if` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred, typename T>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type replace_copy_if(ExPolicy &&policy,
  FwdIter1 first,
  FwdIter1 last,
  FwdIter2 dest,
  Pred &&pred,
  T const &new_value)
```

Copies the all elements from the range `[first, last)` to another range beginning at `dest` replacing all elements satisfying a specific criteria with `new_value`.

**Effects**: Assigns to every iterator `it` in the range `[result, result + (last - first))` either `new_value` or `*(first + (it - result))` depending on whether the following corresponding condition holds: `INVOKE(f, *(first + (i - result))) != false`

The assignments in the parallel `replace_copy_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `last - first` applications of the predicate.

**Template Parameters**

• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **FwdIter1**: The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

• **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

• **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `F` to meet the requirements of `CopyConstructible`. (deduced).

• **T**: The type of the new values to replace (deduced).

**Parameters**

• **policy**: The execution policy to use for the scheduling of the iterations.

• **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **last**: Refers to the end of the sequence of elements the algorithm will be applied to.

• **dest**: Refers to the beginning of the destination range.

• **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns `true` for the elements which need to be replaced. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`.

• **new_value**: Refers to the new value to use as the replacement.

The assignments in the parallel `replace_copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `replace_copy_if` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `replace_copy_if` algorithm returns the iterator to the element in the destination range, one past the last element copied.

```cpp
namespace hpx
{

Functions

template<typename BidirIter>
void reverse(BidirIter first, BidirIter last)
{
    Reverses the order of the elements in the range [first, last). Behaves as if applying std::iter_swap to every pair of iterators first+i, (last-i) - 1 for each non-negative i < (last-first)/2.

    The assignments in the parallel `reverse` algorithm execute in sequential order in the calling thread.

    **Note** Complexity: Linear in the distance between `first` and `last`.

    **Template Parameters**
    • **BidirIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.

    **Parameters**
    • **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
    • **last**: Refers to the end of the sequence of elements the algorithm will be applied to.

    **Return** The `reverse` algorithm returns a `void`.

template<typename ExPolicy, typename BidirIter>
parallel::util::detail::algorithm_result<ExPolicy, void>::type reverse(ExPolicy &&policy, BidirIter first, BidirIter last)
{
    Reverses the order of the elements in the range [first, last). Behaves as if applying std::iter_swap to every pair of iterators first+i, (last-i) - 1 for each non-negative i < (last-first)/2.
}
} // namespace hpx
```
The assignments in the parallel `reverse` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Linear in the distance between `first` and `last`.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **BidirIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.

- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.

The assignments in the parallel `reverse_copy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `reverse` algorithm returns a `hpx::future<void>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `void` otherwise.

```cpp
template<typename BidirIter, typename OutIter>
OutIter reverse_copy (BidirIter first, BidirIter last, Outiter dest)
```

Copies the elements from the range `[first, last)` to another range beginning at `dest_first` in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment `*(dest_first + (last - first) - 1 - i) = *(first + i)` once for each non-negative `i < (last - first)` If the source and destination ranges (that is, `[first, last)` and `[dest_first, dest_first+(last-first))` respectively) overlap, the behavior is undefined.

The assignments in the parallel `reverse_copy` algorithm execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `last - first` assignments.

**Template Parameters**

- **BidirIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.

- **OutIter**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

**Parameters**

- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.

- **dest**: Refers to the begin of the destination range.

**Return** The `reverse_copy` algorithm returns an `OutIter`. The `reverse_copy` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename BidirIter, typename FwdIter>
```
util::detail::algorithm_result<ExPolicy, FwdIter>::type reverse_copy (ExPolicy &&policy, BidirIter first, BidirIter last, FwdIter dest_first)

Copies the elements from the range [first, last) to another range beginning at dest_first in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment *(dest_first + (last - first) - 1 - i) = *(first + i) once for each non-negative i < (last - first) If the source and destination ranges (that is, [first, last) and [dest_first, dest_first+(last-first)) respectively) overlap, the behavior is undefined.

The assignments in the parallel reverse_copy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note  Complexity: Performs exactly last - first assignments.

Template Parameters

- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- BidirIter: The type of the source iterators used (deduced). This iterator type must meet the requirements of an bidirectional iterator.
- FwdIter: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last: Refers to the end of the sequence of elements the algorithm will be applied to.
- dest: Refers to the begin of the destination range.

The assignments in the parallel reverse_copy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The reverse_copy algorithm returns a hpx::future<FwdIter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter otherwise. The reverse_copy algorithm returns the output iterator to the element in the destination range, one past the last element copied.

namespace hpx

namespace parallel
Functions

```cpp
template<typename ExPolicy, typename FwdIter>
util::detail::algorithm_result<ExPolicy, util::in_out_result<FwdIter, FwdIter>>::type rotate(ExPolicy &&policy, FwdIter first, FwdIter new_first, FwdIter last)
```

Performs a left rotation on a range of elements. Specifically, `rotate` swaps the elements in the range `[first, last)` in such a way that the element `new_first` becomes the first element of the new range and `new_first - 1` becomes the last element.

The assignments in the parallel `rotate` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Linear in the distance between `first` and `last`.

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter`: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

- `policy`: The execution policy to use for the scheduling of the iterations.
- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `new_first`: Refers to the element that should appear at the beginning of the rotated range.
- `last`: Refers to the end of the sequence of elements the algorithm will be applied to.

The assignments in the parallel `rotate` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note** The type of dereferenced `FwdIter` must meet the requirements of `MoveAssignable` and `MoveConstructible`.

**Return** The `rotate` algorithm returns a `hpx::future<tagged_pair<tag::begin(FwdIter), tag::end(FwdIter)>>` if the execution policy is of type `parallel_task_policy` and returns `tagged_pair<tag::begin(FwdIter), tag::end(FwdIter)>>` otherwise. The `rotate` algorithm returns the iterator equal to pair(\(first + (last - new\_first)\), last).

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
util::detail::algorithm_result<ExPolicy, util::in_out_result<FwdIter1, FwdIter2>>::type rotate_copy(ExPolicy &&policy, FwdIter1 first, FwdIter1 new_first, FwdIter1 last, FwdIter2 dest_first)
```

1110 Chapter 2. What’s so special about HPX?
Copies the elements from the range [first, last), to another range beginning at dest_first in such a way, that the element new_first becomes the first element of the new range and new_first - 1 becomes the last element.

The assignments in the parallel rotate_copy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly last - first assignments.

**Template Parameters**
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- FwdIter1: The type of the source iterators used (deduced). This iterator type must meet the requirements of an bidirectional iterator.
- FwdIter2: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**
- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- new_first: Refers to the element that should appear at the beginning of the rotated range.
- last: Refers to the end of the sequence of elements the algorithm will be applied to.
- dest_first: Refers to the begin of the destination range.

The assignments in the parallel rotate_copy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The rotate_copy algorithm returns a hpx::future<tagged_pair<tag::in(FwdIter1), tag::out(FwdIter2)>> if the execution policy is of type parallel_task_policy and returns tagged_pair<tag::in(FwdIter1), tag::out(FwdIter2)>> otherwise. The rotate_copy algorithm returns the output iterator to the element past the last element copied.

### namespace hpx

#### Functions

```cpp
template<typename FwdIter, typename FwdIter2, typename Pred = detail::equal_to>
FwdIter search(FwdIter first, FwdIter last, FwdIter2 s_first, FwdIter2 s_last, Pred &&op = Pred())
```

Searches the range [first, last) for any elements in the range [s_first, s_last). Uses a provided predicate to compare elements.

The comparison operations in the parallel search algorithm execute in sequential order in the calling thread.

**Note** Complexity: at most (S*N) comparisons where S = distance(s_first, s_last) and N = distance(first, last).

**Template Parameters**
- FwdIter: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

- FwdIter2: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
• **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`.

**Parameters**

- **first**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s_first**: Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last**: Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op**: Refers to the binary predicate which returns true if the elements should be treated as equal. The signature of the function should be equivalent to

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

**Return** The `search` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `search` algorithm returns an iterator to the beginning of the first subsequence `[s_first, s_last)` in range `[first, last)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, last)`, `last` is returned. Additionally if the size of the subsequence is empty `first` is returned. If no subsequence is found, `last` is returned.

```cpp
template<typename ExPolicy, typename FwdIter, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result<ExPolicy, FwdIter>::type search (ExPolicy &&policy, FwdIter first, FwdIter last, FwdIter2 s_first, FwdIter2 s_last, Pred &&op = Pred())
```

Searches the range `[first, last)` for any elements in the range `[s_first, s_last)`). Uses a provided predicate to compare elements.

The comparison operations in the parallel `search` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: at most `(S*N)` comparisons where `S = distance(s_first, s_last)` and `N = distance(first, last)`.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
• **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`.

**Parameters**

• **policy**: The execution policy to use for the scheduling of the iterations.

• **first**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

• **last**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

• **s_first**: Refers to the beginning of the sequence of elements the algorithm will be searching for.

• **s_last**: Refers to the end of the sequence of elements of the algorithm will be searching for.

• **op**: Refers to the binary predicate which returns true if the elements should be treated as equal. The signature of the function should be equivalent to

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

The comparison operations in the parallel `search` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `search` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `search` algorithm returns an iterator to the beginning of the first subsequence `[s_first, s_last)` in range `[first, last)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, last)`, `last` is returned. Additionally if the size of the subsequence is empty `first` is returned. If no subsequence is found, `last` is returned.

```cpp
template<typename FwdIter, typename FwdIter2, typename Pred = detail::equal_to>
FwdIter search_n(FwdIter first, std::size_t count, FwdIter2 s_first, FwdIter2 s_last, Pred &&op = Pred())
```

Searches the range `[first, last)` for any elements in the range `[s_first, s_last)`. Uses a provided predicate to compare elements.

The comparison operations in the parallel `search_n` algorithm execute in sequential order in the calling thread.

**Note** Complexity: at most \((S*N)\) comparisons where \(S = \text{distance}(s\_first, s\_last)\) and \(N = \text{count}\).

**Template Parameters**

• **FwdIter**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

• **FwdIter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
• **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`

**Parameters**

• **first**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

• **count**: Refers to the range of elements of the first range the algorithm will be applied to.

• **s_first**: Refers to the beginning of the sequence of elements the algorithm will be searching for.

• **s_last**: Refers to the end of the sequence of elements of the algorithm will be searching for.

• **op**: Refers to the binary predicate which returns true if the elements should be treated as equal. The signature of the function should be equivalent to

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

**Return** The `search_n` algorithm returns `FwdIter`. The `search_n` algorithm returns an iterator to the beginning of the last subsequence `[s_first, s_last)` in range `[first, first+count)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, first+count)`, `first` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `first` is also returned.

```cpp
template<typename ExPolicy, typename FwdIter, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result<ExPolicy, FwdIter>::type search_n(ExPolicy &&policy, FwdIter first, std::size_t count, FwdIter2 s_first, FwdIter2 s_last, Pred &&op = Pred())
```

Searches the range `[first, last)` for any elements in the range `[s_first, s_last)`. Uses a provided predicate to compare elements.

The comparison operations in the parallel `search_n` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: at most `(S*N)` comparisons where `S = distance(s_first, s_last)` and `N = count`.

**Template Parameters**

• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **FwdIter**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

• **FwdIter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

• **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`
Parameters

- `policy`: The execution policy to use for the scheduling of the iterations.
- `first`: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- `count`: Refers to the range of elements of the first range the algorithm will be applied to.
- `s_first`: Refers to the beginning of the sequence of elements the algorithm will be searching for.
- `s_last`: Refers to the end of the sequence of elements the algorithm will be searching for.
- `op`: Refers to the binary predicate which returns true if the elements should be treated as equal. The signature of the function should be equivalent to

\[
\text{bool \ pred(const Type1 &a, const Type2 &b);}\]

The signature does not need to have const &., but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

The comparison operations in the parallel `search_n` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The `search_n` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `search_n` algorithm returns an iterator to the beginning of the last subsequence `[s_first, s_last)` in range `[first, first+count)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, first+count)`, `first` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `first` is also returned.

namespace hpx

Functions

template<
typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, 
typename Pred = detail::less>
util::detail::algorithm_result<ExPolicy, FwdIter3>::type::type set_difference (ExPolicy &&policy,
    FwdIter1 first1,
    FwdIter1 last1,
    FwdIter2 first2,
    FwdIter2 last2,
    FwdIter3 dest,
    Pred &&op = Pred())

Constructs a sorted range beginning at `dest` consisting of all elements present in the range `[first1, last1)` and not present in the range `[first2, last2)`. This algorithm expects both input ranges to be sorted with the given binary predicate `f`.

Equivalent elements are treated individually, that is, if some element is found `m` times in `[first1, last1)` and `n` times in `[first2, last2)`, it will be copied to `dest` exactly std::max(m-n, 0) times. The resulting range cannot overlap with either of the input ranges.

Note Complexity: At most \(2*(N1 + N2 - 1)\) comparisons, where \(N1\) is the length of the first sequence and \(N2\) is the length of the second sequence.
The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (sequenced_policy) or in a single new thread spawned from the current thread (for sequenced_task_policy).

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter1**: The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **FwdIter3**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of set_difference requires Pred to meet the requirements of CopyConstructible. This defaults to std::less<>

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2**: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2**: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **op**: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type Type1 must be such that objects of type InIter can be dereferenced and then implicitly converted to Type1.

The application of function objects in parallel algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The set_difference algorithm returns a hpx::future<FwdIter3> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter3 otherwise. The set_difference algorithm returns the output iterator to the element in the destination range, one past the last element copied.
namespace hpx

Functions

template<
    typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3,
    typename Pred = detail::less>
util::detail::algorithm_result<ExPolicy, FwdIter3>::type set_intersection(ExPolicy &&policy,
    FwdIter1 first1, FwdIter1 last1,
    FwdIter2 first2, FwdIter2 last2,
    FwdIter3 dest, Pred &&op = Pred())

Constructs a sorted range beginning at dest consisting of all elements present in both sorted ranges [first1, last1) and [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate \( f \).

If some element is found \( m \) times in [first1, last1) and \( n \) times in [first2, last2), the first \( \min(m, n) \) elements will be copied from the first range to the destination range. The order of equivalent elements is preserved. The resulting range cannot overlap with either of the input ranges.

**Note** Complexity: At most \( 2 \times (N_1 + N_2 - 1) \) comparisons, where \( N_1 \) is the length of the first sequence and \( N_2 \) is the length of the second sequence.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (sequenced_policy) or in a single new thread spawned from the current thread (for sequenced_task_policy).

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter1**: The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **FwdIter3**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of set_intersection requires \( \text{Pred} \) to meet the requirements of CopyConstructible. This defaults to std::less<>

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
• first2: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

• last2: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

• dest: Refers to the beginning of the destination range.

• op: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type Type1 must be such that objects of type InIter can be dereferenced and then implicitly converted to Type1.

The application of function objects in parallel algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The set_intersection algorithm returns a hpx::future<FwdIter3> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter3 otherwise. The set_intersection algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
namespace hpx

Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred = detail::less>
util::detail::algorithm_result<ExPolicy, FwdIter3>::type set_symmetric_difference(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, FwdIter3 dest, Pred &&op = Pred())
```

Constructs a sorted range beginning at dest consisting of all elements present in either of the sorted ranges [first1, last1) and [first2, last2), but not in both of them are copied to the range beginning at dest. The resulting range is also sorted. This algorithm expects both input ranges to be sorted with the given binary predicate f.
If some element is found \(m\) times in \([\text{first}1, \text{last}1)\) and \(n\) times in \([\text{first}2, \text{last}2)\), it will be copied to \(\text{dest}\) exactly \(\text{abs}(m-n)\) times. If \(m > n\), then the last \(m-n\) of those elements are copied from \([\text{first}1, \text{last}1)\), otherwise the last \(n-m\) elements are copied from \([\text{first}2, \text{last}2)\). The resulting range cannot overlap with either of the input ranges.

**Note** Complexity: At most \(2*(\text{N1} + \text{N2} - 1)\) comparisons, where \(\text{N1}\) is the length of the first sequence and \(\text{N2}\) is the length of the second sequence.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (\(\text{sequenced\_policy}\)) or in a single new thread spawned from the current thread (for \(\text{sequenced\_task\_policy}\)).

**Template Parameters**

- **\(\text{ExPolicy}\)**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **\(\text{FwdIter1}\)**: The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **\(\text{FwdIter2}\)**: The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **\(\text{FwdIter3}\)**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **\(\text{Pred}\)**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of \(\text{set\_symmetric\_difference}\) requires \(\text{Pred}\) to meet the requirements of \(\text{Copy\_Constructible}\). This defaults to \(\text{std\_less}\)<>

**Parameters**

- **\(\text{policy}\)**: The execution policy to use for the scheduling of the iterations.
- **\(\text{first1}\)**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **\(\text{last1}\)**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **\(\text{first2}\)**: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **\(\text{last2}\)**: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **\(\text{dest}\)**: Refers to the beginning of the destination range.
- **\(\text{op}\)**: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

\[
\text{bool pred(\text{const Type1 } \&a, \text{const Type1 } \&b);}\]

The signature does not need to have \text{const} \&, but the function must not modify the objects passed to it. The type \(\text{Type1}\) must be such that objects of type \(\text{InIter}\) can be dereferenced and then implicitly converted to \(\text{Type1}\)
The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `set_symmetric_difference` algorithm returns a `hpx::future<FwdIter3>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter3` otherwise. The `set_symmetric_difference` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
namespace hpx

Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred = detail::less>
util::detail::algorithm_result<ExPolicy, FwdIter3>::type::type
set_union(
    ExPolicy &&policy,
    FwdIter1 first1,
    FwdIter1 last1,
    FwdIter2 first2,
    FwdIter2 last2,
    FwdIter3 dest,
    Pred &&op = Pred())
```

Constructs a sorted range beginning at `dest` consisting of all elements present in one or both sorted ranges `[first1, last1)` and `[first2, last2)`. This algorithm expects both input ranges to be sorted with the given binary predicate `f`.

If some element is found `m` times in `[first1, last1)` and `n` times in `[first2, last2)`, then all `m` elements will be copied from `[first1, last1)` to `dest`, preserving order, and then exactly `std::max(n-m, 0)` elements will be copied from `[first2, last2)` to `dest`, also preserving order.

**Note** Complexity: At most `2*(N1 + N2 - 1)` comparisons, where `N1` is the length of the first sequence and `N2` is the length of the second sequence.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (`sequenced_policy`) or in a single new thread spawned from the current thread (for `sequenced_task_policy`).

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- `FwdIter1`: The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- `FwdIter2`: The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- `FwdIter3`: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- `Op`: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_union` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`
Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2**: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2**: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **op**: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type Type1 must be such that objects of type InIter can be dereferenced and then implicitly converted to Type1.

The application of function objects in parallel algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The `set_union` algorithm returns a `hpx::future<FwdIter3>` if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns `FwdIter3` otherwise. The `set_union` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
namespace hpx

namespace parallel

Functions

template<typename ExPolicy, typename RandomIt, typename Comp = detail::less, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, RandomIt>::type sort(ExPolicy &&policy, RandomIt first, RandomIt last, Comp &&comp = Comp(), Proj &&proj = Proj())
```

Sorts the elements in the range [first, last) in ascending order. The order of equal elements is not guaranteed to be preserved. The function uses the given comparison function object `comp` (defaults to using `operator<()`).

A sequence is sorted with respect to a comparator `comp` and a projection `proj` if for every iterator `i` pointing to the sequence and every non-negative integer `n` such that `i + n` is a valid iterator pointing to an element of the sequence, and INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false.

**Note** Complexity: $O(N\log(N))$, where $N = \text{std::distance(first, last)}$ comparisons.
\texttt{comp} has to induce a strict weak ordering on the values.

**Template Parameters**
- \texttt{ExPolicy}: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- \texttt{Iter}: The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- \texttt{Comp}: The type of the function/function object to use (deduced).
- \texttt{Proj}: The type of an optional projection function. This defaults to \texttt{util::projectionIdentity}

**Parameters**
- \texttt{policy}: The execution policy to use for the scheduling of the iterations.
- \texttt{first}: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- \texttt{last}: Refers to the end of the sequence of elements the algorithm will be applied to.
- \texttt{comp}: \texttt{comp} is a callable object. The return value of the INVOKE operation applied to an object of type \texttt{Comp}, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that \texttt{comp} will not apply any non-constant function through the dereferenced iterator.
- \texttt{proj}: Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate \texttt{comp} is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type \texttt{sequenced_policy} execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type \texttt{parallel_policy} or \texttt{parallel_task_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The \texttt{sort} algorithm returns a \texttt{hpx::future<RandomIt>} if the execution policy is of type \texttt{sequenced_task_policy} or \texttt{parallel_task_policy} and returns \texttt{RandomIt} otherwise. The algorithm returns an iterator pointing to the first element after the last element in the input sequence.

namespace \texttt{hpx}

namespace \texttt{parallel}

**Functions**

\begin{verbatim}
template<typename ExPolicy, typename KeyIter, typename ValueIter, typename Compare = detail::less>
util::detail::algorithm_result<ExPolicy, hpx::util::tagged_pair<tag::in1(KeyIter), tag::in2(ValueIter)>>::type
sort_by_key(ExPolicy &&policy, KeyIter key_first, KeyIter key_last, ValueIter value_first, Compare &&comp = Compare())
\end{verbatim}

\begin{itemize}
\item A sequence is sorted with respect to a comparator \texttt{comp} and a projection \texttt{proj} if for every iterator i pointing to the sequence and every non-negative integer n such that i + n is a valid iterator pointing to an element of the sequence, and INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false.
\item **Note** Complexity: O(Nlog(N)), where N = std::distance(first, last) comparisons.
\end{itemize}
• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

• **KeyIter**: The type of the key iterators used (deduced). This iterator type must meet the requirements of a random access iterator.

• **ValueIter**: The type of the value iterators used (deduced). This iterator type must meet the requirements of a random access iterator.

• **Comp**: The type of the function/function object to use (deduced).

**Parameters**

• **policy**: The execution policy to use for the scheduling of the iterations.

• **key_first**: Refers to the beginning of the sequence of key elements the algorithm will be applied to.

• **key_last**: Refers to the end of the sequence of key elements the algorithm will be applied to.

• **value_first**: Refers to the beginning of the sequence of value elements the algorithm will be applied to, the range of elements must match [key_first, key_last)

• **comp**: comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `sort_by-key` algorithm returns a `hpx::future<tagged_pair<tag::in1(KeyIter), tag::in2(ValueIter)>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `otherwise`. The algorithm returns a pair holding an iterator pointing to the first element after the last element in the input key sequence and an iterator pointing to the first element after the last element in the input value sequence.

```cpp
namespace hpx
{

namespace parallel
{

Functions

template<typename ExPolicy, typename RandomIt, typename Sentinel, 
            typename Proj = util::projection_identity,
            typename Compare = detail::less>
util::detail::algorithm_result<ExPolicy, RandomIt>::type stable_sort(ExPolicy &&policy, 
                                               RandomIt first, Sentinel last,
                                               Compare &&comp = 
                                               Compare(), Proj &&proj = Proj())
```

Sorts the elements in the range [first, last) in ascending order. The relative order of equal elements is preserved. The function uses the given comparison function object comp (defaults to using operator<()).

A sequence is sorted with respect to a comparator `comp` and a projection `proj` if for every iterator `i` pointing to the sequence and every non-negative integer `n` such that `i + n` is a valid iterator pointing
to an element of the sequence, and INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false.

**Note** Complexity: $O(N\log(N))$, where $N = \text{std::distance(first, last)}$ comparisons.

`comp` has to induce a strict weak ordering on the values.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **RandomIt**: The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Sentinel**: The type of the end iterators used (deduced). This iterator type must meet the requirements of a random access iterator and must be a valid sentinel type for `RandomIt`.
- **Comp**: The type of the function/function object to use (deduced).
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp**: `comp` is a callable object. The return value of the `INVOKE` operation applied to an object of type `Comp`, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator.
- **proj**: Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate `comp` is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `stable_sort` algorithm returns a `hpx::future<RandomIt>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `RandomIt` otherwise. The algorithm returns an iterator pointing to the first element after the last element in the input sequence.

```cpp
namespace hpx

namespace parallel

Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
std::enable_if<hpx::is_execution_policy<ExPolicy>::value, typename util::detail::algorithm_result<ExPolicy, FwdIter2>::type>::type
```

Exchanges elements between range `[first1, last1)` and another range starting at `first2`. 

---

1124 Chapter 2. What's so special about HPX?
The swap operations in the parallel swap_ranges algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.  

**Note** Complexity: Linear in the distance between first1 and last1

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the swap operations.
- `FwdIter1`: The type of the first range of iterators to swap (deduced). This iterator type must meet the requirements of an forward iterator.
- `FwdIter2`: The type of the second range of iterators to swap (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

- `policy`: The execution policy to use for the scheduling of the iterations.
- `first1`: Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- `last1`: Refers to the end of the first sequence of elements the algorithm will be applied to.
- `first2`: Refers to the beginning of the second sequence of elements the algorithm will be applied to.

The swap operations in the parallel swap_ranges algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The swap_ranges algorithm returns a hpx::future<FwdIter2> if the execution policy is of type parallel_task_policy and returns FwdIter2 otherwise. The swap_ranges algorithm returns iterator to the element past the last element exchanged in the range beginning with first2.

```cpp
namespace hpx

Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename F>
util::detail::algorithm_result<ExPolicy, util::in_out_result<FwdIter1, FwdIter2>>::type transform(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest, F &&f)

Applies the given function f to the range [first, last) and stores the result in another range, beginning at dest.

The invocations of f in the parallel transform algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Exactly last - first applications of f

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which
the execution of the algorithm may be parallelized and the manner in which it executes the invocations of \( f \).

- **FwdIter1**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `transform` requires \( F \) to meet the requirements of `CopyConstructible`.

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\). This is an unary predicate. The signature of this predicate should be equivalent to:

\[
\text{Ret} \quad \text{fun}(\text{const} \ \text{Type} &a);
\]

The signature does not need to have `const&`. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`. The type `Ret` must be such that an object of type `FwdIter2` can be dereferenced and assigned a value of type `Ret`.

The invocations of \( f \) in the parallel `transform` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

### Return

The `transform` algorithm returns a `hpx::future<\text{in_out_result}<\text{FwdIter1, FwdIter2}>>` if the execution policy is of type `parallel_task_policy` and returns `\text{in_out_result}<\text{FwdIter1, FwdIter2}>>` otherwise. The `transform` algorithm returns a tuple holding an iterator referring to the first element after the input sequence and the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename F>
util::detail::algorithm_result<ExPolicy, util::in_out_result<FwdIter1, FwdIter2, FwdIter3>>::type transform(ExPolicy &&policy, FwdIter1 first1, FwdIter2 last1, FwdIter2 first2, FwdIter3 dest, F &&f)
```

Applies the given function \( f \) to pairs of elements from two ranges: one defined by \([\text{first1}, \text{last1})\) and the other beginning at \( \text{first2} \), and stores the result in another range, beginning at \( \text{dest} \).
The invocations of \( f \) in the parallel transform algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Exactly last - first applications of \( f \)

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of \( f \).

- **FwdIter1**: The type of the source iterators for the first range used (deduced). This iterator type must meet the requirements of an forward iterator.

- **FwdIter2**: The type of the source iterators for the second range used (deduced). This iterator type must meet the requirements of an forward iterator.

- **FwdIter3**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of transform requires \( F \) to meet the requirements of CopyConstructible.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.

- **first1**: Refers to the beginning of the first sequence of elements the algorithm will be applied to.

- **last1**: Refers to the end of the first sequence of elements the algorithm will be applied to.

- **first2**: Refers to the beginning of the second sequence of elements the algorithm will be applied to.

- **dest**: Refers to the beginning of the destination range.

- **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type2 &b);
  ```

The signature does not need to have \( \& \). The types Type1 and Type2 must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively. The type Ret must be such that an object of type FwdIter3 can be dereferenced and assigned a value of type Ret.

The invocations of \( f \) in the parallel transform algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The transform algorithm returns a \( \text{hpx::future<in_in_out_result<FwdIter1, FwdIter2, FwdIter3>>} \) if the execution policy is of type parallel_task_policy and returns \( \text{in_in_out_result<FwdIter1, FwdIter2, FwdIter3>} \) otherwise. The transform algorithm returns a tuple holding an iterator referring to the first element after the first input sequence, an iterator referring to the first element after the second input sequence, and the output iterator referring to the element in the destination range, one past the last element copied.
namespace hpx

namespace parallel

Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename T, typename Op, typename Conv>
util::detail::algorithm_result<ExPolicy, FwdIter2>::type transform_exclusive_scan(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest, T init, Op &&op, Conv &&conv)

Assigns through each iterator \( i \) in \([\text{result}, \text{result} + (\text{last} - \text{first}))\) the value of GENERALIZED_NONCOMMUTATIVE_SUM(binary_op, init, conv(*first), \ldots, conv(*((first + (i - result) - 1)))).

The reduce operations in the parallel transform_exclusive_scan algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: \( O(\text{last} - \text{first}) \) applications of the predicates \( \text{op} \) and \( \text{conv} \).

**Template Parameters**

- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- FwdIter1: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- FwdIter2: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- Conv: The type of the unary function object used for the conversion operation.
- T: The type of the value to be used as initial (and intermediate) values (deduced).
- Op: The type of the binary function object used for the reduction operation.

**Parameters**

- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last: Refers to the end of the sequence of elements the algorithm will be applied to.
- dest: Refers to the beginning of the destination range.
- conv: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\). This is a unary predicate. The signature of this predicate should be equivalent to:

```cpp
R fun(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type FwdIter1 can be dereferenced.
and then implicitly converted to Type. The type $R$ must be such that an object of this type can be implicitly converted to $T$.

- **init**: The initial value for the generalized sum.
- **op**: Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

\[
\text{Ret fun(const Type1 &a, const Type1 &b);}
\]

The signature does not need to have const&, but the function must not modify the objects passed to it. The types $Type1$ and $Ret$ must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

The reduce operations in the parallel `transform_exclusive_scan` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither `conv` nor `op` shall invalidate iterators or subranges, or modify elements in the ranges `[first, last)` or `[result, result + (last - first))`.

**Return** The `transform_exclusive_scan` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `transform_exclusive_scan` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

**Note** `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN)` is defined as:
- $a1$ when $N$ is 1
- `op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN))` where $1 < K+1 = M <= N$.

The behavior of `transform_exclusive_scan` may be non-deterministic for a non-associative predicate.

```cpp
namespace hpx

namespace parallel

Functions

```template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Op, typename Conv, typename T>
util::detail::algorithm_result<ExPolicy, FwdIter2>::type transform_inclusive_scan(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest, Op &&op, Conv &&&conv, T init)
```

Assigns through each iterator $i$ in `[result, result + (last - first))` the value of `GENERALIZED_NONCOMMUTATIVE_SUM(op, init, conv(*first), ..., conv(*first + (i - result)))`.  

2.8. API reference 1129
The reduce operations in the parallel `transform_inclusive_scan` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread. 

**Note** Complexity: $O(last - first)$ applications of the predicate $op$.

**Template Parameters**

- $\text{ExPolicy}$: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- $\text{FwdIter1}$: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- $\text{FwdIter2}$: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- $\text{Conv}$: The type of the unary function object used for the conversion operation.
- $\text{T}$: The type of the value to be used as initial (and intermediate) values (deduced).
- $\text{Op}$: The type of the binary function object used for the reduction operation.

**Parameters**

- $\text{policy}$: The execution policy to use for the scheduling of the iterations.
- $\text{first}$: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- $\text{last}$: Refers to the end of the sequence of elements the algorithm will be applied to.
- $\text{dest}$: Refers to the beginning of the destination range.
- $\text{conv}$: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by $[\text{first}, \text{last})$. This is a unary predicate. The signature of this predicate should be equivalent to:

$$R \ fun(\text{const Type \&a});$$

The signature does not need to have const&, but the function must not modify the objects passed to it. The type $\text{Type}$ must be such that an object of type $\text{FwdIter1}$ can be dereferenced and then implicitly converted to $\text{Type}$. The type $R$ must be such that an object of this type can be implicitly converted to $\text{T}$.
- $\text{init}$: The initial value for the generalized sum.
- $\text{op}$: Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

$$\text{Ret \ fun(const Type1 \&a, const Type1 \&b);}$$

The signature does not need to have const&, but the function must not modify the objects passed to it. The types $\text{Type1}$ and $\text{Ret}$ must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

The reduce operations in the parallel `transform_inclusive_scan` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither $\text{conv}$ nor $\text{op}$ shall invalidate iterators or subranges, or modify elements in the ranges $[\text{first}, \text{last})$ or $[\text{result}, \text{result} + (\text{last} - \text{first}))$.

**Return** The `transform_inclusive_scan` algorithm returns a `hpx::future<\text{FwdIter2}>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns $\text{FwdIter2}$ otherwise. The `transform_inclusive_scan` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

**Note** GENERALIZED_NONCOMMUTATIVE_SUM($\text{op, a1, \ldots, aN}$) is defined as:

- $a1$ when $N$ is 1
• \text{op}(\text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(\text{op}, \ a_1, \ldots, \ a_K), \ \text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(\text{op}, \ a_M, \ldots, \ a_N)) \text{ where } 1 < K+1 = M \leq N.

The difference between exclusive\_scan and transform\_inclusive\_scan is that transform\_inclusive\_scan includes the \text{i}th input element in the \text{i}th sum. If \text{op} is not mathematically associative, the behavior of transform\_inclusive\_scan may be non-deterministic.

template<typename \text{ExPolicy}, typename \text{FwdIter1}, typename \text{FwdIter2}, typename \text{Conv}, typename \text{Op}>
util::detail::algorithm_result<\text{ExPolicy}, \text{FwdIter2}>::\text{type} \text{transform\_inclusive\_scan}(\text{ExPolicy} && \text{policy}, \ \text{FwdIter1} && \text{first}, \ \text{FwdIter1} && \text{last}, \ \text{FwdIter2} && \text{dest}, \ \text{Op} && \text{op}, \ \text{Conv} && \text{conv})

Assigns through each iterator \text{i} in \([\text{result}, \text{result} + (\text{last} - \text{first}))\) the value of \text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(\text{op}, \text{conv}(*\text{first}), \ldots, \text{conv}(*(\text{first} + (\text{i} - \text{result}))))).

The reduce operations in the parallel transform\_inclusive\_scan algorithm invoked with an execution policy object of type sequenced\_policy execute in sequential order in the calling thread.

Note Complexity: \(O(\text{last} - \text{first})\) applications of the predicate \text{op}.

Template Parameters
• \text{ExPolicy}: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• \text{FwdIter1}: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
• \text{FwdIter2}: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
• \text{Conv}: The type of the unary function object used for the conversion operation.
• \text{T}: The type of the value to be used as initial (and intermediate) values (deduced).
• \text{Op}: The type of the binary function object used for the reduction operation.

Parameters
• \text{policy}: The execution policy to use for the scheduling of the iterations.
• \text{first}: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• \text{last}: Refers to the end of the sequence of elements the algorithm will be applied to.
• \text{dest}: Refers to the beginning of the destination range.
• \text{conv}: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\). This is a unary predicate. The signature of this predicate should be equivalent to:

\[
R \ fun(const Type &a);
\]

The signature does not need to have \text{const}, but the function must not modify the objects passed to it. The type \text{Type} must be such that an object of type \text{FwdIter1} can be dereferenced and then implicitly converted to \text{Type}. The type \text{R} must be such that an object of this type can be implicitly converted to \text{T}.
• \text{op}: Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be
equivalent to:

```cpp
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types `Type1` and `Ret` must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

The reduce operations in the parallel `transform_inclusive_scan` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither `conv` nor `op` shall invalidate iterators or subranges, or modify elements in the ranges `[first,last)` or `[result, result + (last - first))`.

**Return** The `transform_inclusive_scan` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise.

The `transform_inclusive_scan` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

**Note** `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, . . . , aN)` is defined as:

- `a1` when `N` is 1
- `op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, . . . , aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, . . . , aN))` where `1 < K+1 = M <= N`.

The difference between `exclusive_scan` and `transform_inclusive_scan` is that `transform_inclusive_scan` includes the ith input element in the ith sum.

```cpp
namespace hpx

Functions

template<typename ExPolicy, typename FwdIter, typename T, typename Reduce, typename Convert>
util::detail::algorithm_result<ExPolicy, T>::type transform_reduce(ExPolicy &&policy, FwdIter first, FwdIter last, T init, Reduce &&red_op, Convert &&conv_op)
```

Returns `GENERALIZED_SUM(red_op, init, conv_op(*first), . . . , conv_op(*last))`.

The reduce operations in the parallel `transform_reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: `O(last - first)` applications of the predicates `red_op` and `conv_op`.

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter`: The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- `F`: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `copy_if` requires `F` to meet the requirements of `CopyConstructible`.
- `T`: The type of the value to be used as initial (and intermediate) values (deduced).
- `Reduce`: The type of the binary function object used for the reduction operation.
• Convert: The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

Parameters

• policy: The execution policy to use for the scheduling of the iterations.
• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• last: Refers to the end of the sequence of elements the algorithm will be applied to.
• conv_op: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a unary predicate. The signature of this predicate should be equivalent to:

```cpp
R fun(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`. The type `R` must be such that an object of this type can be implicitly converted to `T`.

• init: The initial value for the generalized sum.

• red_op: Specifies the function (or function object) which will be invoked for each of the values returned from the invocation of `conv_op`. This is a binary predicate. The signature of this predicate should be equivalent to:

```cpp
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types `Type1`, `Type2`, and `Ret` must be such that an object of a type as returned from `conv_op` can be implicitly converted to any of those types.

The reduce operations in the parallel `transform_reduce` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `transform_reduce` and `accumulate` is that the behavior of `transform_reduce` may be non-deterministic for non-associative or non-commutative binary predicate.

Return The `transform_reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `parallel_task_policy` and returns `T` otherwise. The `transform_reduce` algorithm returns the result of the generalized sum over the values returned from `conv_op` when applied to the elements given by the input range `[first, last)`.

Note GENERALIZED_SUM(op, a1, . . . , aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(op, b1, . . . , bK), GENERALIZED_SUM(op, bM, . . . , bN)), where:
  - b1, . . . , bN may be any permutation of a1, . . . , aN and
  - 1 < K+1 = M <= N.
template<
  typename ExPolicy,  
  typename FwdIter1,
  typename FwdIter2,  
  typename T,  
  typename Reduce,  
  typename Convert
>
util::detail::algorithm_result<ExPolicy, T>::type transform_reduce(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, T init, Reduce &&red_op, Convert &&conv_op)

Returns the result of accumulating init with the inner products of the pairs formed by the elements of two ranges starting at first1 and first2.

The operations in the parallel transform_reduce algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: \( O(last - first) \) applications of the predicate \( op2 \).

### Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the first source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the second source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T**: The type of the value to be used as return) values (deduced).

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the first sequence of elements the result will be calculated with.
- **last1**: Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2**: Refers to the beginning of the second sequence of elements the result will be calculated with.
- **init**: The initial value for the sum.

The operations in the parallel transform_reduce algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The transform_reduce algorithm returns a \( hpx::future<T> \) if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns \( T \) otherwise.
Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the first source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the second source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T**: The type of the value to be used as return values (deduced).
- **Reduce**: The type of the binary function object used for the multiplication operation.
- **Convert**: The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the first sequence of elements the result will be calculated with.
- **last1**: Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2**: Refers to the beginning of the second sequence of elements the result will be calculated with.
- **init**: The initial value for the sum.
- **red_op**: Specifies the function (or function object) which will be invoked for the initial value and each of the return values of *op2*. This is a binary predicate. The signature of this predicate should be equivalent to:

  ```cpp
  Ret fun(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Ret* must be such that it can be implicitly converted to a type of *T*.

- **conv_op**: Specifies the function (or function object) which will be invoked for each of the input values of the sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

  ```cpp
  Ret fun(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Ret* must be such that it can be implicitly converted to an object for the second argument type of *op1*.

The operations in the parallel *transform_reduce* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The *transform_reduce* algorithm returns a *hpx::future<T>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *T* otherwise.

namespace hpx

2.8. API reference

Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
std::enable_if<hpx::is_execution_policy<ExPolicy>::value, typename util::detail::algorithm_result<ExPolicy, FwdIter2>::type>::type
uninitialized_copy(ExPolicy&& policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest)

Copies the elements in the range, defined by [first, last), to an uninitialized memory area beginning at dest. If an exception is thrown during the copy operation, the function has no effects.

The assignments in the parallel uninitialized_copy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note  Complexity: Performs exactly last - first assignments.

Template Parameters

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• FwdIter1: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
• FwdIter2: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

• policy: The execution policy to use for the scheduling of the iterations.
• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• last: Refers to the end of the sequence of elements the algorithm will be applied to.
• dest: Refers to the beginning of the destination range.

The assignments in the parallel uninitialized_copy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return  The uninitialized_copy algorithm returns a hpx::future<FwdIter2>, if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter2 otherwise. The uninitialized_copy algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename ExPolicy, typename FwdIter1, typename Size, typename FwdIter2>
std::enable_if<hpx::is_execution_policy<ExPolicy>::value, typename util::detail::algorithm_result<ExPolicy, FwdIter2>::type>::type
uninitialized_copy_n(ExPolicy&& policy, FwdIter1 first, Size count, FwdIter2 dest)
Copies the elements in the range \([\text{first}, \text{first} + \text{count}), \text{starting from first and proceeding to first} + \text{count} - 1., \text{to another range beginning at dest. If an exception is thrown during the copy operation, the function has no effects.}\]

The assignments in the parallel \textit{uninitialized_copy_n} algorithm invoked with an execution policy object of type \textit{sequenced_policy} execute in sequential order in the calling thread.

\textbf{Note} Complexity: Performs exactly \textit{count} assignments, if \textit{count} > 0, no assignments otherwise.

\textbf{Template Parameters}

\begin{itemize}
\item \textbf{ExPolicy}: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
\item \textbf{FwdIter1}: The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
\item \textbf{Size}: The type of the argument specifying the number of elements to apply \textit{f} to.
\item \textbf{FwdIter2}: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
\end{itemize}

\textbf{Parameters}

\begin{itemize}
\item \textbf{policy}: The execution policy to use for the scheduling of the iterations.
\item \textbf{first}: Refers to the beginning of the sequence of elements the algorithm will be applied to.
\item \textbf{count}: Refers to the number of elements starting at \textit{first} the algorithm will be applied to.
\item \textbf{dest}: Refers to the beginning of the destination range.
\end{itemize}

The assignments in the parallel \textit{uninitialized_copy_n} algorithm invoked with an execution policy object of type \textit{parallel_policy} or \textit{parallel_task_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

\textbf{Return} The \textit{uninitialized_copy_n} algorithm returns a hpx::future<\textit{FwdIter2}> if the execution policy is of type \textit{sequenced_task_policy} or \textit{parallel_task_policy} and returns \textit{FwdIter2} otherwise. The \textit{uninitialized_copy_n} algorithm returns the output iterator to the element in the destination range, one past the last element copied.

\begin{verbatim}
namespace hpx

namespace parallel

Functions

template<typename ExPolicy, typename FwdIter>
util::detail::algorithm_result<ExPolicy>::type uninitialized_default_construct (ExPolicy &&policy, FwdIter first, FwdIter last)

Constructs objects of type typename iterator_traits<ForwardIt>::value_type in the uninitialized storage designated by the range \([\text{first}, \text{last})\) by default-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel \textit{uninitialized_default_construct} algorithm invoked with an execution policy object of type \textit{sequenced_policy} execute in sequential order in the calling thread.

\textbf{Note} Complexity: Performs exactly \textit{last} - \textit{first} assignments.
\end{verbatim}
Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.

The assignments in the parallel `uninitialized_default_construct` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return

The `uninitialized_default_construct` algorithm returns a `hpx::future<void>`, if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `void` otherwise.

```cpp
template<typename ExPolicy, typename FwdIter, typename Size>
util::detail::algorithm_result<ExPolicy, FwdIter>::type uninitialized_default_construct_n
(ExPolicy &&policy, FwdIter first, Size count)
```

Constructs objects of type `typename iterator_traits<ForwardIt>::value_type` in the uninitialized storage designated by the range `[first, first + count)` by default-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel `uninitialized_default_construct_n` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

Note Complexity: Performs exactly `count` assignments, if `count > 0`, no assignments otherwise.

Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size**: The type of the argument specifying the number of elements to apply `f` to.

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count**: Refers to the number of elements starting at `first` the algorithm will be applied to.

The assignments in the parallel `uninitialized_default_construct_n` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return

The `uninitialized_default_construct_n` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `uninitialized_default_construct_n` algorithm returns the iterator to the element in the source range, one past the last element constructed.

```cpp
namespace hpx
```
namespace parallel

Functions

template<typename ExPolicy, typename FwdIter, typename T>
std::enable_if<hpx::is_execution_policy<ExPolicy>::value, typename util::detail::algorithm_result<ExPolicy>::type>::type
uninitialized_fill(ExPolicy&& policy, FwdIter first, FwdIter last, T const& value)

Copies the given value to an uninitialized memory area, defined by the range [first, last). If an exception is thrown during the initialization, the function has no effects.

The initializations in the parallel uninitialized_fill algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Linear in the distance between first and last

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T**: The type of the value to be assigned (deduced).

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **value**: The value to be assigned.

The initializations in the parallel uninitialized_fill algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The uninitialized_fill algorithm returns a hpx::future<void>, if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns nothing otherwise.

template<typename ExPolicy, typename FwdIter, typename Size, typename T>
std::enable_if<hpx::is_execution_policy<ExPolicy>::value, typename util::detail::algorithm_result<ExPolicy>::type>::type
uninitialized_fill_n(ExPolicy&& policy, FwdIter first, Size count, T const& value)
Copies the given value value to the first count elements in an uninitialized memory area beginning at first. If an exception is thrown during the initialization, the function has no effects.

The initializations in the parallel uninitialized_fill_n algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread. **Note** Complexity: Performs exactly count assignments, if count > 0, no assignments otherwise.

**Template Parameters**
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- FwdIter: The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- Size: The type of the argument specifying the number of elements to apply f to.
- T: The type of the value to be assigned (deduced).

**Parameters**
- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- count: Refers to the number of elements starting at first the algorithm will be applied to.
- value: The value to be assigned.

The initializations in the parallel uninitialized_move algorithm invoked with an execution policy object of type sequenced_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The uninitialized_fill_n algorithm returns a hpx::future<void>, if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns nothing otherwise.

```
namespace hpx

namespace parallel

Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
util::detail::algorithm_result<ExPolicy, FwdIter2>::type uninitialized_move (ExPolicy &&policy,
FwdIter1 first,
FwdIter1 last,
FwdIter2 dest)
```

Moves the elements in the range, defined by [first, last), to an uninitialized memory area beginning at dest. If an exception is thrown during the initialization, some objects in [first, last) are left in a valid but unspecified state.

The assignments in the parallel uninitialized_move algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread. **Note** Complexity: Performs exactly last - first move operations.

**Template Parameters**
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- FwdIter1: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
• FwdIter2: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters
• policy: The execution policy to use for the scheduling of the iterations.
• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• last: Refers to the end of the sequence of elements the algorithm will be applied to.
• dest: Refers to the beginning of the destination range.

The assignments in the parallel uninitialized_move algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The uninitialized_move algorithm returns a hpx::future<FwdIter2>, if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter2 otherwise. The uninitialized_move algorithm returns the output iterator to the element in the destination range, one past the last element moved.

The assignments in the parallel uninitialized_move_n algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Performs exactly count movements, if count > 0, no move operations otherwise.

Template Parameters
• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• FwdIter1: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
• Size: The type of the argument specifying the number of elements to apply f to.
• FwdIter2: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters
• policy: The execution policy to use for the scheduling of the iterations.
• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• count: Refers to the number of elements starting at first the algorithm will be applied to.
• dest: Refers to the beginning of the destination range.

The assignments in the parallel uninitialized_move_n algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The uninitialized_move_n algorithm returns a hpx::future<

namespace hpx
namespace parallel

Functions

template<typename ExPolicy, typename FwdIter>
util::detail::algorithm_result<ExPolicy>::type uninitialized_value_construct (ExPolicy &&policy, FwdIter first, FwdIter last)

Constructs objects of type typename iterator_traits<ForwardIt>::value_type in the uninitialized storage designated by the range [first, last) by default-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel uninitialized_value_construct algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Performs exactly last - first assignments.

Template Parameters
• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• FwdIter: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters
• policy: The execution policy to use for the scheduling of the iterations.
• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• last: Refers to the end of the sequence of elements the algorithm will be applied to.

The assignments in the parallel uninitialized_value_construct algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The uninitialized_value_construct algorithm returns a hpx::future<void>, if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns void otherwise.

template<typename ExPolicy, typename FwdIter, typename Size>
util::detail::algorithm_result<ExPolicy, FwdIter>::type uninitialized_value_construct_n (ExPolicy &&policy, FwdIter first, Size count)

Constructs objects of type typename iterator_traits<ForwardIt>::value_type in the uninitialized storage designated by the range [first, first + count) by default-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel uninitialized_value_construct_n algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Performs exactly count assignments, if count > 0, no assignments otherwise.
Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size**: The type of the argument specifying the number of elements to apply \( f \) to.

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count**: Refers to the number of elements starting at \( \text{first} \) the algorithm will be applied to.

The assignments in the parallel `uninitialized_value_construct_n` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return

The `uninitialized_value_construct_n` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `uninitialized_value_construct_n` algorithm returns the iterator to the element in the source range, one past the last element constructed.

```cpp
namespace hpx

namespace parallel

Functions

template<typename ExPolicy, typename FwdIter, typename Pred = detail::equal_to, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, FwdIter>::type unique (ExPolicy &&policy, FwdIter first, FwdIter last, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Eliminates all but the first element from every consecutive group of equivalent elements from the range \([\text{first}, \text{last})\) and returns a past-the-end iterator for the new logical end of the range.

The assignments in the parallel `unique` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than \( \text{last} - \text{first} \) assignments, exactly \( \text{last} - \text{first} - 1 \) applications of the predicate \( \text{pred} \) and no more than twice as many applications of the projection \( \text{proj} \).

Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `unique` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
• **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an binary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to both `Type1` and `Type2`.

• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel `unique` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return**  The `unique` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `unique` algorithm returns the iterator to the new end of the range.

The assignments in the parallel `unique_copy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note**  Complexity: Performs not more than `last - first` assignments, exactly `last - first - 1` applications of the predicate `pred` and no more than twice as many applications of the projection `proj`.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `unique_copy` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an binary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a, const Type &b);
```
The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type FwdIter1 can be dereferenced and then implicitly converted to Type.

• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel `unique_copy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `unique_copy` algorithm returns a `hpx::future<tagged_pair<tag::in(FwdIter1), tag::out(FwdIter2)>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `tagged_pair<tag::in(FwdIter1), tag::out(FwdIter2)>` otherwise. The `unique_copy` algorithm returns the pair of the source iterator to last, and the destination iterator to the end of the dest range.

```cpp
namespace hpx

namespace ranges

Functions

template<
    typename FwdIter, typename Sent, typename Proj = hpx::parallel::util::projection_identity,
    typename Pred = detail::equal_to>
FwdIter adjacent_find(FwdIter first, Sent last, Pred &&pred = Pred(), Proj &&proj = Proj())

Searches the range [first, last) for two consecutive identical elements.

Note Complexity: Exactly the smaller of (result - first) + 1 and (last - first) - 1 application of the predicate where result is the value returned.

**Return** The `adjacent_find` algorithm returns an iterator to the first of the identical elements. If no such elements are found, `last` is returned.

**Template Parameters**
- **FwdIter**: The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent**: The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`
- **Pred**: The type of an optional function/function object to use.

**Parameters**
- **first**: Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **pred**: The binary predicate which returns `true` if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &`, but the function must not modify the objects passed to it. The types `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.
template<typename ExPolicy, typename FwdIter, typename Sent, typename Proj = hpx::parallel::util::projection_identity, typename Pred = detail::equal_to>
util::detail::algorithm_result<ExPolicy, FwdIter>::type adjacent_find(ExPolicy &&policy, FwdIter first, Sent last, Pred &&pred = Pred(), Proj &&proj = Proj())

Searches the range [first, last) for two consecutive identical elements. This version uses the given binary predicate pred.

The comparison operations in the parallel adjacent_find invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Exactly the smaller of (result - first) + 1 and (last - first) - 1 application of the predicate where result is the value returned.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent**: The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **Proj**: The type of an optional projection function. This defaults to util::projection_identity
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of adjacent_find requires Pred to meet the requirements of CopyConstructible. This defaults to std::equal_to<>

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **pred**: The binary predicate which returns true if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 must be such that objects of type FwdIter can be dereferenced and then implicitly converted to Type1.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel adjacent_find invoked with an execution policy object of type sequenced_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of adjacent_find is available if the user decides to provide their algorithm their own binary predicate pred.

**Return** The adjacent_find algorithm returns a hpx::future<InIter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns InIter otherwise. The adjacent_find algorithm returns an iterator to the first of the identical elements. If no such elements are found, last is returned.

template<typename Rng, typename Proj = hpx::parallel::util::projection_identity, typename Pred = detail::equal_to>
adjacent_find

Searches the range rng for two consecutive identical elements.

**Note** Complexity: Exactly the smaller of \((\text{result} - \text{std::begin(rng)}) + 1\) and \((\text{std::begin(rng)} - \text{std::end(rng)}) - 1\) applications of the predicate where *result* is the value returned

**Return** The *adjacent_find* algorithm returns an iterator to the first of the identical elements. If no such elements are found, *last* is returned.

**Template Parameters**
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Proj**: The type of an optional projection function. This defaults to *util::projection_identity*
- **Pred**: The type of an optional function/function object to use.

**Parameters**
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **pred**: The binary predicate which returns true if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const & , but the function must not modify the objects passed to it. The types *Type1* must be such that objects of type *FwdIter* can be dereferenced and then implicitly converted to *Type1*.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel *adjacent_find* invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

**Note** Complexity: Exactly the smaller of \((\text{result} - \text{std::begin(rng)}) + 1\) and \((\text{std::begin(rng)} - \text{std::end(rng)}) - 1\) applications of the predicate where *result* is the value returned

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
• **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`.

• **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>

**Parameters**

• **policy**: The execution policy to use for the scheduling of the iterations.

• **rng**: Refers to the sequence of elements the algorithm will be applied to.

• **pred**: The binary predicate which returns `true` if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel `adjacent_find` invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of `adjacent_find` is available if the user decides to provide their algorithm their own binary predicate `pred`.

**Return** The `adjacent_find` algorithm returns a `hpx::future<InIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `InIter` otherwise. The `adjacent_find` algorithm returns an iterator to the first of the identical elements. If no such elements are found, `last` is returned.

```cpp
namespace hpx

namespace ranges

Functions

```

```cpp
template<typename ExPolicy, typename Rng, typename F, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, bool>::type none_of(ExPolicy &&policy, Rng &&rng, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate `f` returns true for no elements in the range `rng`.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: At most std:distance(begin(rng), end(rng)) applications of the predicate `f`

**Template Parameters**

• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

• **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

• **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `none_of` requires `F` to meet the requirements of `CopyConstructible`.

• **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`
Parameters
- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\). The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `none_of` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `none_of` algorithm returns true if the unary predicate `f` returns true for no elements in the range, false otherwise. It returns true if the range is empty.

```cpp
template<typename ExPolicy, typename Rng, typename F, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, bool>::type
any_of(ExPolicy &&policy, Rng &&rng, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate `f` returns true for at least one element in the range `rng`.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate `f`

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `none_of` requires `F` to meet the requirements of `CopyConstructible`.
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`
Return The `any_of` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `any_of` algorithm returns true if the unary predicate `f` returns true for at least one element in the range, false otherwise. It returns false if the range is empty.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread. **Note** Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate `f`

Template Parameters
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- `F`: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `none_of` requires `F` to meet the requirements of `CopyConstructible`.
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`

Parameters
- `policy`: The execution policy to use for the scheduling of the iterations.
- `rng`: Refers to the sequence of elements the algorithm will be applied to.
- `f`: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- `proj`: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The `all_of` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `all_of` algorithm returns true if the unary predicate `f` returns true for all elements in the range, false otherwise. It returns true if the range is empty.
Functions

template<typename ExPolicy, typename Iter1, typename Sent1, typename FwdIter>
hpx::parallel::util::detail::algorithm_result<ExPolicy, hpx::ranges::copy_result<Iter1, Iter>>::type copy (ExPolicy &&policy, Iter1 iter, Sent1 sent, FwdIter dest)

Copies the elements in the range, defined by [first, last), to another range beginning at dest.

The assignments in the parallel copy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Performs exactly last - first assignments.

Template Parameters
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- Iter1: The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- Sent1: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- FwdIter: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters
- policy: The execution policy to use for the scheduling of the iterations.
- iter: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- sent: Refers to the end of the sequence of elements the algorithm will be applied to.
- dest: Refers to the beginning of the destination range.

The assignments in the parallel copy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The copy algorithm returns a hpx::future<hpx::ranges::copy_result<FwdIter1, FwdIter1>> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns hpx::ranges::copy_result<FwdIter1, FwdIter1> otherwise. The copy algorithm returns the pair of the input iterator last and the output iterator to the element in the destination range, one past the last element copied.

template<typename ExPolicy, typename Rng, typename FwdIter>
hpx::parallel::util::detail::algorithm_result<ExPolicy, hpx::ranges::copy_result<typename hpx::traits::range_traits<Rng>::iterator_type, FwdIter>>::type copy (ExPolicy &&policy, Rng &&rng, FwdIter dest)

Copies the elements in the range rng to another range beginning at dest.
The assignments in the parallel copy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly std::distance(begin(rng), end(rng)) assignments.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **FwdIter**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.

The assignments in the parallel copy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The copy algorithm returns a `hpx::future<ranges::copy_result<iterator_t<Rng>, FwdIter2>>` if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns `ranges::copy_result<iterator_t<Rng>, FwdIter2>` otherwise. The copy algorithm returns the pair of the input iterator last and the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename Size, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result<ExPolicy, hpx::ranges::copy_n_result<FwdIter1, FwdIter2>>::type
copy_n(ExPolicy&& policy, FwdIter1 first, Size count, FwdIter2 dest)
```

Copies the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest.

The assignments in the parallel copy_n algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `count` assignments, if `count > 0`, no assignments otherwise.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size**: The type of the argument specifying the number of elements to apply `f` to.
- **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **count**: Refers to the number of elements starting at `first` the algorithm will be applied to.
• **dest**: Refers to the beginning of the destination range.

The assignments in the parallel `copy_n` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `copy_n` algorithm returns a `hpx::future<ranges::copy_n_result<FwdIter1, FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::copy_n_result<FwdIter1, FwdIter2>` otherwise. The `copy` algorithm returns the pair of the input iterator forwarded to the first element after the last in the input sequence and the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename Sent1, typename FwdIter, typename F, typename Proj = hpx::parallel::util::projection_identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, hpx::ranges::copy_if_result<typename hpx::traits::range_traits<Rng>::iterator_type, OutIter>>::type
```

Copies the elements in the range, defined by `[first, last)` to another range beginning at `dest`. Copies only the elements for which the predicate `f` returns true. The order of the elements that are not removed is preserved.

The assignments in the parallel `copy_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than `std::distance(begin(rng), end(rng))` assignments, exactly `std::distance(begin(rng), end(rng))` applications of the predicate `f`.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1**: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for `FwdIter1`.
- **FwdIter**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `copy_if` requires `F` to meet the requirements of `CopyConstructible`.
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`.

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **iter**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent**: Refers to the end of the sequence of elements the algorithm will be applied to.
• dest: Refers to the beginning of the destination range.
• f: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns \textit{true} for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have \texttt{const}, but the function must not modify the objects passed to it. The type \textit{Type} must be such that an object of type \textit{InIter} can be dereferenced and then implicitly converted to \textit{Type}.

• \texttt{proj}: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel \textit{copy_if} algorithm invoked with an execution policy object of type \textit{parallel_policy} or \textit{parallel_task_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

\textbf{Return} The \textit{copy_if} algorithm returns a \texttt{hpx::future<ranges::copy_if_result<iterator_t<Rng>,\newline\texttt{FwdIter2>>>>} if the execution policy is of type \textit{sequenced_task_policy} or \textit{parallel_task_policy} and returns \texttt{ranges::copy_if_result<iterator_t<Rng>,\texttt{FwdIter2}> otherwise. The \textit{copy_if} algorithm returns the pair of the input iterator \texttt{last} and the output iterator to the element in the destination range, one past the last element copied.

```
template<\texttt{typename ExPolicy, typename Rng, typename OutIter, typename F, typename Proj = hpx::parallel::util::\texttt{projection_identity}>}
\text{hpx::parallel::util::detail::algorithm_result<ExPolicy, hpx::ranges::copy_if_result<\texttt{typename hpx::traits::range_traits<Rng>::iterator_type},\texttt{OutIter}>}}
```

Copies the elements in the range \texttt{rng} to another range beginning at \texttt{dest}. Copies only the elements for which the predicate \texttt{f} returns true. The order of the elements that are not removed is preserved.

The assignments in the parallel \textit{copy_if} algorithm invoked with an execution policy object of type \textit{sequenced_policy} execute in sequential order in the calling thread.

\textbf{Note} Complexity: Performs not more than std::distance(begin(rng), end(rng)) assignments, exactly std::distance(begin(rng), end(rng)) applications of the predicate \texttt{f}.

\textbf{Template Parameters}
• ExPolicy: The type of the execution policy to use (docked). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• Rng: The type of the source range used (docked). The iterators extracted from this range type must meet the requirements of an input iterator.
• OutIter: The type of the iterator representing the destination range (docked). This iterator type must meet the requirements of an output iterator.
• F: The type of the function/function object to use (docked). Unlike its sequential form, the
parallel overload of `copy_if` requires $F$ to meet the requirements of `CopyConstructible`.

- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

  ```cpp
  bool pred(const Type &a);
  ```

  The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `InIter` can be dereferenced and then implicitly converted to `Type`.

- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel `copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

#### Return

The `copy_if` algorithm returns a `hpx::future<ranges::copy_if_result<iterator_t<Rng>, FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::copy_if_result<iterator_t<Rng>, FwdIter2>` otherwise. The `copy_if` algorithm returns the pair of the input iterator `last` and the output iterator to the element in the destination range, one past the last element copied.

```cpp
namespace hpx

namespace ranges

Functions

```cpp
template<typename ExPolicy, typename Rng, typename T, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<iterator_t<Rng>>::difference_type>
count(ExPolicy &&policy, Rng &&rng, T const &value, Proj &&proj = Proj())
```

Returns the number of elements in the range `[first, last)` satisfying a specific criteria. This version counts the elements that are equal to the given `value`.

The comparisons in the parallel `count` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `last - first` comparisons.
Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the comparisons.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **T**: The type of the value to search for (deduced).
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **value**: The value to search for.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Note** The comparisons in the parallel `count` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `count` algorithm returns a `hpx::future<difference_type>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `difference_type` otherwise (where `difference_type` is defined by `std::iterator_traits<FwdIter>::difference_type`). The `count` algorithm returns the number of elements satisfying the given criteria.

```cpp
template<typename ExPolicy, typename Rng, typename F, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<Rng>::iterator_type>
count_if(ExPolicy&& policy, Rng&& rng, F&& f, Proj&& proj = Proj())
```

Returns the number of elements in the range `[first, last)` satisfying a specific criteria. This version counts elements for which predicate `f` returns true.

**Note** Complexity: Performs exactly `last - first` applications of the predicate.

**Note** The assignments in the parallel `count_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** The assignments in the parallel `count_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `count_if` algorithm returns `hpx::future<difference_type>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `difference_type` otherwise (where `difference_type` is defined by `std::iterator_traits<FwdIter>::difference_type`). The `count` algorithm returns the number of elements satisfying the given criteria.

Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the comparisons.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
• **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `count_if` requires `F` to meet the requirements of `CopyConstructible`.

• **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`.

**Parameters**

• **policy**: The execution policy to use for the scheduling of the iterations.

• **rng**: Refers to the sequence of elements the algorithm will be applied to.

• **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

```cpp
namespace hpx
namespace ranges

Functions

template<typename ExPolicy>
util::detail::algorithm_result<ExPolicy, typename traits::range_iterator<Rng>::type>::type
destroy(ExPolicy &&policy, Rng &&rng)
```

Destroys objects of type `typename iterator_traits<ForwardIt>::value_type` in the range `[first, last)`.

The operations in the parallel `destroy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `last-first` operations.

**Template Parameters**

• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

**Parameters**

• **policy**: The execution policy to use for the scheduling of the iterations.

• **rng**: Refers to the sequence of elements the algorithm will be applied to.

The operations in the parallel `destroy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `destroy` algorithm returns a `hpx::future<void>`, if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `void` otherwise.

```cpp
template<typename ExPolicy, typename FwdIter, typename Size>
```
util::detail::algorithm_result<ExPolicy, FwdIter>::type **destroy_n**(ExPolicy &&policy, FwdIter first, Size count)

Destroys objects of type typename iterator_traits<ForwardIt>::value_type in the range [first, first + count).

The operations in the parallel destroy_n algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly count operations, if count > 0, no assignments otherwise.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size**: The type of the argument specifying the number of elements to apply this algorithm to.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count**: Refers to the number of elements starting at first the algorithm will be applied to.

The operations in the parallel destroy_n algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The destroy_n algorithm returns a hpx::future<FwdIter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter otherwise. The destroy_n algorithm returns the iterator to the element in the source range, one past the last element constructed.

namespace hpx

namespace ranges

**Functions**

template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Pred = ranges::equal_to, typename Proj1 = util::projection_identity, typename Proj2 = util::projection_identity>

util::detail::algorithm_result<ExPolicy, bool>::type **equal**(ExPolicy &&policy, Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())

Returns true if the range [first1, last1) is equal to the range [first2, last2), and false otherwise.

The comparison operations in the parallel equal algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: At most min(last1 - first1, last2 - first2) applications of the predicate f.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter1**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1**: The type of the source iterators used for the end of the first range (deduced).
• Iter2: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
• Sent2: The type of the source iterators used for the end of the second range (deduced).
• Pred: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of \texttt{equal} requires \texttt{Pred} to meet the requirements of \texttt{CopyConstructible}. This defaults to \texttt{std::equal\_to<>}
• Proj1: The type of an optional projection function applied to the first range. This defaults to \texttt{util::projection\_identity}
• Proj2: The type of an optional projection function applied to the second range. This defaults to \texttt{util::projection\_identity}

**Parameters**
- policy: The execution policy to use for the scheduling of the iterations.
- first1: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- last1: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- first2: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- last2: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- op: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types \texttt{Type1} and \texttt{Type2} must be such that objects of types \texttt{FwdIter1} and \texttt{FwdIter2} can be dereferenced and then implicitly converted to \texttt{Type1} and \texttt{Type2} respectively.

- proj1: Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate \texttt{is} invoked.
- proj2: Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate \texttt{is} invoked.

The comparison operations in the parallel \texttt{equal} algorithm invoked with an execution policy object of type \texttt{parallel\_policy} or \texttt{parallel\_task\_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note** The two ranges are considered equal if, for every iterator \(i\) in the range \([\text{first1}, \text{last1})\), \(\star i\) equals \(\star (\text{first2} + (i - \text{first1}))\). This overload of \texttt{equal} uses \texttt{operator==} to determine if two elements are equal.

**Return** The \texttt{equal} algorithm returns a \texttt{hpx::future<bool>} if the execution policy is of type \texttt{sequenced\_task\_policy} or \texttt{parallel\_task\_policy} and returns \texttt{bool} otherwise. The \texttt{equal} algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range \([\text{first1}, \text{last1})\) does not equal the length of the range \([\text{first2}, \text{last2})\), it returns false.

```cpp
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred = ranges::equal\_to, typename Proj1 = util::projection\_identity, typename Proj2 = util::projection\_identity>
util::detail::algorithm\_result<ExPolicy, bool>::type equal(ExPolicy &&policy, Rng1 &&rng1, Rng2 &&rng2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2());
```

Returns true if the range \([\text{first1}, \text{last1})\) is equal to the range starting at \text{first2}, and false otherwise.

The comparison operations in the parallel \texttt{equal} algorithm invoked with an execution policy object of type \texttt{sequenced\_policy} execute in sequential order in the calling thread.
Note  Complexity: At most $last1 - first1$ applications of the predicate $f$.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1**: The type of the first source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Rng2**: The type of the second source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`
- **Proj1**: The type of an optional projection function applied to the first range. This defaults to `util::projection_identity`
- **Proj2**: The type of an optional projection function applied to the second range. This defaults to `util::projection_identity`

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng1**: Refers to the first sequence of elements the algorithm will be applied to.
- **rng2**: Refers to the second sequence of elements the algorithm will be applied to.
- **op**: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively. 
- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel `equal` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note**  The two ranges are considered equal if, for every iterator `i` in the range `[first1,last1)`, `*i` equals `*(first2 + (i - first1))`. This overload of `equal` uses `operator==` to determine if two elements are equal.

**Return**  The `equal` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `equal` algorithm returns true if the elements in the two ranges are equal, otherwise it returns false.
**Functions**

```cpp
template<typename ExPolicy, typename Rng, typename T>
util::detail::algorithm_result<ExPolicy>::type fill(ExPolicy &&policy, Rng &&rng, T const &value)
```

Assigns the given value to the elements in the range `[first, last)`.

The comparisons in the parallel `fill` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `last - first` assignments.

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

- `T`: The type of the value to be assigned (deduced).

**Parameters**

- `policy`: The execution policy to use for the scheduling of the iterations.

- `rng`: Refers to the sequence of elements the algorithm will be applied to.

- `value`: The value to be assigned.

The comparisons in the parallel `fill` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `fill` algorithm returns a `hpx::future<void>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `difference_type` otherwise (where `difference_type` is defined by `void`).

```cpp
template<typename ExPolicy, typename Iterator, typename Size, typename T>
util::detail::algorithm_result<ExPolicy, Iterator>::type fill_n(ExPolicy &&policy, Iterator first, Size count, T const &value)
```

Assigns the given value value to the first `count` elements in the range beginning at `first` if `count > 0`. Does nothing otherwise.

The comparisons in the parallel `fill_n` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `count` assignments, for `count > 0`.

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- `Iterator`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
HPX Documentation, master

- **Size**: The type of the argument specifying the number of elements to apply \( f \) to.
- **T**: The type of the value to be assigned (deduced).

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count**: Refers to the number of elements starting at \( first \) the algorithm will be applied to.
- **value**: The value to be assigned.

The comparisons in the parallel \( \text{fill}_n \) algorithm invoked with an execution policy object of type \( \text{parallel}_{-}\text{policy} \) or \( \text{parallel}_{-}\text{task}_{-}\text{policy} \) are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The \( \text{fill}_n \) algorithm returns a \( \text{hpx}_{-}\text{future}_{<}\text{void}> \) if the execution policy is of type \( \text{sequenced}_{-}\text{task}_{-}\text{policy} \) or \( \text{parallel}_{-}\text{task}_{-}\text{policy} \) and returns \( \text{difference}_{-}\text{type} \) otherwise (where \( \text{difference}_{-}\text{type} \) is defined by \( \text{void} \)).

```cpp
namespace hpx

namespace ranges

Functions

template<typename ExPolicy, typename Iter, typename Sent, typename T, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, Iter>::type find(ExPolicy &&policy, Iter first, Sent last, T const &val, Proj &&proj = Proj())

Returns the first element in the range \([\text{first}, \text{last})\) that is equal to \( \text{val} \).
```

The comparison operations in the parallel \( \text{find} \) algorithm invoked with an execution policy object of type \( \text{sequenced}_{-}\text{policy} \) execute in sequential order in the calling thread.

**Note** Complexity: At most \( \text{last} - \text{first} \) applications of the operator\( \text{==} \).

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter**: The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent**: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for \( \text{Iter} \).
- **T**: The type of the value to find (deduced).
- **Proj**: The type of an optional projection function. This defaults to \( \text{util}_{::}\text{projection}_{-}\text{identity} \).

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **val**: the value to compare the elements to

1162 Chapter 2. What’s so special about HPX?
• proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel find algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The find algorithm returns a hpx::future<FwdIter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter otherwise. The find algorithm returns the first element in the range [first, last) that is equal to val. If no such element in the range of [first, last) is equal to val, then the algorithm returns last.

template<
  typename ExPolicy, 
  typename Rng, 
  typename T, 
  typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, Iter>::type find(
  ExPolicy &&policy, 
  Rng &&rng, 
  T const &val, 
  Proj &&proj = Proj())

Returns the first element in the range [first, last) that is equal to value

The comparison operations in the parallel find algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: At most last - first applications of the operator==().

Template Parameters

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• Rng: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
• T: The type of the value to find (deduced).
• Proj: The type of an optional projection function. This defaults to util::projection_identity

Parameters

• policy: The execution policy to use for the scheduling of the iterations.
• rng: Refers to the sequence of elements the algorithm will be applied to.
• val: the value to compare the elements to
• proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel find algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The find algorithm returns a hpx::future<FwdIter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter otherwise. The find algorithm returns the first element in the range [first, last) that is equal to val. If no such element in the range of [first, last) is equal to val, then the algorithm returns last.

template<
  typename ExPolicy, 
  typename Iter1, 
  typename Sent1, 
  typename Iter2, 
  typename Sent2, 
  typename Pred = ranges::equal_to,
  typename Proj1 = util::projection_identity,
  typename Proj2 = util::projection_identity>

```
util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng>::type>::type
find_end(ExPolicy&& policy,
Iter1 first1,
Sent1 last1,
Iter2 first2,
Sent2 last2,
Pred &&op = Pred(),
Proj1 &&proj1 = Proj1(),
Proj2 &&proj2 = Proj2())
```

Returns the last subsequence of elements [first2, last2) found in the range [first1, last1) using the given predicate \( f \) to compare elements.

The comparison operations in the parallel `find_end` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: at most \( S*(N-S+1) \) comparisons where \( S = \text{distance}(\text{first2}, \text{last2}) \) and \( N = \text{distance}(\text{first1}, \text{last1}) \).

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Iter1`: The type of the begin source iterators for the first sequence used (deduced). This iterator type must meet the requirements of an forward iterator.
- `Sent1`: The type of the end source iterators for the first sequence used (deduced). This iterator type must meet the requirements of an sentinel for `Iter1`.
- `Iter2`: The type of the begin source iterators for the second sequence used (deduced). This iterator type must meet the requirements of an forward iterator.
- `Sent2`: The type of the end source iterators for the second sequence used (deduced). This iterator type must meet the requirements of an sentinel for `Iter2`.
- `Pred`: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `replace` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`
- `Proj1`: The type of an optional projection function applied to the first sequence. This defaults to `util::projection_identity`
- `Proj2`: The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`

**Parameters**
- `policy`: The execution policy to use for the scheduling of the iterations.
- `first1`: Refers to the beginning of the first sequence of elements the algorithm will be applied to.
• **last1**: Refers to the end of the first sequence of elements the algorithm will be applied to.
• **first2**: Refers to the beginning of the second sequence of elements the algorithm will be applied to.
• **last2**: Refers to the end of the second sequence of elements the algorithm will be applied to.
• **op**: The binary predicate which returns `true` if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
def bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types `iterator_t<Rng>` and `iterator_t<Rng2>` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

• **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first range of type dereferenced `iterator_t<Rng1>` as a projection operation before the function `op` is invoked.

• **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second range of type dereferenced `iterator_t<Rng2>` as a projection operation before the function `op` is invoked.

The comparison operations in the parallel `find_end` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of `find_end` is available if the user decides to provide the algorithm their own predicate `op`.

**Returns** The `find_end` algorithm returns a `hpx::future<iterator_t<Rng>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `iterator_t<Rng>` otherwise. The `find_end` algorithm returns an iterator to the beginning of the last subsequence `rng2` in range `rng`. If the length of the subsequence `rng2` is greater than the length of the range `rng`, `end(rng)` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `end(rng)` is also returned.

```cpp
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred = ranges::equal_to, typename Proj1 = util::projection_identity, typename Proj2 = util::projection_identity>
util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng1>::type>::type find_end(ExPolicy &&policy, Rng1 &&rng, Rng2 &&rng2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Returns the last subsequence of elements `rng2` found in the range `rng` using the given predicate `f` to compare elements.
The comparison operations in the parallel `find_end` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: at most $S*(N-S+1)$ comparisons where $S = \text{distance}(\text{begin(rng2)}, \text{end(rng2)})$ and $N = \text{distance}(\text{begin(rng)}, \text{end(rng)})$.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1**: The type of the first source range (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **Rng2**: The type of the second source range (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `replace` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`.
- **Proj1**: The type of an optional projection function applied to the first sequence. This defaults to `util::projection_identity`
- **Proj2**: The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the first sequence of elements the algorithm will be applied to.
- **rng2**: Refers to the second sequence of elements the algorithm will be applied to.
- **op**: The binary predicate which returns `true` if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `iterator_t<Rng>` and `iterator_t<Rng2>` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first range of type dereferenced `iterator_t<Rng1>` as a projection operation before the function `op` is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second range of type dereferenced `iterator_t<Rng2>` as a projection operation before the function `op` is invoked.

The comparison operations in the parallel `find_end` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of `find_end` is available if the user decides to provide the algorithm their own predicate `op`.

**Return** The `find_end` algorithm returns a `hpx::future<iterator_t<Rng>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `iterator_t<Rng>` otherwise. The `find_end` algorithm returns an iterator to the beginning of the last subsequence `rng2` in range `rng`. If the length of the subsequence `rng2` is greater than the length of the range `rng`, `end(rng)` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `end(rng)` is also returned.
util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng1>::type>::type 

find_first_of (ExPolicy &&policy,
Iter1 first1,
Sent1 last1,
Iter2 first2,
Sent2 last2,
Pred &&op = Pred(),
Proj1 &&proj1 = Proj1(),
Proj2 &&proj2 = Proj2())

Searches the range [first1, last1) for any elements in the range [first2, last2). Uses binary predicate \( p \) to compare elements.

The comparison operations in the parallel find_first_of algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: at most \((S*N)\) comparisons where \( S = \text{distance(first2, last2)} \) and \( N = \text{distance(first1, last1)} \).

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter1**: The type of the begin source iterators for the first sequence used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1**: The type of the end source iterators for the first sequence used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2**: The type of the begin source iterators for the second sequence used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2**: The type of the end source iterators for the second sequence used (deduced). This iterator type must meet the requirements of an sentinel for Iter2.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of replace requires \( Pred \) to meet the requirements of CopyConstructible. This defaults to std::equal_to<>
- **Proj1**: The type of an optional projection function. This defaults to util::projection_identity and is applied to the elements in \( rng1 \).
- **Proj2**: The type of an optional projection function. This defaults to util::projection_identity and is applied to the elements in \( rng2 \).

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- last1: Refers to the end of the first sequence of elements the algorithm will be applied to.
- first2: Refers to the beginning of the second sequence of elements the algorithm will be applied to.
- last2: Refers to the end of the second sequence of elements the algorithm will be applied to.
- op: The binary predicate which returns true if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types iterator_t<Rng1> and iterator_t<Rng2> can be dereferenced and then implicitly converted to Type1 and Type2 respectively.

- proj1: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced iterator_t<Rng1> before the function op is invoked.
- proj2: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced iterator_t<Rng2> before the function op is invoked.

The comparison operations in the parallel find_first_of algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of find_first_of is available if the user decides to provide the algorithm their own predicate op.

Return The find_end algorithm returns a hpx::future<iterator_t<Rng1>> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns iterator_t<Rng1> otherwise. The find_first_of algorithm returns an iterator to the first element in the range rng1 that is equal to an element from the range rng2. If the length of the subsequence rng2 is greater than the length of the range rng1, end(rng1) is returned. Additionally if the size of the subsequence is empty or no subsequence is found, end(rng1) is also returned.

```cpp
template<
    typename ExPolicy,
    typename Rng1,
    typename Rng2,
    typename Pred = ranges::equal_to,
    typename Proj1 = util::projection_identity,
    typename Proj2 = util::projection_identity>
util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng1>::type>::type
find_first_of(
    ExPolicy &&policy,
    Rng1 &&rng1,
    Rng2 &&rng2,
    Pred &&op = Pred(),
    Proj1 &&proj1 = Proj1(),
    Proj2 &&proj2 = Proj2())
```

Searches the range rng1 for any elements in the range rng2. Uses binary predicate p to compare elements.
The comparison operations in the parallel find_first_of algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: at most ($S*N$) comparisons where $S = \text{distance}(\text{begin(rng2)}, \text{end(rng2)})$ and $N = \text{distance}(\text{begin(rng1)}, \text{end(rng1)})$.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1**: The type of the first source range (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **Rng2**: The type of the second source range (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of replace requires Pred to meet the requirements of CopyConstructible. This defaults to std::equal_to<>.
- **Proj1**: The type of an optional projection function. This defaults to util::projection_identity and is applied to the elements in rng1.
- **Proj2**: The type of an optional projection function. This defaults to util::projection_identity and is applied to the elements in rng2.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng1**: Refers to the first sequence of elements the algorithm will be applied to.
- **rng2**: Refers to the second sequence of elements the algorithm will be applied to.
- **op**: The binary predicate which returns true if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types iterator_t<Rng1> and iterator_t<Rng2> can be dereferenced and then implicitly converted to Type1 and Type2 respectively.

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced iterator_t<Rng1> before the function op is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced iterator_t<Rng2> before the function op is invoked.

The comparison operations in the parallel find_first_of algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of find_first_of is available if the user decides to provide the algorithm their own predicate op.

**Return** The find_end algorithm returns a hpx::future<iterator_t<Rng1>> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns iterator_t<Rng1> otherwise. The find_first_of algorithm returns an iterator to the first element in the range rng1 that is equal to an element from the range rng2. If the length of the subsequence rng2 is greater than the length of the range rng1, end(rng1) is returned. Additionally if the size of the subsequence is empty or no subsequence is found, end(rng1) is also returned.
Functions

template<typename InIter, typename Sent, typename F, typename Proj = util::projection_identity>
hp::ranges::for_each_result<InIter, F> for_each(InIter first, Sent last, F && f, Proj && proj = Proj())

Applies f to the result of dereferencing every iterator in the range [first, last).

If f returns a result, the result is ignored.

Note Complexity: Applies f exactly last - first times.

If the type of first satisfies the requirements of a mutable iterator, f may apply non-constant functions through the dereferenced iterator.

Applies f to the result of dereferencing every iterator in the range [first, first + count), starting from first and proceeding to first + count - 1.

Return {last, std::move(f)} where last is the iterator corresponding to the input sentinel last.

Template Parameters

• InIter: The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an input iterator.
• Sent: The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
• F: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of for_each requires F to meet the requirements of CopyConstructible.
• Proj: The type of an optional projection function. This defaults to util::projection_identity

Parameters

• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• last: Refers to the end of the sequence of elements the algorithm will be applied to.
• f: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```cpp
<ignored> pred(const Type &a);
```

The signature does not need to have const&. The type Type must be such that an object of type InIter can be dereferenced and then implicitly converted to Type.
• proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

If f returns a result, the result is ignored.

Note Complexity: Applies f exactly last - first times.

If the type of first satisfies the requirements of a mutable iterator, f may apply non-constant functions through the dereferenced iterator.

Return {first + count, std::move(f)}

Template Parameters

• InIter: The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an input iterator.
• Size: The type of the argument specifying the number of elements to apply f to.
• F: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of for_each requires F to meet the requirements of CopyConstructible.
• Proj: The type of an optional projection function. This defaults to util::projection_identity

Parameters

• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **count**: Refers to the number of elements starting at `first` the algorithm will be applied to.
• **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. The signature of this predicate should be equivalent to:

```cpp
<ignored> pred(const Type &a);
```

The signature does not need to have `const&`. The type `Type` must be such that an object of type `InIter` can be dereferenced and then implicitly converted to `Type`.
• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

```cpp
template<typename ExPolicy, typename FwdIter, typename Sent, typename F, typename Proj = util::projection_identity>
FwdIter for_each(ExPolicy &&policy, FwdIter first, Sent last, F &&f, Proj &&proj = Proj())
```

Applies `f` to the result of dereferencing every iterator in the range `[first, last)`.

If `f` returns a result, the result is ignored.

**Note** Complexity: Applies `f` exactly `last - first` times.

If the type of `first` satisfies the requirements of a mutable iterator, `f` may apply non-constant functions through the dereferenced iterator.

Unlike its sequential form, the parallel overload of `for_each` does not return a copy of its `Function` parameter, since parallelization may not permit efficient state accumulation.

**Return** The `for_each` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. It returns `last`.

**Template Parameters**
• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
• **FwdIter**: The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
• **Sent**: The type of the source sentinel (deduced). This sentinel type must be a sentinel for `InIter`.
• **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `for_each` requires `F` to meet the requirements of `CopyConstructible`.
• **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`.

**Parameters**
• **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
• **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. The signature of this predicate should be equivalent to:

```cpp
<ignored> pred(const Type &a);
```

The signature does not need to have `const&`. The type `Type` must be such that an object of type `InIter` can be dereferenced and then implicitly converted to `Type`.
• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

```cpp
template<typename Rng, typename F, typename Proj = util::projection_identity>
```
Applies \( f \) to the result of dereferencing every iterator in the given range \( rng \).

If \( f \) returns a result, the result is ignored.

**Note** Complexity: Applies \( f \) exactly \( \text{size}(rng) \) times.

If the type of \( \text{first} \) satisfies the requirements of a mutable iterator, \( f \) may apply non-constant functions through the dereferenced iterator.

**Return** \{std::end(rng), std::move(f)\}

**Template Parameters**
- \( Rng \): The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- \( F \): The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \( \text{for}\_\text{each} \) requires \( F \) to meet the requirements of \text{CopyConstructible}.
- \( Proj \): The type of an optional projection function. This defaults to util::projection_identity

**Parameters**
- \( \text{policy} \): The execution policy to use for the scheduling of the iterations.
- \( \text{rng} \): Refers to the sequence of elements the algorithm will be applied to.
- \( \text{f} \): Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\). The signature of this predicate should be equivalent to:

  ```cpp
  <\text{ignored}> \text{pred}(\text{const } \text{Type }&a);
  ```

  The signature does not need to have \text{const}\. The type \( \text{Type} \) must be such that an object of type \text{InIter} \ can be dereferenced and then implicitly converted to \text{Type}.
- \( \text{proj} \): Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate \text{is} invoked.

```
template<\text{typename ExPolicy, typename Rng, typename F, typename Proj = util::projection_identity}>
util::detail::algorithm_result<\text{ExPolicy, typename hpx::traits::range_iterator<Rng>::type}>\text{for}\_\text{each} (\text{ExPolicy} \&\&\text{policy}, \text{Rng } \&\&\text{rng}, \text{F } \&\&\text{f}, \text{Proj } \&\&\text{proj} = \text{Proj}())
```

Applies \( f \) to the result of dereferencing every iterator in the given range \( rng \).
If \( f \) returns a result, the result is ignored.

**Note** Complexity: Applies \( f \) exactly \( \text{size}(\text{rng}) \) times.

If the type of \( \text{first} \) satisfies the requirements of a mutable iterator, \( f \) may apply non-constant functions through the dereferenced iterator.

Unlike its sequential form, the parallel overload of \textit{for_each} does not return a copy of its \textit{Function} parameter, since parallelization may not permit efficient state accumulation.

The application of function objects in parallel algorithm invoked with an execution policy object of type \textit{sequenced_policy} execute in sequential order in the calling thread.

**Template Parameters**

- \textit{ExPolicy}: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- \textit{Rng}: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- \textit{F}: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \textit{for_each} requires \( F \) to meet the requirements of \textit{CopyConstructible}.
- \textit{Proj}: The type of an optional projection function. This defaults to util::projection_identity

**Parameters**

- \textit{policy}: The execution policy to use for the scheduling of the iterations.
- \textit{rng}: Refers to the sequence of elements the algorithm will be applied to.
- \textit{f}: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\). The signature of this predicate should be equivalent to:

\[
\text{<ignored>} \ \text{pred}(\text{const} \ \text{Type} \ &a);
\]

The signature does not need to have const&. The type \textit{Type} must be such that an object of type \textit{InIter} can be dereferenced and then implicitly converted to \textit{Type}.

- \textit{proj}: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type \textit{parallel_policy} or \textit{parallel_task_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The \textit{for_each} algorithm returns a \textit{hpx::future<\textit{FwdIter}>} if the execution policy is of type \textit{sequenced_task_policy} or \textit{parallel_task_policy} and returns \textit{FwdIter} otherwise. It returns \textit{last}.

```cpp
template<typename \textit{ExPolicy}, typename \textit{FwdIter}, typename \textit{Size}, typename \textit{F}, typename \textit{Proj} = util::projection_identity util::detail::algorithm_result<\textit{ExPolicy}, \textit{FwdIter}>::type \textit{for_each_n} (\textit{ExPolicy} &\&\textit{policy}, \textit{FwdIter} \textit{first}, \textit{Size} \textit{count}, \textit{F} &\&\textit{f}, \textit{Proj} &\&\textit{proj} = \textit{Proj}())
```

Applies \( f \) to the result of dereferencing every iterator in the range \([\text{first}, \text{first} + \text{count})\), starting from \textit{first} and proceeding to \textit{first} + \text{count} - 1.

If \( f \) returns a result, the result is ignored.

**Note** Complexity: Applies \( f \) exactly \( \text{count} \) times.

If the type of \( \text{first} \) satisfies the requirements of a mutable iterator, \( f \) may apply non-constant functions through the dereferenced iterator.

Unlike its sequential form, the parallel overload of \textit{for_each} does not return a copy of its \textit{Function} parameter, since parallelization may not permit efficient state accumulation.
Return The for_each algorithm returns a hpx::future<FwdIter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter otherwise. It returns last.

Template Parameters
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- FwdIter: The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- Size: The type of the argument specifying the number of elements to apply f to.
- F: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of for_each requires F to meet the requirements of CopyConstructible.
- Proj: The type of an optional projection function. This defaults to util::projection_identity

Parameters
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- count: Refers to the number of elements starting at first the algorithm will be applied to.
- f: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```cpp
<ignored> pred(const Type &a);
```

The signature does not need to have const&. The type Type must be such that an object of type InIter can be dereferenced and then implicitly converted to Type.
- proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

namespace hpx

namespace ranges

Functions

```cpp
template<typename Iter, typename Sent, typename ...Args>
void for_loop(Iter first, Sent last, Args&&... args)
```

The for_loop implements loop functionality over a range specified by iterator bounds. These algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of for_loop without specifying an execution policy is equivalent to specifying hpx::execution::seq as the execution policy.

Requires: Iter shall meet the requirements of an input iterator type. The args parameter pack shall have at least one element, comprising objects returned by invocations of reduction and/or induction function templates followed by exactly one element invocable element-access function, f. f shall meet the requirements of MoveConstructible.

Template Parameters
- Iter: The type of the iteration variable (input iterator).
- Sent: The type of the source sentinel (deduced). This sentinel type must be a sentinel for Iter.
- Args: A parameter pack, it’s last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

Parameters
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last: Refers to the end of the sequence of elements the algorithm will be applied to.
• **args**: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

```cpp
<ignored> pred(Iter const& a, ...);
```

The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Effects**: Applies \( f \) to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the **args** parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by **first**. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the **args** parameter pack excluding **f**, an additional argument is passed to each application of **f** as follows:

**Note** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

**Note** The order of the elements of the input sequence is important for determining ordinal position of an application of **f**, even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of **f** in the input sequence.

**Complexity**: Applies **f** exactly once for each element of the input sequence.

**Remarks**: If **f** returns a result, the result is ignored.

```cpp
template<typename ExPolicy, typename Iter, typename Sent, typename ...Args>
util::detail::algorithm_result<ExPolicy>::type for_loop(ExPolicy &&policy, Iter first, Sent last, Args&&... args)
```

The for_loop implements loop functionality over a range specified by iterator bounds. These algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

**Requires**: **Iter** shall meet the requirements of a forward iterator type. The **args** parameter pack shall have at least one element, comprising objects returned by invocations of reduction and/or induction function templates followed by exactly one element invocable element-access function, \( f \). **f** shall meet the requirements of MoveConstructible.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Iter**: The type of the iteration variable (forward iterator).
- **Sent**: The type of the source sentinel (forward iterator).
- **Args**: A parameter pack, it’s last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
• **args**: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects.

The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

```cpp
<ignored> pred(Iter const& a, ...);
```

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Effects**: Applies \( f \) to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the `args` parameter pack. The length of the input sequence is `last - first`.

The first element in the input sequence is specified by `first`. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the `args` parameter pack excluding `f`, an additional argument is passed to each application of `f` as follows:

**Note** As described in the C++ standard, arithmetic on non-random-access iterators is performed using `advance` and `distance`.

**Note** The order of the elements of the input sequence is important for determining ordinal position of an application of \( f \), even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of \( f \) in the input sequence.

**Complexity**: Applies \( f \) exactly once for each element of the input sequence.

**Remarks**: If \( f \) returns a result, the result is ignored.

**Return** The `for_loop` algorithm returns a `hpx::future<void>` if the execution policy is of type `hpx::execution::sequenced_task_policy` or `hpx::execution::parallel_task_policy` and returns `void` otherwise.

```cpp
template<typename Rng, typename ...Args>
void for_loop (Rng &&rng, Args&&... args)
```

The `for_loop` implements loop functionality over a range specified by a range. These algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of `for_loop` without specifying an execution policy is equivalent to specifying `hpx::execution::seq` as the execution policy.

**Requires**: `Rng::iterator` shall meet the requirements of an input iterator type. The `args` parameter pack shall have at least one element, comprising objects returned by invocations of `reduction` and/or `induction` function templates followed by exactly one element invocable element-access function, \( f \). \( f \) shall meet the requirements of `MoveConstructible`.

**Template Parameters**
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
• **Args**: A parameter pack, it’s last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**

• **rng**: Refers to the of the sequence of elements the algorithm will be applied to.
• **args**: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

```
<ignored> pred(Rng::iterator const& a, ...);
```

The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Effects**: Applies \( f \) to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the \( args \) parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by \( first \). Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the \( args \) parameter pack excluding \( f \), an additional argument is passed to each application of \( f \) as follows:

**Note** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

**Note** The order of the elements of the input sequence is important for determining ordinal position of an application of \( f \), even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of \( f \) in the input sequence.

**Complexity**: Applies \( f \) exactly once for each element of the input sequence.

**Remarks**: If \( f \) returns a result, the result is ignored.

```cpp
template<typename ExPolicy, typename Rng, typename ...Args>
util::detail::algorithm_result<ExPolicy>::type for_loop(
    ExPolicy &&policy,
    Rng &&rng,
    Args&&... args)
```

The for_loop implements loop functionality over a range specified by a range. These algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

**Requires**: \( Rng::iterator \) shall meet the requirements of a forward iterator type. The \( args \) parameter pack shall have at least one element, comprising objects returned by invocations of reduction and/or induction function templates followed by exactly one element invocable element-access function, \( f \). \( f \) shall meet the requirements of MoveConstructible.

**Template Parameters**

• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
• **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
• **Args**: A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **args**: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\) should expose a signature equivalent to:

```cpp
<ignored> pred(Rng::iterator const & a, ...);
```

The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

### Effects

Applies \(f\) to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the \(args\) parameter pack. The length of the input sequence is \(\text{last} - \text{first}\).

The first element in the input sequence is specified by \(\text{first}\). Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the \(args\) parameter pack excluding \(f\), an additional argument is passed to each application of \(f\) as follows:

**Note** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

**Note** The order of the elements of the input sequence is important for determining ordinal position of an application of \(f\), even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of \(f\) in the input sequence.

### Complexity

Applies \(f\) exactly once for each element of the input sequence.

### Remarks

If \(f\) returns a result, the result is ignored.

**Return** The \(for\_loop\) algorithm returns a \(hpx::future<\text{void}>\) if the execution policy is of type \(hpx::execution::sequenced\_task\_policy\) or \(hpx::execution::parallel\_task\_policy\) and returns \(\text{void}\) otherwise.

```cpp
template<typename Iter, typename Sent, typename S, typename ...Args>
void for_loop_strided(Iter first, Sent last, S stride, Args&&... args)
```

The \(for\_loop\_strided\) implements loop functionality over a range specified by iterator bounds. These algorithms resemble \(for\_each\) from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of \(for\_loop\_strided\) without specifying an execution policy is equivalent to specifying \(hpx::execution::seq\) as the execution policy.

**Requires**: \(Iter\) shall meet the requirements of an input iterator type. The \(args\) parameter pack shall have at least one element, comprising objects returned by invocations of \(reduction\) and/or \(induction\) function templates followed by exactly one element invocable element-access function. \(f\), \(f\) shall meet the requirements of MoveConstructible.
**Template Parameters**

- **Iter**: The type of the iteration variable (input iterator).
- **Sent**: The type of the source sentinel (deduced). This sentinel type must be a sentinel for Iter.
- **S**: The type of the stride variable. This should be an integral type.
- **Args**: A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**

- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **stride**: Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if Iter meets the requirements of a bidirectional iterator.
- **args**: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

  \[
  \text{<ignored> pred(Iter const& a, ...);} 
  \]

  The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Effects**: Applies \( f \) to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the \( args \) parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by \( first \). Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the \( args \) parameter pack excluding \( f \), an additional argument is passed to each application of \( f \) as follows:

**Note**  As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

**Note**  The order of the elements of the input sequence is important for determining ordinal position of an application of \( f \), even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of \( f \) in the input sequence.

**Complexity**: Applies \( f \) exactly once for each element of the input sequence.

**Remarks**: If \( f \) returns a result, the result is ignored.

```cpp
template<
    typename ExPolicy,
    typename Iter, 
    typename Sent, 
    typename S, 
    typename... Args>
```

The for_loop_strided implements loop functionality over a range specified by iterator bounds. These algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

**Requires**: \( Iter \) shall meet the requirements of a forward iterator type. The \( args \) parameter pack shall have at least one element, comprising objects returned by invocations of reduction and/or induction function templates followed by exactly one element invocable element-access function, \( f \). \( f \) shall meet the requirements of MoveConstructible.

**Template Parameters**
• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

• **Iter**: The type of the iteration variable (forward iterator).

• **Sent**: The type of the source sentinel (deduced). This sentinel type must be a sentinel for Iter.

• **S**: The type of the stride variable. This should be an integral type.

• **Args**: A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **stride**: Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if Iter meets the requirements a bidirectional iterator.
- **args**: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects.

The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

```cpp
<ignored> pred(Iter const& a, ...);
```

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Effects**: Applies \( f \) to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the **args** parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by **first**. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the **args** parameter pack excluding \( f \), an additional argument is passed to each application of \( f \) as follows:

**Note** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

**Note** The order of the elements of the input sequence is important for determining ordinal position of an application of \( f \), even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of \( f \) in the input sequence.

**Complexity**: Applies \( f \) exactly once for each element of the input sequence.

**Remarks**: If \( f \) returns a result, the result is ignored.

**Return** The **for_loop_strided** algorithm returns a `hpx::future<void>` if the execution policy is of type `hpx::execution::sequenced_task_policy` or `hpx::execution::parallel_task_policy` and returns `void` otherwise.

```cpp
template<
    typename Rng,
    typename S,
    typename ...
        Args
>
void for_loop_strided( Rng &&rng, S stride, Args&&... args)
```

The for_loop_strided implements loop functionality over a range specified by a range. These algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.
The execution of `for_loop_strided` without specifying an execution policy is equivalent to specifying `hpx::execution::seq` as the execution policy.

**Requires:** `Rng::iterator` shall meet the requirements of an input iterator type. The `args` parameter pack shall have at least one element, comprising objects returned by invocations of `reduction` and/or `induction` function templates followed by exactly one element invocable element-access function, `f`. `f` shall meet the requirements of MoveConstructible.

**Template Parameters**
- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- `S`: The type of the stride variable. This should be an integral type.
- `Args`: A parameter pack, it's last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**
- `rng`: Refers to the of the sequence of elements the algorithm will be applied to.
- `stride`: Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if `Rng::iterator` meets the requirements a bidirectional iterator.
- `args`: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)` should expose a signature equivalent to:

```cpp
<ignored> pred(Rng::iterator const & a, ...);
```

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Effects:** Applies `f` to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the `args` parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by `first`. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the `args` parameter pack excluding `f`, an additional argument is passed to each application of `f` as follows:

**Note** As described in the C++ standard, arithmetic on non-random-access iterators is performed using `advance` and `distance`.

**Note** The order of the elements of the input sequence is important for determining ordinal position of an application of `f`, even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of `f` in the input sequence.

**Complexity:** Applies `f` exactly once for each element of the input sequence.

**Remarks:** If `f` returns a result, the result is ignored.

```cpp
template<typename ExPolicy, typename Rng, typename S, typename ...Args>
util::detail::algorithm_result<ExPolicy>::type for_loop_strided(ExPolicy &&policy, Rng &&rng, S stride, Args&&... args)
```

The `for_loop_strided` implements loop functionality over a range specified by a range. These al-
algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

Requires: Rng::iterator shall meet the requirements of a forward iterator type. The args parameter pack shall have at least one element, comprising objects returned by invocations of reduction and/or induction function templates followed by exactly one element invocable element-access function, f. f shall meet the requirements of MoveConstructible.

Template Parameters
• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
• Rng: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
• S: The type of the stride variable. This should be an integral type.
• Args: A parameter pack, it’s last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

Parameters
• policy: The execution policy to use for the scheduling of the iterations.
• rng: Refers to the sequence of elements the algorithm will be applied to.
• stride: Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if Rng::iterator meets the requirements a bidirectional iterator.
• args: The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

```cpp
<ignored> pred(Rng::iterator const & a, ...);
```

The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

Effects: Applies f to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the args parameter pack. The length of the input sequence is last-first.

The first element in the input sequence is specified by first. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the args parameter pack excluding f, an additional argument is passed to each application of f as follows:

Note As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

Note The order of the elements of the input sequence is important for determining ordinal position of an application of f, even though the applications themselves may be unordered.

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of f in the input sequence.

Complexity: Applies f exactly once for each element of the input sequence.

Remarks: If f returns a result, the result is ignored.
Return The for_loop_strided algorithm returns a `hpx::future<void>` if the execution policy is of type `hpx::execution::sequenced_task_policy` or `hpx::execution::parallel_task_policy` and returns `void` otherwise.

namespace hpx

namespace ranges

Functions

template<typename ExPolicy, typename Rng, typename F>
util::detail::algorithm_result<ExPolicy, typeof(hpx::traits::range_iterator<Rng>::type)>::type generate(ExPolicy &&policy, Rng &&rng, F &&f)

Assign each element in range [first, last) a value generated by the given function object f

The assignments in the parallel generate algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

Note Complexity: Exactly `distance(first, last)` invocations of f and assignments.

Template Parameters
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- Rng: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- F: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of equal requires F to meet the requirements of CopyConstructible.

Parameters
- policy: The execution policy to use for the scheduling of the iterations.
- rng: Refers to the sequence of elements the algorithm will be applied to.
- f: generator function that will be called. signature of function should be equivalent to the following:

```cpp
Ret fun();
```

The type Ret must be such that an object of type FwdIter can be dereferenced and assigned a value of type Ret.

The assignments in the parallel generate algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The replace_if algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns FwdIter otherwise. It returns last.

template<typename ExPolicy, typename Iter, typename Sent, typename F>
util::detail::algorithm_result<ExPolicy, Iter>::type generate(ExPolicy &&policy, Iter first, Sent last, F &&f)

Assign each element in range [first, last) a value generated by the given function object f
The assignments in the parallel `generate` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Exactly $distance(first, last)$ invocations of $f$ and assignments.

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Iter`: The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- `Sent`: The type of the source end iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- `F`: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires $F$ to meet the requirements of `CopyConstructible`.

**Parameters**
- `policy`: The execution policy to use for the scheduling of the iterations.
- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last`: Refers to the end of the sequence of elements the algorithm will be applied to.
- `f`: generator function that will be called. signature of function should be equivalent to the following:

```cpp
Ret fun();
```

The type `Ret` must be such that an object of type `FwdIter` can be dereferenced and assigned a value of type `Ret`.

The assignments in the parallel `generate` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `replace_if` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. It returns `last`.

```cpp
template<typename ExPolicy, typename FwdIter, typename Size, typename F>
util::detail::algorithm_result<ExPolicy, FwdIter>::type generate_n(ExPolicy &&policy, FwdIter first, Size count, F &&f)
```

Assigns each element in range `[first, first+count)` a value generated by the given function object $g$.

The assignments in the parallel `generate_n` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Exactly $count$ invocations of $f$ and assignments, for $count > 0$.

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter`: The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- `F`: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires $F$ to meet the requirements of `CopyConstructible`.

**Parameters**
- `policy`: The execution policy to use for the scheduling of the iterations.
- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `count`: Refers to the number of elements in the sequence the algorithm will be applied to.
• **f**: Refers to the generator function object that will be called. The signature of the function should be equivalent to

\[ \text{Ret fun();} \]

The type \( \text{Ret} \) must be such that an object of type \( \text{OutputIt} \) can be dereferenced and assigned a value of type \( \text{Ret} \).

The assignments in the parallel \( \text{generate_n} \) algorithm invoked with an execution policy object of type \( \text{parallel_policy} \) or \( \text{parallel_task_policy} \) are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return**: The \( \text{replace_if} \) algorithm returns a \( \text{hpx::future<FwdIter>} \) if the execution policy is of type \( \text{sequenced_task_policy} \) or \( \text{parallel_task_policy} \) and returns \( \text{FwdIter} \) otherwise. It returns \( \text{last} \).

```cpp
namespace hpx

namespace ranges

Functions

template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Pred = std::less, typename Proj1 = std::util::projection_identity, typename Proj2 = std::util::projection_identity>

\[ \text{util::detail::algorithm_result<ExPolicy, bool>::type includes(ExPolicy && policy, Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Pred && op = Pred(), Proj1 && proj1 = Proj1(), Proj2 && proj2 = Proj2())} \]

Returns true if every element from the sorted range \([\text{first2}, \text{last2})\) is found within the sorted range \([\text{first1}, \text{last1})\). Also returns true if \([\text{first2}, \text{last2})\) is empty. The version expects both ranges to be sorted with the user supplied binary predicate \( f \).

The comparison operations in the parallel \( \text{includes} \) algorithm invoked with an execution policy object of type \( \text{sequenced_policy} \) execute in sequential order in the calling thread.

**Note**: At most \( 2^* (N1+N2-1) \) comparisons, where \( N1 = \text{std::distance(first1, last1)} \) and \( N2 = \text{std::distance(first2, last2)} \).

**Template Parameters**
- \( \text{ExPolicy} \): The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- \( \text{Iter1} \): The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- \( \text{Sent1} \): The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for \( \text{Iter1} \).
- \( \text{Iter2} \): The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
- \( \text{Sent2} \): The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for \( \text{Iter2} \).
- \( \text{Pred} \): The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of \( \text{includes} \) requires \( \text{Pred} \) to meet the requirements of \( \text{CopyConstructible} \). This defaults to \( \text{std::less<>} \).
- \( \text{Proj1} \): The type of an optional projection function applied to the first sequence. This defaults to \( \text{util::projection_identity} \).
• **Proj2**: The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`.

### Parameters
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2**: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2**: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op**: The binary predicate which returns true if the elements should be treated as includes. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

The comparison operations in the parallel `includes` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

### Return
The `includes` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `includes` algorithm returns true every element from the sorted range `[first2, last2)` is found within the sorted range `[first1, last1)`. Also returns true if `[first2, last2)` is empty. The version expects both ranges to be sorted with the user supplied binary predicate `f`.

```cpp
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred = detail::less, typename Proj1 = util::projection_identity, typename Proj2 = util::projection_identity>
util::detail::algorithm_result<ExPolicy, bool>::type
includes(ExPolicy &&policy, Rng1 &&rng1, Rng2 &&rng2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Returns true if every element from the sorted range `[first2, last2)` is found within the sorted range `[first1, last1)`. Also returns true if `[first2, last2)` is empty. The version expects both ranges to be sorted with the user supplied binary predicate `f`.

The comparison operations in the parallel `includes` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

### Note
At most \(2^*(N_1+N_2-1)\) comparisons, where \(N_1 = \text{std::distance(first1, last1)}\) and \(N_2 = \text{std::distance(first2, last2)}\).

### Template Parameters
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1**: The type of the source range used (deduced). The iterators extracted from this range...
type must meet the requirements of an input iterator.

- **Rng2**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `includes` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`
- **Proj1**: The type of an optional projection function applied to the first sequence. This defaults to `util::projection_identity`
- **Proj2**: The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng1**: Refers to the first sequence of elements the algorithm will be applied to.
- **rng2**: Refers to the second sequence of elements the algorithm will be applied to.
- **op**: The binary predicate which returns true if the elements should be treated as includes. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

The comparison operations in the parallel `includes` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `includes` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `includes` algorithm returns true every element from the sorted range `[first2, last2)` is found within the sorted range `[first1, last1)`. Also returns true if `[first2, last2)` is empty.

### namespace hpx

#### Functions

```cpp
template<typename ExPolicy, typename Iter, typename Sent, typename Comp = detail::less, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, bool>::type
is_heap(ExPolicy &&policy, Iter first, Sent last,
    Comp &&comp = Comp(), Proj &&proj
    = Proj())
```

Returns whether the range is max heap. That is, true if the range is max heap, false otherwise. The function uses the given comparison function object `comp` (defaults to using `operator<()`).

**Note** Complexity: Performs at most N applications of the comparison `comp`, at most 2 * N applications of the projection `proj`, where N = last - first.
• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **Iter**: The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

• **Sent**: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.

• **Comp**: The type of the function/function object to use (deduced).

• **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

---

**Parameters**

• **policy**: The execution policy to use for the scheduling of the iterations.

• **iter**: Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **sent**: Refers to the end of the sequence of elements the algorithm will be applied to.

• **comp**: `comp` is a callable object. The return value of the INVOKE operation applied to an object of type `Comp`, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator.

• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Return** The `is_heap` algorithm returns a `hpx:future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `is_heap` algorithm returns whether the range is max heap. That is, true if the range is max heap, false otherwise. The function uses the given comparison function object `comp` (defaults to using operator<()).

`comp` has to induce a strict weak ordering on the values.

**Note** Complexity: Performs at most N applications of the comparison `comp`, at most 2 * N applications of the projection `proj`, where N = last - first.

---

**Template Parameters**

• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
• Comp: The type of the function/function object to use (deduced).

• Proj: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

• policy: The execution policy to use for the scheduling of the iterations.

• rng: Refers to the sequence of elements the algorithm will be applied to.

• comp: `comp` is a callable object. The return value of the INVOKE operation applied to an object of type `Comp`, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator.

• proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate `is` invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `is_heap` algorithm returns a `hx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `is_heap` algorithm returns whether the range is max heap. That is, true if the range is max heap, false otherwise.

```cpp
template<typename ExPolicy, typename Iter, typename Sent, typename Comp = detail::less, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, Iter>::type is_heap_until(ExPolicy &&policy, Iter first, Sent sent, Comp &&comp = Comp(), Proj &&proj = Proj())
```

Returns the upper bound of the largest range beginning at `first` which is a max heap. That is, the last iterator `it` for which range `[first, it)` is a max heap. The function uses the given comparison function object `comp` (defaults to using operator<()).

`comp` has to induce a strict weak ordering on the values.

**Note** Complexity: Performs at most N applications of the comparison `comp`, at most 2 * N applications of the projection `proj`, where N = last - first.

**Template Parameters**

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• Iter: The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

• Sent: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.

• Comp: The type of the function/function object to use (deduced).

• Proj: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

• policy: The execution policy to use for the scheduling of the iterations.

• iter: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **sent**: Refers to the end of the sequence of elements the algorithm will be applied to.

• **comp**: `comp` is a callable object. The return value of the INVOKE operation applied to an object of type `Comp`, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator.

• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `is_heap_until` algorithm returns a `hpx::future<RandIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `RandIter` otherwise. The `is_heap_until` algorithm returns the upper bound of the largest range beginning at first which is a max heap. That is, the last iterator `it` for which range `[first, it)` is a max heap. The function uses the given comparison function object `comp` (defaults to using operator<()).

*comp* has to induce a strict weak ordering on the values.

**Note** Complexity: Performs at most N applications of the comparison `comp`, at most 2 * N applications of the projection `proj`, where N = last - first.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a random access iterator.

- **Comp**: The type of the function/function object to use (deduced).

- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`.
• **policy**: The execution policy to use for the scheduling of the iterations.

• **rng**: Refers to the sequence of elements the algorithm will be applied to.

• **comp**: `comp` is a callable object. The return value of the INVOKE operation applied to an object of type `Comp`, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator.

• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `is_heap_until` algorithm returns a `hpx::future<RandIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `RandIter` otherwise. The `is_heap_until` algorithm returns the upper bound of the largest range beginning at `first` which is a max heap. That is, the last iterator `it` for which range `[first, it)` is a max heap.

```cpp
namespace hpx

namespace ranges

Functions

template<typename FwdIter, typename Sent, typename Pred = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>
bool is_sorted (FwdIter first, Sent last, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Determines if the range `[first, last)` is sorted. Uses `pred` to compare elements.

The comparison operations in the parallel `is_sorted` algorithm executes in sequential order in the calling thread.

**Note** Complexity: at most (N+S-1) comparisons where N = distance(first, last). S = number of partitions

**Template Parameters**

- **FwdIter**: The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred**: The type of an optional function/function object to use.
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- **first**: Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred**: Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a, const Type &b);
```
The signature does not need to have const &, but the function must not modify the objects passed to it. The type Type must be such that objects of types FwdIter can be dereferenced and then implicitly converted to Type.

- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Return** The is_sorted algorithm returns a bool. The is_sorted algorithm returns true if each element in the sequence [first, last) satisfies the predicate passed. If the range [first, last) contains less than two elements, the function always returns true.

```
template<typename ExPolicy, typename FwdIter, typename Sent, typename Pred = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>
bool is_sorted(ExPolicy &&policy, FwdIter first, Sent last, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Determines if the range [first, last) is sorted. Uses pred to compare elements.

The comparison operations in the parallel is_sorted algorithm invoked with an execution policy object of type sequenced_policy executes in sequential order in the calling thread.

**Note** Complexity: at most (N+S-1) comparisons where $N = \text{distance(first, last)}$. $S = \text{number of partitions}$

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of is_sorted requires Pred to meet the requirements of CopyConstructible. This defaults to std::less
- **Proj**: The type of an optional projection function. This defaults to util::projection_identity

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred**: Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```
bool pred(const Type &a, const Type &b);
```

The comparison operations in the parallel is_sorted algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The is_sorted algorithm returns a hpx::future<bool> if the execution policy is of type
The \texttt{is_sorted} algorithm returns a \texttt{bool} if each element in the sequence \texttt{[first, last)} satisfies the predicate passed. If the range \texttt{[first, last)} contains less than two elements, the function always returns true.

\begin{verbatim}
template<typename Rng, typename Pred = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>
bool is_sorted(ExPolicy &&policy, Rng &&rng, Pred &&pred = Pred(), Proj &&proj = Proj())
\end{verbatim}

Determines if the range \texttt{rng} is sorted. Uses \texttt{pred} to compare elements.

The comparison operations in the parallel \texttt{is_sorted} algorithm executes in sequential order in the calling thread.

**Note** Complexity: at most (N+S-1) comparisons where \( N = \text{size(rng)} \). \( S = \text{number of partitions} \)

**Template Parameters**
- \texttt{Rng}: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- \texttt{Pred}: The type of an optional function/function object to use.
- \texttt{Proj}: The type of an optional projection function. This defaults to \texttt{util::projection_identity}

**Parameters**
- \texttt{rng}: Refers to the sequence of elements the algorithm will be applied to.
- \texttt{pred}: Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

\begin{verbatim}
bool pred(const Type &a, const Type &b);
\end{verbatim}

The signature does not need to have \texttt{const &}, but the function must not modify the objects passed to it. The type \texttt{Type} must be such that objects of types \texttt{FwdIter} can be dereferenced and then implicitly converted to \texttt{Type}.
- \texttt{proj}: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate \texttt{is} invoked.

**Return** The \texttt{is_sorted} algorithm returns a \texttt{bool}. The \texttt{is_sorted} algorithm returns true if each element in the \texttt{rng} satisfies the predicate passed. If the range \texttt{rng} contains less than two elements, the function always returns true.

\begin{verbatim}
template<typename ExPolicy, typename Rng, typename Pred = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::detail::algorithm_result<ExPolicy, bool>::type>
\end{verbatim}

Determines if the range \texttt{rng} is sorted. Uses \texttt{pred} to compare elements.

The comparison operations in the parallel \texttt{is_sorted} algorithm invoked with an execution policy object of type \texttt{sequenced_policy} executes in sequential order in the calling thread.

**Note** Complexity: at most (N+S-1) comparisons where \( N = \text{size(rng)} \). \( S = \text{number of partitions} \)

**Template Parameters**
- \texttt{ExPolicy}: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- \texttt{Rng}: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- \texttt{Pred}: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of \texttt{is_sorted} requires \texttt{Pred} to meet the requirements of \texttt{CopyConstructible}. This defaults to std::less<>
• **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **pred**: Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a, const Type &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel `is_sorted` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `is_sorted` algorithm returns a `hpx::future<bool>` if the execution policy is of type `task_execution_policy` and returns `bool` otherwise. The `is_sorted` algorithm returns a `bool` if each element in the range `rng` satisfies the predicate passed. If the range `rng` contains less than two elements, the function always returns `true`.

```cpp
template<typename FwdIter, typename Sent, typename Pred = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>
FwdIter is_sorted_until (FwdIter first, Sent last, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Returns the first element in the range `[first, last)` that is not sorted. Uses a predicate to compare elements or the less than operator.

The comparison operations in the parallel `is_sorted_until` algorithm execute in sequential order in the calling thread.

**Note** Complexity: at most \((N+S-1)\) comparisons where \(N = \text{distance(first, last)}\). \(S = \text{number of partitions}\)

**Template Parameters**
- **FwdIter**: The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred**: The type of an optional function/function object to use.
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**
- **first**: Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred**: Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a, const Type &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.
**Return** The `is_sorted_until` algorithm returns a `FwdIter`. The `is_sorted_until` algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, last is returned.

```
template<typename ExPolicy, typename FwdIter, typename Sent, typename Pred = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>

hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type
is_sorted_until(ExPolicy &&policy, FwdIter first, Sent last, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Returns the first element in the range `[first, last)` that is not sorted. Uses a predicate to compare elements or the less than operator.

The comparison operations in the parallel `is_sorted_until` algorithm invoked with an execution policy object of type `sequenced_policy` executes in sequential order in the calling thread.

**Note** Complexity: at most \((N+S-1)\) comparisons where \(N = \text{distance(first, last)}\). \(S = \text{number of partitions}\)

**Template Parameters**
- *ExPolicy*: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- *FwdIter*: The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- *Pred*: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `is_sorted_until` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`
- *Proj*: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**
- *policy*: The execution policy to use for the scheduling of the iterations.
- *first*: Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- *last*: Refers to the end of the sequence of elements of that the algorithm will be applied to.
- *pred*: Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a, const Type &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- *proj*: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel `is_sorted_until` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion.
in unspecified threads, and indeterminately sequenced within each thread.

Return The `is_sorted_until` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `is_sorted_until` algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, last is returned.

```
template<typename Rng, typename Pred = hpx::parallel::v1::detail::less, typename Proj = hpx::parallel::util::projection_identity>
std::future<typename hpx::traits::range_iterator<Rng>::type> is_sorted_until(ExPolicy &&policy, Rng &&rng, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Returns the first element in the range `rng` that is not sorted. Uses a predicate to compare elements or the less than operator.

The comparison operations in the parallel `is_sorted_until` algorithm execute in sequential order in the calling thread.

**Note** Complexity: at most `(N+S-1)` comparisons where `N = size(rng)`, `S = number of partitions`

Template Parameters

- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- `Pred`: The type of an optional function/function object to use.
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`

Parameters

- `rng`: Refers to the sequence of elements the algorithm will be applied to.
- `pred`: Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

**Return** The `is_sorted_until` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `is_sorted_until` algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, last is returned.

```cpp
namespace hpx

namespace ranges

Functions
```

```cpp
template<typename InIter1, typename Sent1, typename InIter2, typename Sent2, typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 = hpx::parallel::util::projection_identity, typename Pred = detail::less>
bool lexicographical_compare(InIter1 first1, Sent1 last1, InIter2 first2, Sent2 last2, Pred &&pred = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Checks if the first range \([\text{first1}, \text{last1}]\) is lexicographically less than the second range \([\text{first2}, \text{last2}]\). uses a provided predicate to compare elements.
The comparison operations in the parallel `lexicographical_compare` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: At most \(2 \times \min(N_1, N_2)\) applications of the comparison operation, where \(N_1 = \text{std::distance(first1, last)}\) and \(N_2 = \text{std::distance(first2, last2)}\).

**Template Parameters**
- `InIter1`: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an input iterator.
- `Sent1`: The type of the source sentinel (deduced). This sentinel type must be a sentinel for `InIter1`.
- `InIter2`: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an input iterator.
- `Sent2`: The type of the source sentinel (deduced). This sentinel type must be a sentinel for `InIter2`.
- `Pred`: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `lexicographical_compare` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`.
- `Proj1`: The type of an optional projection function for `FwdIter1`. This defaults to `util::projection_identity`.
- `Proj2`: The type of an optional projection function for `FwdIter2`. This defaults to `util::projection_identity`.

**Parameters**
- `first1`: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- `last1`: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- `first2`: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- `last2`: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- `pred`: Refers to the comparison function that the first and second ranges will be applied to.
- `proj1`: Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate is invoked.
- `proj2`: Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel `lexicographical_compare` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note** Lexicographical comparison is an operation with the following properties
- Two ranges are compared element by element
- The first mismatching element defines which range is lexicographically less or greater than the other
- If one range is a prefix of another, the shorter range is lexicographically less than the other
- If two ranges have equivalent elements and are of the same length, then the ranges are lexicographically equal
- An empty range is lexicographically less than any non-empty range
- Two empty ranges are lexicographically equal

**Return** The `lexicographical_compare` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `lexicographical_compare` algorithm returns true if the first range is lexicographically less, otherwise it returns false. range [first2, last2), it returns false.
Checks if the first range [first1, last1) is lexicographically less than the second range [first2, last2), uses a provided predicate to compare elements.

The comparison operations in the parallel \texttt{lexicographical\_compare} algorithm invoked with an execution policy object of type \texttt{sequenced\_policy} execute in sequential order in the calling thread.

\textbf{Note} Complexity: At most 2 * min(N1, N2) applications of the comparison operation, where N1 = std::distance(first1, last) and N2 = std::distance(first2, last2).

\textbf{Template Parameters}

- \texttt{ExPolicy}: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- \texttt{FwdIter1}: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- \texttt{Sent1}: The type of the source sentinel (deduced). This sentinel type must be a sentinel for \texttt{FwdIter1}.
- \texttt{FwdIter2}: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- \texttt{Sent2}: The type of the source sentinel (deduced). This sentinel type must be a sentinel for \texttt{FwdIter2}.
- \texttt{Pred}: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of \texttt{lexicographical\_compare} requires \texttt{Pred} to meet the requirements of \texttt{CopyConstructible}. This defaults to std::less\langle\rangle.
- \texttt{Proj1}: The type of an optional projection function for \texttt{FwdIter1}. This defaults to \texttt{util::projection\_identity}.
- \texttt{Proj2}: The type of an optional projection function for \texttt{FwdIter2}. This defaults to \texttt{util::projection\_identity}.

\textbf{Parameters}

- \texttt{policy}: The execution policy to use for the scheduling of the iterations.
- \texttt{first1}: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
• last1: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
• first2: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
• last2: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
• pred: Refers to the comparison function that the first and second ranges will be applied to
• proj1: Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate is invoked.
• proj2: Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel lexicographical_compare algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note Lexicographical comparison is an operation with the following properties
• Two ranges are compared element by element
• The first mismatching element defines which range is lexicographically less or greater than the other
• If one range is a prefix of another, the shorter range is lexicographically less than the other
• If two ranges have equivalent elements and are of the same length, then the ranges are lexicographically equal
• An empty range is lexicographically less than any non-empty range
• Two empty ranges are lexicographically equal

Return The lexicographically_compare algorithm returns a hpx::future<bool> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns bool otherwise. The lexicographically_compare algorithm returns true if the first range is lexicographically less, otherwise it returns false. range [first2, last2), it returns false.

```
template<
    typename Rng1,
    typename Rng2,
    typename Proj1 = hpx::parallel::util::projection_identity,
    typename Proj2 = hpx::parallel::util::projection_identity,
    typename Pred = std::less<>
>
bool lexicographical_compare( Rng1 &&rng1, Rng2 &&rng2, Pred &&pred = Pred(),
    Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Checks if the first range rng1 is lexicographically less than the second range rng2. uses a provided predicate to compare elements.

The comparison operations in the parallel lexicographical_compare algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Note Complexity: At most 2 * min(N1, N2) applications of the comparison operation, where N1 = std::distance(std::begin(rng1), std::end(rng1)) and N2 = std::distance(std::begin(rng2), std::end(rng2)).

Template Parameters
• Rng1: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
• Rng2: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
• Pred: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of lexicographical_compare requires Pred to meet the requirements of CopyConstructible. This defaults to std::less<>
• Proj1: The type of an optional projection function for elements of the first range. This defaults to util::projection_identity
• Proj2: The type of an optional projection function for elements of the second range. This defaults to util::projection_identity

Parameters
• rng1: Refers to the sequence of elements the algorithm will be applied to.
• rng2: Refers to the sequence of elements the algorithm will be applied to.
• pred: Refers to the comparison function that the first and second ranges will be applied to
• proj1: Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate is invoked.
• proj2: Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate is invoked.

Note Lexicographical comparison is an operation with the following properties
• Two ranges are compared element by element
• The first mismatching element defines which range is lexicographically less or greater than the other
• If one range is a prefix of another, the shorter range is lexicographically less than the other
• If two ranges have equivalent elements and are of the same length, then the ranges are lexicographically equal
• An empty range is lexicographically less than any non-empty range
• Two empty ranges are lexicographically equal

Return The lexicographically_compare algorithm returns bool. The lexicographically_compare algorithm returns true if the first range is lexicographically less, otherwise it returns false. range [first2, last2), it returns false.

template<typename ExPolicy, typename Rng1, typename Rng2, typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 = hpx::parallel::util::projection_identity, typename Pred = detail::less>
    parallel::util::detail::algorithm_result<ExPolicy, bool>::type
    lexicographical_compare(
        ExPolicy &&policy,
        Rng1 &&rng1,
        Rng2 &&rng2,
        Pred &&pred = Pred(),
        Proj1 &&proj1 = Proj1(),
        Proj2 &&proj2 = Proj2())

Checks if the first range rng1 is lexicographically less than the second range rng2. uses a provided predicate to compare elements.

The comparison operations in the parallel lexicographical_compare algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: At most 2 * min(N1, N2) applications of the comparison operation, where N1 = std::distance(std::begin(rng1), std::end(rng1)) and N2 = std::distance(std::begin(rng2), std::end(rng2)).

Template Parameters
• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• **Rng1**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

• **Rng2**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

• **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `lexicographical_compare` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>

• **Proj1**: The type of an optional projection function for elements of the first range. This defaults to `util::projection_identity`

• **Proj2**: The type of an optional projection function for elements of the second range. This defaults to `util::projection_identity`

**Parameters**

• **policy**: The execution policy to use for the scheduling of the iterations.

• **rng1**: Refers to the sequence of elements the algorithm will be applied to.

• **rng2**: Refers to the sequence of elements the algorithm will be applied to.

• **pred**: Refers to the comparison function that the first and second ranges will be applied to

• **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate is invoked.

• **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel `lexicographical_compare` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note** Lexicographical comparison is an operation with the following properties

• Two ranges are compared element by element

• The first mismatching element defines which range is lexicographically less or greater than the other

• If one range is a prefix of another, the shorter range is lexicographically less than the other

• If two ranges have equivalent elements and are of the same length, then the ranges are lexicographically equal

• An empty range is lexicographically less than any non-empty range

• Two empty ranges are lexicographically equal

**Return** The `lexicographical_compare` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `lexicographical_compare` algorithm returns true if the first range is lexicographically less, otherwise it returns false. range [first2, last2), it returns false.

```cpp
namespace hpx{

namespace ranges{

```
Constructs a max heap in the range [first, last).

The predicate operations in the parallel make_heap algorithm invoked with an execution policy object of type sequential_execution_policy executes in sequential order in the calling thread.

**Note** Complexity: at most (3*N) comparisons where N = distance(first, last).

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Comp**: The type of the function/function object to use (deduced).
- **Proj**: The type of an optional projection function. This defaults to util::projection_identity

**Parameters**
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **comp**: Refers to the binary predicate which returns true if the first argument should be treated as less than the second. The signature of the function should be equivalent to

```cpp
bool comp(const Type &a, const Type &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type Type must be such that objects of types RndIter can be dereferenced and then implicitly converted to Type.
- **proj**: Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate comp is invoked.

The comparison operations in the parallel make_heap algorithm invoked with an execution policy object of type parallel_execution_policy or parallel_task_execution_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The make_heap algorithm returns a hpx::future<Iter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns Iter otherwise. It returns last.
util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng>::type>::type make_heap(ExPolicy &&policy, Rng &&rng, Proj &&proj = Proj{})

Constructs a max heap in the range [first, last). Uses the operator < for comparisons.

The predicate operations in the parallel make_heap algorithm invoked with an execution policy object of type sequential_execution_policy executes in sequential order in the calling thread.

**Note** Complexity: at most (3*N) comparisons where N = distance(first, last).

**Template Parameters**
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- Rng: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- Proj: The type of an optional projection function. This defaults to util::projection_identity

**Parameters**
- rng: Refers to the sequence of elements the algorithm will be applied to.
- proj: Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate comp is invoked.

The comparison operations in the parallel make_heap algorithm invoked with an execution policy object of type parallel_execution_policy or parallel_task_execution_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The make_heap algorithm returns a hpx::future<void> if the execution policy is of type task_execution_policy and returns void otherwise.

namespace hpx

namespace ranges

**Functions**

template<typename ExPolicy, typename Iter1, typename Sent, typename Iter2, typename Sent2, typename Iter3, typename Comp = hpx::ranges::less, typename Proj1 = util::projection_identity, typename Proj2 = util::projection_identity>
Merges two sorted ranges \([\text{first1}, \text{last1})\) and \([\text{first2}, \text{last2})\) into one sorted range beginning at \(\text{dest}\). The order of equivalent elements in each of the original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. The destination range cannot overlap with either of the input ranges.

The assignments in the parallel \textit{merge} algorithm invoked with an execution policy object of type \textit{sequenced\_policy} execute in sequential order in the calling thread.

\textbf{Note} Complexity: Performs \(O(\text{std::distance(first1, last1)} + \text{std::distance(first2, last2)})\) applications of the comparison \textit{comp} and the each projection.

\textbf{Template Parameters}

- \textit{ExPolicy}: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- \textit{Iter1}: The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an random access iterator.
- \textit{Sent1}: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for \textit{Iter1}.
- \textit{Iter2}: The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an random access iterator.
- \textit{Sent2}: The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for \textit{Iter2}.
- \textit{Iter3}: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an random access iterator.
- \textit{Comp}: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \textit{merge} requires \textit{Comp} to meet the requirements of \textit{CopyConstructible}. This defaults to \textit{std::less\:<>}
- \textit{Proj1}: The type of an optional projection function to be used for elements of the first range. This defaults to \textit{util::projection\_identity}
• **Proj2**: The type of an optional projection function to be used for elements of the second range. This defaults to `util::projection_identity`

**Parameters**

• **policy**: The execution policy to use for the scheduling of the iterations.
• **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
• **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
• **first2**: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
• **last2**: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
• **dest**: Refers to the beginning of the destination range.
• **comp**: `comp` is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```cpp
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `RandIter1` and `RandIter2` can be dereferenced and then implicitly converted to both `Type1` and `Type2`

• **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual comparison `comp` is invoked.
• **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual comparison `comp` is invoked.

The assignments in the parallel `merge` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `merge` algorithm returns a `hpx::future<merge_result<Iter1, Iter2, Iter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `merge_result<Iter1, Iter2, Iter3>` otherwise. The `merge` algorithm returns the tuple of the source iterator `last1`, the source iterator `last2`, the destination iterator to the end of the `dest` range.

```cpp
template<typename ExPolicy, typename Rng1, typename Rng2, typename RandIter3, typename Comp = hpx::ranges::less>
```

Chapter 2. What's so special about HPX?
Merges two sorted ranges [first1, last1) and [first2, last2) into one sorted range beginning at dest. The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. The destination range cannot overlap with either of the input ranges.

The assignments in the parallel merge algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Performs \( O(\text{std::distance(first1, last1)} + \text{std::distance(first2, last2)}) \) applications of the comparison \( \text{comp} \) and the each projection.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1**: The type of the first source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- **Rng2**: The type of the second source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- **RandIter3**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an random access iterator.
- **Comp**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of merge requires \( \text{Comp} \) to meet the requirements of CopyConstructible. This defaults to \( \text{std::less<>()} \)
- **Proj1**: The type of an optional projection function to be used for elements of the first range. This defaults to \( \text{util::projection_identity} \)
- **Proj2**: The type of an optional projection function to be used for elements of the second range. This defaults to \( \text{util::projection_identity} \)

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng1**: Refers to the first range elements the algorithm will be applied to.
- **rng2**: Refers to the second range elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
• **comp**: `comp` is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```cpp
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `RandIter1` and `RandIter2` can be dereferenced and then implicitly converted to both `Type1` and `Type2`.

• **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual comparison `comp` is invoked.

• **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual comparison `comp` is invoked.

The assignments in the parallel `merge` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `merge` algorithm returns a `hpx::future<merge_result<RandIter1, RandIter2, RandIter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `merge_result<RandIter1, RandIter2, RandIter3>` otherwise. The `merge` algorithm returns the tuple of the source iterator `last1`, the source iterator `last2`, the destination iterator to the end of the `dest` range.

```cpp
template<typename ExPolicy, typename Iter, typename Sent, typename Comp = hpx::ranges::less, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, Iter>::type inplace_merge(ExPolicy &&policy, Iter first, Iter middle, Sent last, Comp &&comp = Comp(), Proj &&proj = Proj())
```

Merges two consecutive sorted ranges `[first, middle)` and `[middle, last)` into one sorted range `[first, last)`. The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range.

The assignments in the parallel `inplace_merge` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs O(std::distance(first, last)) applications of the comparison `comp` and the each projection.

**Template Parameters**

• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **Iter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an random access iterator.

• **Sent**: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for `Iter1`.

• **Comp**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `inplace_merge` requires `Comp` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`

• **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

• **policy**: The execution policy to use for the scheduling of the iterations.

• **first**: Refers to the beginning of the first sorted range the algorithm will be applied to.

• **middle**: Refers to the end of the first sorted range and the beginning of the second sorted range.
range the algorithm will be applied to.
- **last**: Refers to the end of the second sorted range the algorithm will be applied to.
- **comp**: `comp` is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `RandIter` can be dereferenced and then implicitly converted to both `Type1` and `Type2`.

- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel `inplace_merge` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `inplace_merge` algorithm returns a `hpx::future<Iter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `Iter` otherwise. The `inplace_merge` algorithm returns the source iterator `last`.

```cpp
template<
  typename ExPolicy, typename Rng, typename RandIter, typename Comp = hpx::ranges::less, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, RandIter>::type
inplace_merge(ExPolicy &&policy,
              Rng &&rng,
              RandIter middle,
              Comp &&comp = Comp(),
              Proj &&proj = Proj())
```

Merges two consecutive sorted ranges `[first, middle)` and `[middle, last)` into one sorted range `[first, last)`. The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range.

The assignments in the parallel `inplace_merge` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs O(std::distance(first, last)) applications of the comparison `comp` and the each projection.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- **RandIter**: The type of the source iterators used (deduced). This iterator type must meet the requirements of an random access iterator.
- **Comp**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `inplace_merge` requires `Comp` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the range of elements the algorithm will be applied to.
- **middle**: Refers to the end of the first sorted range and the beginning of the second sorted range the algorithm will be applied to.
- **comp**: `comp` is a callable object which returns true if the first argument is less than the second,
and false otherwise. The signature of this comparison should be equivalent to:

```cpp
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types RandIter can be dereferenced and then implicitly converted to both Type1 and Type2

- `proj`: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel `inplace_merge` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `inplace_merge` algorithm returns a `hpx::future<RandIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `RandIter` otherwise. The `inplace_merge` algorithm returns the source iterator `last`

namespace hpx

namespace parallel

Functions

```cpp
template<typename ExPolicy, typename Rng, typename Proj = util::projection_identity, typename F = detail::less>
util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_traits<Rng>::iterator_type>::type
min_element(ExPolicy &&policy, Rng &&rng, F &&f = F(), Proj &&proj = Proj());
```

Finds the smallest element in the range `[first, last)` using the given comparison function `f`.

The comparisons in the parallel `min_element` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Exactly `max(N-1, 0)` comparisons, where `N = std::distance(first, last)`.

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- `F`: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `min_element` requires `F` to meet the requirements of `CopyConstructible`.
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`
• policy: The execution policy to use for the scheduling of the iterations.
• rng: Refers to the sequence of elements the algorithm will be applied to.
• f: The binary predicate which returns true if the left argument is less than the right element.

The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

• proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The comparisons in the parallel `min_element` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `min_element` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `min_element` algorithm returns the iterator to the smallest element in the range `[first, last)`. If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```
template<typename ExPolicy, typename Rng, typename Proj = util::projection_identity, typename F = detail::less>
util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_traits<Rng>::iterator_type>::type
max_element(
    ExPolicy &&policy,
    Rng &&rng,
    F &&f = F(),
    Proj &&proj = Proj()
)
```

Finds the greatest element in the range `[first, last)` using the given comparison function `f`.

The comparisons in the parallel `max_element` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Exactly `max(N-1, 0)` comparisons, where `N = std::distance(first, last)`.

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- `F`: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `max_element` requires `F` to meet the requirements of `CopyConstructible`.
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`.

**Parameters**
- `policy`: The execution policy to use for the scheduling of the iterations.
- `rng`: Refers to the sequence of elements the algorithm will be applied to.
• f: The binary predicate which returns true if the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

• proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The comparisons in the parallel `max_element` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The `max_element` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `max_element` algorithm returns the iterator to the smallest element in the range `[first, last)`. If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```cpp
template<typename ExPolicy, typename Rng, typename Proj = util::projection_identity, typename F = detail::less>
util::detail::algorithm_result<ExPolicy, hpx::util::tagged_pair<tag::min, typename hpx::traits::range_traits<Rng>::iterator_type>,
tag::max
typename hpx::traits::range_traits<Rng>::iterator_type>::type
minmax_element(ExPolicy &&policy, Rng &&rng, F &&f = F(), Proj &&proj = Proj()Finds the greatest element in the range [first, last) using the given comparison function f.
```

The comparisons in the parallel `minmax_element` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

Note Complexity: At most \( \max(\floor{3/2*(N-1)}, 0) \) applications of the predicate, where \( N = \text{std::distance(first, last)} \).

Template Parameters
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- Rng: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- F: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `minmax_element` requires F to meet the requirements of `CopyConstructible`.
- Proj: The type of an optional projection function. This defaults to `util::projection_identity`.

Parameters
- policy: The execution policy to use for the scheduling of the iterations.
- rng: Refers to the sequence of elements the algorithm will be applied to.
- f: The binary predicate which returns true if the left argument is less than the right element. This argument is optional and defaults to std::less. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.
• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The comparisons in the parallel *minmax_element* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The *minmax_element* algorithm returns a *hpx:future<tagged_pair<tag::min(FwdIter), tag::max(FwdIter)>*>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *tagged_pair<tag::min(FwdIter), tag::max(FwdIter)>* otherwise. The *minmax_element* algorithm returns a pair consisting of an iterator to the smallest element as the first element and an iterator to the greatest element as the second. Returns std::make_pair(first, first) if the range is empty. If several elements are equivalent to the smallest element, the iterator to the first such element is returned. If several elements are equivalent to the largest element, the iterator to the last such element is returned.

```cpp
namespace hpx
namespace ranges

Functions

template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Pred = ranges::equal_to, typename Proj1 = util::projection_identity, typename Proj2 = util::projection_identity>
util::detail::algorithm_result<ExPolicy, ranges::mismatch_result<FwdIter1, FwdIter2>>::type mismatch(ExPolicy&& policy, FwdIter1 first1, Iter1 last1, FwdIter2 first2, Iter2 last2, Pred&& op = Pred(), Proj1&& proj1 = Proj1(), Proj2&& proj2 = Proj2())
```

Returns true if the range [first1, last1) is mismatch to the range [first2, last2), and false otherwise.

The comparison operations in the parallel *mismatch* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

**Note** Complexity: At most min(last1 - first1, last2 - first2) applications of the predicate *f*. If FwdIter1 and FwdIter2 meet the requirements of *RandomAccessIterator* and (last1 - first1) != (last2 - first2) then no applications of the predicate *f* are made.

---

2.8. API reference 1213
Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter1**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1**: The type of the source iterators used for the end of the first range (deduced).
- **Iter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2**: The type of the source iterators used for the end of the second range (deduced).
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `mismatch` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`.
- **Proj1**: The type of an optional projection function applied to the first range. This defaults to `util::projection_identity`.
- **Proj2**: The type of an optional projection function applied to the second range. This defaults to `util::projection_identity`.

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2**: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2**: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op**: The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel `mismatch` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note** The two ranges are considered mismatch if, for every iterator i in the range [first1, last1), *i mismatchs *(first2 + (i - first1)). This overload of mismatch uses operator== to determine if two elements are mismatch.

**Return** The `mismatch` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `mismatch` algorithm returns true if the elements in the two ranges are mismatch, otherwise it returns false. If the length of the range [first1, last1) does not mismatch the length of the range [first2, last2), it returns false.

```cpp
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred = ranges::equal_to, typename Proj1
```
util::detail::algorithm_result<ExPolicy, ranges::mismatch_result<FwdIter1, FwdIter2>>::type mismatch (ExPolicy &&policy, Rng1 &&rng1, Rng2 &&rng2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())

Returns std::pair with iterators to the first two non-equivalent elements.

The comparison operations in the parallel mismatch algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: At most last1 - first1 applications of the predicate f.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1**: The type of the first source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Rng2**: The type of the second source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of mismatch requires Pred to meet the requirements of CopyConstructible. This defaults to std::equal_to<>.
- **Proj1**: The type of an optional projection function applied to the first range. This defaults to util::projection_identity
- **Proj2**: The type of an optional projection function applied to the second range. This defaults to util::projection_identity

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng1**: Refers to the first sequence of elements the algorithm will be applied to.
- **rng2**: Refers to the second sequence of elements the algorithm will be applied to.
- **op**: The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively.
- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate is invoked.
• **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate is invoked. The comparison operations in the parallel mismatch algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The *mismatch* algorithm returns a `hpx::future<std::pair<FwdIter1, FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `std::pair<FwdIter1, FwdIter2>` otherwise. The *mismatch* algorithm returns the first mismatching pair of elements from two ranges: one defined by `[first1, last1)` and another defined by `[first2, last2)`.

```cpp
namespace hpx
{

    Functions

    template<typename ExPolicy, typename FwdIter1, typename Sent1, typename FwdIter>
    util::detail::algorithm_result<ExPolicy, ranges::move_result<FwdIter1, FwdIter>>::type move(ExPolicy&& policy, FwdIter1 iter, Sent1 sent, FwdIter dest)
    {
        // Implementation...
    }

    Moves the elements in the range `rng` to another range beginning at `dest`. After this operation the elements in the moved-from range will still contain valid values of the appropriate type, but not necessarily the same values as before the move.

    The assignments in the parallel *copy* algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

    **Note** Complexity: Performs exactly `std::distance(begin(rng), end(rng))` assignments.

    **Template Parameters**

    • **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

    • **FwdIter1**: The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

    • **Sent1**: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for FwdIter1.

    • **FwdIter**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

    **Parameters**

    • **policy**: The execution policy to use for the scheduling of the iterations.

    • **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.

    • **last**: Refers to the end of the sequence of elements the algorithm will be applied to.

1216 Chapter 2. What's so special about *HPX*?
**dest:** Refers to the beginning of the destination range.

The assignments in the parallel *copy* algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The *move* algorithm returns a `hpx::future<ranges::move_result<iterator_t<Rng>, FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::move_result<iterator_t<Rng>, FwdIter2>` otherwise. The *move* algorithm returns the pair of the input iterator `last` and the output iterator to the element in the destination range, one past the last element moved.

```
template<typename ExPolicy, typename Rng, typename FwdIter>
util::detail::algorithm_result<ExPolicy, ranges::move_result<typename hpx::traits::range_traits<Rng>::iterator_type, FwdIter>>::type
move(ExPolicy&& policy, Rng&& rng, FwdIter dest)
```

Moves the elements in the range `rng` to another range beginning at `dest`. After this operation the elements in the moved-from range will still contain valid values of the appropriate type, but not necessarily the same values as before the move.

The assignments in the parallel *copy* algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `std::distance(begin(rng), end(rng))` assignments.

**Template Parameters**

- **ExPolicy:** The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **Rng:** The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

- **FwdIter:** The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

- **policy:** The execution policy to use for the scheduling of the iterations.

- **rng:** Refers to the sequence of elements the algorithm will be applied to.

- **dest:** Refers to the beginning of the destination range.

The assignments in the parallel *copy* algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The *move* algorithm returns a `hpx::future<ranges::move_result<iterator_t<Rng>, FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::move_result<iterator_t<Rng>, FwdIter2>` otherwise. The *move* algorithm returns the pair
of the input iterator last and the output iterator to the element in the destination range, one past the last element moved.

namespace hpx

namespace parallel

Functions

template<typename ExPolicy, typename Rng, typename Pred, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng>::type>::type
partition(ExPolicy &&policy, Rng &&rng, Pred &&pred, Proj &&proj = Proj())

Reorders the elements in the range rng in such a way that all elements for which the predicate pred returns true precede the elements for which the predicate pred returns false. Relative order of the elements is not preserved.

The assignments in the parallel partition algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Performs at most 2 * N swaps, exactly N applications of the predicate and projection, where N = std::distance(begin(rng), end(rng)).

Template Parameters

- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- Rng: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- Pred: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of partition requires Pred to meet the requirements of CopyConstructible.
- Proj: The type of an optional projection function. This defaults to util::projection_identity

Parameters

- policy: The execution policy to use for the scheduling of the iterations.
- rng: Refers to the sequence of elements the algorithm will be applied to.
- pred: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by the range rng. This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

  ```cpp
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type FwdIter can be dereferenced and then implicitly converted to Type.
- proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.
The assignments in the parallel partition algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The partition algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type parallel_task_policy and returns `FwdIter` otherwise. The partition algorithm returns the iterator to the first element of the second group.

```cpp
template<typename ExPolicy, typename Rng, typename FwdIter2, typename FwdIter3, typename Pred, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, hpx::util::tagged_tuple<
    hpx::traits::range_iterator<Rng>::type,
    tag::in>
FwdIter2, tag::out2FwdIter3>>::type partition_copy(ExPolicy &&policy, Rng &&rng, FwdIter2 dest_true, FwdIter3 dest_false, Pred &&pred, Proj &&proj = Proj())
```

Copies the elements in the range `rng`, to two different ranges depending on the value returned by the predicate `pred`. The elements, that satisfy the predicate `pred`, are copied to the range beginning at `dest_true`. The rest of the elements are copied to the range beginning at `dest_false`. The order of the elements is preserved.

The assignments in the parallel partition_copy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Performs not more than N assignments, exactly N applications of the predicate `pred`, where N = std::distance(begin(rng), end(rng)).

Template Parameters
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the iterator representing the destination range for the elements that satisfy the predicate `pred` (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter3**: The type of the iterator representing the destination range for the elements that don’t satisfy the predicate `pred` (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `partition_copy` requires `Pred` to meet the requirements of CopyConstructible.
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`.

Parameters
- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **dest_true**: Refers to the beginning of the destination range for the elements that satisfy the predicate `pred`.
- **dest_false**: Refers to the beginning of the destination range for the elements that don’t satisfy the predicate `pred`.
- **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by the range `rng`. This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced.
and then implicitly converted to Type.

- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel `partition_copy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `partition_copy` algorithm returns a `hpx::future<tagged_tuple<tag::in(InIter), tag::out1(OutIter1), tag::out2(OutIter2)>>` if the execution policy is of type `parallel_task_policy` and returns `tagged_tuple<tag::in(InIter), tag::out1(OutIter1), tag::out2(OutIter2)>>` otherwise. The `partition_copy` algorithm returns the tuple of the source iterator last, the destination iterator to the end of the `dest_true` range, and the destination iterator to the end of the `dest_false` range.

```cpp
namespace hpx

namespace ranges

Functions

```template<
    typename ExPolicy,
    typename FwdIter,
    typename Sent,
    typename T,
    typename F>

util::detail::algorithm_result<
    ExPolicy,
    T>::type
reduce(
    ExPolicy &&policy,
    FwdIter first,
    Sent last,
    T init,
    F &&f)
```

Returns GENERALIZED_SUM(f, init, *first, \ldots, *(first + (last - first) - 1)).

The reduce operations in the parallel `reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: $O(last - first)$ applications of the predicate $f$.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent**: The type of the source sentinel used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `copy_if` requires $F$ to meet the requirements of `CopyConstructible`.
- **T**: The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&. The types `Type1 Ret` must be such that an object of type `FwdIterB` can be dereferenced and then implicitly converted to any of those types.

- **init**: The initial value for the generalized sum.
The reduce operations in the parallel `copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `reduce` and `accumulate` is that the behavior of `reduce` may be non-deterministic for non-associative or non-commutative binary predicate.

**Return** The `reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `T` otherwise. The `reduce` algorithm returns the result of the generalized sum over the elements given by the input range `[first, last)`.  

**Note** `GENERALIZED_SUM(op, a1, ... , aN)` is defined as follows:
- `a1` when `N` is `1`
- `op(GENERALIZED_SUM(op, b1, ... , bK), GENERALIZED_SUM(op, bM, ... , bN))`, where:
  - `b1, ..., bN` may be any permutation of `a1, ..., aN` and
  - `1 < K+1 = M <= N`.

```cpp
template<typename ExPolicy, typename FwdIter, typename Sent, typename T>
util::detail::algorithm_result<ExPolicy, T>::type reduce(ExPolicy&& policy, FwdIter first, Sent last, T init)
    Returns GENERALIZED_SUM(+, init, *first, ..., *(first + (last - first) - 1)).
```

The reduce operations in the parallel `reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.  

**Note** Complexity: `O(last - first)` applications of the operator+().  

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter`: The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- `Sent`: The type of the source sentinel used (deduced). This iterator type must meet the requirements of an forward iterator.
- `T`: The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**
- `policy`: The execution policy to use for the scheduling of the iterations.
- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last`: Refers to the end of the sequence of elements the algorithm will be applied to.
- `init`: The initial value for the generalized sum.

The reduce operations in the parallel `copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `reduce` and `accumulate` is that the behavior of `reduce` may be non-deterministic for non-associative or non-commutative binary predicate.

**Return** The `reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `T` otherwise. The `reduce` algorithm returns the result of the generalized sum (applying operator+) over the elements given by the input range `[first, last)

**Note** `GENERALIZED_SUM(+, a1, ... , aN)` is defined as follows:
- `a1` when `N` is `1`
- `op(GENERALIZED_SUM(+, b1, ... , bK), GENERALIZED_SUM(+, bM, ... , bN))`, where:
– b1, . . . , bN may be any permutation of a1, . . . , aN and
– 1 < K + 1 = M ≤ N.

The reduce operations in the parallel reduce algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: \( O(\text{last} - \text{first}) \) applications of the operator+().

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source begin iterator used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Sent**: The type of the source sentinel used (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.

The difference between reduce and accumulate is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

**Return** The reduce algorithm returns a `hpx::future<T>` if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns T otherwise (where T is the value_type of `FwdIterB`). The reduce algorithm returns the result of the generalized sum (applying operator+() over the elements given by the input range [first, last]).

**Note** The type of the initial value (and the result type) T is determined from the value_type of the used `FwdIterB`.

**Note** GENERALIZED_SUM(+, a1, . . . , aN) is defined as follows:
- a1 when N is 1
- \( \text{op}(\text{GENERALIZED}_{-}\text{SUM}(+, b1, . . . , bK), \text{GENERALIZED}_{-}\text{SUM}(+, bM, . . . , bN)) \), where:
  – b1, . . . , bN may be any permutation of a1, . . . , aN and
  – 1 < K + 1 = M ≤ N.
The reduce operations in the parallel `reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: \( O(\text{last} - \text{first}) \) applications of the predicate \( f \).

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `copy_if` requires \( F \) to meet the requirements of `CopyConstructible`.
- **T**: The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\). This is a binary predicate. The signature of this predicate should be equivalent to:

  ```cpp
  Ret fun(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have `const&`. The types \( \text{Type1 Ret} \) must be such that an object of type `FwdIterB` can be dereferenced and then implicitly converted to any of those types.
- **init**: The initial value for the generalized sum.

The reduce operations in the parallel `copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `reduce` and `accumulate` is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

**Return** The `reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns \( T \) otherwise. The `reduce` algorithm returns the result of the generalized sum over the elements given by the input range \([\text{first}, \text{last})\).

**Note** GENERALIZED_SUM(op, \( a_1, \ldots, a_N \)) is defined as follows:
- \( a_1 \) when \( N = 1 \)
- \( \text{op}(\text{GENERALIZED_SUM}(\text{op}, \ b_1, \ldots, b_K), \ \text{GENERALIZED_SUM}(\text{op}, \ b_M, \ldots, b_N)) \), where:
  - \( b_1, \ldots, b_N \) may be any permutation of \( a_1, \ldots, a_N \) and
  - \( 1 < K+1 = M \leq N \).

```cpp
template<typename ExPolicy, typename Rng, typename T>
util::detail::algorithm_result<ExPolicy, T>::type reduce(ExPolicy &&policy, Rng &&rng, T init)
Returns GENERALIZED_SUM(+, init, *first, \ldots, *(first + (last - first) - 1)).
```

The reduce operations in the parallel `reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: \( O(\text{last} - \text{first}) \) applications of the operator\(+\).
• T: The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **init**: The initial value for the generalized sum.

The reduce operations in the parallel `copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `reduce` and `accumulate` is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

**Return** The `reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `T` otherwise. The `reduce` algorithm returns the result of the generalized sum (applying operator+) over the elements given by the input range `[first, last)`.

**Note** GENERALIZED_SUM(+, a1, . . . , aN) is defined as follows:

- a1 when N is 1
- op(GENERALIZED_SUM(+, b1, . . . , bK), GENERALIZED_SUM(+, bM, . . . , bN)), where:
  - b1, . . . , bN may be any permutation of a1, . . . , aN and
  - 1 < K+1 = M <= N.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.

The reduce operations in the parallel `reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: O(last - first) applications of the operator+().

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.

The reduce operations in the parallel `copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `reduce` and `accumulate` is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

**Return** The `reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `T` otherwise (where `T` is the value_type of `FwdIterB`). The `reduce` algorithm returns the result of the generalized sum (applying operator+) over the elements given by the input range `[first, last)`.
The type of the initial value (and the result type) \( T \) is determined from the value_type of the used \( FwdIter \).

**Note** GENERALIZED_SUM\((+, a_1, \ldots, a_N)\) is defined as follows:
- \( a_1 \) when \( N = 1 \)
- \( \text{op}(\text{GENERALIZED_SUM}(+, b_1, \ldots, b_K), \text{GENERALIZED_SUM}(+, b_M, \ldots, b_N)) \), where:
  - \( b_1, \ldots, b_N \) may be any permutation of \( a_1, \ldots, a_N \) and
  - \( 1 < K+1 = M \leq N \).

```cpp
namespace hpx

namespace ranges

Functions

template<typename FwdIter, typename Sent, typename T, typename Proj = util::projection_identity>
subrange_t<FwdIter, Sent> remove (FwdIter first, Sent last, T const &value, Proj &&proj = Proj())
    Removes all elements that are equal to `value` from the range `[first, last)` and returns a subrange `[ret, last)`, where `ret` is a past-the-end iterator for the new end of the range.

The assignments in the parallel `remove` algorithm execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than `last - first` assignments, exactly `last - first` applications of the operator `==` and the projection `proj`.

**Template Parameters**
- \( FwdIter \): The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- \( Sent \): The type of the end iterators used (deduced). This sentinel type must be a sentinel for \( FwdIter \).
- \( T \): The type of the value to remove (deduced). This value type must meet the requirements of `CopyConstructible`.
- \( Proj \): The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**
- \( \text{first} \): Refers to the beginning of the sequence of elements the algorithm will be applied to.
- \( \text{last} \): Refers to the end of the sequence of elements the algorithm will be applied to.
- \( \text{value} \): Specifies the value of elements to remove.
- \( \text{proj} \): Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Return** The `remove` algorithm returns a `subrange_t<FwdIter, Sent>`. The `remove` algorithm returns an object `{ret, last}`, where `ret` is a past-the-end iterator for a new subrange of the values all in valid but unspecified state.
parallel::util::detail::algorithm_result<ExPolicy, subrange_t<FwdIter, Sent>>::type remove (ExPolicy &&policy, FwdIter first, Sent last, T const &value, Proj &&proj = Proj())

Removes all elements that are equal to value from the range [first, last) and and returns a subrange [ret, last), where ret is a past-the-end iterator for the new end of the range.

The assignments in the parallel remove algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note**  Complexity: Performs not more than last - first assignments, exactly last - first applications of the operator==() and the projection proj.

**Template Parameters**
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- FwdIter: The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- Sent: The type of the end iterators used (deduced). This sentinel type must be a sentinel for FwdIter.
- T: The type of the value to remove (deduced). This value type must meet the requirements of CopyConstructible.
- Proj: The type of an optional projection function. This defaults to util::projection_identity

**Parameters**
- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last: Refers to the end of the sequence of elements the algorithm will be applied to.
- value: Specifies the value of elements to remove.
- proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel remove algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return**  The remove algorithm returns a hpx::future<subrange_t<FwdIter, Sent>>. The remove algorithm returns an object [ret, last], where ret is a past-the-end iterator for a new subrange of the values all in valid but unspecified state.

template<typename Rng, typename T, typename Proj = util::projection_identity>
subrange_t<typename hpx::traits::range_iterator<Rng>::type> remove (Rng &&rng, T const &value, Proj &&proj = Proj())

Removes all elements that are equal to value from the range rng and and returns a subrange [ret, util::end(rng)], where ret is a past-the-end iterator for the new end of the range.
The assignments in the parallel remove algorithm execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than `util::end(rng)`
- `util::begin(rng)` assignments, exactly `util::end(rng) - util::begin(rng)` applications of the operator`==()` and the projection `proj`.

**Template Parameters**
- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- `T`: The type of the value to remove (deduced). This value type must meet the requirements of `CopyConstructible`.
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`.

**Parameters**
- `rng`: Refers to the sequence of elements the algorithm will be applied to.
- `value`: Specifies the value of elements to remove.
- `proj`: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Return** The `remove` algorithm returns a `subrange_t<typename hpx::traits::range_iterator<Rng>::type>`.

Removes all elements that are equal to `value` from the range `rng` and and returns a subrange `[ret, util::end(rng))`, where ret is a past-the-end iterator for the new subrange of the values all in valid but unspecified state.

```cpp
template<typename ExPolicy, typename Rng, typename T, typename Proj = util::projection_identity>
parallel::util::detail::algorithm_result<ExPolicy, subrange_t<typename hpx::traits::range_iterator<Rng>::type>> remove(
    ExPolicy&& policy,
    Rng&& rng,
    T const& value,
    Proj&& proj = Proj())
```

Removes all elements that are equal to `value` from the range `rng` and and returns a subrange `[ret, util::end(rng))`, where ret is a past-the-end iterator for the new end of the range.

The assignments in the parallel remove algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than `util::end(rng)`
- `util::begin(rng)` assignments, exactly `util::end(rng) - util::begin(rng)` applications of the operator`==()` and the projection `proj`.

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- `T`: The type of the value to remove (deduced). This value type must meet the requirements of `CopyConstructible`.
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`.

**Parameters**
- `policy`: The execution policy to use for the scheduling of the iterations.
• **rng**: Refers to the sequence of elements the algorithm will be applied to.
• **value**: Specifies the value of elements to remove.
• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel `remove` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `remove` algorithm returns a `hpx::future< subrange_t<typename hpx::traits::range_iterator<Rng>::type>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `remove` algorithm returns the iterator to the new end of the range.

The assignments in the parallel `remove_if` algorithm execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than last - first assignments, exactly last - first applications of the predicate `pred` and the projection `proj`.

**Template Parameters**
- **FwdIter**: The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Sent**: The type of the end iterators used (deduced). This sentinel type must be a sentinel for `FwdIter`.
- **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `remove_if` requires `Pred` to meet the requirements of `CopyConstructible`.
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Return** The `remove_if` algorithm returns a `subrange_t<FwdIter, Sent>`. The `remove_if` algorithm returns an object `{ret, last}`, where ret is a past-the-end iterator for a new subrange of the values all in valid but unspecified state.
Removes all elements for which predicate `pred` returns true from the range `[first, last)` and returns a subrange `[ret, last)`, where ret is a past-the-end iterator for the new end of the range.

The assignments in the parallel `remove_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note**  Complexity: Performs not more than `last - first` assignments, exactly `last - first` applications of the predicate `pred` and the projection `proj`.

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter`: The type of the source iterators used for the source. This iterator type must meet the requirements of a forward iterator.
- `Sent`: The type of the end iterators used (deduced). This sentinel type must be a sentinel for `FwdIter`.
- `Pred`: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `remove_if` requires `Pred` to meet the requirements of `CopyConstructible`.
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`.

**Parameters**

- `policy`: The execution policy to use for the scheduling of the iterations.
- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last`: Refers to the end of the sequence of elements the algorithm will be applied to.
- `pred`: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- `proj`: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel `remove_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return**  The `remove_if` algorithm returns a `hpx::future<subrange_t<FwdIter, Sent>>`. The `remove_if` algorithm returns an object `{ret, last}`, where ret is a past-the-end iterator for a new
subrange of the values all in valid but unspecified state.

```cpp
template<typename Rng, typename T, typename Proj = util::projection_identity>
subrange_t<typename hpx::traits::range_iterator<Rng>::type> remove_if (Rng &&rng, Pred &&pred, Proj &&proj = Proj())
```

Removes all elements that are equal to value from the range rng and and returns a subrange [ret, util::end(rng)), where ret is a past-the-end iterator for the new end of the range.

The assignments in the parallel remove_if algorithm execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than `util::end(rng) • util::begin(rng)` assignments, exactly `util::end(rng) - util::begin(rng)` applications of the operator==() and the projection proj.

**Template Parameters**
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of remove_if requires Pred to meet the requirements of CopyConstructible.
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns true for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type FwdIter can be dereferenced and then implicitly converted to Type.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Return** The remove_if algorithm returns a subrange_t<typename hpx::traits::range_iterator<Rng>::type>. The remove_if algorithm returns an object [ret, last), where ret is a past-the-end iterator for a new subrange of the values all in valid but unspecified state.

```cpp
template<typename ExPolicy, typename Rng, typename Pred, typename Proj = util::projection_identity>
parallel::util::detail::algorithm_result<ExPolicy, subrange_t<typename hpx::traits::range_iterator<Rng>::type>> remove_if (ExPolicy &&policy, Rng &&rng, Pred &&pred, Proj &&proj = Proj())
```

Removes all elements that are equal to value from the range rng and and returns a subrange [ret, util::end(rng)), where ret is a past-the-end iterator for the new end of the range.
The assignments in the parallel remove_if algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than `util::end(rng)`
- `util::begin(rng)` assignments, exactly `util::end(rng) - util::begin(rng)` applications of the operator==() and the projection proj.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of remove_if requires Pred to meet the requirements of CopyConstructible.
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`.

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns true for the required elements. The signature of this predicate should be equivalent to:

  ```cpp
def pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type FwdIter can be dereferenced and then implicitly converted to Type.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel remove_if algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The remove_if algorithm returns a `hpx::future<hpx::traits::range_iterator<Rng>::type>` if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter otherwise. The remove_if algorithm returns an object {ret, last}, where ret is a past-the-end iterator for a new subrange of the values all in valid but unspecified state.

```cpp
namespace hpx

namespace ranges

Functions

template<typename Iter, typename Sent, typename T1, typename T2, typename Proj = hpx::parallel::util::projection_identity>
Iter replace(Iter first, Sent sent, T1 const &old_value, T2 const &new_value, Proj &&proj = Proj())
```

Replaces all elements satisfying specific criteria with new_value in the range [first, last).

Effects: Substitutes elements referred by the iterator it in the range [first, last) with new_value, when the following corresponding conditions hold: INVOKE(proj, *i) == old_value
Note Complexity: Performs exactly last - first assignments.

The assignments in the parallel replace algorithm execute in sequential order in the calling thread.

Template Parameters
- **Iter**: The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- **Sent**: The type of the end iterators used (deduced). This sentinel type must be a sentinel for **Iter**.
- **T1**: The type of the old value to replace (deduced).
- **T2**: The type of the new values to replace (deduced).
- **Proj**: The type of an optional projection function. This defaults to *util::projection_identity*

Parameters
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **old_value**: Refers to the old value of the elements to replace.
- **new_value**: Refers to the new value to use as the replacement.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Return The replace algorithm returns an **Iter**.

template<typename Rng, typename T1, typename T2, typename Proj = *hpx::parallel::util::projection_identity*>  
*hpx::traits::range_iterator<Rng>::type replace (Rng &&rng, T1 const &old_value, T2 const &new_value, Proj &proj = Proj())  
Represents an iterator to the sequence of elements in the range range that satisfy the specified criteria.

Effects: Substitutes elements referred by the iterator it in the range rng with new_value, when the following corresponding conditions hold: INVOKE(proj, *i) == old_value

Note Complexity: Performs exactly util::end(rng) - util::begin(rng) assignments.

The assignments in the parallel replace algorithm execute in sequential order in the calling thread.

Template Parameters
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **T1**: The type of the old value to replace (deduced).
- **T2**: The type of the new values to replace (deduced).
- **Proj**: The type of an optional projection function. This defaults to *util::projection_identity*

Parameters
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **old_value**: Refers to the old value of the elements to replace.
- **new_value**: Refers to the new value to use as the replacement.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Return The replace algorithm returns an hpx::traits::range_iterator<Rng>::type.

template<typename ExPolicy, typename Iter, typename Sent, typename T1, typename T2, typename Proj = hpx::parallel::util::projection_identity*>  
*hpx::parallel::util::detail::algorithm_result<ExPolicy, Iter>::type replace (ExPolicy &&policy, Iter first, Sent sent, T1 const &old_value, T2 const &new_value, Proj &proj = Proj())  
Represents an iterator to the sequence of elements in the range [first, last] that satisfy the specified criteria.
Effects: Substitutes elements referred by the iterator it in the range [first, last) with new_value, when the following corresponding conditions hold: INVOKE(proj, *i) == old_value

Note: Complexity: Performs exactly last - first assignments.

The assignments in the parallel replace algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Template Parameters
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- Iter: The type of the source iterator used (deduced). The iterator type must meet the requirements of a forward iterator.
- Sent: The type of the end iterators used (deduced). This sentinel type must be a sentinel for Iter.
- T1: The type of the old value to replace (deduced).
- T2: The type of the new values to replace (deduced).
- Proj: The type of an optional projection function. This defaults to util::projection_identity

Parameters
- policy: The execution policy to use for the scheduling of the iterations.
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last: Refers to the end of the sequence of elements the algorithm will be applied to.
- old_value: Refers to the old value of the elements to replace.
- new_value: Refers to the new value to use as the replacement.
- proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel replace algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return: The replace algorithm returns a hpx::future<Iter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns Iter otherwise.

Replaces all elements satisfying specific criteria with new_value in the range rng.

Effects: Substitutes elements referred by the iterator it in the range rng with new_value, when the
The assignments in the parallel `replace` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Template Parameters**
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- Rng: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- T1: The type of the old value to replace (deduced).
- T2: The type of the new values to replace (deduced).
- Proj: The type of an optional projection function. This defaults to `util::projection_identity`.

**Parameters**
- policy: The execution policy to use for the scheduling of the iterations.
- rng: Refers to the sequence of elements the algorithm will be applied to.
- old_value: Refers to the old value of the elements to replace.
- new_value: Refers to the new value to use as the replacement.
- proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked. The assignments in the parallel `replace` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Return**
The `replace` algorithm returns an `hpx::future<hpx::traits::range_iterator<Rng>::type>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `hpx::traits::range_iterator<Rng>::type` otherwise.

```cpp
template<
typename Iter, typename Sent, typename Pred, typename T, typename Proj = hpx::parallel::util::projection_identity>
Iter replace_if (Iter first, Sent sent, Pred &&pred, T const &new_value, Proj &&proj = Proj())
```

Replaces all elements satisfying specific criteria (for which predicate `f` returns true) with `new_value` in the range `[first, sent)`.

**Effects:** Substitutes elements referred by the iterator it in the range `[first, sent)` with `new_value`, when the following corresponding conditions hold: `INVOKE(f, INVOKE(proj, *it)) != false`.

**Note** Complexity: Performs exactly `sent - first` applications of the predicate.

The assignments in the parallel `replace_if` algorithm execute in sequential order in the calling thread.

**Template Parameters**
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- Iter: The type of the source iterator used (deduced). The iterator type must meet the requirements of a forward iterator.
- Sent: The type of the end iterators used (deduced). This sentinel type must be a sentinel for `Iter`.
- Pred: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `F` to meet the requirements of `CopyConstructible`. (deduced).
- T: The type of the new values to replace (deduced).
• Proj: The type of an optional projection function. This defaults to `util::projection_identity`

Parameters
• policy: The execution policy to use for the scheduling of the iterations.
• first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• last: Refers to the end of the sequence of elements the algorithm will be applied to.
• pred: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns `true` for the elements which need to replaced. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `Iter` can be dereferenced and then implicitly converted to `Type`.
• new_value: Refers to the new value to use as the replacement.
• proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Return The `replace_if` algorithm returns an `Iter` It returns last.

```cpp
template<typename Rng, typename Pred, typename T, typename Proj = hpx::parallel::util::projection_identity>
hpx::traits::range_iterator<Rng>::type replace_if(Rng &&rng, Pred &&pred, T const &new_value, Proj &&proj = Proj())
```

Replaces all elements satisfying specific criteria (for which predicate `pred` returns true) with `new_value` in the range `rng`.

Effects: Substitutes elements referred by the iterator it in the range rng with new_value, when the following corresponding conditions hold: INVOKE(f, INVOKE(proj, *it)) != false

Note Complexity: Performs exactly `util::end(rng) - util::begin(rng)` applications of the predicate.

The assignments in the parallel `replace` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

Template Parameters
• Rng: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
• Pred: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `F` to meet the requirements of `CopyConstructible`. (deduced).
• T: The type of the new values to replace (deduced).
• Proj: The type of an optional projection function. This defaults to `util::projection_identity`

Parameters
• rng: Refers to the sequence of elements the algorithm will be applied to.
• pred: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by rng. This is an unary predicate which returns `true` for the elements which need to replaced. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.
• new_value: Refers to the new value to use as the replacement.
• proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.
The assignments in the parallel `replace` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `replace_if` algorithm returns an `hpx::traits::range_iterator<Rng>::type`. It returns last.

```cpp
template<typename ExPolicy, typename Iter, typename Sent, typename Pred, typename T, typename Proj = hpx::parallel::util::projection_identity>
```

Replaces all elements satisfying specific criteria (for which predicate `pred` returns true) with `new_value` in the range `rng`.

Effects: Substitutes elements referred by the iterator `it` in the range `rng` with `new_value`, when the following corresponding conditions hold: `INVOKE(f, INVOKE(proj, *it)) != false`

**Note** Complexity: Performs exactly `util::end(rng) - util::begin(rng)` applications of the predicate.

The assignments in the parallel `replace_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Iter`: The type of the source iterator used (deduced). The iterator type must meet the requirements of a forward iterator.
- `Sent`: The type of the end iterators used (deduced). This sentinel type must be a sentinel for `Iter`.
- `Pred`: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible` (deduced).
- `T`: The type of the new values to replace (deduced).
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- `policy`: The execution policy to use for the scheduling of the iterations.
- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last`: Refers to the end of the sequence of elements the algorithm will be applied to.
- `pred`: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the elements which need to be replaced. The signature of this predicate should be equivalent to:

  ```cpp
  bool pred(const Type &a);
  ```

  The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- `new_value`: Refers to the new value to use as the replacement.
- `proj`: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel `replace_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `replace_if` algorithm returns a `hpx::future<Iter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy`. It returns `last`.

```cpp
template<typename ExPolicy, typename Rng, typename Pred, typename T, typename Proj = hpx::parallel::util::projection_identity>
```
Replaces all elements satisfying specific criteria (for which predicate \texttt{pred} returns true) with \texttt{new\_value} in the range \texttt{rng}.

Effects: Substitutes elements referred by the iterator \texttt{it} in the range \texttt{rng} with \texttt{new\_value}, when the following corresponding conditions hold: \texttt{INVOKE(f, INVOKE(proj, *it)) \neq false}

\textbf{Note} Complexity: Performs exactly \texttt{util::end(rng) - util::begin(rng)} applications of the predicate.

The assignments in the parallel \texttt{replace} algorithm invoked with an execution policy object of type \texttt{sequenced\_policy} execute in sequential order in the calling thread.

\textbf{Template Parameters}

- \texttt{ExPolicy}: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- \texttt{Rng}: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- \texttt{Pred}: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \texttt{equal} requires \texttt{F} to meet the requirements of \texttt{CopyConstructible}. (deduced).
- \texttt{T}: The type of the new values to replace (deduced).
- \texttt{Proj}: The type of an optional projection function. This defaults to \texttt{util::projection\_identity}

\textbf{Parameters}

- \texttt{policy}: The execution policy to use for the scheduling of the iterations.
- \texttt{rng}: Refers to the sequence of elements the algorithm will be applied to.
- \texttt{pred}: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \texttt{rng}. This is an unary predicate which returns \texttt{true} for the elements which need to be replaced. The signature of this predicate should be equivalent to:

\begin{verbatim}
bool pred(const Type &a);
\end{verbatim}

The signature does not need to have \texttt{const\&}, but the function must not modify the objects passed to it. The type \texttt{Type} must be such that an object of type \texttt{FwdIter} can be dereferenced and then implicitly converted to \texttt{Type}.
- \texttt{new\_value}: Refers to the new value to use as the replacement.
- \texttt{proj}: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate \texttt{is} invoked.

The assignments in the parallel \texttt{replace} algorithm invoked with an execution policy object of type \texttt{parallel\_policy} or \texttt{parallel\_task\_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
Return The replace_if algorithm returns a hpx::future<typename hpx::traits::range_iterator<Rng>::type> if the execution policy is of type sequenced_task_policy or parallel_task_policy. It returns last.

template<typename InIter, typename Sent, typename OutIter, typename T1, typename T2, typename Proj = hpx::parallel::util::projection_identity>
replace_copy_result<InIter, OutIter> replace_copy(InIter first, Sent sent, OutIter dest, T1 const &old_value, T2 const &new_value, Proj &&proj = Proj())

Copies the all elements from the range [first, sent) to another range beginning at dest replacing all elements satisfying a specific criteria with new_value.

Effects: Assigns to every iterator it in the range [result, result + (sent - first)) either new_value or *(first + (it - result)) depending on whether the following corresponding condition holds: INVOKE(proj, *(first + (i - result))) == old_value

The assignments in the parallel replace_copy algorithm execute in sequential order in the calling thread.

Note Complexity: Performs exactly sent - first applications of the predicate.

Template Parameters
- Iter: The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- Sent: The type of the end iterators used (deduced). This sentinel type must be a sentinel for Iter.
- OutIter: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- T1: The type of the old value to replace (deduced).
- T2: The type of the new values to replace (deduced).
- Proj: The type of an optional projection function. This defaults to util::projection_identity

Parameters
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- sent: Refers to the end of the sequence of elements the algorithm will be applied to.
- dest: Refers to the beginning of the destination range.
- old_value: Refers to the old value of the elements to replace.
- new_value: Refers to the new value to use as the replacement.
- proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Return The replace_copy algorithm returns an in_out_result<InIter, OutIter>. The copy algorithm returns the pair of the input iterator last and the output iterator to the element in the destination range, one past the last element copied.
replace_copy_result<typename hpx::traits::range_iterator<Rng>::type, OutIter> replace_copy(Rng &&rng, OutIter dest, T1 const &old_value, T2 const &new_value, Proj &&proj = Proj())

Copies the all elements from the range \( \text{rbg} \) to another range beginning at \( \text{dest} \) replacing all elements satisfying a specific criteria with \( \text{new\_value} \).

Effects: Assigns to every iterator \( \text{it} \) in the range \([\text{result}, \text{result} + (\text{util\_end}(\text{rng}) - \text{util\_begin}(\text{rng})))\) either \( \text{new\_value} \) or \((\text{first} + (\text{it} - \text{result}))\) depending on whether the following corresponding condition holds:

\[
\text{INVOKED}(\text{proj}, (\text{first} + (\text{it} - \text{result}))) == \text{old\_value}
\]

The assignments in the parallel \textit{replace\_copy} algorithm execute in sequential order in the calling thread.

\textbf{Note} Complexity: Performs exactly \text{util\_end}(\text{rng}) - \text{util\_begin}(\text{rng}) applications of the predicate.

**Template Parameters**

- \( \text{Rng} \): The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- \( \text{OutIter} \): The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- \( \text{T1} \): The type of the old value to replace (deduced).
- \( \text{T2} \): The type of the new values to replace (deduced).
- \( \text{Proj} \): The type of an optional projection function. This defaults to \text{util\_projection\_identity}

**Parameters**

- \( \text{rng} \): Refers to the sequence of elements the algorithm will be applied to.
- \( \text{dest} \): Refers to the beginning of the destination range.
- \( \text{old\_value} \): Refers to the old value of the elements to replace.
- \( \text{new\_value} \): Refers to the new value to use as the replacement.
- \( \text{proj} \): Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Return** The \textit{replace\_copy} algorithm returns an \textit{in\_out\_result<typename hpx::traits::range_iterator<Rng>::type, OutIter>}. The \textit{copy} algorithm returns the pair of the input iterator \textit{last} and the output iterator to the element in the destination range, one past the last element copied.
Copies the all elements from the range \([first, sent)\) to another range beginning at \(dest\) replacing all elements satisfying a specific criteria with \(new_value\).

Effects: Assigns to every iterator \(it\) in the range \([result, result + (sent - first))\) either \(new_value\) or \(*(first + (i - result))) == old_value\)

The assignments in the parallel replace_copy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly \(sent - first\) applications of the predicate.

### Template Parameters
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the source iterator used (deduced). The iterator type must meet the requirements of an forward iterator.
- **Sent**: The type of the end iterators used (deduced). This sentinel type must be a sentinel for Iter.
- **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T1**: The type of the old value to replace (deduced).
- **T2**: The type of the new values to replace (deduced).
- **Proj**: The type of an optional projection function. This defaults to util::projection_identity

### Parameters
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **old_value**: Refers to the old value of the elements to replace.
- **new_value**: Refers to the new value to use as the replacement.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel replace_copy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
**Return** The `replace_copy` algorithm returns a `hpx::future<in_out_result<FwdIter1, FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `in_out_result<FwdIter1, FwdIter2>` otherwise. The `copy` algorithm returns the pair of the forward iterator `last` and the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename Rng, typename FwdIter, typename T1, typename T2, typename Proj = hpx::parallel::util::projection_identity>
template<typename ExPolicy, typename Rng, typename FwdIter, typename T1, typename T2, typename Proj = hpx::parallel::util::projection_identity>
```

Copies the all elements from the range rbg to another range beginning at `dest` replacing all elements satisfying a specific criteria with `new_value`.

**Effects:** Assigns to every iterator `it` in the range `[result, result + (util::end(rng) - util::begin(rng))]` either `new_value` or `*(first + (i - result))` depending on whether the following corresponding condition holds: `INVOKE(proj, *(first + (i - result))) == old_value`

The assignments in the parallel `replace_copy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `util::end(rng) - util::begin(rng)` applications of the predicate.

**Template Parameters**
- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- `FwdIter`: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- `T1`: The type of the old value to replace (deduced).
- `T2`: The type of the new values to replace (deduced).
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**
- `policy`: The execution policy to use for the scheduling of the iterations.
- `rng`: Refers to the sequence of elements the algorithm will be applied to.
- `dest`: Refers to the beginning of the destination range.
- `old_value`: Refers to the old value of the elements to replace.
- `new_value`: Refers to the new value to use as the replacement.
- `proj`: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.
The assignments in the parallel `replace_copy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `replace_copy` algorithm returns a `hpx::future<in_out_result< typename hpx::traits::range_iterator<Rng>::type, FwdIter>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `in_out_result< typename hpx::traits::range_iterator<Rng>::type, FwdIter>>` The `copy` algorithm returns the pair of the input iterator `last` and the forward iterator to the element in the destination range, one past the last element copied.

**Template Parameters**
- **InIter**: The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- **Sent**: The type of the end iterators used (deduced). This sentinel type must be a sentinel for `InIter`.
- **OutIter**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible` (deduced).
- **T**: The type of the new values to replace (deduced).
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`.

**Parameters**
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent**: Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the elements which need to replaced. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- **new_value**: Refers to the new value to use as the replacement.
- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.
Return The `replace_copy_if` algorithm returns a `in_out_result<InIter, OutIter>`. The `replace_copy_if` algorithm returns the input iterator last and the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<
typename Rng,
typename OutIter,
typename Pred,
typename T,
typename Proj = hpx::parallel::util::projection_identity>
replace_copy_if_result<
typename hpx::traits::range_iterator<Rng>::type,
OutIter>
replace_copy_if(
    Rng &&rng,
    OutIter dest,
    Pred &&pred,
    T const &new_value,
    Proj &&proj
)
```

Copies the all elements from the range `rng` to another range beginning at `dest` replacing all elements satisfying a specific criteria with `new_value`.

Effects: Assigns to every iterator `it` in the range `[result, result + (util::end(rng) - util::begin(rng)))` either `new_value` or `*(first + (it - result))` depending on whether the following corresponding condition holds: `INVOKE(f, INVOKE(proj, *(first + (i - result)))) != false`

The assignments in the parallel `replace_copy_if` algorithm execute in sequential order in the calling thread.

Note Complexity: Performs exactly `util::end(rng) - util::begin(rng)` applications of the predicate.

Template Parameters
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **OutIter**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible` (deduced).
- **T**: The type of the new values to replace (deduced).
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`.

Parameters
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the elements which need to replaced. The signature of this predicate should be equivalent to:

  ```cpp
  bool pred(const Type &a);
  ```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- **new_value**: Refers to the new value to use as the replacement.
**proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Return** The `replace_copy_if` algorithm returns an `in_out_result<typename hpx::traits::range_iterator<Rng>::type, OutIter>`. The `replace_copy_if` algorithm returns the input iterator `last` and the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename Sent, typename FwdIter2, typename Pred, typename T, typename Proj = hpx::parallel::util::projection_identity>
parallel::util::detail::algorithm_result<ExPolicy, replace_copy_if_result<FwdIter1, FwdIter2>>::type replace_copy_if(ExPolicy &&policy, FwdIter1 first, Sent sent, FwdIter2 dest, Pred &&pred, T const &new_value, Proj &&proj = Proj())
```

Copies the all elements from the range `[first, sent)` to another range beginning at `dest` replacing all elements satisfying a specific criteria with `new_value`.

**Effects**: Assigns to every iterator `it` in the range `[result, result + (sent - first))` either `new_value` or `*(first + (it - result))` depending on whether the following corresponding condition holds: `INVOKE(f, INVOKE(proj, *(first + (i - result)))) != false`

The assignments in the parallel `replace_copy_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `sent - first` applications of the predicate.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1**: The type of the source iterator used (deduced). The iterator type must meet the requirements of a forward iterator.
- **Sent**: The type of the end iterators used (deduced). This sentinel type must be a sentinel for `InIter`.
- **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible`.
- **T**: The type of the new values to replace (deduced).
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
• **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **sent**: Refers to the end of the sequence of elements the algorithm will be applied to.
• **dest**: Refers to the beginning of the destination range.
• **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns **true** for the elements which need to replaced. The signature of this predicate should be equivalent to:

```cpp
template<typename Type>
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type **Type** must be such that an object of type **FwdIter** can be dereferenced and then implicitly converted to **Type**.
• **new_value**: Refers to the new value to use as the replacement.
• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel `replace_copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `replace_copy_if` algorithm returns an **hpx::future<FwdIter1, FwdIter2>**. The `replace_copy_if` algorithm returns the input iterator `last` and the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename Rng, typename FwdIter, typename Pred, typename T, typename Proj = hpx::parallel::util::projection_identity>
ExPolicy &&policy, Rng &&rng, FwdIter dest, Pred &&pred, T const &new_value,
Proj &&proj = Proj() )
```

Copies the all elements from the range `rng` to another range beginning at `dest` replacing all elements satisfying a specific criteria with `new_value`.

Effects: Assigns to every iterator it in the range [result, result + (util::end(rng) - util::begin(rng))] either new_value or *(first + (it - result)) depending on whether the following corresponding condition holds: INVOKE(f, INVOKE(proj, *(first + (i - result)))) != false

The assignments in the parallel `replace_copy_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `util::end(rng) - util::begin(rng)` applications of the predicate.

**Template Parameters**
• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

2.8. API reference 1245
• **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
• **OutIter**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
• **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of equal requires Pred to meet the requirements of CopyConstructible (deduced).
• **T**: The type of the new values to replace (deduced).
• **Proj**: The type of an optional projection function. This defaults to util::projection_identity

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns true for the elements which need to replaced. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type FwdIter can be dereferenced and then implicitly converted to Type.
• **new_value**: Refers to the new value to use as the replacement.
• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel replace_copy_if algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The replace_copy_if algorithm returns an hpx::future<in_out_result<typename hpx::traits::range_iterator<Rng>::type, OutIter>>. The replace_copy_if algorithm returns the input iterator last and the output iterator to the element in the destination range, one past the last element copied.

```cpp
namespace hpx

namespace ranges

Functions

template<typename Iter, typename Sent>
Iter reverse(Iter first, Sent last)
Reverses the order of the elements in the range [first, last). Behaves as if applying std::iter_swap to every pair of iterators first+i, (last-i) - 1 for each non-negative i < (last-first)/2.

The assignments in the parallel reverse algorithm execute in sequential order in the calling thread.

**Note** Complexity: Linear in the distance between first and last.

**Template Parameters**

- **Iter**: The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- **Sent**: The type of the end iterators used (deduced). This sentinel type must be a sentinel for Iter.
Parameters
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.

**Return** The `reverse` algorithm returns a `Iter`. It returns `last`.

```cpp
template<typename Rng>
hpx::traits::range_iterator<Rng>::type reverse (Rng &&rng)
```

Uses `rng` as the source range, as if using `util::begin(rng)` as `first` and `ranges::end(rng)` as `last`. Reverses the order of the elements in the range `[first, last)`. Behaves as if applying `std::iter_swap` to every pair of iterators `first+i`, `(last-i) - 1` for each non-negative `i < (last-first)/2`.

The assignments in the parallel `reverse` algorithm execute in sequential order in the calling thread.

**Note** Complexity: Linear in the distance between `first` and `last`.

**Template Parameters**
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a bidirectional iterator.

**Parameters**
- **rng**: Refers to the sequence of elements the algorithm will be applied to.

```cpp
template<typename ExPolicy, typename Iter, typename Sent>
parallel::util::detail::algorithm_result<ExPolicy, Iter>::type reverse (ExPolicy &&policy, Iter first, Sent last)
```

Reverses the order of the elements in the range `[first, last)`. Behaves as if applying `std::iter_swap` to every pair of iterators `first+i`, `(last-i) - 1` for each non-negative `i < (last-first)/2`.

The assignments in the parallel `reverse` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Linear in the distance between `first` and `last`.

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter**: The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- **Sent**: The type of the end iterators used (deduced). This sentinel type must be a sentinel for `Iter`.

**Parameters**
- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements the algorithm will be applied to.

The assignments in the parallel `reverse` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `reverse` algorithm returns a `hpx::future<Iter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `Iter` otherwise. It returns `last`.

```cpp
template<typename ExPolicy, typename Rng>
```
parallel::util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng>::type>::type reverse (ExPolicy &&policy, Rng &&rng)

Uses rng as the source range, as if using util::begin(rng) as first and ranges::end(rng) as last. Reverses the order of the elements in the range [first, last). Behaves as if applying std::iter_swap to every pair of iterators first+i, (last-i) - 1 for each non-negative i < (last-first)/2.

The assignments in the parallel reverse algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Linear in the distance between first and last.

Template Parameters
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- Rng: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a bidirectional iterator.

Parameters
- policy: The execution policy to use for the scheduling of the iterations.
- rng: Refers to the sequence of elements the algorithm will be applied to.

The assignments in the parallel reverse algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The reverse algorithm returns a hpx::future<typename hpx::traits::range_iterator<Rng>::type> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns hpx::future<typename hpx::traits::range_iterator<Rng>::type> otherwise. It returns last.

template<typename Iter, typename Sent, typename OutIter> reverse_copy_result<Iter, OutIter> reverse_copy (Iter first, Sent last, OutIter result)

Copies the elements from the range [first, last) to another range beginning at result in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment *(result + (last - first) - 1 - i) = *(first + i) once for each non-negative i < (last - first) If the source and destination ranges (that is, [first, last) and [result, result+(last-first)) respectively) overlap, the behavior is undefined.

The assignments in the parallel reverse_copy algorithm execute in sequential order in the calling thread.

Note Complexity: Performs exactly last - first assignments.

Template Parameters
- Iter: The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- Sent: The type of the end iterators used (deduced). This sentinel type must be a sentinel for Iter.
- OutIter: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

Parameters
- first: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last: Refers to the end of the sequence of elements the algorithm will be applied to.
- result: Refers to the begin of the destination range.
The `reverse_copy` algorithm returns a `reverse_copy_result<Iter, OutIter>`. The `reverse_copy` algorithm returns the pair of the input iterator forwarded to the first element after the last in the input sequence and the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename Rng, typename OutIter>
ranges::reverse_copy_result<
typename hpx::traits::range_iterator<Rng>::type,
OutIter>
reverse_copy(
Rng &&rng,
OutIter result)
```

Uses `rng` as the source range, as if using `util::begin(rng)` as `first` and `ranges::end(rng)` as `last`. Copies the elements from the range `[first, last)` to another range beginning at `result` in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment `*(result + (last - first) - 1 - i) = *(first + i)` once for each non-negative `i < (last - first)` If the source and destination ranges (that is, `[first, last)` and `[result, result+(last-first))` respectively) overlap, the behavior is undefined.

The assignments in the parallel `reverse_copy` algorithm execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly `last - first` assignments.

**Template Parameters**
- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a bidirectional iterator.
- `OutputIter`: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

**Parameters**
- `rng`: Refers to the sequence of elements the algorithm will be applied to.
- `result`: Refers to the begin of the destination range.

**Return** The `reverse_copy` algorithm returns a `ranges::reverse_copy_result<` typename hpx::traits::range_iterator<Rng>::type, OutIter>`::type. The `reverse_copy` algorithm returns an object equal to `{last, result + N}` where `N = last - first`

```cpp
template<typename ExPolicy, typename Iter, typename Sent, typename OutIter>
parallel::util::detail::algorithm_result<ExPolicy, reverse_copy_result<Iter, OutIter>::type>
reverse_copy(
ExPolicy &&policy,
Iter first,
Sent last,
OutIter result)
```

Copies the elements from the range `[first, last)` to another range beginning at `result` in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment `*(result + (last - first) - 1 - i) = *(first + i)` once for each non-negative `i < (last - first)` If the source and destination ranges (that is, `[first, last)` and `[result, result+(last-first))` respectively) overlap, the behavior is undefined.
The assignments in the parallel `reverse_copy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly last - first assignments.

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Iter`: The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- `Sent`: The type of the end iterators used (deduced). This sentinel type must be a sentinel for `Iter`.
- `OutIter`: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

**Parameters**

- `policy`: The execution policy to use for the scheduling of the iterations.
- `first`: Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last`: Refers to the end of the sequence of elements the algorithm will be applied to.
- `result`: Refers to the begin of the destination range.

The assignments in the parallel `reverse_copy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `reverse_copy` algorithm returns a `hpx::future<reverse_copy_result<Iter, OutIter>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `reverse_copy_result<Iter, OutIter>` otherwise. The `reverse_copy` algorithm returns the pair of the input iterator forwarded to the first element after the last in the input sequence and the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename Rng, typename OutIter>
util::detail::algorithm_result<ExPolicy, ranges::reverse_copy_result<typename hpx::traits::range_iterator<Rng>::type, OutIter>> reverse_copy(ExPolicy&& policy, Rng&& rng, OutIter result)
```

Uses `rng` as the source range, as if using `util::begin(rng)` as `first` and `ranges::end(rng)` as `last`. Copies the elements from the range `[first, last)` to another range beginning at `result` in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment *(result + (last - first) - 1 - i) = *(first + i)* once for each non-negative i < (last - first) If the source and destination ranges (that is, `[first, last)` and `[result, result+(last-first))` respectively) overlap, the behavior is undefined.

The assignments in the parallel `reverse_copy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly last - first assignments.

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type
must meet the requirements of a bidirectional iterator.

• OutputIter: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

Parameters

• policy: The execution policy to use for the scheduling of the iterations.
• rng: Refers to the sequence of elements the algorithm will be applied to.
• result: Refers to the begin of the destination range.

The assignments in the parallel reverse_copy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return

The reverse_copy algorithm returns a hpx::future<ranges::reverse_copy_result<

typename hpx::traits::range_iterator<Rng>::type, OutIter>> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns ranges::reverse_copy_result<

typename hpx::traits::range_iterator<Rng>::type, OutIter> otherwise. The reverse_copy algorithm returns an object equal to {last, result + N} where N = last - first.

namespace hpx

namespace parallel

Functions

template<typename ExPolicy, typename Rng>
util::detail::algorithm_result<ExPolicy, util::in_out_result<
typename hpx::traits::range_iterator<Rng>::type, typename

Performs a left rotation on a range of elements. Specifically, rotate swaps the elements in the range [first, last) in such a way that the element new_first becomes the first element of the new range and new_first - 1 becomes the last element.

The assignments in the parallel rotate algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Linear in the distance between first and last.

Template Parameters

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• Rng: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.

Parameters

• policy: The execution policy to use for the scheduling of the iterations.
• rng: Refers to the sequence of elements the algorithm will be applied to.
• middle: Refers to the element that should appear at the beginning of the rotated range.
The assignments in the parallel rotate algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note** The type of dereferenced FwdIter must meet the requirements of MoveAssignable and MoveConstructible.

**Return** The rotate algorithm returns a hpx::future<tagged_pair<tag::begin(FwdIter), tag::end(FwdIter)>> if the execution policy is of type parallel_task_policy and returns tagged_pair<tag::begin(FwdIter), tag::end(FwdIter)>> otherwise. The rotate algorithm returns the iterator equal to pair(first + (last - new_first), last).

Copies the elements from the range [first, last), to another range beginning at dest_first in such a way, that the element new_first becomes the first element of the new range and new_first - 1 becomes the last element.

The assignments in the parallel rotate_copy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Performs exactly last - first assignments.

**Template Parameters**
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- Rng: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- OutIter: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

**Parameters**
- policy: The execution policy to use for the scheduling of the iterations.
- rng: Refers to the sequence of elements the algorithm will be applied to.
- middle: Refers to the element that should appear at the beginning of the rotated range.
- dest_first: Refers to the begin of the destination range.

The assignments in the parallel rotate_copy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The rotate_copy algorithm returns a hpx::future<tagged_pair<tag::in(FwdIter), tag::out(OutIter)>> if the execution policy is of type parallel_task_policy and returns tagged_pair<tag::in(FwdIter), tag::out(OutIter)>> otherwise. The rotate_copy algorithm returns the output iterator to the element past the last element copied.
namespace hpx

namespace ranges

Functions

template<typename FwdIter, typename Sent, typename FwdIter2, typename Sent2, typename Pred = hpx::ranges::equal_to, typename Proj1 = parallel::util::projection_identity, typename Proj2 = parallel::util::projection_identity>
FwdIter search (FwdIter first, Sent last, FwdIter2 s_first, Sent2 s_last, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())

Searches the range [first, last) for any elements in the range [s_first, s_last). Uses a provided predicate to compare elements.

The comparison operations in the parallel search algorithm execute in sequential order in the calling thread.

Note Complexity: at most (S*N) comparisons where S = distance(s_first, s_last) and N = distance(first, last).

Template Parameters

- **FwdIter**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent**: The type of the source sentinel used for the first range (deduced). This iterator type must meet the requirements of an sentinel.
- **FwdIter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2**: The type of the source sentinel used for the second range (deduced). This iterator type must meet the requirements of an sentinel.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of adjacent_find requires Pred to meet the requirements of CopyConstructible. This defaults to std::equal_to<>
- **Proj1**: The type of an optional projection function. This defaults to util::projection_identity and is applied to the elements of type dereferenced FwdIter.
- **Proj2**: The type of an optional projection function. This defaults to util::projection_identity and is applied to the elements of type dereferenced FwdIter2.

Parameters

- **first**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s_first**: Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last**: Refers to the end of the sequence of elements the algorithm will be searching for.
- **op**: Refers to the binary predicate which returns true if the elements should be treated as equal. The signature of the function should be equivalent to

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced FwdIter1 as a projection operation before the actual predicate is invoked.
proj2: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `FwdIter2` as a projection operation before the actual predicate is invoked.

**Return** The `search` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `search` algorithm returns an iterator to the beginning of the first subsequence `[s_first, s_last)` in range `[first, last)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, last)`, `last` is returned. Additionally if the size of the subsequence is empty `first` is returned. If no subsequence is found, `last` is returned.

```cpp
template<typename ExPolicy, typename FwdIter, typename Sent, typename FwdIter2, typename Sent2, typename Pred = hpx::ranges::equal_to, typename Proj1 = parallel::util::projection_identity, typename Proj2 = parallel::util::projection_identity>
util::detail::algorithm_result<ExPolicy, FwdIter>::type
search(ExPolicy &&policy, FwdIter first, Sent last, FwdIter2 s_first, Sent2 s_last, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Searches the range `[first, last)` for any elements in the range `[s_first, s_last)` using a provided predicate to compare elements.

The comparison operations in the parallel `search` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.  
**Note** Complexity: at most (S*N) comparisons where $S = \text{distance}(s\text{\_first}, s\text{\_last})$ and $N = \text{distance}(\text{first}, \text{last})$.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent**: The type of the source sentinel used for the first range (deduced). This iterator type must meet the requirements of an sentinel.
- **FwdIter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2**: The type of the source sentinel used for the second range (deduced). This iterator type must meet the requirements of an sentinel.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`
- **Proj1**: The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements of type dereferenced `FwdIter`.
- **Proj2**: The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements of type dereferenced `FwdIter2`.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s_first**: Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last**: Refers to the end of the sequence of elements the algorithm will be searching for.
- **op**: Refers to the binary predicate which returns true if the elements should be treated as equal.
the signature of the function should be equivalent to

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const & but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively

- `proj1`: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `FwdIter1` as a projection operation before the actual predicate is invoked.
- `proj2`: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `FwdIter2` as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel `search` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `search` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `search` algorithm returns an iterator to the beginning of the first subsequence `[s_first, s_last)` in range `[first, last)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, last)`, `last` is returned. Additionally if the size of the subsequence is empty `first` is returned. If no subsequence is found, `last` is returned.

```cpp
template<typename Rng1, typename Rng2, typename Pred = hpx::ranges::equal_to, typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 = hpx::parallel::util::projection_identity>
    hpx::traits::range_iterator<Rng1>::type search(Rng1 &&rng1, Rng2 &&rng2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Searches the range `[first, last)` for any elements in the range `[s_first, s_last)`. Uses a provided predicate to compare elements.

The comparison operations in the parallel `search` algorithm execute in sequential order in the calling thread.

**Note** Complexity: at most \((S*N)\) comparisons where \(S = \text{distance}(s\_first, s\_last)\) and \(N = \text{distance}(\text{first}, \text{last})\).

**Template Parameters**
- `Rng1`: The type of the examine range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- `Rng2`: The type of the search range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- `Pred`: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>
- `Proj1`: The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements of `Rng1`.
- `Proj2`: The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements of `Rng2`.

**Parameters**
- `rng1`: Refers to the sequence of elements the algorithm will be examining.
- `rng2`: Refers to the sequence of elements the algorithm will be searching for.
- `op`: Refers to the binary predicate which returns true if the elements should be treated as equal.

the signature of the function should be equivalent to
bool pred(const Type1 &a, const Type2 &b);

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively.

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of rng1 as a projection operation before the actual predicate is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of rng2 as a projection operation before the actual predicate is invoked.

**Return** The search algorithm returns a hpx::future<FwdIter> if the execution policy is of type task_execution_policy and returns FwdIter otherwise. The search algorithm returns an iterator to the beginning of the first subsequence [s_first, s_last) in range [first, last). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, last), last is returned. Additionally if the size of the subsequence is empty first is returned. If no subsequence is found, last is returned.

```
template<
    typename ExPolicy, typename Rng1, typename Rng2, 
    typename Pred = hpx::ranges::equal_to, 
    typename Proj1 = hpx::parallel::util::projection_identity,  
    typename Proj2 = hpx::parallel::util::projection_identity
>

hpx::parallel::util::detail::algorithm_result<
    ExPolicy, typenamex hpx::traits::range_iterator<Rng1>::type>::type
search(
    ExPolicy &&policy, 
    Rng1 &&rng1, 
    Rng2 &&rng2, 
    Pred &&op = Pred(), 
    Proj1 &&proj1 = Proj1(), 
    Proj2 &&proj2 = Proj2() 
    )
```

Searches the range [first, last) for any elements in the range [s_first, s_last). Uses a provided predicate to compare elements.

The comparison operations in the parallel search algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: at most (S*N) comparisons where S = distance(s_first, s_last) and N = distance(first, last).

**Template Parameters**
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1**: The type of the examine range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2**: The type of the search range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form,
the parallel overload of adjacent_find requires Pred to meet the requirements of CopyConstructible. This defaults to std::equal_to<>.

- Proj1: The type of an optional projection function. This defaults to util::projection_identity and is applied to the elements of Rng1.
- Proj2: The type of an optional projection function. This defaults to util::projection_identity and is applied to the elements of Rng2.

**Parameters**

- policy: The execution policy to use for the scheduling of the iterations.
- rng1: Refers to the sequence of elements the algorithm will be examining.
- rng2: Refers to the sequence of elements the algorithm will be searching for.
- op: Refers to the binary predicate which returns true if the elements should be treated as equal.
  
  The signature of the function should be equivalent to

  ```cpp
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const & but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively.

- proj1: Specifies the function (or function object) which will be invoked for each of the elements of rng1 as a projection operation before the actual predicate is invoked.
- proj2: Specifies the function (or function object) which will be invoked for each of the elements of rng2 as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel search algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return**

The search algorithm returns a hpx::future<FwdIter> if the execution policy is of type task_execution_policy and returns FwdIter otherwise. The search algorithm returns an iterator to the beginning of the first subsequence [s_first, s_last) in range [first, last). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, last), last is returned. Additionally if the size of the subsequence is empty first is returned. If no subsequence is found, last is returned.

```cpp
template<typename FwdIter, typename FwdIter2, typename Sent2, typename Pred = hpx::ranges::equal_to, typename Proj1 = parallel::util::projection_identity, typename Proj2 = parallel::util::projection_identity>
FwdIter search_n(ExPolicy &&policy, FwdIter first, std::size_t count, FwdIter2 s_first, Sent s_last, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Searches the range [first, last) for any elements in the range [s_first, s_last). Uses a provided predicate to compare elements.

The comparison operations in the parallel search_n algorithm execute in sequential order in the calling thread.

**Note** Complexity: at most (S*N) comparisons where S = distance(s_first, s_last) and N = count.

**Template Parameters**

- FwdIter: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- FwdIter2: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- Sent2: The type of the source sentinel used for the second range (deduced). This iterator type must meet the requirements of an sentinel.
- Pred: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of adjacent_find requires Pred to meet the requirements of CopyConstructible. This defaults to std::equal_to<>
Parameters

- **first**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **count**: Refers to the range of elements of the first range the algorithm will be applied to.
- **s_first**: Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last**: Refers to the end of the sequence of elements the algorithm will be searching for.
- **op**: Refers to the binary predicate which returns true if the elements should be treated as equal. The signature of the function should be equivalent to

  ```
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively.
- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced FwdIter1 as a projection operation before the actual predicate is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced FwdIter2 as a projection operation before the actual predicate is invoked.

**Return** The `search_n` algorithm returns FwdIter. The `search_n` algorithm returns an iterator to the beginning of the last subsequence [s_first, s_last) in range [first, first+count). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, first+count), `first` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `first` is also returned.

```
template<typename ExPolicy, typename FwdIter, typename FwdIter2, typename Sent2, typename Pred = hpx::ranges::equal_to, typename Proj1 = parallel::util::projection_identity, typename Proj2 = parallel::util::projection_identity>
util::detail::algorithm_result<ExPolicy, FwdIter>::type
search_n(ExPolicy &&policy, FwdIter first, std::size_t count, FwdIter2 s_first, Sent2 s_last, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Searches the range [first, last) for any elements in the range [s_first, s_last). Uses a provided predicate to compare elements.

The comparison operations in the parallel `search_n` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: at most (S*N) comparisons where S = distance(s_first, s_last) and N = count.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter**: The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2**: The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2**: The type of the source sentinel used for the second range (deduced). This iterator type must meet the requirements of a sentinel.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to std::equal_to<>
Parameters

• **policy**: The execution policy to use for the scheduling of the iterations.
• **first**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
• **count**: Refers to the range of elements of the first range the algorithm will be applied to.
• **s_first**: Refers to the beginning of the sequence of elements the algorithm will be searching for.
• **s_last**: Refers to the end of the sequence of elements the algorithm will be searching for.
• **op**: Refers to the binary predicate which returns true if the elements should be treated as equal. The signature of the function should be equivalent to

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &., but the function must not modify the objects passed to it. The types **Type1** and **Type2** must be such that objects of types **FwdIter1** and **FwdIter2** can be dereferenced and then implicitly converted to **Type1** and **Type2** respectively.

• **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced **FwdIter1** as a projection operation before the actual predicate is invoked.
• **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced **FwdIter2** as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel `search_n` algorithm invoked with an execution policy object of type **parallel_policy** or **parallel_task_policy** are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return**

The `search_n` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type **task_execution_policy** and returns `FwdIter` otherwise. The `search_n` algorithm returns an iterator to the beginning of the last subsequence [s_first, s_last) in range [first, first+count). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, first+count), `first` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `first` is also returned.

```cpp
template<typename Rng1, typename Rng2, typename Pred = hpx::ranges::equal_to, typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 = hpx::parallel::util::projection_identity>

hpx::traits::range_iterator<Rng1>::type search_n(Rng1 &&rng1, std::size_t count, Rng2 &&rng2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Searches the range [first, last) for any elements in the range [s_first, s_last). Uses a provided predicate to compare elements.

The comparison operations in the parallel `search` algorithm execute in sequential order in the calling thread.

**Note** Complexity: at most (S*N) comparisons where S = distance(s_first, s_last) and N = distance(first, last).

**Template Parameters**

• **Rng1**: The type of the examine range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
• **Rng2**: The type of the search range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
• **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires **Pred** to meet the requirements of `CopyConstructible`. This defaults to std::equal_to<>.
• **Proj1**: The type of an optional projection function. This defaults to `util::projection_identity`
and is applied to the elements of Rng1.

- **Proj2**: The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements of Rng2.

**Parameters**

- **rng1**: Refers to the sequence of elements the algorithm will be examining.
- **count**: The number of elements to apply the algorithm on.
- **rng2**: Refers to the sequence of elements the algorithm will be searching for.
- **op**: Refers to the binary predicate which returns true if the elements should be treated as equal. The signature of the function should be equivalent to

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of rng1 as a projection operation before the actual predicate is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of rng2 as a projection operation before the actual predicate is invoked.

**Return**

The `search` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `search` algorithm returns an iterator to the beginning of the first subsequence `[s_first, s_last)` in range `[first, last)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, last)`, `last` is returned. Additionally if the size of the subsequence is empty `first` is returned. If no subsequence is found, `last` is returned.

```
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred = hpx::ranges::equal_to, typename Proj1 = hpx::parallel::util::projection_identity, typename Proj2 = hpx::parallel::util::projection_identity>

hpx::parallel::util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng1>::type>::type
search_n(
    ExPolicy &&policy,
    Rng1 &&rng1,
    std::size_t count,
    Rng2 &&rng2,
    Pred &&op = Pred(),
    Proj1 &&proj1 = Proj1(),
    Proj2 &&proj2 = Proj2())
```

Searches the range `[first, last)` for any elements in the range `[s_first, s_last)`. Uses a provided predicate to compare elements.

The comparison operations in the parallel `search` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.
Note Complexity: at most \(S \times N\) comparisons where \(S = distance(s\_first, s\_last)\) and \(N = distance(first, last)\).

Template Parameters
- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1**: The type of the examine range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2**: The type of the search range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`.
- **Proj1**: The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements of `Rng1`.
- **Proj2**: The type of an optional projection function. This defaults to `util::projection_identity` and is applied to the elements of `Rng2`.

Parameters
- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng1**: Refers to the sequence of elements the algorithm will be examining.
- **count**: The number of elements to apply the algorithm on.
- **rng2**: Refers to the sequence of elements the algorithm will be searching for.
- **op**: Refers to the binary predicate which returns true if the elements should be treated as equal. The signature of the function should be equivalent to

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.
- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of `rng1` as a projection operation before the actual predicate is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of `rng2` as a projection operation before the actual predicate is invoked.

The comparison operations in the parallel `search` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Return The `search` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `search` algorithm returns an iterator to the beginning of the first subsequence `[s_first, s_last)` in range `[first, last)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, last), last` is returned. Additionally if the size of the subsequence is empty `first` is returned. If no subsequence is found, `last` is returned.
Functions

```cpp
template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3 = detail::algorithm_result<ExPolicy, ranges::set_difference_result<Iter1, Iter3>>::type

util::detail::algorithm_result<ExPolicy, ranges::set_difference_result<Iter1, Iter3>>::type set_difference(ExPolicy&& policy, Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Iter3 dest, Pred&& op = Pred(), Proj1&& proj1 = Proj1(), Proj2&& proj2 = Proj2())
```

Constructs a sorted range beginning at dest consisting of all elements present in the range [first1, last1) and not present in the range [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate \( f \).

Equivalent elements are treated individually, that is, if some element is found \( m \) times in [first1, last1) and \( n \) times in [first2, last2), it will be copied to dest exactly std::max(m - n, 0) times. The resulting range cannot overlap with either of the input ranges.

**Note** Complexity: At most \( 2^*(N_1 + N_2 - 1) \) comparisons, where \( N_1 \) is the length of the first sequence and \( N_2 \) is the length of the second sequence.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (sequenced_policy) or in a single new thread spawned from the current thread (for sequenced_task_policy).

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Iter1**: The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent1**: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2**: The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
• **Sent2**: The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for Iter2.

• **Iter3**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

• **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_difference` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`

• **Proj1**: The type of an optional projection function applied to the first sequence. This defaults to `util::projection_identity`

• **Proj2**: The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2**: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2**: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **op**: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`.

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

### Return

The `set_difference` algorithm returns a `hpx::future<ranges::set_difference_result<Iter1, Iter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::set_difference_result<Iter1, Iter3>` otherwise. The `set_difference` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename Rng1, typename Rng2, typename Iter3, typename Pred = detail::less, typename
```
Constructs a sorted range beginning at dest consisting of all elements present in the range [first1, last1) and not present in the range [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate \( f \).

Equivalent elements are treated individually, that is, if some element is found \( m \) times in [first1, last1) and \( n \) times in [first2, last2), it will be copied to dest exactly \( \max(m-n, 0) \) times. The resulting range cannot overlap with either of the input ranges.

**Note** Complexity: At most \( 2 \cdot (N1 + N2 - 1) \) comparisons, where \( N1 \) is the length of the first sequence and \( N2 \) is the length of the second sequence.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (sequenced_policy) or in a single new thread spawned from the current thread (for sequenced_task_policy).

**Template Parameters**
- \( \text{ExPolicy} \): The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- \( \text{Rng1} \): The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- \( \text{Rng2} \): The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- \( \text{Iter3} \): The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- \( \text{Pred} \): The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of \( \text{set_difference} \) requires \( \text{Pred} \) to meet the requirements of CopyConstructible. This defaults to std::less<\>.
- \( \text{Proj1} \): The type of an optional projection function applied to the first sequence. This defaults to \( \text{util::projection_identity} \)
- \( \text{Proj2} \): The type of an optional projection function applied to the second sequence. This defaults to \( \text{util::projection_identity} \)
Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng1**: Refers to the first sequence of elements the algorithm will be applied to.
- **rng2**: Refers to the second sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **op**: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type *Type1* must be such that objects of type *InIter* can be dereferenced and then implicitly converted to *Type1*.

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate *op* is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate *op* is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The *set_difference* algorithm returns a `hpx::future<ranges::set_difference_result<Iter1, Iter3>>` if the execution policy is of type `sequenced_task_policy` and returns `ranges::set_difference_result<Iter1, Iter3>` otherwise. where *Iter1* is `range_iterator_t<Rng1>` and *Iter2* is `range_iterator_t<Rng2>` The *set_difference* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
namespace hpx

namespace ranges

Functions

template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3, typename Pred = detail::less, typename Proj1 =util::projection_identity, typename Proj2 =util::projection_identity>
```
util::detail::algorithm_result<ExPolicy, ranges::set_intersection_result<Iter1, Iter2, Iter3>>::type set_intersection(ExPolicy&& policy, Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Iter3 dest, Pred&& op = Pred(), Proj1&& proj1 = Proj1(), Proj2&& proj2 = Proj2())

Constructs a sorted range beginning at dest consisting of all elements present in both sorted ranges [first1, last1) and [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate f.

If some element is found m times in [first1, last1) and n times in [first2, last2), the first std::min(m, n) elements will be copied from the first range to the destination range. The order of equivalent elements is preserved. The resulting range cannot overlap with either of the input ranges.

**Note** Complexity: At most 2*(N1 + N2 - 1) comparisons, where N1 is the length of the first sequence and N2 is the length of the second sequence.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (sequenced_policy) or in a single new thread spawned from the current thread (for sequenced_task_policy).

**Template Parameters**
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- Iter1: The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- Sent1: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- Iter2: The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
- Sent2: The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for Iter2.
- Iter3: The type of the iterator representing the destination range (deduced). This iterator
type must meet the requirements of an output iterator.

- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_intersection` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>
- **Proj1**: The type of an optional projection function applied to the first sequence. This defaults to `util::projection_identity`
- **Proj2**: The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2**: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2**: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **op**: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `set_intersection` algorithm returns a `hpx::future<ranges::set_intersection_result<Iter1, Iter2, Iter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::set_intersection_result<Iter1, Iter2, Iter3>` otherwise. The `set_intersection` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename Rng1, typename Rng2, typename Iter3, typename Pred = detail::less, typen"
Constructs a sorted range beginning at dest consisting of all elements present in both sorted ranges [first1, last1) and [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate f.

If some element is found m times in [first1, last1) and n times in [first2, last2), the first std::min(m, n) elements will be copied from the first range to the destination range. The order of equivalent elements is preserved. The resulting range cannot overlap with either of the input ranges.

**Note** Complexity: At most 2*(N1 + N2 - 1) comparisons, where N1 is the length of the first sequence and N2 is the length of the second sequence.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (sequenced_policy) or in a single new thread spawned from the current thread (for sequenced_task_policy).

**Template Parameters**
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- Rng1: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- Rng2: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- Iter3: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- Pred: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of set_intersection requires Pred to meet the requirements of CopyConstructible. This defaults to std::less<>.
- Proj1: The type of an optional projection function applied to the first sequence. This defaults to util::projection_identity
- Proj2: The type of an optional projection function applied to the second sequence. This defaults to util::projection_identity
Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng1**: Refers to the first sequence of elements the algorithm will be applied to.
- **rng2**: Refers to the second sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **op**: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.

namespace ranges

Functions

template<
    typename ExPolicy,
    typename Iter1,
    typename Sent1,
    typename Iter2,
    typename Sent2,
    typename Iter3
>
```
Constructs a sorted range beginning at `dest` consisting of all elements present in either of the sorted ranges `[first1, last1)` and `[first2, last2)`, but not in both of them are copied to the range beginning at `dest`. The resulting range is also sorted. This algorithm expects both input ranges to be sorted with the given binary predicate `f`.

If some element is found `m` times in `[first1, last1)` and `n` times in `[first2, last2)`, it will be copied to `dest` exactly `std::abs(m-n)` times. If `m>n`, then the last `m-n` of those elements are copied from `[first1,last1)`, otherwise the last `n-m` elements are copied from `[first2,last2)`. The resulting range cannot overlap with either of the input ranges.

**Note** Complexity: At most `2*(N1 + N2 - 1)` comparisons, where `N1` is the length of the first sequence and `N2` is the length of the second sequence. The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (`sequenced_policy`) or in a single new thread spawned from the current thread (`sequenced_task_policy`).

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- `Iter1`: The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- `Sent1`: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for `Iter1`.
- `Iter2`: The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
- `Sent2`: The type of the end source iterators used (deduced) representing the second sequence.
This iterator type must meet the requirements of an sentinel for Iter2.

- **Iter3**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_symmetric_difference` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`
- **Proj1**: The type of an optional projection function applied to the first sequence. This defaults to `util::projection_identity`
- **Proj2**: The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2**: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2**: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **op**: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `set_symmetric_difference` algorithm returns a `hpx::future<ranges::set_symmetric_difference_result<Iter1, Iter2, Iter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::set_symmetric_difference_result<Iter1, Iter2, Iter3>` otherwise. The `set_symmetric_difference` algorithm returns the output iterator to the element in the destination range, one past the last element copied.
HPX Documentation, master

util::detail::algorithm_result<ExPolicy, ranges::set_symmetric_difference_result<typename traits::range_iterator<Rng1>::type, typename traits::range_iterator<Rng2>::type, Iter3>::type

Constructs a sorted range beginning at dest consisting of all elements present in either of the sorted ranges [first1, last1) and [first2, last2), but not in both of them are copied to the range beginning at dest. The resulting range is also sorted. This algorithm expects both input ranges to be sorted with the given binary predicate f.

If some element is found m times in [first1, last1) and n times in [first2, last2), it will be copied to dest exactly std::abs(m-n) times. If m>n, then the last m-n of those elements are copied from [first1,last1), otherwise the last n-m elements are copied from [first2,last2). The resulting range cannot overlap with either of the input ranges.

Note  Complexity: At most 2*(N1 + N2 - 1) comparisons, where N1 is the length of the first sequence and N2 is the length of the second sequence.
The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (sequenced_policy) or in a single new thread spawned from the current thread (for sequenced_task_policy).

Template Parameters

- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- Rng1: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- Rng2: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- Iter3: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- Pred: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of set_symmetric_difference requires Pred to meet the requirements of CopyConstructible. This defaults to std::less<>
- Proj1: The type of an optional projection function applied to the first sequence. This defaults to util::projection_identity
• **Proj2**: The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`.

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng1**: Refers to the first sequence of elements the algorithm will be applied to.
- **rng2**: Refers to the second sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **op**: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`.

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `set_symmetric_difference` algorithm returns a `hpx::future<ranges::set_symmetric_difference_result<Iter1, Iter2, Iter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::set_symmetric_difference_result<Iter1, Iter2, Iter3>` otherwise. where `Iter1` is `range_iterator_t<Rng1>` and `Iter2` is `range_iterator_t<Rng2>` The `set_symmetric_difference` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
namespace hpx

namespace ranges

Functions

template<
typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3
```
Constructs a sorted range beginning at dest consisting of all elements present in one or both sorted ranges \([\text{first1}, \text{last1})\) and \([\text{first2}, \text{last2})\). This algorithm expects both input ranges to be sorted with the given binary predicate \(f\).

If some element is found \(m\) times in \([\text{first1}, \text{last1})\) and \(n\) times in \([\text{first2}, \text{last2})\), then all \(m\) elements will be copied from \([\text{first1}, \text{last1})\) to dest, preserving order, and then exactly \(\text{std::max(n-m, 0)}\) elements will be copied from \([\text{first2}, \text{last2})\) to dest, also preserving order.

**Note** Complexity: At most \(2^*(N_1 + N_2 - 1)\) comparisons, where \(N_1\) is the length of the first sequence and \(N_2\) is the length of the second sequence.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (for \text{sequencedpolicy} or in a single new thread spawned from the current thread (for \text{sequenced_task_policy}).

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Iter1**: The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent1**: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2**: The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent2**: The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for Iter2.
- **Iter3**: The type of the iterator representing the destination range (deduced). This iterator
type must meet the requirements of an output iterator.

- **Pred**: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_union` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`
- **Proj1**: The type of an optional projection function applied to the first sequence. This defaults to `util::projection_identity`
- **Proj2**: The type of an optional projection function applied to the second sequence. This defaults to `util::projection_identity`

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **first1**: Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1**: Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2**: Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2**: Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **op**: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

  ```cpp
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

### Return

The `set_union` algorithm returns a `hpx::future<ranges::set_union_result<Iter1, Iter2, Iter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::set_union_result<Iter1, Iter2, Iter3>` otherwise. The `set_union` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename Rng1, typename Rng2, typename Iter3, typename Pred = detail::less, typename
```
**set_union**

Constructs a sorted range beginning at dest consisting of all elements present in one or both sorted ranges [first1, last1) and [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate `f`.

If some element is found `m` times in [first1, last1) and `n` times in [first2, last2), then all `m` elements will be copied from [first1, last1) to dest, preserving order, and then exactly std::max(n-m, 0) elements will be copied from [first2, last2) to dest, also preserving order.

**Note** Complexity: At most 2*(N1 + N2 - 1) comparisons, where N1 is the length of the first sequence and N2 is the length of the second sequence.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (sequenced_policy) or in a single new thread spawned from the current thread (for sequenced_task_policy).

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- `Rng1`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- `Rng2`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- `Iter3`: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- `Pred`: The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of set_union requires Pred to meet the requirements of CopyConstructible. This defaults to std::less<>
- `Proj1`: The type of an optional projection function applied to the first sequence. This defaults to util::projection_identity
- `Proj2`: The type of an optional projection function applied to the second sequence. This defaults to util::projection_identity
Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng1**: Refers to the first sequence of elements the algorithm will be applied to.
- **rng2**: Refers to the second sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **op**: The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`.

- **proj1**: Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.
- **proj2**: Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `set_union` algorithm returns a `hpx::future<ranges::set_union_result<Iter1, Iter2, Iter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::set_union_result<Iter1, Iter2, Iter3>` otherwise. where `Iter1` is `range_iterator_t<Rng1>` and `Iter2` is `range_iterator_t<Rng2>` The `set_union` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
namespace hpx

namespace parallel

Functions

```cpp
template<typename ExPolicy, typename Rng, typename Compare = v1::detail::less, typename Proj = util::projection_property,
util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng>::type>::type sort(ExPolicy
&&policy,
Rng &&rng,
Compare &&comp
= Compare(),
Proj &&proj
= Proj())
```

Sorts the elements in the range `rng` in ascending order. The order of equal elements is not guaranteed to be preserved. The function uses the given comparison function object `comp` (defaults to using operator<()).
A sequence is sorted with respect to a comparator `comp` and a projection `proj` if for every iterator `i` pointing to the sequence and every non-negative integer `n` such that `i + n` is a valid iterator pointing to an element of the sequence, and `INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false.

**Note** Complexity: O(Nlog(N)), where N = std::distance(begin(rng), end(rng)) comparisons. `comp` has to induce a strict weak ordering on the values.

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- `Rng`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- `Comp`: The type of the function/function object to use (deduced).
- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`.

**Parameters**

- `policy`: The execution policy to use for the scheduling of the iterations.
- `rng`: Refers to the sequence of elements the algorithm will be applied to.
- `comp`: `comp` is a callable object. The return value of the `INVOKE` operation applied to an object of type `Comp`, when contextually converted to `bool`, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator.
- `proj`: Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate `comp` is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `sort` algorithm returns a `hpx::future<Iter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `Iter` otherwise. It returns `last`.

```cpp
namespace hpx

namespace parallel
```
Functions

```cpp
template<typename ExPolicy, typename Rng, typename Compare = v1::detail::less, typename Proj = util::projection_identity>
util::detail::algorithm_result<
    ExPolicy,
    typename hpx::traits::range_iterator<Rng>::type>::type
stable_sort(
    ExPolicy&& policy,
    Rng&& rng,
    Compare&& comp = Compare(),
    Proj&& proj = Proj())
```

Sorts the elements in the range [first, last) in ascending order. The relative order of equal elements is preserved. The function uses the given comparison function object `comp` (defaults to using operator<()).

A sequence is sorted with respect to a comparator `comp` and a projection `proj` if for every iterator `i` pointing to the sequence and every non-negative integer `n` such that `i + n` is a valid iterator pointing to an element of the sequence, and `INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false.

**Note** Complexity: O(Nlog(N)), where `N = std::distance(first, last)` comparisons. `comp` has to induce a strict weak ordering on the values.

**Template Parameters**

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Comp**: The type of the function/function object to use (deduced).
- **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **comp**: `comp` is a callable object. The return value of the `INVOKE` operation applied to an object of type `Comp`, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator.
- **proj**: Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate `comp` is invoked.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `stable_sort` algorithm returns a `hpx::future<RandomIt>` if the execution policy is of type `sequenced_policy`. If the execution policy is of type `parallel_policy` or `parallel_task_policy`, the return type is a `hpx::future<void>`.
sequenced_task_policy or parallel_task_policy and returns RandomIt otherwise. The algorithm returns an iterator pointing to the first element after the last element in the input sequence.

namespace hpx

namespace ranges

Functions

template<
typename ExPolicy,
typename Rng,
typename OutIter,
typename F,
typename Proj = util::projection_identity>
util::detail::algorithm_result<
ExPolicy,
ranges::unary_transform_result<
util::traits::range_iterator<Rng>::type,
OutIter>>

Applies the given function \( f \) to the given range \( rng \) and stores the result in another range, beginning at \( \text{dest} \).

The invocations of \( f \) in the parallel transform algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: Exactly size(rng) applications of \( f \)

Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of \( f \).
- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **OutIter**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **F**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of transform requires \( F \) to meet the requirements of CopyConstructible.
- **Proj**: The type of an optional projection function. This defaults to util::projection_identity

Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **dest**: Refers to the beginning of the destination range.
- **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\). This is an unary predicate. The signature of this predicate should be equivalent to:

\[
\text{Ret} \ f(\text{const} \ \text{Type} \ &\ a);
\]
The signature does not need to have const&. The type Type must be such that an object of type `range_iterator<Rng>::type` can be dereferenced and then implicitly converted to Type. The type Ret must be such that an object of type `OutIter` can be dereferenced and assigned a value of type Ret.

- proj: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate f is invoked.

The invocations of f in the parallel transform algorithm invoked with an execution policy object of type `parallel_policy` or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The transform algorithm returns a `hpx::future<ranges::unary_transform_result<range_iterator<Rng>::type, OutIter>` if the execution policy is of type parallel_task_policy and returns `ranges::unary_transform_result<range_iterator<Rng>::type, OutIter>` otherwise. The transform algorithm returns a tuple holding an iterator referring to the first element after the input sequence and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename Sent1, typename FwdIter2, typename F, typename Proj = hpx::parallel::util::projection_identity>
parallel::util::detail::algorithm_result<ExPolicy, ranges::unary_transform_result<FwdIter1, FwdIter2>>::type transform(ExPolicy &&policy, FwdIter1 first, Sent1 last, FwdIter2 dest, F &&f, Proj &&proj = Proj())
```

Applies the given function f to the given range rng and stores the result in another range, beginning at dest.

The invocations of f in the parallel transform algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: Exactly size(rng) applications of f

**Template Parameters**
- ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of f.
- FwdIter1: The type of the source iterators for the first range used (deduced). This iterator type must meet the requirements of an forward iterator.
- Sent1: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for FwdIter1.
- FwdIter2: The type of the source iterators for the first range used (deduced). This iterator type must meet the requirements of an forward iterator.
- F: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of transform requires F to meet the requirements of CopyConstructible.
- Proj: The type of an optional projection function. This defaults to `util::projection_identity Parameters`
• **policy**: The execution policy to use for the scheduling of the iterations.
• **first**: Refers to the beginning of the first sequence of elements the algorithm will be applied to.
• **last**: Refers to the end of the sequence of elements the algorithm will be applied to.
• **dest**: Refers to the beginning of the destination range.
• **f**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate. The signature of this predicate should be equivalent to:

```cpp
Ret fun(const Type &a);
```

The signature does not need to have const&. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`. The type `Ret` must be such that an object of type `FwdIter2` can be dereferenced and assigned a value of type `Ret`.

• **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate `f` is invoked.

The invocations of `f` in the parallel `transform` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `transform` algorithm returns a `hpx::future<ranges::unary_transform_result<FwdIter1, FwdIter2>>` if the execution policy is of type `parallel_task_policy` and returns `ranges::unary_transform_result<FwdIter1, FwdIter2>` otherwise. The `transform` algorithm returns a tuple holding an iterator referring to the first element after the input sequence and the output iterator to the element in the destination range, one past the last element copied.

Applies the given function `f` to pairs of elements from two ranges: one defined by `rng` and the other beginning at `first2`, and stores the result in another range, beginning at `dest`.
The invocations of \( f \) in the parallel \textit{transform} algorithm invoked with an execution policy object of type \texttt{sequenced\_policy} execute in sequential order in the calling thread.

\textbf{Note} Complexity: Exactly size(rng) applications of \( f \)

\textbf{Template Parameters}
- \texttt{ExPolicy}: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of \( f \).
- \texttt{FwdIter1}: The type of the source iterators for the first range used (deduced). This iterator type must meet the requirements of an forward iterator.
- \texttt{Sent1}: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for FwdIter1.
- \texttt{FwdIter2}: The type of the source iterators for the first range used (deduced). This iterator type must meet the requirements of an forward iterator.
- \texttt{Sent2}: The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for FwdIter2.
- \texttt{FwdIter3}: The type of the source iterators for the first range used (deduced). This iterator type must meet the requirements of an forward iterator.
- \texttt{F}: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \textit{transform} requires \( F \) to meet the requirements of \texttt{CopyConstructible}.
- \texttt{Proj1}: The type of an optional projection function to be used for elements of the first sequence. This defaults to \texttt{util::projection\_identity}
- \texttt{Proj2}: The type of an optional projection function to be used for elements of the second sequence. This defaults to \texttt{util::projection\_identity}

\textbf{Parameters}
- \texttt{policy}: The execution policy to use for the scheduling of the iterations.
- \texttt{first1}: Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- \texttt{last1}: Refers to the end of the first sequence of elements the algorithm will be applied to.
- \texttt{first2}: Refers to the beginning of the second sequence of elements the algorithm will be applied to.
- \texttt{last2}: Refers to the end of the second sequence of elements the algorithm will be applied to.
- \texttt{dest}: Refers to the beginning of the destination range.
- \texttt{f}: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \texttt{[first, last)}. This is a binary predicate. The signature of this predicate should be equivalent to:

\[
\text{Ret fun(const Type1 &a, const Type2 &b);}\]

The signature does not need to have \texttt{const\&}. The types \texttt{Type1} and \texttt{Type2} must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to \texttt{Type1} and \texttt{Type2} respectively. The type \texttt{Ret} must be such that an object of type FwdIter3 can be dereferenced and assigned a value of type \texttt{Ret}.
- \texttt{proj1}: Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate \( f \) is invoked.
- \texttt{proj2}: Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate \( f \) is invoked.

The invocations of \( f \) in the parallel \textit{transform} algorithm invoked with an execution policy object of type \texttt{parallel\_policy} or \texttt{parallel\_task\_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

\textbf{Return} The \textit{transform} algorithm returns a \texttt{hp\_\_future\:ranges\:binary\_transform\_result\<FwdIter1, FwdIter2, FwdIter3\>} if the execution policy is of type \texttt{parallel\_task\_policy} and returns \texttt{ranges\:binary\_transform\_result\<FwdIter1, FwdIter2, FwdIter3\>} otherwise. The \textit{transform} algorithm returns a tuple holding an iterator referring to the first element after the first input se-
quence, an iterator referring to the first element after the second input sequence, and the output
iterator referring to the element in the destination range, one past the last element copied.

namespace hpx

Functions

template<typename ExPolicy, typename Rng, typename T, typename Reduce, typename Convert>
util::detail::algorithm_result<ExPolicy, T>::type transform_reduce(ExPolicy &&policy, Rng &&rng, T init, Reduce &&red_op, Convert &&conv_op)

Returns GENERALIZED_SUM(red_op, init, conv_op(*first), . . . , conv_op(*(first + (last - first) - 1))).

The reduce operations in the parallel transform_reduce algorithm invoked with an execution policy object
of type sequenced_policy execute in sequential order in the calling thread.

Note Complexity: O(last - first) applications of the predicates red_op and conv_op.

Template Parameters

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which
  the execution of the algorithm may be parallelized and the manner in which it executes the as-
  signments.

• Rng: The type of the source range used (deduced). The iterators extracted from this range type
  must meet the requirements of an input iterator.

• F: The type of the function/function object to use (deduced). Unlike its sequential form, the
  parallel overload of copy_if requires F to meet the requirements of CopyConstructible.

• T: The type of the value to be used as initial (and intermediate) values (deduced).

• Reduce: The type of the binary function object used for the reduction operation.

• Convert: The type of the unary function object used to transform the elements of the input
  sequence before invoking the reduce function.

Parameters

• policy: The execution policy to use for the scheduling of the iterations.

• rng: Refers to the sequence of elements the algorithm will be applied to.

• init: The initial value for the generalized sum.

• red_op: Specifies the function (or function object) which will be invoked for each of the values
  returned from the invocation of conv_op. This is a binary predicate. The signature of this predicate
  should be equivalent to:

  Ret fun(const Type1 &a, const Type2 &b);

  The signature does not need to have const&, but the function must not modify the objects passed
to it. The types Type1, Type2, and Ret must be such that an object of a type as returned from
conv_op can be implicitly converted to any of those types.

• conv_op: Specifies the function (or function object) which will be invoked for each of the
  elements in the sequence specified by [first, last). This is a unary predicate. The signature of this
  predicate should be equivalent to:
The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `Iter` can be dereferenced and then implicitly converted to `Type`. The type `R` must be such that an object of this type can be implicitly converted to `T`.

The reduce operations in the parallel `transform_reduce` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `transform_reduce` and `accumulate` is that the behavior of `transform_reduce` may be non-deterministic for non-associative or non-commutative binary predicate.

**Return** The `transform_reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `parallel_task_policy` and returns `T` otherwise. The `transform_reduce` algorithm returns the result of the generalized sum over the values returned from `conv_op` when applied to the elements given by the input range `[first, last)`.

**Note** `GENERALIZED_SUM(op, a1, \ldots, aN)` is defined as follows:

- `a1` when `N` is 1
- `op(GENERALIZED_SUM(op, b1, \ldots, bK), GENERALIZED_SUM(op, bM, \ldots, bN))`, where:
  - `b1, \ldots, bN` may be any permutation of `a1, \ldots, aN` and
  - `1 < K+1 = M <= N`.

```cpp
template<typename ExPolicy, typename Rng1, typename FwdIter2, typename T>
util::detail::algorithm_result<ExPolicy, T>::type transform_reduce(ExPolicy &&policy, Rng1 &&rng1, FwdIter2 first2, T init)
```

Returns the result of accumulating `init` with the inner products of the pairs formed by the elements of two ranges starting at `first1` and `first2`.

The operations in the parallel `transform_reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: $O(last - first)$ applications of the predicate `op2`.

**Template Parameters**

- `ExPolicy`: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- `Rng1`: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

- `FwdIter2`: The type of the second source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

- `T`: The type of the value to be used as return) values (deduced).

**Parameters**

- `policy`: The execution policy to use for the scheduling of the iterations.

- `rng1`: Refers to the sequence of elements the algorithm will be applied to.
• first2: Refers to the beginning of the second sequence of elements the result will be calculated with.
• init: The initial value for the sum.

The operations in the parallel transform_reduce algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The transform_reduce algorithm returns a hpx::future<T> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns T otherwise.

template<typename ExPolicy, typename Rng1, typename FwdIter2, typename T, typename Reduce, typename Convert>
util::detail::algorithm_result<ExPolicy, T>::type transform_reduce(ExPolicy &&policy, Rng1 &&rng1, FwdIter2 first2, T init, Reduce &&red_op, Convert &&conv_op)

Returns the result of accumulating init with the inner products of the pairs formed by the elements of two ranges starting at first1 and first2.

The operations in the parallel transform_reduce algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note** Complexity: O(last - first) applications of the predicate op2.

**Template Parameters**

• ExPolicy: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• Rng1: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
• FwdIter2: The type of the second source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
• T: The type of the value to be used as return) values (deduced).
• Reduce: The type of the binary function object used for the multiplication operation.
• Convert: The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

**Parameters**

• policy: The execution policy to use for the scheduling of the iterations.
• rng1: Refers to the sequence of elements the algorithm will be applied to.
• first2: Refers to the beginning of the second sequence of elements the result will be calculated with.
• init: The initial value for the sum.
• red_op: Specifies the function (or function object) which will be invoked for the initial value and each of the return values of op2. This is a binary predicate. The signature of this predicate should be equivalent to should be equivalent to:
The signature does not need to have const&, but the function must not modify the objects passed to it. The type Ret must be such that it can be implicitly converted to a type of T.

- **conv_op**: Specifies the function (or function object) which will be invoked for each of the input values of the sequence. This is a binary predicate. The signature of this predicate should be equivalent to

  ```cpp
  Ret fun(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type Ret must be such that it can be implicitly converted to an object for the second argument type of op1.

The operations in the parallel `transform_reduce` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `transform_reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns T otherwise.

```cpp
namespace hpx

namespace parallel

Functions

```cpp
    template<typename ExPolicy, typename Rng, typename Pred = detail::equal_to, typename Proj = util::projection_identity>
    util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_iterator<Rng>::type>::type
    unique(ExPolicy &&policy,
           Rng &&rng,
           Pred &&pred = Pred(),
           Proj &&proj = Proj())
```  

Eliminates all but the first element from every consecutive group of equivalent elements from the range rng and returns a past-the-end iterator for the new logical end of the range.

The assignments in the parallel `unique` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note** Complexity: Performs not more than N assignments, exactly N - 1 applications of the predicate pred and no more than twice as many applications of the projection proj, where N = std::distance(begin(rng), end(rng)).

**Template Parameters**
• **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.

• **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `unique` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>

• **Proj**: The type of an optional projection function. This defaults to `util::projection_identity`

### Parameters

- **policy**: The execution policy to use for the scheduling of the iterations.
- **rng**: Refers to the sequence of elements the algorithm will be applied to.
- **pred**: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an binary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a, const Type &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`.

- **proj**: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel `unique` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

### Return

The `unique` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `unique` algorithm returns the iterator to the new end of the range.

```cpp
template<typename ExPolicy, typename Rng, typename FwdIter2, typename Pred = detail::equal_to, typename Proj = util::projection_identity>
util::detail::algorithm_result<ExPolicy, hpx::util::tagged_pair<tag::in<
    hpx::traits::range_iterator<Rng>,
tag::out
FwdIter2>>>(
    typename unique_copyExPolicy &&policy,
    Rng &&rng,
    FwdIter2 dest,
    Pred &&pred = Pred(),
    Proj &&proj = Proj())Copies the elements from the range `rng`, to another range beginning at `dest` in such a way that there are no consecutive equal elements. Only the first element of each group of equal elements is copied.
```

The assignments in the parallel `unique_copy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

### Note

**Complexity**: Performs not more than \(N\) assignments, exactly \(N - 1\) applications of the predicate `pred`, where \(N = \text{std::distance}(begin(rng), end(rng))\).

### Template Parameters

- **ExPolicy**: The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **Rng**: The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.

- **FwdIter2**: The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

- **Pred**: The type of the function/function object to use (deduced). Unlike its sequential form,
the parallel overload of `unique_copy` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`

- `Proj`: The type of an optional projection function. This defaults to `util::projection_identity`

**Parameters**

- `policy`: The execution policy to use for the scheduling of the iterations.
- `rng`: Refers to the sequence of elements the algorithm will be applied to.
- `dest`: Refers to the beginning of the destination range.
- `pred`: Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by the range `rng`. This is an binary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

```cpp
def pred(const Type &a, const Type &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`.

- `proj`: Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

The assignments in the parallel `unique_copy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Return** The `unique_copy` algorithm returns a `hpx::future<tagged_pair<tag::in(FwdIter1),
tag::out(FwdIter2)>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `tagged_pair<tag::in(FwdIter1),
tag::out(FwdIter2)>>` otherwise. The `unique_copy` algorithm returns the pair of the source iterator to `last`, and the destination iterator to the end of the `dest` range.

Functions

template<
typename Value,
typename ... Args>
void construct_object (Value *ptr, Args&&... args)
create an object in the memory specified by ptr

Template Parameters
• Value::typename of the object to create
• Args::parameters for the constructor

Parameters
• [in] ptr::pointer to the memory where to create the object
• [in] args::arguments to the constructor

template<
typename Value>
void destroy_object (Value *ptr)
destroy an object in the memory specified by ptr

Template Parameters
• Value::typename of the object to create

Parameters
• [in] ptr::pointer to the object to destroy

template<
typename Iter,
typename Sent>
void init (Iter first, Sent last, typename std::iterator_traits<Iter>::value_type &val)
Initialize a range of objects with the object val moving across them

Return range initialized

Parameters
• [in] r::range of elements not initialized
• [in] val::object used for the initialization

template<
typename Value,
typename ... Args>
void construct (Value *ptr, Args&&... args)
create an object in the memory specified by ptr
Template Parameters
- **Value**: typename of the object to create
- **Args**: parameters for the constructor

Parameters
- **[in]** `ptr`: pointer to the memory where to create the object
- **[in]** `args`: arguments to the constructor

```cpp
template<typename Iter1, typename Sent1, typename Iter2>
Iter2 init_move(Iter2 it_dest, Iter1 first, Sent1 last)
```
Move objects.

Template Parameters
- **Iter**: iterator to the elements
- **Value**: typename of the object to create

Parameters
- **[in]** `itdest`: iterator to the final place of the objects
- **[in]** `R`: range to move

```cpp
template<typename Iter, typename Sent>
Value* uninit_move(Value* ptr, Iter first, Sent last)
```
Move objects to uninitialized memory.

Template Parameters
- **Iter**: iterator to the elements
- **Value**: typename of the object to construct

Parameters
- **[in]** `ptr`: pointer to the memory where to create the object
- **[in]** `R`: range to move

```cpp
template<typename Iter, typename Sent>
void destroy(Iter first, Sent last)
```
Move objects to uninitialized memory.

Template Parameters
- **Iter**: iterator to the elements
- **Value**: typename of the object to construct

Parameters
- **[in]** `buf1`: iterator to the first element in the first buffer
- **[in]** `end_buf1`: final iterator of first buffer
- **[in]** `buf2`: iterator to the first iterator to the second buffer
- **[in]** `end_buf2`: final iterator of the second buffer
- **[in]** `buf_out`: buffer where move the elements merged
- **[in]** `comp`: comparison object

```cpp
template<typename Iter1, typename Sent1, typename Iter2, typename Compare>
Iter2 full_merge(Iter1 buf1, Sent1 end_buf1, Iter1 buf2, Sent1 end_buf2, Iter2 buf_out, Compare comp)
```
Merge two contiguous buffers pointed by buf1 and buf2, and put in the buffer pointed by buf_out.
template<typename Iter, typename Sent, typename Value, typename Compare>
Value *uninit_full_merge(Iter first1, Sent last1, Iter first2, Sent last2, Value *it_out, Compare comp)

Merge two contiguous buffers pointed by first1 and first2, and put in the uninitialized buffer pointed by it_out.

**Parameters**
- [in] first1: iterator to the first element in the first buffer
- [in] last: last iterator of the first buffer
- [in] first2: iterator to the first element to the second buffer
- [in] last2: final iterator of the second buffer
- [in] it_out: uninitialized buffer where move the elements merged
- [in] comp: comparison object

template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Compare>
Iter2 half_merge(Iter1 buf1, Sent1 end_buf1, Iter2 buf2, Sent2 end_buf2, Iter2 buf_out, Compare comp)

: Merge two buffers. The first buffer is in a separate memory. The second buffer have a empty space before buf2 of the same size than the (end_buf1 - buf1)

**Remark**
The elements pointed by Iter1 and Iter2 must be the same

**Parameters**
- [in] buf1: iterator to the first element of the first buffer
- [in] end_buf1: iterator to the last element of the first buffer
- [in] buf2: iterator to the first element of the second buffer
- [in] end_buf2: iterator to the last element of the second buffer
- [in] buf_out: iterator to the first element to the buffer where put the result
- [in] comp: object for Compare two elements of the type pointed by the Iter1 and Iter2

template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3, typename Compare>
bool in_place_merge_uncontiguous(Iter1 src1, Sent1 end_src1, Iter2 src2, Sent2 end_src2, Iter3 aux, Compare comp)

Merge two non contiguous buffers, placing the results in the buffers for to do this use an auxiliary buffer pointed by aux

**Parameters**
- [in] src1: iterator to the first element of the first buffer
- [in] end_src1: last iterator of the first buffer
- [in] src2: iterator to the first element of the second buffer
- [in] end_src2: last iterator of the second buffer
- [in] aux: iterator to the first element of the auxiliary buffer
- [in] comp: object for to Compare elements

**Exceptions**

- 

template<typename Iter1, typename Sent1, typename Iter2, typename Compare>
bool in_place_merge(Iter1 src1, Iter1 src2, Sent1 end_src2, Iter2 buf, Compare comp)

: merge two contiguous buffers, using an auxiliary buffer pointed by buf

**Parameters**
- [in] src1: iterator to the first position of the first buffer
- [in] src2: final iterator of the first buffer and first iterator of the second buffer
- [in] end_src2: final iterator of the second buffer
- [in] buf: iterator to buffer used as auxiliary memory
- [in] comp: object for to Compare elements
namespace hpx
namespace parallel
namespace util

Functions

template<typename Iter, typename Sent, typename Compare>
bool less_range(Iter it1, std::uint32_t pos1, Sent it2, std::uint32_t pos2, Compare comp)
  Compare the elements pointed by it1 and it2, and if they are equals, compare their position, doing
  a stable comparison.

Return  result of the comparison
Parameters
• [in] it1:: iterator to the first element
• [in] pos1:: position of the object pointed by it1
• [in] it2:: iterator to the second element
• [in] pos2:: position of the element pointed by it2
• [in] comp:: comparison object

template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Compare>
util::range<Iter1, Sent1> full_merge4 (util::range<Iter1, Sent1> &dest, util::range<Iter2, Sent2> vrage_input[4], std::uint32_t nrange_input, Compare comp)
  Merge four ranges.

Return  range with all the elements move with the size adjusted
Parameters
• [in] dest:: range where move the elements merged. Their size must be greater or equal
  than the sum of the sizes of the ranges in the array R
• [in] R:: array of ranges to merge
• [in] nrange_input:: number of ranges in R
• [in] comp:: comparison object

template<typename Value, typename Iter, typename Sent, typename Compare>
util::range<Value*> uninit_full_merge4 (util::range<Value*> dest, util::range<Iter, Sent> vrage_input[4],
  std::uint32_t nrange_input, Compare comp)
  Merge four ranges and put the result in uninitialized memory.

Return  range with all the elements move with the size adjusted
Parameters
• [in] dest:: range where create and move the elements merged. Their size must be greater
  or equal than the sum of the sizes of the ranges in the array R
• [in] R:: array of ranges to merge
• [in] nrange_input:: number of ranges in vrage_input
• [in] comp:: comparison object

void merge_level4 (util::range<Iter1, Sent1> dest, std::vector<util::range<Iter2, Sent2>> &v_input, std::vector<util::range<Iter1, Sent1>> &v_output, Compare comp)
Merge the ranges in the vector v_input using full_merge4. The v_output vector is used as auxiliary memory in the internal process. The final results is in the dest range. All the ranges of v_output are inside the range dest
Return range with all the elements moved
Parameters
• [in] dest:: range where move the elements merged
• [in] v_input:: vector of ranges to merge
• [in] v_output:: vector of ranges obtained
• [in] comp:: comparison object

template<typename Value, typename Iter, typename Sent, typename Compare>
void uninit_merge_level4 (util::range<Value*> dest, std::vector<util::range<Iter, Sent>> &v_input, std::vector<util::range<Value*>> &v_output, Compare comp)
Merge the ranges over uninitialized memory in the vector v_input using full_merge4. The v_output vector is used as auxiliary memory in the internal process. The final results is in the dest range. All the ranges of v_output are inside the range dest
Return range with all the elements moved
Parameters
• [in] dest:: range where move the elements merged
• [in] v_input:: vector of ranges to merge
• [in] v_output:: vector of ranges obtained
• [in] comp:: comparison object

template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Compare>
util::range<Iter2, Sent2> merge_vector4 (util::range<Iter1, Sent1> range_input, util::range<Iter2, Sent2> range_output, std::vector<util::range<Iter1, Sent1>> &v_input, std::vector<util::range<Iter2, Sent2>> &v_output, Compare comp)
Merge the ranges in the vector v_input using merge_level4. The v_output vector is used as auxiliary memory in the internal process. The final results is in the range_output range. All the ranges of v_output are inside the range range_output. All the ranges of v_input are inside the range range_input
Parameters
• [in] range_input:: range including all the ranges of v_input

namespace hpx
namespace parallel

namespace util

Functions

constexpr std::uint32_t nbits32 (std::uint32_t num)
Obtain the number of bits equal or greater than num.

  Return  Number of bits
Parameters  • [in] num: : Number to examine
Exceptions  • none:

constexpr std::uint32_t nbits64 (std::uint64_t num)
Obtain the number of bits equal or greater than num.

  Return  Number of bits
Parameters  • [in] num: : Number to examine
Exceptions  • none:

template<typename Iterator, typename Sentinel = Iterator>
using range = hpx::util::iterator_range<Iterator, Sentinel>

Functions

template<typename Iter, typename Sent>
range<Iter, Sent> concat (range<Iter, Sent> const &it1, range<Iter, Sent> const &it2)
concatenate two contiguous ranges

Return range resulting of the concatenation

Parameters
  • [in] it1:: first range
  • [in] it2:: second range
template<typename \texttt{Iter1}, typename \texttt{Sent1}, typename \texttt{Iter2}, typename \texttt{Sent2}>
\begin{align*}
\text{range<Iter2, Iter2> } & \text{ \texttt{init} } \text{(range<Iter2, Sent2> } \text{ \texttt{const } } & \text{ dest, range<Iter1, Sent1> } \text{ \texttt{const } } & \text{ src) } \\
\text{ Move objects from the range src to dest.}
\end{align*}

\textbf{Return} range with the objects moved and the size adjusted

\textbf{Parameters}
\begin{itemize}
\item \texttt{[in]} \texttt{dest}:: range where move the objects
\item \texttt{[in]} \texttt{src}:: range from where move the objects
\end{itemize}

template<typename \texttt{Iter1}, typename \texttt{Sent1}, typename \texttt{Iter2}, typename \texttt{Sent2}>
\begin{align*}
\text{range<Iter2, Sent2> } & \text{ \texttt{uninit} } \text{\texttt{move} (range<Iter2, Sent2> } \text{ \texttt{const } } & \text{ dest, range<Iter1, Sent1> } \text{ \texttt{const } } & \text{ src) } \\
\text{ Move objects from the range src creating them in dest.}
\end{align*}

\textbf{Return} range with the objects moved and the size adjusted

\textbf{Parameters}
\begin{itemize}
\item \texttt{[in]} \texttt{dest}:: range where move and create the objects
\item \texttt{[in]} \texttt{src}:: range from where move the objects
\end{itemize}

template<typename \texttt{Iter}, typename \texttt{Sent}>
\begin{align*}
\text{void } & \text{ \texttt{destroy_range} (range<Iter, Sent> } \text{ } \texttt{r) } \\
\text{ destroy a range of objects}
\end{align*}

\textbf{Parameters}
\begin{itemize}
\item \texttt{[in]} \texttt{r}:: range to destroy
\end{itemize}

template<typename \texttt{Iter}, typename \texttt{Sent}>
\begin{align*}
\text{range<Iter, Sent> } & \text{ \texttt{init} (range<Iter, Sent> } \text{ } \texttt{const } & \text{ } \texttt{r, typename } \\
\text{ std::iterator_traits<Iter>::value_type } & \text{ \texttt{val}) } \\
\text{ initialize a range of objects with the object val moving across them}
\end{align*}

\textbf{Return} range initialized

\textbf{Parameters}
\begin{itemize}
\item \texttt{[in]} \texttt{r}:: range of elements not initialized
\item \texttt{[in]} \texttt{val}:: object used for the initialization
\end{itemize}

template<typename \texttt{Iter1}, typename \texttt{Sent1}, typename \texttt{Iter2}, typename \texttt{Sent2}, typename \texttt{Compare}>
\begin{align*}
\text{bool } & \text{ \texttt{is_mergeable} (range<Iter1, Sent1> } \text{ \texttt{const } } & \text{ } \texttt{src1, range<Iter2, Sent2> } \text{ \texttt{const } } & \text{ } \texttt{src2, } \texttt{Compare } \texttt{comp) } \\
\text{ : indicate if two ranges have a possible merge}
\end{align*}

\textbf{Parameters}
\begin{itemize}
\item \texttt{[in]} \texttt{src1}:: first range
\item \texttt{[in]} \texttt{src2}:: second range
\item \texttt{[in]} \texttt{comp}:: object for to compare elements
\end{itemize}

\textbf{Exceptions}
\begin{itemize}
\item
\end{itemize}

template<typename \texttt{Iter1}, typename \texttt{Sent1}, typename \texttt{Iter2}, typename \texttt{Sent2}, typename \texttt{Iter3}, typename \texttt{Sent3}>
\begin{align*}
\text{range<Iter3, Sent3> } & \text{ \texttt{full_merge} (range<Iter3, Sent3> } \text{ \texttt{const } } & \text{ } \texttt{dest, range<Iter1, Sent1> } \text{ \texttt{const } } & \text{ } \texttt{src1, range<Iter2, Sent2> } \texttt{const } & \text{ } \texttt{src2, Compare } \texttt{comp) } \\
\text{ Merge two contiguous ranges src1 and src2, and put the result in the range dest, returning the}
\end{align*}
range merged.

**Return** range with the elements merged and the size adjusted

**Parameters**
- [in] `dest`: range where locate the elements merged. the size of dest must be greater or equal than the sum of the sizes of src1 and src2.
- [in] `src1`: first range to merge.
- [in] `src2`: second range to merge.

```cpp
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Value, typename Compare>
range<Value*>& uninit_full_merge(const range<Value*>& &dest, range<Iter1, Sent1> const &src1, range<Iter2, Sent2> const &src2, Compare comp)
```

Merge two contiguous ranges `src1` and `src2`, and create and move the result in the uninitialized range `dest`, returning the range merged.

**Return** range with the elements merged and the size adjusted

**Parameters**
- [in] `dest`: range where locate the elements merged. the size of dest must be greater or equal than the sum of the sizes of src1 and src2. Initially is uninitialized memory.
- [in] `src1`: first range to merge.
- [in] `src2`: second range to merge.

```cpp
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Compare>
range<Iter2, Sent2> half_merge(range<Iter2, Sent2> const &dest, range<Iter1, Sent1> const &src1, range<Iter2, Sent2> const &src2, Compare comp)
```

: Merge two buffers. The first buffer is in a separate memory.

**Return**: range with the two buffers merged

**Parameters**
- [in] `dest`: range where finish the two buffers merged.
- [in] `src1`: first range to merge in a separate memory.
- [in] `src2`: second range to merge, in the final part of the range where deposit the final results.
- [in] `comp`: object for compare two elements of the type pointed by the Iter1 and Iter2.

```cpp
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3, typename Sent3>
bool in_place_merge_uncontiguous(range<Iter1, Sent1> const &src1, range<Iter2, Sent2> const &src2, range<Iter3, Sent3>& aux, Compare comp)
```

: merge two non contiguous buffers `src1`, `src2`, using the range `aux` as auxiliary memory.

**Parameters**
- [in] `src1`: first range to merge.
- [in] `src2`: second range to merge.
- [in] `aux`: auxiliary range used in the merge.
- [in] `comp`: object for to compare elements.

**Exceptions**

```cpp
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Compare>  
```
range<Iter1, Sent1> in_place_merge (range<Iter1, Sent1> const &src1, range<Iter1, Sent1> const &src2, range<Iter2, Sent2> &buf, Compare comp)

: merge two contiguous buffers (src1, src2) using buf as auxiliary memory

Parameters

• [in] src1: first range to merge
• [in] src1: second range to merge
• [in] buf: auxiliary memory used in the merge
• [in] comp: object for to compare elements

Exceptions

template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Compare>
void merge_flow (range<Iter1, Sent1> rng1, range<Iter2, Sent2> rbuf, range<Iter1, Sent1> rng2, Compare cmp)

: merge two contiguous buffers

Template Parameters

• Iter: iterator to the elements
• compare: object for to compare two elements pointed by Iter iterators

Parameters

• [in] first: iterator to the first element
• [in] last: iterator to the element after the last in the range
• [in] comp: object for to compare elements

Exceptions

namespace hpx

struct launch : public detail::policy_holder<>
    #include <launch_policy.hpp> Launch policies for hpx::async etc.

public functions

constexpr launch ()
    Default constructor. This creates a launch policy representing all possible launch modes

constexpr launch (detail::async_policy)
    Create a launch policy representing asynchronous execution.

constexpr launch (detail::fork_policy)
    Create a launch policy representing asynchronous execution. The new thread is executed in a preferred way

constexpr launch (detail::sync_policy)
    Create a launch policy representing synchronous execution.

constexpr launch (detail::deferred_policy)
    Create a launch policy representing deferred execution.

constexpr launch (detail::apply_policy)
    Create a launch policy representing fire and forget execution.

template<typename F>
constexpr launch (detail::select_policy<F> const &p)
    Create a launch policy representing fire and forget execution.
Public Static Attributes

- `const detail::async_policy async` Predefined launch policy representing asynchronous execution.
- `const detail::fork_policy fork` Predefined launch policy representing asynchronous execution. The new thread is executed in a preferred way.
- `const detail::sync_policy sync` Predefined launch policy representing synchronous execution.
- `const detail::deferred_policy deferred` Predefined launch policy representing deferred execution.
- `const detail::apply_policy apply` Predefined launch policy representing fire and forget execution.
- `const detail::select_policy_generator select` Predefined launch policy representing delayed policy selection.

namespace hpx

Functions

```
template<typename F, typename ...Ts>
auto sync (F &&f, Ts&&... ts)
```

**async_combinators**

The contents of this module can be included with the header `hpx/modules/async_combinators.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/async_combinators.hpp`, not the particular header in which the functionality you would like to use is defined. namespace hpx

namespace lcos

Functions

```
template<typename Future, typename F>
std::enable_if<!std::is_void<typename traits::future_traits<Future>::type>::value, std::size_t>::type wait (Future &&f1, F &&f)
```

The one argument version is special in the sense that it returns the expected value directly (without wrapping it into a tuple).

```
template<typename Future, typename F>
std::enable_if<!std::is_void<typename traits::future_traits<Future>::type>::value, std::size_t>::type wait (Future &&f1, F &&f)
```
template<typename Future, typename F>
std::size_t wait (std::vector<Future> &lazy_values, F &&f, std::int32_t = 10)

namespace hpx

Functions

template<typename ...Ts>
tuple<future<Ts>...> split_future (future<tuple<Ts...>> &&f)
The function split_future is an operator allowing to split a given future of a sequence of values (any tuple, std::pair, or std::array) into an equivalent container of futures where each future represents one of the values from the original future. In some sense this function provides the inverse operation of when_all.

Return Returns an equivalent container (same container type as passed as the argument) of futures, where each future refers to the corresponding value in the input parameter. All of the returned futures become ready once the input future has become ready. If the input future is exceptional, all output futures will be exceptional as well.

Note The following cases are special:

tuple<future<void>> > split_future(future<tuple<> > && f);
array<future<void>, 1> split_future(future<array<T, 0> > && f);

here the returned futures are directly representing the futures which were passed to the function.

Parameters

• f: [in] A future holding an arbitrary sequence of values stored in a tuple-like container. This facility supports hpx::tuple<>, std::pair<T1, T2>, and std::array<T, N>

template<typename T>
std::vector<future<T>> split_future (future<std::vector<T>> &&f, std::size_t size)
The function split_future is an operator allowing to split a given future of a sequence of values (any std::vector) into a std::vector of futures where each future represents one of the values from the original std::vector. In some sense this function provides the inverse operation of when_all.

Return Returns a std::vector of futures, where each future refers to the corresponding value in the input parameter. All of the returned futures become ready once the input future has become ready. If the input future is exceptional, all output futures will be exceptional as well.

Parameters

• f: [in] A future holding an arbitrary sequence of values stored in a std::vector.
• size: [in] The number of elements the vector will hold once the input future has become ready
Functions

template<typename InputIter>
void wait_all (InputIter first, InputIter last)

The function wait_all is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

Note The function wait_all returns after all futures have become ready. All input futures are still valid after wait_all returns. Exceptional futures will not cause wait_all to throw an exception.

Parameters

• first: The iterator pointing to the first element of a sequence of future or shared_future objects for which wait_all should wait.
• last: The iterator pointing to the last element of a sequence of future or shared_future objects for which wait_all should wait.

template<typename R>
void wait_all (std::vector<future<R>> &&futures)

The function wait_all is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

Note The function wait_all returns after all futures have become ready. All input futures are still valid after wait_all returns. Exceptional futures will not cause wait_all to throw an exception.

Parameters

• futures: A vector or array holding an arbitrary amount of future or shared_future objects for which wait_all should wait.

template<typename R, std::size_t N>
void wait_all (std::array<future<R>, N> &&futures)

The function wait_all is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

Note The function wait_all returns after all futures have become ready. All input futures are still valid after wait_all returns. Exceptional futures will not cause wait_all to throw an exception.

Parameters

• futures: A vector or array holding an arbitrary amount of future or shared_future objects for which wait_all should wait.

template<typename ...T>
void wait_all (T&&... futures)

The function wait_all is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

Note The function wait_all returns after all futures have become ready. All input futures are still valid after wait_all returns. Exceptional futures will not cause wait_all to throw an exception.

Parameters
• futures: An arbitrary number of future or shared_future objects, possibly holding different types for which wait_all should wait.

template<typename InputIter>
InputIter wait_all_n(InputIter begin, std::size_t count)

The function wait_all_n is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing.

Return  The function wait_all_n will return an iterator referring to the first element in the input sequence after the last processed element.

Note  The function wait_all_n returns after all futures have become ready. All input futures are still valid after wait_all_n returns. Exceptional futures will not cause wait_all to throw an exception.

Parameters

• begin: The iterator pointing to the first element of a sequence of future or shared_future objects for which wait_all_n should wait.

• count: The number of elements in the sequence starting at first.

namespace hpx

Functions

template<typename InputIter>
void wait_any(InputIter first, InputIter last, error_code &ec = throws)

The function wait_any is a non-deterministic choice operator. It OR-composes all future objects given and returns after one future of that list finishes execution.

Note  The function wait_any returns after at least one future has become ready. All input futures are still valid after wait_any returns.

Note  As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Note  None of the futures in the input sequence are invalidated.

Parameters

• first: [in] The iterator pointing to the first element of a sequence of future or shared_future objects for which wait_any should wait.

• last: [in] The iterator pointing to the last element of a sequence of future or shared_future objects for which wait_any should wait.

• ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

template<typename R>
void wait_any(std::vector<future<R>> &futures, error_code &ec = throws)

The function wait_any is a non-deterministic choice operator. It OR-composes all future objects given and returns after one future of that list finishes execution.

Note  The function wait_any returns after at least one future has become ready. All input futures are still valid after wait_any returns.
**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Parameters**

- `futures`: [in] A vector holding an arbitrary amount of `future` or `shared_future` objects for which `wait_any` should wait.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
template<typename R, std::size_t N> void hpx::wait_any(std::array< future< R >, N > & futures, error_code & ec = throws)
```

The function `wait_any` is a non-deterministic choice operator. It OR-composes all future objects given and returns after one future of that list finishes execution.

**Note** The function `wait_any` returns after at least one future has become ready. All input futures are still valid after `wait_any` returns.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Note** None of the futures in the input sequence are invalidated.

**Parameters**

- `futures`: [in] An array holding an arbitrary amount of `future` or `shared_future` objects for which `wait_any` should wait.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
template<typename ...T>
void wait_any(error_code & ec, T&&... futures)
```

The function `wait_any` is a non-deterministic choice operator. It OR-composes all future objects given and returns after one future of that list finishes execution.

**Note** The function `wait_any` returns after at least one future has become ready. All input futures are still valid after `wait_any` returns.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Note** None of the futures in the input sequence are invalidated.

**Parameters**

- `futures`: [in] An arbitrary number of `future` or `shared_future` objects, possibly holding different types for which `wait_any` should wait.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
template<typename ...T>
void wait_any(T&&... futures)
```

The function `wait_any` is a non-deterministic choice operator. It OR-composes all future objects given and returns after one future of that list finishes execution.
**Note** The function `wait_any` returns after at least one future has become ready. All input futures are still valid after `wait_any` returns.

**Note** None of the futures in the input sequence are invalidated.

**Parameters**

- `futures`: [in] An arbitrary number of `future` or `shared_future` objects, possibly holding different types for which `wait_any` should wait.

```cpp
template<typename InputIter>
InputIter wait_any_n (InputIter first, std::size_t count, error_code &ec = throws)
```

The function `wait_any_n` is a non-deterministic choice operator. It OR-composes all future objects given and returns after one future of that list finishes execution.

**Note** The function `wait_any_n` returns after at least one future has become ready. All input futures are still valid after `wait_any_n` returns.

**Return** The function `wait_all_n` will return an iterator referring to the first element in the input sequence after the last processed element.

**Note** As long as `ec` is not pre-initialized to `hpx::throws` this function doesn’t throw but returns the result code using the parameter `ec`. Otherwise it throws an instance of `hpx::exception`.

**Note** None of the futures in the input sequence are invalidated.

**Parameters**

- `first`: [in] The iterator pointing to the first element of a sequence of `future` or `shared_future` objects for which `wait_any_n` should wait.
- `count`: [in] The number of elements in the sequence starting at `first`.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

```cpp
namespace hpx
```

**Functions**

```cpp
template<typename F, typename Future>
void wait_each (F &&f, std::vector<Future> &&futures)
```

The function `wait_each` is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns after they finished executing. Additionally, the supplied function is called for each of the passed futures as soon as the future has become ready. `wait_each` returns after all futures have been become ready.

**Note** This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a `future` to be processed or a type that `std::size_t` is implicitly convertible to as the first parameter and the `future` as the second parameter. The first parameter will correspond to the index of the current `future` in the collection.

**Parameters**

- `f`: The function which will be called for each of the input futures once the future has become ready.
• **futures**: A vector holding an arbitrary amount of *future* or *shared_future* objects for which `wait_each` should wait.

```cpp
template<typename F, typename Iterator>
void wait_each(F &&f, Iterator begin, Iterator end)
```

The function `wait_each` is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns after they finished executing. Additionally, the supplied function is called for each of the passed futures as soon as the future has become ready. `wait_each` returns after all futures have been become ready.

**Note** This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a `future` to be processed or a type that `std::size_t` is implicitly convertible to as the first parameter and the `future` as the second parameter. The first parameter will correspond to the index of the current `future` in the collection.

**Parameters**

- `f`: The function which will be called for each of the input futures once the future has become ready.
- `begin`: The iterator pointing to the first element of a sequence of `future` or `shared_future` objects for which `wait_each` should wait.
- `end`: The iterator pointing to the last element of a sequence of `future` or `shared_future` objects for which `wait_each` should wait.

```cpp
template<typename F, typename ...T>
void wait_each(F &&f, T&&... futures)
```

The function `wait_each` is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns after they finished executing. Additionally, the supplied function is called for each of the passed futures as soon as the future has become ready. `wait_each` returns after all futures have been become ready.

**Note** This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a `future` to be processed or a type that `std::size_t` is implicitly convertible to as the first parameter and the `future` as the second parameter. The first parameter will correspond to the index of the current `future` in the collection.

**Parameters**

- `f`: The function which will be called for each of the input futures once the future has become ready.
- `futures`: An arbitrary number of `future` or `shared_future` objects, possibly holding different types for which `wait_each` should wait.

```cpp
template<typename F, typename Iterator>
void wait_each_n(F &&f, Iterator begin, std::size_t count)
```

The function `wait_each` is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns after they finished executing. Additionally, the supplied function is called for each of the passed futures as soon as the future has become ready.

**Note** This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a `future` to be processed or a type that `std::size_t` is implicitly convertible to as the first parameter and the `future` as the second parameter. The first parameter will correspond to the index of the current `future` in the collection.
is implicitly convertible to as the first parameter and the future as the second parameter. The first parameter will correspond to the index of the current future in the collection.

Parameters

• \( f \): The function which will be called for each of the input futures once the future has become ready.
• \( \text{begin} \): The iterator pointing to the first element of a sequence of future or shared_future objects for which \( \text{wait\_each\_n} \) should wait.
• \( \text{count} \): The number of elements in the sequence starting at \( \text{first} \).

namespace hpx

Functions

template<typename InputIter>
future<vector<future<typename std::iterator_traits<InputIter>::value_type>>> \textbf{wait\_some} (std::size_t \textit{n}, Iterator \textit{first}, Iterator \textit{last}, error_code \&\textit{ec} = throws)

The function \textit{wait\_some} is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after \( n \) of them finished executing.

Note The future returned by the function \textit{wait\_some} becomes ready when at least \( n \) argument futures have become ready.

Return Returns a future holding the same list of futures as has been passed to \textit{wait\_some}. If the input cardinality is unknown at compile time and the futures are all of the same type.

Note Calling this version of \textit{wait\_some} where \textit{first} == \textit{last}, returns a future with an empty vector that is immediately ready. Each future and shared_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by \textit{wait\_some} will not throw an exception, but the futures held in the output collection may.

Parameters

• \textit{n}: [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
• \textit{first}: [in] The iterator pointing to the first element of a sequence of future or shared_future objects for which \textit{when\_all} should wait.
• \textit{last}: [in] The iterator pointing to the last element of a sequence of future or shared_future objects for which \textit{when\_all} should wait.
• \textit{ec}: [in,out] this represents the error status on exit, if this is pre-initialized to \textit{hpx::throws} the function will throw on error instead.

template<typename R>
The function `wait_some` is an operator allowing to join on the result of all given futures. It **AND**-composes all future objects given and returns a new future object representing the same list of futures after `n` of them finished executing.

**Note** The function `wait_all` returns after `n` futures have become ready. All input futures are still valid after `wait_all` returns.

**Note** Each future and shared_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by `wait_some` will not throw an exception, but the futures held in the output collection may.

**Parameters**

- `n`: [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- `futures`: [in] A vector holding an arbitrary amount of `future` or `shared_future` objects for which `wait_some` should wait.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialzed to `hpx::throws` the function will throw on error instead.

**Example**

```cpp
void wait_some (std::size_t n, std::vector<future<R>> &&futures, error_code &ec = throws)
```

The function `wait_some` is an operator allowing to join on the result of all given futures. It **AND**-composes all future objects given and returns a new future object representing the same list of futures after `n` of them finished executing.

**Note** The function `wait_all` returns after `n` futures have become ready. All input futures are still valid after `wait_all` returns.

**Note** Each future and shared_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by `wait_some` will not throw an exception, but the futures held in the output collection may.

**Parameters**

- `n`: [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- `futures`: [in] An array holding an arbitrary amount of `future` or `shared_future` objects for which `wait_some` should wait.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Example**

```cpp
void wait_some (std::size_t n, std::array<future<R>, N> &&futures, error_code &ec = throws)
```

The function `wait_some` is an operator allowing to join on the result of all given futures. It **AND**-composes all future objects given and returns a new future object representing the same list of futures after `n` of them finished executing.

**Note** The function `wait_all` returns after `n` futures have become ready. All input futures are still valid after `wait_all` returns.

**Note** Each future and shared_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by `wait_some` will not throw an exception, but the futures held in the output collection may.

**Parameters**

- `n`: [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- `futures`: [in] An array holding an arbitrary amount of `future` or `shared_future` objects for which `wait_some` should wait.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Example**

```cpp
void wait_some (std::size_t n, T&&... futures, error_code &ec = throws)
```

The function `wait_some` is an operator allowing to join on the result of all given futures. It **AND**-composes all future objects given and returns a new future object representing the same list of futures after `n` of them finished executing.

**Note** The function `wait_all` returns after `n` futures have become ready. All input futures are still valid after `wait_all` returns.
Note Calling this version of wait_some where first == last, returns a future with an empty vector that is immediately ready. Each future and shared_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by wait_some will not throw an exception, but the futures held in the output collection may.

Parameters

- \( n \): [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- \( \text{futures} \): [in] An arbitrary number of future or shared_future objects, possibly holding different types for which wait_some should wait.
- \( \text{ec} \): [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

```
template<typename InputIter>
InputIter wait_some_n (std::size_t n, Iterator first, std::size_t count, error_code &ec = throws)
```

The function wait_some_n is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after \( n \) of them finished executing.

Note The function wait_all returns after \( n \) futures have become ready. All input futures are still valid after wait_all returns.

Return This function returns an Iterator referring to the first element after the last processed input element.

Note Calling this version of wait_some_n where count == 0, returns a future with the same elements as the arguments that is immediately ready. Possibly none of the futures in that vector are ready. Each future and shared_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by wait_some_n will not throw an exception, but the futures held in the output collection may.

Parameters

- \( n \): [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- \( \text{first} \): [in] The iterator pointing to the first element of a sequence of future or shared_future objects for which when_all should wait.
- \( \text{count} \): [in] The number of elements in the sequence starting at \( \text{first} \).
- \( \text{ec} \): [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

namespace hpx

Functions

```
template<typename InputIter, typename Container = std::vector<future<typename std::iterator_traits<InputIter>::value_type>>> future<Container> when_all (InputIter first, InputIter last)
```

The function when_all is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after they finished executing.

Return Returns a future holding the same list of futures as has been passed to when_all.
future<Container<future<R>>>: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output container will be the same as given by the input iterator.

Note Calling this version of when_all where first == last, returns a future with an empty container that is immediately ready. Each future and shared_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by when_all will not throw an exception, but the futures held in the output collection may.

Parameters

- first: [in] The iterator pointing to the first element of a sequence of future or shared_future objects for which when_all should wait.
- last: [in] The iterator pointing to the last element of a sequence of future or shared_future objects for which when_all should wait.

template<typename Range>
future<Range> when_all(Range &&values)

The function when_all is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after they finished executing.

Return Returns a future holding the same list of futures as has been passed to when_all.

- future<Container<future<R>>>: If the input cardinality is unknown at compile time and the futures are all of the same type.

Note Calling this version of when_all where the input container is empty, returns a future with an empty container that is immediately ready. Each future and shared_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by when_all will not throw an exception, but the futures held in the output collection may.

Parameters

- values: [in] A range holding an arbitrary amount of future or shared_future objects for which when_all should wait.

template<typename ...T>
future<tuple<future<T>...>> when_all(T&&... futures)

The function when_all is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after they finished executing.

Return Returns a future holding the same list of futures as has been passed to when_all.

- future<tuple<future<T0>, future<T1>, future<T2>...>>: If inputs are fixed in number and are of heterogeneous types. The inputs can be any arbitrary number of future objects.
- future<tuple<> if when_all is called with zero arguments. The returned future will be initially ready.

Note Each future and shared_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by when_all will not throw an exception, but the futures held in the output collection may.

Parameters
• futures: [in] An arbitrary number of future or shared_future objects, possibly holding different types for which when_all should wait.

template<typename InputIter, typename Container = std::vector<typename std::iterator_traits<
    InputIter>::value_type>> when_all_n(InputIter begin, std::size_t count)

The function when_all_n is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after they finished executing.

Return  Returns a future holding the same list of futures as has been passed to when_all_n.

• future<Container<future<R>>>: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output vector will be the same as given by the input iterator.

Note  As long as ec is not pre-initialized to hpx::throws this function doesn’t throw but returns the result code using the parameter ec. Otherwise it throws an instance of hpx::exception.

Note  None of the futures in the input sequence are invalidated.

Parameters

• begin: [in] The iterator pointing to the first element of a sequence of future or shared_future objects for which wait_all_n should wait.

• count: [in] The number of elements in the sequence starting at first.

Exceptions

• This: function will throw errors which are encountered while setting up the requested operation only. Errors encountered while executing the operations delivering the results to be stored in the futures are reported through the futures themselves.

namespace hpx

Functions

template<typename InputIter, typename Container = std::vector<typename std::iterator_traits<
    InputIter>::value_type>> when_any(InputIter first, InputIter last)

The function when_any is a non-deterministic choice operator. It OR-composes all future objects given and returns a new future object representing the same list of futures after one future of that list finishes execution.

Return  Returns a when_any_result holding the same list of futures as has been passed to when_any and an index pointing to a ready future.

• future<when_any_result<Container<future<R>>>>: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output container will be the same as given by the input iterator.

Parameters

• first: [in] The iterator pointing to the first element of a sequence of future or shared future objects for which when_any should wait.

• last: [in] The iterator pointing to the last element of a sequence of future or shared future objects for which when_any should wait.
template<typename Range>
future<when_any_result<Range>> when_any (Range &values)

The function when_any is a non-deterministic choice operator. It OR-composes all future objects given and returns a new future object representing the same list of futures after one future of that list finishes execution.

**Return**

Returns a when_any_result holding the same list of futures as has been passed to when_any and an index pointing to a ready future.

- future<when_any_result<Container<future<R>>>>: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output container will be the same as given by the input iterator.

**Parameters**

- values: [in] A range holding an arbitrary amount of futures or shared_future objects for which when_any should wait.

template<typename ... T>
future<when_any_result<tuple<future<T>...>>> when_any (T&... futures)

The function when_any is a non-deterministic choice operator. It OR-composes all future objects given and returns a new future object representing the same list of futures after one future of that list finishes execution.

**Return**

Returns a when_any_result holding the same list of futures as has been passed to when_any and an index pointing to a ready future.

- future<when_any_result<tuple<future<T0>, future<T1>...>>>: If inputs are fixed in number and are of heterogeneous types. The inputs can be any arbitrary number of future objects.
- future<when_any_result<tuple>>> if when_any is called with zero arguments. The returned future will be initially ready.

**Parameters**

- futures: [in] An arbitrary number of future or shared_future objects, possibly holding different types for which when_any should wait.

template<typename InputIter, typename Container = vector<future<typename std::iterator_traits<InputIter>::value_type>>> future<when_any_result<Container>> when_any_n (InputIter first, std::size_t count)

The function when_any_n is a non-deterministic choice operator. It OR-composes all future objects given and returns a new future object representing the same list of futures after one future of that list finishes execution.

**Return**

Returns a when_any_result holding the same list of futures as has been passed to when_any and an index pointing to a ready future.

- future<when_any_result<Container<future<R>>>>: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output container will be the same as given by the input iterator.

**Note**

None of the futures in the input sequence are invalidated.

**Parameters**

- first: [in] The iterator pointing to the first element of a sequence of future or shared_future objects for which when_any_n should wait.
• count: [in] The number of elements in the sequence starting at first.

```cpp
template<typename Sequence>
struct when_any_result
    #include <when_any.hpp> Result type for when_any, contains a sequence of futures and an index pointing to a ready future.

Public Members

std::size_t index
    The index of a future which has become ready.

Sequence futures
    The sequence of futures as passed to hpx::when_any.
```

```cpp
namespace hpx

Functions

template<typename F, typename Future>
future<void> when_each (F &&f, std::vector<Future> &&futures)
    The function when_each is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns a new future object representing the event of all those futures having finished executing. It also calls the supplied callback for each of the futures which becomes ready.

Note This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a future to be processed or a type that std::size_t is implicitly convertible to as the first parameter and the future as the second parameter. The first parameter will correspond to the index of the current future in the collection.

Return Returns a future representing the event of all input futures being ready.

Parameters

• f: The function which will be called for each of the input futures once the future has become ready.

• futures: A vector holding an arbitrary amount of future or shared_future objects for which wait_each should wait.

template<typename F, typename Iterator>
future<Iterator> when_each (F &&f, Iterator begin, Iterator end)
    The function when_each is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns a new future object representing the event of all those futures having finished executing. It also calls the supplied callback for each of the futures which becomes ready.

Note This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a future to be processed or a type that std::size_t is implicitly convertible to as the first parameter and the future as the second parameter. The first parameter will correspond to the index of the current future in the collection.

Return Returns a future representing the event of all input futures being ready.

Parameters
• \( f \): The function which will be called for each of the input futures once the future has become ready.

• \( \text{begin} \): The iterator pointing to the first element of a sequence of future or shared_future objects for which \( \text{wait\_each} \) should wait.

• \( \text{end} \): The iterator pointing to the last element of a sequence of future or shared_future objects for which \( \text{wait\_each} \) should wait.

```cpp
template<typename F, typename ...Ts>
future<void> when_each(F &&f, Ts&&... futures)
```

The function \( \text{when\_each} \) is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns a new future object representing the event of all those futures having finished executing. It also calls the supplied callback for each of the futures which becomes ready.

**Note** This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a future to be processed or a type that \( \text{std::size\_t} \) is implicitly convertible to as the first parameter and the future as the second parameter. The first parameter will correspond to the index of the current future in the collection.

**Return** Returns a future representing the event of all input futures being ready.

**Parameters**

• \( f \): The function which will be called for each of the input futures once the future has become ready.

• \( \text{futures} \): An arbitrary number of future or shared_future objects, possibly holding different types for which \( \text{wait\_each} \) should wait.

```cpp
template<typename F, typename Iterator>
future<Iterator> when_each_n(F &&f, Iterator begin, std::size_t count)
```

The function \( \text{when\_each\_n} \) is an operator allowing to join on the results of all given futures. It AND-composes all future objects given and returns a new future object representing the event of all those futures having finished executing. It also calls the supplied callback for each of the futures which becomes ready.

**Note** This function consumes the futures as they are passed on to the supplied function. The callback should take one or two parameters, namely either a future to be processed or a type that \( \text{std::size\_t} \) is implicitly convertible to as the first parameter and the future as the second parameter. The first parameter will correspond to the index of the current future in the collection.

**Return** Returns a future holding the iterator pointing to the first element after the last one.

**Parameters**

• \( f \): The function which will be called for each of the input futures once the future has become ready.

• \( \text{begin} \): The iterator pointing to the first element of a sequence of future or shared_future objects for which \( \text{wait\_each\_n} \) should wait.

• \( \text{count} \): The number of elements in the sequence starting at \( \text{first} \).
Functions

```cpp
template<typename InputIter, typename Container = vector<future<typename std::iterator_traits<InputIter>::value_type>>>
future<when_some_result<Container>> when_some (std::size_t n, Iterator first, Iterator last, error_code &ec = throws)
```

The function when_some is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after n of them finished executing.

**Note** The future returned by the function when_some becomes ready when at least n argument futures have become ready.

**Return** Returns a when_some_result holding the same list of futures as has been passed to when_some and indices pointing to ready futures.

- future<when_some_result<Container<future<R>>>: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output container will be the same as given by the input iterator.

**Note** Calling this version of when_some where first == last, returns a future with an empty container that is immediately ready. Each future and shared_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by when_some will not throw an exception, but the futures held in the output collection may.

**Parameters**

- n: [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- first: [in] The iterator pointing to the first element of a sequence of future or shared_future objects for which when_all should wait.
- last: [in] The iterator pointing to the last element of a sequence of future or shared_future objects for which when_all should wait.
- ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

```cpp
template<typename Range>
future<when_some_result<Range>> when_some (std::size_t n, Range &&futures, error_code &ec = throws)
```

The function when_some is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after n of them finished executing.

**Note** The future returned by the function when_some becomes ready when at least n argument futures have become ready.

**Return** Returns a when_some_result holding the same list of futures as has been passed to when_some and indices pointing to ready futures.

- future<when_some_result<Container<future<R>>>: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output container will be the same as given by the input iterator.

**Note** Each future and shared_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by when_some will not throw an exception, but the futures held in the output collection may.
Parameters

- **n**: [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- **futures**: [in] A container holding an arbitrary amount of future or shared_future objects for which when_some should wait.
- **ec**: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

```
template<typename ...T>
future<when_some_result<tuple<future<T>...>>>
when_some (std::size_t n, error_code &ec, T&&... futures)
```

The function when_some is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after n of them finished executing.

**Note** The future returned by the function when_some becomes ready when at least n argument futures have become ready.

**Return** Returns a when_some_result holding the same list of futures as has been passed to when_some and an index pointing to a ready future..

- future<when_some_result<tuple<future<T0>, future<T1>,...>>: If inputs are fixed in number and are of heterogeneous types. The inputs can be any arbitrary number of future objects.
- future<when_some_result<tuple<>>> if when_some is called with zero arguments. The returned future will be initially ready.

**Note** Each future and shared_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by when_some will not throw an exception, but the futures held in the output collection may.

Parameters

- **n**: [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- **ec**: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.
- **futures**: [in] An arbitrary number of future or shared_future objects, possibly holding different types for which when_some should wait.

```
template<typename ...T>
future<when_some_result<tuple<future<T>...>>>
when_some (std::size_t n, T&&... futures)
```

The function when_some is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after n of them finished executing.

**Note** The future returned by the function when_some becomes ready when at least n argument futures have become ready.

**Return** Returns a when_some_result holding the same list of futures as has been passed to when_some and an index pointing to a ready future..

- future<when_some_result<tuple<future<T0>, future<T1>,...>>: If inputs are fixed in number and are of heterogeneous types. The inputs can be any arbitrary number of future objects.
future<when_some_result<tuple<>>> if when_some is called with zero arguments. The returned future will be initially ready.

Note Each future and shared_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by when_some will not throw an exception, but the futures held in the output collection may.

Parameters

- n: [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- futures: [in] An arbitrary number of future or shared_future objects, possibly holding different types for which when_some should wait.

template<typename InputIter, typename Container = vector<future<typename std::iterator_traits<InputIter>::value_type>>> future<when_some_result<Container>> when_some_n (std::size_t n, Iterator first, std::size_t count, error_code &ec = throws)

The function when_some_n is an operator allowing to join on the result of all given futures. It AND-composes all future objects given and returns a new future object representing the same list of futures after n of them finished executing.

Note The future returned by the function when_some_n becomes ready when at least n argument futures have become ready.

Return Returns a when_some_result holding the same list of futures as has been passed to when_some and indices pointing to ready futures.

- future<when_some_result<Container<future<R>>>: If the input cardinality is unknown at compile time and the futures are all of the same type. The order of the futures in the output container will be the same as given by the input iterator.

Note Calling this version of when_some_n where count == 0, returns a future with the same elements as the arguments that is immediately ready. Possibly none of the futures in that container are ready. Each future and shared_future is waited upon and then copied into the collection of the output (returned) future, maintaining the order of the futures in the input collection. The future returned by when_some_n will not throw an exception, but the futures held in the output collection may.

Parameters

- n: [in] The number of futures out of the arguments which have to become ready in order for the returned future to get ready.
- first: [in] The iterator pointing to the first element of a sequence of future or shared_future objects for which when_all should wait.
- count: [in] The number of elements in the sequence starting at first.
- ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.
Public Members

\texttt{std::vector<\texttt{std::size\_}> indices}
List of indices of futures which became ready.

Sequence \texttt{futures}
The sequence of futures as passed to \texttt{hpx::when\_some}.

template<typename F>
friend constexpr auto tag_fallback_dispatch(transform_t, F &&f)
```

namespace hpx

```cpp
namespace execution

struct auto_chunk_size
#include <auto_chunk_size.hpp>
```

Loop iterations are divided into pieces and then assigned to threads. The number of loop iterations combined is determined based on measurements of how long the execution of 1% of the overall number of iterations takes. This executor parameters type makes sure that as many loop iterations are combined as necessary to run for the amount of time specified.

Public Functions

```cpp
constexpr auto_chunk_size(std::uint64_t num_iters_for_timing = 0)
```

Construct an auto_chunk_size executor parameters object

**Note** Default constructed auto_chunk_size executor parameter types will use 80 microseconds as the minimal time for which any of the scheduled chunks should run.

```cpp
auto_chunk_size(hpx::chrono::steady_duration const &rel_time, std::uint64_t num_iters_for_timing = 0)
```

Construct an auto_chunk_size executor parameters object

**Parameters**

- `rel_time`: [in] The time duration to use as the minimum to decide how many loop iterations should be combined.

namespace parallel

```cpp
namespace execution

Typedefs

typedef hpx::is_sequenced_execution_policy<T> instead
```

namespace hpx

```cpp
namespace execution

struct dynamic_chunk_size
#include <dynamic_chunk_size.hpp>
```

Loop iterations are divided into pieces of size chunk_size and
then dynamically scheduled among the threads; when a thread finishes one chunk, it is dynamically assigned another. If \( \text{chunk}\_\text{size} \) is not specified, the default chunk size is 1.

**Note** This executor parameters type is equivalent to OpenMP’s DYNAMIC scheduling directive.

### Public Functions

**constexpr dynamic_chunk_size**

```cpp
constexpr dynamic_chunk_size (std::size_t chunk_size = 1)
```

Construct a dynamic_chunk_size executor parameters object

**Parameters**

- `chunk_size`: [in] The optional chunk size to use as the number of loop iterations to schedule together. The default chunk size is 1.

```cpp
namespace hpx

namespace parallel

namespace execution

hpx::parallel::execution::has_pending_closures_t has_pending_closures

hpx::parallel::execution::get_pu_mask_t get_pu_mask

hpx::parallel::execution::set_scheduler_mode_t set_scheduler_mode

struct get_pu_mask_t : public hpx::functional::tag_fallback<get_pu_mask_t>

#include <execution_information.hpp> Retrieve the bitmask describing the processing units the given thread is allowed to run on

All threads::executors invoke sched.get_pu_mask().

**Note** If the executor does not support this operation, this call will always invoke hpx::threads::get_pu_mask()

**Parameters**

- `exec`: [in] The executor object to use for querying the number of pending tasks.
- `topo`: [in] The topology object to use to extract the requested information.
- `thread_num`: [in] The sequence number of the thread to retrieve information for.
Private Functions

```cpp
template<typename Executor>
decltype(auto) friend tag_fallback_dispatch (get pu_mask_t, Executor&&, threads::topology &topo, std::size_t thread_num)

template<typename Executor>
decltype(auto) friend tag_dispatch (get pu_mask_t, Executor &&exec, threads::topology &topo, std::size_t thread_num)
```

```cpp
struct has_pending_closures_t : public hpx::functional::tag_fallback<has_pending_closures_t>
#include <execution_information.hpp> Retrieve whether this executor has operations pending or not.
```

**Note** If the executor does not expose this information, this call will always return false.

**Parameters**
- `exec`: [in] The executor object to use to extract the requested information for.

Private Functions

```cpp
template<typename Executor>
decltype(auto) friend tag_fallback_dispatch (has_pending_closures_t, Executor&&)

template<typename Executor>
decltype(auto) friend tag_dispatch (has_pending_closures_t, Executor &&exec)
```

```cpp
struct set_scheduler_mode_t : public hpx::functional::tag_fallback<set_scheduler_mode_t>
#include <execution_information.hpp> Set various modes of operation on the scheduler underneath the given executor.
```

**Note** This calls exec.set_scheduler_mode(mode) if it exists; otherwise it does nothing.

**Parameters**
- `exec`: [in] The executor object to use.
- `mode`: [in] The new mode for the scheduler to pick up

Friends

```cpp
template<typename Executor, typename Mode>
void tag_fallback_dispatch (set_scheduler_mode_t, Executor&&, Mode const&)

```

```cpp
struct mark_begin_execution_t : public hpx::functional::tag_fallback<mark_begin_execution_t>
#include <execution_parameters_fwd.hpp> Mark the begin of a parallel algorithm execution

Note This calls params.mark_begin_execution(exec) if it exists; otherwise it does nothing.

Parameters

- params: [in] The executor parameters object to use as a fallback if the executor does not expose
Private Functions

template<typename Parameters, typename Executor>
decay(auto) friend tag fallback dispatch (mark begin execution_t, Parameters &&params, Executor &&exec)

struct mark end execution_t : public hpx::functional::tag fallback<mark end execution_t>
#include <execution_parameters_fwd.hpp> Mark the end of a parallel algorithm execution

Parameters
  • params: [in] The executor parameters object to use as a fallback if the executor does not expose

Private Functions

template<typename Parameters, typename Executor>
decay(auto) friend tag fallback dispatch (mark end execution_t, Parameters &&params, Executor &&exec)

struct mark end of scheduling t : public hpx::functional::tag fallback<mark end of scheduling t>
#include <execution_parameters_fwd.hpp> Mark the end of scheduling tasks during parallel algorithm execution

Parameters
  • params: [in] The executor parameters object to use as a fallback if the executor does not expose

Private Functions

template<typename Parameters, typename Executor>
decay(auto) friend tag fallback dispatch (mark end of scheduling t, Parameters &&params, Executor &&exec)

struct maximal number of chunks t : public hpx::functional::tag fallback<maximal number of chunks>
#include <execution_parameters_fwd.hpp> Return the largest reasonable number of chunks to create for a single algorithm invocation.

Parameters
  • params: [in] The executor parameters object to use for determining the number of chunks for the given number of cores.
  • exec: [in] The executor object which will be used for scheduling of the loop iterations.
  • cores: [in] The number of cores the number of chunks should be determined for.
  • num_tasks: [in] The number of tasks the chunk size should be determined for.
Private Functions

```cpp
template<typename Parameters, typename Executor>
dcltype(auto) friend tag_fallback_dispatch(maximal_number_of_chunks_t,
    Parameters &&params, Executor &&exec, std::size_t cores,
    std::size_t num_tasks)
```

**struct processing_units_count_t : public hpx:functional::tag_fallback<processing_units_count_t>**

#include <execution_parameters_fwd.hpp> Retrieve the number of (kernel-)threads used by the associated executor.

**Note** This calls params.processing_units_count(Executor&) if it exists; otherwise it forwards the request to the executor parameters object.

**Parameters**
- `params`: [in] The executor parameters object to use as a fallback if the executor does not expose

Private Functions

```cpp
template<typename Parameters, typename Executor>
dcltype(auto) friend tag_fallback_dispatch(processing_units_count_t,
    Parameters &&params, Executor &&exec)
```

**struct reset_thread_distribution_t : public hpx:functional::tag_fallback<reset_thread_distribution_t>**

#include <execution_parameters_fwd.hpp> Reset the internal round robin thread distribution scheme for the given executor.

**Note** This calls params.reset_thread_distribution(exec) if it exists; otherwise it does nothing.

**Parameters**
- `params`: [in] The executor parameters object to use for resetting the thread distribution scheme.
- `exec`: [in] The executor object to use.

Private Functions

```cpp
template<typename Parameters, typename Executor>
dcltype(auto) friend tag_fallback_dispatch(reset_thread_distribution_t,
    Parameters &&params, Executor &&exec)
```

namespace hpx

namespace execution

**struct guided_chunk_size**

#include <guided_chunk_size.hpp> Iterations are dynamically assigned to threads in blocks as threads request them until no blocks remain to be assigned. Similar to dynamic_chunk_size except that the block size decreases each time a number of loop iterations is given to a thread. The size of the initial block is proportional to `number_of_iterations / number_of_cores`. Subsequent blocks are proportional

Chapter 2. What’s so special about HPX?
to \textit{number\_of\_iterations\_remaining} / \textit{number\_of\_cores}. The optional chunk size parameter defines the minimum block size. The default chunk size is 1.

\textbf{Note} This executor parameters type is equivalent to OpenMP’s GUIDED scheduling directive.

\textbf{Public Functions}

\texttt{constexpr guided\_chunk\_size} (\texttt{std\::size\_t min\_chunk\_size = 1})

Construct a guided\_chunk\_size executor parameters object

\begin{itemize}
  \item \texttt{min\_chunk\_size:} \texttt{[in]} The optional minimal chunk size to use as the minimal number of loop iterations to schedule together. The default minimal chunk size is 1.
\end{itemize}

namespace hpx

namespace execution

\texttt{struct persistent\_auto\_chunk\_size}

\texttt{#include <persistent\_auto\_chunk\_size.hpp>} Loop iterations are divided into pieces and then assigned to threads. The number of loop iterations combined is determined based on measurements of how long the execution of 1\% of the overall number of iterations takes. This executor parameters type makes sure that as many loop iterations are combined as necessary to run for the amount of time specified.

\textbf{Public Functions}

\texttt{constexpr persistent\_auto\_chunk\_size} (\texttt{std\::uint64\_t num\_iters\_for\_timing = 0})

Construct a persistent\_auto\_chunk\_size executor parameters object

\texttt{persistent\_auto\_chunk\_size} (\texttt{hpx\::chrono\::steady\_duration const &time\_cs, std\::uint64\_t num\_iters\_for\_timing = 0})

Construct a persistent\_auto\_chunk\_size executor parameters object

\begin{itemize}
  \item \texttt{time\_cs:} The execution time for each chunk.
\end{itemize}

\texttt{persistent\_auto\_chunk\_size} (\texttt{hpx\::chrono\::steady\_duration const &time\_cs, hpx\::chrono\::steady\_duration const &rel\_time, std\::uint64\_t num\_iters\_for\_timing = 0})

Construct an persistent\_auto\_chunk\_size executor parameters object

\begin{itemize}
  \item \texttt{rel\_time:} \texttt{[in]} The time duration to use as the minimum to decide how many loop iterations should be combined.
  \item \texttt{time\_cs:} The execution time for each chunk.
\end{itemize}

struct is_sequenced_execution_policy : public hpx::detail::is_sequenced_execution_policy<std::decay<T>::type>
#include <is_execution_policy.hpp> Extension: Detect whether given execution policy does not enable parallelization

2.8. API reference
1. The type `is_sequenced_execution_policy` can be used to detect non-parallel execution policies for the purpose of excluding function signatures from otherwise ambiguous overload resolution participation.

2. If `T` is the type of a standard or implementation-defined execution policy, `is_sequenced_execution_policy<T>` shall be publicly derived from `integral_constant<bool, true>`, otherwise from `integral_constant<bool, false>`.

3. The behavior of a program that adds specializations for `is_sequenced_execution_policy` is undefined.

```cpp
namespace hpx

namespace parallel

namespace traits

Functions

`size_t count_bits(bool value)`

executors

The contents of this module can be included with the header `hpx/modules/executors.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/executors.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

```cpp
namespace hpx

namespace execution

namespace experimental

Functions

```
Public Functions

```cpp
template<typename Executor, typename Enable = std::enable_if_t<hpx::traits::is_executor_any_v<Executor>>>
constexpr annotating_executor (Executor &&exec, char const *annotation = nullptr)
```

```cpp
namespace hpx
namespace parallel
namespace execution

Typedefs

`using current_executor = parallel::execution::thread_pool_executor`

namespace this_thread

Functions

```cpp
parallel::execution::current_executor get_executor (error_code &ec = throws)
```

Returns a reference to the executor which was used to create the current thread.

Exceptions

- If: &ec != &throws, never throws, but will set ec to an appropriate value when an error occurs. Otherwise, this function will throw an `hpx::exception` with an error code of `hpx::yield_aborted` if it is signaled with `wait_aborted`. If called outside of a HPX-thread, this function will throw an `hpx::exception` with an error code of `hpx::null_thread_id`. If this function is called while the thread-manager is not running, it will throw an `hpx::exception` with an error code of `hpx::invalid_status`.

namespace threads

Functions

```cpp
parallel::execution::current_executor get_executor (thread_id_type const &id, error_code &ec = throws)
```

Returns a reference to the executor which was used to create the given thread.

Exceptions

- If: &ec != &throws, never throws, but will set ec to an appropriate value when an error occurs. Otherwise, this function will throw an `hpx::exception` with an error code of `hpx::yield_aborted` if it is signaled with `wait_aborted`. If called outside of a HPX-thread, this function will throw an `hpx::exception` with an error code of `hpx::null_thread_id`. If this function is called while the thread-manager is not running, it will throw an `hpx::exception` with an error code of `hpx::invalid_status`.

struct parallel_policy
#include <execution_policy.hpp> The class parallel_policy is an execution policy type used as a
unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm’s
execution may be parallelized.

Public Types

using executor_type = parallel_executor
The type of the executor associated with this execution policy.

using executor_parameters_type = parallel::execution::extract_executor_parameters<executor_type>::type
The type of the associated executor parameters object which is associated with this execution
policy

using execution_category = parallel_execution_tag
The category of the execution agents created by this execution policy.

Public Functions

constexpr parallel_task_policy operator() (task_policy_tag) const
Create a new parallel_policy referencing a chunk size.

Return The new parallel_policy
Parameters
• tag: [in] Specify that the corresponding asynchronous execution policy should be used
template<type> Executor>
constexpr decltype(auto) on (Executor &exec) const
Create a new parallel_policy referencing an executor and a chunk size.

Return The new parallel_policy
Parameters
• **exec**: [in] The executor to use for the execution of the parallel algorithm the returned execution policy is used with

```
template< typename ... Parameters >
constexpr decltype(auto) with (Parameters&&... params) const
Create a new parallel_policy from the given execution parameters
```

**Note** Requires: is_executor_parameters<Parameters>::value is true

**Return** The new parallel_policy

**Template Parameters**
- **Parameters**: The type of the executor parameters to associate with this execution policy.

**Parameters**
- **params**: [in] The executor parameters to use for the execution of the parallel algorithm the returned execution policy is used with.

```
executor_type & executor() const
Return the associated executor object.
```

```
constexpr executor_type const & executor() const

Parameters
  • params: [in] The executor parameters to use for the execution of the parallel algorithm the
            returned execution policy is used with.

evaluator_type & executor ()
Return the associated executor object.

`constexpr evaluator_type const & executor () const`
Return the associated executor object.

evaluator_parameters_type & parameters ()
Return the associated executor parameters object.

`constexpr evaluator_parameters_type const & parameters () const`
Return the associated executor parameters object.

```
template<type Executor_, type Parameters_>
struct rebind
#include <execution_policy.hpp> Rebind the type of executor used by this execution policy. The
execution category of Executor shall not be weaker than that of this execution policy
```
Public Types

```cpp
template<>
template<>
using type = parallel_task_policy_shim<Executor_, Parameters_>
```

The type of the rebound execution policy.

```cpp
struct parallel_unsequenced_policy
#include <execution_policy.hpp>
```

The class `parallel_unsequenced_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm’s execution may be parallelized and vectorized.

Public Types

```cpp
using executor_type = parallel_executor
```

The type of the executor associated with this execution policy.

```cpp
using executor_parameters_type = parallel::execution::extract_executor_parameters<executor_type>::type
```

The type of the associated executor parameters object which is associated with this execution policy.

```cpp
using execution_category = parallel_execution_tag
```

The category of the execution agents created by this execution policy.

Public Functions

```cpp
parallel_unsequenced_policy operator() (task_policy_tag) const
```

Create a new `parallel_unsequenced_policy` from itself

Return  The new `parallel_unsequenced_policy`

Parameters

- `tag`: [in] Specify that the corresponding asynchronous execution policy should be used

```cpp
executor_type &executor ()
```

Return the associated executor object.

```cpp
constexpr executor_type const &executor () const
```

Return the associated executor object.

```cpp
executor_parameters_type &parameters ()
```

Return the associated executor parameters object.

```cpp
constexpr executor_parameters_type const &parameters () const
```

Return the associated executor parameters object.

struct sequenced_policy
#include <execution_policy.hpp> The class sequenced_policy is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and require that a parallel algorithm’s execution may not be parallelized.

Public Types

using executor_type = sequenced_executor
The type of the executor associated with this execution policy.

using executor_parameters_type = parallel::execution::extract_executor_parameters<executor_type>::type
The type of the associated executor parameters object which is associated with this execution policy.

using execution_category = sequenced_execution_tag
The category of the execution agents created by this execution policy.

Public Functions

constexpr sequenced_task_policy operator() (task_policy_tag) const
Create a new sequenced_task_policy.

Return The new sequenced_task_policy
Parameters
• tag: [in] Specify that the corresponding asynchronous execution policy should be used

template<typename Executor>
constexpr decltype(auto) on (Executor &exec) const
Create a new sequenced_policy from the given executor

Note Requires: is_executor<Executor>::value is true
Return The new sequenced_policy
Template Parameters
• Executor: The type of the executor to associate with this execution policy.
Parameters
- **exec**: [in] The executor to use for the execution of the parallel algorithm the returned execution policy is used with.

```cpp
template<typename Parameters>
constexpr decltype(auto) with (Parameters&&... params) const
Create a new sequenced_policy from the given execution parameters
```

**Note** Requires: all parameters are executor_parameters, different parameter types can’t be duplicated

**Return** The new sequenced_policy

**Template Parameters**

- **Parameters**: The type of the executor parameters to associate with this execution policy.

**Parameters**

- **params**: [in] The executor parameters to use for the execution of the parallel algorithm the returned execution policy is used with.

```cpp
executor_type &executor ()
Return the associated executor object.
```

```cpp
constexpr executor_type const &executor () const
Return the associated executor object.
```

```cpp
executor_parameters_type &parameters ()
Return the associated executor parameters object.
```

```cpp
constexpr executor_parameters_type const &parameters () const
Return the associated executor parameters object.
```

using type = sequenced_policy_shim<Executor_, Parameters_>
```

The type of the rebound execution policy.

```cpp
template<typename Executor, typename Parameters>
struct sequenced_policy_shim
#include <execution_policy.hpp>
```

The class `sequenced_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and require that a parallel algorithm’s execution may not be parallelized.

Public Types

```cpp
template<>
using executor_type = std::decay_t<Executor>
```

The type of the executor associated with this execution policy.

```cpp
template<>
using executor_parameters_type = std::decay_t<Parameters>
```

The type of the associated executor parameters object which is associated with this execution policy.

```cpp
template<>
using execution_category = typename hpx::traits::executor_execution_category<executor_type>::type
```

The category of the execution agents created by this execution policy.

Public Functions

```cpp
constexpr sequenced_task_policy_shim<Executor, Parameters> operator() (task_policy_tag) const
```

Create a new `sequenced_task_policy`.

**Return** The new `sequenced_task_policy_shim`

**Parameters**

- `tag`: [in] Specify that the corresponding asynchronous execution policy should be used

```cpp
template<typename Executor_>
constexpr decltype(auto) on (Executor_&& exec) const
```

Create a new `sequenced_policy` from the given executor

**Note** Requires: is_executor<Executor>::value is true

**Return** The new `sequenced_policy`

**Template Parameters**

- `Executor`: The type of the executor to associate with this execution policy.

**Parameters**

- `exec`: [in] The executor to use for the execution of the parallel algorithm the returned execution policy is used with.

```cpp
template<typename ...Parameters_>
constexpr decltype(auto) with (Parameters_&... params) const
```

Create a new `sequenced_policy_shim` from the given execution parameters
Note Requires: all parameters are executor_parameters, different parameter types can’t be duplicated

Return The new sequenced_policy_shim

Template Parameters
- Parameters: The type of the executor parameters to associate with this execution policy.

Parameters
- params: [in] The executor parameters to use for the execution of the parallel algorithm the returned execution policy is used with.

executor_type &executor()
Return the associated executor object.

constexpr executor_type const &executor() const
Return the associated executor object.

executor_parameters_type &parameters()
Return the associated executor parameters object.

constexpr executor_parameters_type const &parameters() const
Return the associated executor parameters object.

template<typename Executor_, typename Parameters_>
struct rebind
#include <execution_policy.hpp> Rebind the type of executor used by this execution policy. The execution category of Executor shall not be weaker than that of this execution policy

Public Types

template<>
template::<
using type = sequenced_policy_shim<Executor_, Parameters_>
The type of the rebound execution policy.

struct sequenced_task_policy
#include <execution_policy.hpp> Extension: The class sequenced_task_policy is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm’s execution may not be parallelized (has to run sequentially).

The algorithm returns a future representing the result of the corresponding algorithm when invoked with the sequenced_policy.

Public Types

using executor_type = sequenced_executor
The type of the executor associated with this execution policy.

using executor_parameters_type = parallel::execution::extract_executor_parameters<executor_type>::type
The type of the associated executor parameters object which is associated with this execution policy

using execution_category = sequenced_execution_tag
The category of the execution agents created by this execution policy.
Public Functions

```cpp
constexpr sequenced_task_policy operator() (task_policy_tag) const
Create a new sequenced_task_policy from itself

Return  The new sequenced_task_policy
Parameters
• tag: [in] Specify that the corresponding asynchronous execution policy should be used
```

```cpp
template<typename Executor>
constexpr decltype(auto) on (Executor &&exec) const
Create a new sequenced_task_policy from the given executor

Note  Requires: is_executor<Executor>::value is true
Return  The new sequenced_task_policy
Template Parameters
• Executor: The type of the executor to associate with this execution policy.
Parameters
• exec: [in] The executor to use for the execution of the parallel algorithm the returned
  execution policy is used with.
```

```cpp
template<typename ...Parameters>
constexpr decltype(auto) with (Parameters&... params) const
Create a new sequenced_task_policy from the given execution parameters

Note  Requires: all parameters are executor_parameters, different parameter types can’t be dupli-
  cated
Return  The new sequenced_task_policy
Template Parameters
• Parameters: The type of the executor parameters to associate with this execution policy.
Parameters

struct unsequenced_policy
#include <execution_policy.hpp>
```

The class `unsequenced_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm’s execution may be vectorized.

Public Types

```
using executor_type = sequenced_executor
```

The type of the executor associated with this execution policy.

```
using executor_parameters_type = parallel::execution::extract_executor_parameters<executor_type>::type
```

The type of the associated executor parameters object which is associated with this execution policy

```
using execution_category = sequenced_execution_tag
```

The category of the execution agents created by this execution policy.

Public Functions

```
unsequenced_policy operator() (task_policy_tag) const
```

Create a new `parallel_unsequenced_policy` from itself

Return

The new `parallel_unsequenced_policy`

Parameters

- `tag`: [in] Specify that the corresponding asynchronous execution policy should be used

```
executor_type &executor ()
```

Return the associated executor object.

```
constexpr executor_type const &executor () const
```

Return the associated executor object.

```
executor_parameters_type &parameters ()
```

Return the associated executor parameters object.

```
constexpr executor_parameters_type const &parameters () const
```

Return the associated executor parameters object.

class fork_join_executor
#include <fork_join_executor.hpp> An executor with fork-join (blocking) semantics.

The fork_join_executor creates on construction a set of worker threads that are kept alive for the duration of the executor. Copying the executor has reference semantics, i.e. copies of a fork_join_executor hold a reference to the worker threads of the original instance. Scheduling work through the executor concurrently from different threads is undefined behaviour.

The executor keeps a set of worker threads alive for the lifetime of the executor, meaning other work will not be executed while the executor is busy or waiting for work. The executor has a customizable delay after which it will yield to other work. Since starting and resuming the worker threads is a slow operation the executor should be reused whenever possible for multiple adjacent parallel algorithms or invocations of bulk_(a)sync_execute.

Public Types

enum loop_schedule
Type of loop schedule for use with the fork_join_executor. loop_schedule::static_ implies no work-stealing; loop_schedule::dynamic allows stealing when a worker has finished its local work.
Values:
static_
dynamic

Public Functions

fork_join_executor (threads::thread_priority priority = threads::thread_priority::high,
threads::thread_stacksize stacksize =
threads::thread_stacksize::small_, loop_schedule schedule =
loop_schedule::static_, std::chrono::nanoseconds yield_delay =
std::chrono::milliseconds(1))
Construct a fork_join_executor.

Parameters
- priority: The priority of the worker threads.
- stacksize: The stacksize of the worker threads.
- schedule: The loop schedule of the parallel regions.
- yield_delay: The time after which the executor yields to other work if it hasn’t received any new work for bulk execution.

pack_traversal

The contents of this module can be included with the header hpx/modules/pack_traversal.hpp. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header hpx/modules/pack_traversal.hpp, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

```cpp
namespace hpx

namespace util

Functions

```cpp
template<typename Mapper, typename... T><unspecified> hpx::util::map_pack(Mapper && mapper, T &&... pack)
```

Maps the pack with the given mapper.

This function tries to visit all plain elements which may be wrapped in:
- homogeneous containers (std::vector, std::list)
- heterogeneous containers (hpx::tuple, std::pair, std::array) and re-assembles the pack with the result of the mapper. Mapping from one type to a different one is supported.

Elements that aren’t accepted by the mapper are routed through and preserved through the hierarchy.

```cpp
// Maps all integers to floats
map_pack([](int value) {
    return float(value);
},
    i, hpx::make_tuple(2, std::vector<int>{3, 4}), 5);
```

Return The mapped element or in case the pack contains multiple elements, the pack is wrapped into a hpx::tuple.

Exceptions
- std::exception: like objects which are thrown by an invocation to the mapper.

Parameters
• mapper: A callable object, which accept an arbitrary type and maps it to another type or the same one.
• pack: An arbitrary variadic pack which may contain any type.

amespace hpx

namespace util

Functions

template<typename Visitor, typename ...T>
auto traverse_pack_async (Visitor &&visitor, T&&... pack)
Traverses the pack with the given visitor in an asynchronous way.

This function works in the same way as traverse_pack, however, we are able to suspend and continue the traversal at later time. Thus we require a visitor callable object which provides three operator() overloads as depicted by the code sample below:

```cpp
struct my_async_visitor
{
    template <typename T>
    bool operator()(async_traverse_visit_tag, T&& element)
    {
        return true;
    }

    template <typename T, typename N>
    void operator()(async_traverse_detach_tag, T&& element, N&& next)
    {
    }

    template <typename T>
    void operator()(async_traverse_complete_tag, T&& pack)
    {
    }
};
```

See traverse_pack for a detailed description about the traversal behavior and capabilities.

Return A hpx::intrusive_ptr that references an instance of the given visitor object.

Parameters
• visitor: A visitor object which provides the three operator() overloads that were described above. Additionally the visitor must be compatible for referencing it from a hpx::intrusive_ptr. The visitor should must have a virtual destructor!
• pack: The arbitrary parameter pack which is traversed asynchronously. Nested objects inside containers and tuple like types are traversed recursively.

template<typename Allocator, typename Visitor, typename ...T>
auto traverse_pack_async_allocator (Allocator const &alloc, Visitor &&visitor, T&&... pack)
Traverses the pack with the given visitor in an asynchronous way.

This function works in the same way as traverse_pack, however, we are able to suspend and continue the traversal at later time. Thus we require a visitor callable object which provides three operator() overloads as depicted by the code sample below:
```cpp
struct my_async_visitor
{
  template<typename T>
  bool operator()(async_traverse_visit_tag, T&& element)
  {
    return true;
  }

  template<typename T, typename N>
  void operator()(async_traverse_detach_tag, T&& element, N&& next)
  {
  }

  template<typename T>
  void operator()(async_traverse_complete_tag, T&& pack)
  {
  }
};
```

See `traverse_pack` for a detailed description about the traversal behavior and capabilities.

**Return** A `hpx::intrusive_ptr` that references an instance of the given visitor object.

**Parameters**

- `visitor`: A visitor object which provides the three `operator()` overloads that were described above. Additionally the visitor must be compatible for referencing it from a `hpx::intrusive_ptr`. The visitor should have a virtual destructor!
- `pack`: The arbitrary parameter pack which is traversed asynchronously. Nested objects inside containers and tuple like types are traversed recursively.
- `alloc`: Allocator instance to use to create the traversal frame.

**namespace hpx**

**Functions**

```cpp
template<typename ...Args>
auto unwrap(Args&&... args)
{
  A helper function for retrieving the actual result of any `hpx::future` like type which is wrapped in an arbitrary way.

  Unwraps the given pack of arguments, so that any `hpx::future` object is replaced by its future result type in the argument pack:
  - `hpx::future<int> -> int`
  - `hpx::future<std::vector<float>> -> std::vector<float>`
  - `std::vector<hpx::future<float>> -> std::vector<float>`

  The function is capable of unwrapping `hpx::future` like objects that are wrapped inside any container or tuple like type, see `hpx::util::map_pack()` for a detailed description about which surrounding types are supported. Non `hpx::future` like types are permitted as arguments and passed through.

  // Single arguments
  int i1 = hpx::unwrap(hpx::make_ready_future(0));
```
// Multiple arguments
hpx::tuple<
        int,
        int>
    i2 =
    hpx::unwrap(hpx::make_ready_future(1),
                 hpx::make_ready_future(2));

**Note** This function unwraps the given arguments until the first traversed nested hpx::future which cor-responds to an unwrapping depth of one. See hpx::unwrap_n() for a function which unwraps the given arguments to a particular depth or hpx::unwrap_all() that unwraps all future like objects recursively which are contained in the arguments.

**Return** Depending on the count of arguments this function returns a hpx::tuple containing the unwrapped arguments if multiple arguments are given. In case the function is called with a single argument, the argument is unwrapped and returned.

**Parameters**
- `args`: the arguments that are unwrapped which may contain any arbitrary future or non future type.

**Exceptions**
- `std::exception`: like objects in case any of the given wrapped hpx::future objects were resolved through an exception. See hpx::future::get() for details.

```
template<
    std::size_t Depth,
    typename ... Args>
auto unwrap_n(Args&&... args)
    An alternative version of hpx::unwrap(), which unwraps the given arguments to a certain depth of hpx::future like objects.
```

See unwrap for a detailed description.

**Template Parameters**
- `Depth`: The count of hpx::future like objects which are unwrapped maximally.

```
template<
    typename ... Args>
auto unwrap_all(Args&&... args)
    An alternative version of hpx::unwrap(), which unwraps the given arguments recursively so that all con-tained hpx::future like objects are replaced by their actual value.
```

See hpx::unwrap() for a detailed description.

```
template<typename T>
auto unwrapping(T&& callable)
    Returns a callable object which unwraps its arguments upon invocation using the hpx::unwrap() function and then passes the result to the given callable object.
```

```
auto callable = hpx::unwrapping([](int left, int right) {
    return left + right;
});

int i1 = callable(hpx::make_ready_future(1),
                 hpx::make_ready_future(2));
```
See hpx::unwrap() for a detailed description.

**Parameters**

- **callable**: the callable object which which is called with the result of the corresponding unwrap function.

```cpp
template<std::size_t Depth, typename T>
auto unwrapping_n (T &&callable)
```

Returns a callable object which unwraps its arguments upon invocation using the hpx::unwrap_n() function and then passes the result to the given callable object.

See hpx::unwrapping() for a detailed description.

```cpp
template<typename T>
auto unwrapping_all (T &&callable)
```

Returns a callable object which unwraps its arguments upon invocation using the hpx::unwrap_all() function and then passes the result to the given callable object.

See hpx::unwrapping() for a detailed description.

**namespace functional**

thread_pool_util

The contents of this module can be included with the header `hpx/modules/thread_pool_util.hpp`. These headers may be used by user-code but are not guaranteed stable (neither header location nor contents). You are using these at your own risk. If you wish to use non-public functionality from a module we strongly suggest only including the module header `hpx/modules/thread_pool_util.hpp`, not the particular header in which the functionality you would like to use is defined. See Public API for a list of names that are part of the public HPX API.

```cpp
namespace hpx
{
    namespace threads
    {

    Functions

    hpx::future<void> resume_processing_unit(thread_pool_base &pool, std::size_t virt_core)
    Resumes the given processing unit. When the processing unit has been resumed the returned future will be ready.

    Note Can only be called from an HPX thread. Use resume_processing_unit_cb or to resume the processing unit from outside HPX. Requires that the pool has threads::policies::enable_elasticity set.
    Return A future<void> which is ready when the given processing unit has been resumed.
    Parameters
    • virt_core: [in] The processing unit on the pool to be resumed. The processing units are indexed starting from 0.

    void resume_processing_unit_cb(thread_pool_base &pool,
                                 util::function_nonser<void>
                                 > callback, std::size_t virt_core, error_code &ec = throws
    Resumes the given processing unit. Takes a callback as a parameter which will be called when the processing unit has been resumed.

    Note Requires that the pool has threads::policies::enable_elasticity set.
    Parameters
    • callback: [in] Callback which is called when the processing unit has been suspended.
    • virt_core: [in] The processing unit to resume.
    • ec: [in,out] this represents the error status on exit, if this is pre-initialized to hpx::throws the function will throw on error instead.

    hpx::future<void> suspend_processing_unit(thread_pool_base &pool, std::size_t virt_core)
   Suspends the given processing unit. When the processing unit has been suspended the returned future will be ready.

    Note Can only be called from an HPX thread. Use suspend_processing_unit_cb or to suspend the processing unit from outside HPX. Requires that the pool has threads::policies::enable_elasticity set.
    Return A future<void> which is ready when the given processing unit has been suspended.
    Parameters
    • virt_core: [in] The processing unit on the pool to be suspended. The processing units are indexed starting from 0.
    Exceptions
    • hpx::exception: if called from outside the HPX runtime.
```
void suspend_processing_unit_cb (util::function_nonser<void> callback, thread_pool_base &pool, std::size_t virt_core, error_code &ec = throws)

Suspends the given processing unit. Takes a callback as a parameter which will be called when the processing unit has been suspended.

**Note** Requires that the pool has threads::policies::enable_elasticity set.

**Parameters**
- `callback`: [in] Callback which is called when the processing unit has been suspended.
- `virt_core`: [in] The processing unit to suspend.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

hpx::future<void> resume_pool (thread_pool_base &pool)

Resumes the thread pool. When the all OS threads on the thread pool have been resumed the returned future will be ready.

**Note** Can only be called from an HPX thread. Use resume_cb or resume_direct to suspend the pool from outside HPX.

**Return** A `future<void>` which is ready when the thread pool has been resumed.

**Exceptions**
- `hpx::exception`: if called from outside the HPX runtime.

void resume_pool_cb (thread_pool_base &pool, util::function_nonser<void> callback, error_code &ec = throws)

Resumes the thread pool. Takes a callback as a parameter which will be called when all OS threads on the thread pool have been resumed.

**Parameters**
- `callback`: [in] called when the thread pool has been resumed.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

hpx::future<void> suspend_pool (thread_pool_base &pool)

Suspends the thread pool. When the all OS threads on the thread pool have been suspended the returned future will be ready.

**Note** Can only be called from an HPX thread. Use suspend_cb or suspend_direct to suspend the pool from outside HPX. A thread pool cannot be suspended from an HPX thread running on the pool itself.

**Return** A `future<void>` which is ready when the thread pool has been suspended.

**Exceptions**
- `hpx::exception`: if called from outside the HPX runtime.

void suspend_pool_cb (thread_pool_base &pool, util::function_nonser<void> callback, error_code &ec = throws)

Suspends the thread pool. Takes a callback as a parameter which will be called when all OS threads on the thread pool have been suspended.

**Note** A thread pool cannot be suspended from an HPX thread running on the pool itself.

**Parameters**
- `callback`: [in] called when the thread pool has been suspended.
- `ec`: [in,out] this represents the error status on exit, if this is pre-initialized to `hpx::throws` the function will throw on error instead.

**Exceptions**
- `hpx::exception`: if called from an HPX thread which is running on the pool itself.

`hpx::parallel::execution::sync_execute_after_t` sync_execute_after

struct async_execute_after_t : public hpx::functional::tag_fallback<async_execute_after_t>

#include <timed_execution_fwd.hpp> Customization point of asynchronous execution agent creation supporting timed execution.

This asynchronously creates a single function invocation f() using the associated executor at the given point in time.

Return f(ts...)’s result through a future

Note This calls exec.async_execute_after(rel_time, f, ts...), if available, otherwise it emulates timed scheduling by delaying calling execution::async_execute() on the underlying non-time-scheduled execution agent.

Parameters

- `exec`: [in] The executor object to use for scheduling of the function f.
- `rel_time`: [in] The duration of time after which the given function should be scheduled to run.
- `f`: [in] The function which will be scheduled using the given executor.
- `ts...`: [in] Additional arguments to use to invoke f.
Private Functions

template<typename Executor, typename F, typename ...Ts>
declayte(auto) friend tag_fallback_dispatch (async_execute_after_t,
  Executor &&exec,
  hpx::chrono::steady_duration const &rel_time, F &&f, Ts&&...
  ts)

#include <timed_execution_fwd.hpp>
Customization point of asynchronous execution agent creation supporting timed execution.
This asynchronously creates a single function invocation f(ts...) using the associated executor at the
given point in time.

Return  f(ts...)’s result through a future
Note  This calls exec.async_execute_at(abs_time, f, ts...), if available, otherwise it emulates
timed scheduling by delaying calling execution::async_execute() on the underlying non-time-
scheduled execution agent.
Parameters
  • exec: [in] The executor object to use for scheduling of the function f.
  • abs_time: [in] The point in time the given function should be scheduled at to run.
  • f: [in] The function which will be scheduled using the given executor.
  • ts...: [in] Additional arguments to use to invoke f.

Private Functions

template<typename Executor, typename F, typename ...Ts>
declayte(auto) friend tag_fallback_dispatch (async_execute_at_t,
  Executor &&exec,
  hpx::chrono::steady_time_point const &abs_time, F &&f, Ts&&...
  ts)

#include <timed_execution_fwd.hpp>
Customization point of asynchronous fire & forget execution agent creation supporting timed execution.
This asynchronously (fire & forget) creates a single function invocation f() using the associated executor at the
given point in time.

Note  This calls exec.post_after(rel_time, f, ts...), if available, otherwise it emulates timed
scheduling by delaying calling execution::post() on the underlying non-time-scheduled execution agent.
Parameters
  • exec: [in] The executor object to use for scheduling of the function f.
  • rel_time: [in] The duration of time after which the given function should be scheduled to run.
  • f: [in] The function which will be scheduled using the given executor.
  • ts...: [in] Additional arguments to use to invoke f.
Private Functions

template<typename Executor, typename F, typename ...Ts>
decltype(auto) friend tag_fallback_dispatch(post_after_t, Executor &&exec,
    hpx::chrono::steady_duration const &rel_time, F &&f, Ts&&... ts)

struct post_at_t : public hpx::functional::tag_fallback<post_at_t>
#include <timed_execution_fwd.hpp> Customization point of asynchronous fire & forget execution agent creation supporting timed execution.

This asynchronously (fire & forget) creates a single function invocation f() using the associated executor at the given point in time.

Note This calls exec.post_at(abs_time, f, ts...), if available, otherwise it emulates timed scheduling by delaying calling execution::post() on the underlying non-time-scheduled execution agent.

Parameters

• exec: [in] The executor object to use for scheduling of the function f.
• abs_time: [in] The point in time the given function should be scheduled at to run.
• f: [in] The function which will be scheduled using the given executor.
• ts...: [in] Additional arguments to use to invoke f.

Private Functions

template<typename Executor, typename F, typename ...Ts>
decltype(auto) friend tag_fallback_dispatch(sync_execute_after_t, Executor &&exec,
    hpx::chrono::steady_time_point const &abs_time, F &&f, Ts&&... ts)

struct sync_execute_after_t : public hpx::functional::tag_fallback<sync_execute_after_t>
#include <timed_execution_fwd.hpp> Customization point of synchronous execution agent creation supporting timed execution.

This synchronously creates a single function invocation f() using the associated executor at the given point in time.

Return f(ts...)'s result

Note This calls exec.sync_execute_after(rel_time, f, ts...), if available, otherwise it emulates timed scheduling by delaying calling execution::sync_execute() on the underlying non-time-scheduled execution agent.

Parameters

• exec: [in] The executor object to use for scheduling of the function f.
• rel_time: [in] The duration of time after which the given function should be scheduled to run.
• f: [in] The function which will be scheduled using the given executor.
• ts...: [in] Additional arguments to use to invoke f.
Private Functions

template<typename Executor, typename F, typename ...Ts>
decltype(auto) friend tag_fallback_dispatch (sync_execute_after_t,
   Executor &&exec,
   hpx::chrono::steady_duration const &rel_time, F &&f, Ts&&...
   ts)

struct sync_execute_at_t : public hpx::functional::tag_fallback<
sync_execute_at_t>
#include <timed_execution_fwd.hpp> Customization point of synchronous execution agent cre-
ation supporting timed execution.

This synchronously creates a single function invocation f() using the associated executor at the
given point in time.

Return f(ts...)'s result
Note This calls exec.sync_execute_at(abs_time, f, ts...), if available, otherwise it emulates
timed scheduling by delaying calling execution::sync_execute() on the underlying non-time-
scheduled execution agent.

Parameters
• exec: [in] The executor object to use for scheduling of the function f.
• abs_time: [in] The point in time the given function should be scheduled at to run.
• f: [in] The function which will be scheduled using the given executor.
• ts...: [in] Additional arguments to use to invoke f.

Private Functions

2.9 Contributing to HPX

HPX development happens on Github. The following sections are a collection of useful information related to HPX development.

2.9.1 Contributing to HPX

The main source of information to understand the process of how to contribute to HPX can be found in this document\(^{243}\). This is a living document that is constantly updated with relevant information.

2.9.2 HPX governance model

The HPX project is a meritocratic, consensus-based community project. Anyone with an interest in the project can join the community, contribute to the project design and participate in the decision making process. This document\(^{244}\) describes how that participation takes place and how to set about earning merit within the project community.

2.9.3 Release procedure for HPX

Below is a step by step procedure for making an HPX release. We aim to produce two releases per year: one in March-April, and one in September-October.

This is a living document and may not be totally current or accurate. It is an attempt to capture current practices in making an HPX release. Please update it as appropriate.

One way to use this procedure is to print a copy and check off the lines as they are completed to avoid confusion.

1. Notify developers that a release is imminent.
2. Write release notes in `docs/sphinx/releases/whats_new_$VERSION.rst`. Keep adding merged PRs and closed issues to this until just before the release is made. Use `tools/generate_pr_issue_list.sh` to generate the lists. Add the new release notes to the table of contents in `docs/sphinx/releases.rst`.
3. Build the docs, and proof-read them. Update any documentation that may have changed, and correct any typos. Pay special attention to:
   - `docs/sphinx/releases/whats_new_$VERSION.rst`
   - `docs/sphinx/about_hpx/people.rst`
4. This step does not apply to patch releases. For both APEX and libCDS:

\(^{243}\) https://github.com/STEllAR-GROUP/hpx/blob/master/.github/CONTRIBUTING.md
\(^{244}\) http://hpx.stellar-group.org/documents/governance/
• Change the release branch to be the most current release tag available in the APEX/libCDS git_external section in the main CMakeLists.txt. Please contact the maintainers of the respective packages to generate a new release to synchronize with the HPX release (APEX\textsuperscript{245}, libCDS\textsuperscript{246}).

5. If there have been any commits to the release branch since the last release, create a tag from the old release branch before deleting the old release branch in the next step.

6. Unprotect the release branch in the github repository settings so that it can be deleted and recreated (tick “Allow force pushes” in the release branch settings of the repository).

7. Reset the release branch to the latest stable state on master and force push to origin/release. If you are creating a patch release, branch from the release tag for which you want to create a patch release.

   • git checkout -b release (or just checkout in case the it exists)
   • git reset --hard stable
   • git push --force origin release

8. Protect the release branch again to disable force pushes.

9. Check out the release branch.

10. Make sure `HPX\_VERSION\_MAJOR/MINOR/SUBMINOR` in CMakeLists.txt contain the correct values. Change them if needed.

11. This step does not apply to patch releases. Remove features which have been deprecated for at least 2 releases. This involves removing build options which enable those features from the main CMakeLists.txt and also deleting all related code and tests from the main source tree.

   The general deprecation policy involves a three-step process we have to go through in order to introduce a breaking change:
   
   a. First release cycle: add a build option that allows for explicitly disabling any old (now deprecated) code.
   
   b. Second release cycle: turn this build option OFF by default.
   
   c. Third release cycle: completely remove the old code.

   The main CMakeLists.txt contains a comment indicating for which version the breaking change was introduced first. In the case of deprecated features which don’t have a replacement yet, we keep them around in case (like Vc for example).

12. Update the minimum required versions if necessary (compilers, dependencies, etc.) in building_hpx.rst.

13. Verify that the jenkins setup for the release branch on rostam is running and does not display any errors.

14. Repeat the following steps until satisfied with the release.

   1. Change `HPX\_VERSION\_TAG` in CMakeLists.txt to `-rcN`, where \( N \) is the current iteration of this step. Start with `-rc1`.
   
   2. Create a pre-release on GitHub using the script `tools/roll_release.sh`. This script automatically tag with the corresponding release number. The script requires that you have the STEllAR Group signing key.
   
   3. This step is not necessary for patch releases. Notify hpx-users@stellar-group.org and stellar@cct.lsu.edu of the availability of the release candidate. Ask users to test the candidate by checking out the release candidate tag.
   
   4. Allow at least a week for testing of the release candidate.

\textsuperscript{245} http://github.com/khuck/xpress-apex
\textsuperscript{246} https://github.com/STEllAR-GROUP/libcds
• Use `git merge` when possible, and fall back to `git cherry-pick` when needed. For patch releases `git cherry-pick` is most likely your only choice if there have been significant unrelated changes on master since the previous release.

• Go back to the first step when enough patches have been added.

• If there are no more patches, continue to make the final release.

15. Update any occurrences of the latest stable release to refer to the version about to be released. For example, `quickstart.rst` contains instructions to check out the latest stable tag. Make sure that refers to the new version.

16. Add a new entry to the RPM changelog (in `cmake/packaging/rpm/Changelog.txt`) with the new version number and a link to the corresponding changelog.

17. Change `HPX_VERSION_TAG` in `CMakeLists.txt` to an empty string.

18. Add the release date to the caption of the current “What’s New” section in the docs, and change the value of `HPX_VERSION_DATE` in `CMakeLists.txt`.

19. Create a release on GitHub using the script `tools/roll_release.sh`. This script automatically tag the with the corresponding release number. The script requires that you have the STEllAR Group signing key.

20. Update the websites (stellar-group.org\textsuperscript{247}, stellar-group.org\textsuperscript{248} and stellar.cct.lsu.edu\textsuperscript{249}). You can login on wordpress through this page <https://stellar-group.org/wp-login.php>. You can update the pages with the following:

• Update links on the downloads page. Link to the release on GitHub.

• Documentation links on the docs page (link to generated documentation on GitHub Pages). Follow the style of previous releases.

• A new blog post announcing the release, which links to downloads and the “What’s New” section in the documentation (see previous releases for examples).

21. Merge release branch into master.

22. Post-release cleanup. Create a new pull request against master with the following changes:

1. Modify the release procedure if necessary.

2. Change `HPX_VERSION_TAG` in `CMakeLists.txt` back to `-trunk`.

3. Increment `HPX_VERSION_MINOR` in `CMakeLists.txt`.

23. Update Vcpkg (https://github.com/Microsoft/vcpkg) to pull from latest release.

• Update version number in CONTROL

• Update tag and SHA512 to that of the new release

• Update version number in `hpx/package.py` and SHA256 to that of the new release

25. Announce the release on hpx-users@stellar-group.org, stellar@cct.lsu.edu, allct@cct.lsu.edu, faculty@cse.lsu.edu, faculty@ece.lsu.edu, xpress@crest.iu.edu, the HPX Slack channel, the IRC channel, Sonia Sachs, our list of external collaborators, isocpp.org, reddit.com, HPC Wire, Inside HPC, Heise Online, and a CCT press release.

\textsuperscript{247} https://stellar-group.org
\textsuperscript{248} https://stellar-group.org
\textsuperscript{249} https://stellar.cct.lsu.edu
2.9.4 Testing HPX

To ensure correctness of HPX, we ship a large variety of unit and regression tests. The tests are driven by the CTest\textsuperscript{250} tool and are executed automatically by buildbot (see HPX Buildbot Website\textsuperscript{251}) on each commit to the HPX Github\textsuperscript{252} repository. In addition, it is encouraged to run the test suite manually to ensure proper operation on your target system. If a test fails for your platform, we highly recommend submitting an issue on our HPX Issues\textsuperscript{253} tracker with detailed information about the target system.

Running tests manually

Running the tests manually is as easy as typing `make tests && make test`. This will build all tests and run them once the tests are built successfully. After the tests have been built, you can invoke separate tests with the help of the `ctest` command. You can list all available test targets using `make help | grep tests`. Please see the CTest Documentation\textsuperscript{254} for further details.

Issue tracker

If you stumble over a bug or missing feature in HPX, please submit an issue to our HPX Issues\textsuperscript{255} page. For more information on how to submit support requests or other means of getting in contact with the developers, please see the Support Website\textsuperscript{256} page.

Continuous testing

In addition to manual testing, we run automated tests on various platforms. You can see the status of the current master head by visiting the HPX Buildbot Website\textsuperscript{257}. We also run tests on all pull requests using both CircleCI\textsuperscript{258} and a combination of CDash\textsuperscript{259} and pycicle\textsuperscript{260}. You can see the dashboards here: CircleCI HPX dashboard\textsuperscript{261} and CDash HPX dashboard\textsuperscript{262}.

2.9.5 Using docker for development

Although it can often be useful to set up a local development environment with system-provided or self-built dependencies, Docker\textsuperscript{263} provides a convenient alternative to quickly get all the dependencies needed to start development of HPX. Our testing setup on CircleCI\textsuperscript{264} uses a docker image to run all tests.

To get started you need to install Docker\textsuperscript{265} using whatever means is most convenient on your system. Once you have Docker\textsuperscript{266} installed, you can pull or directly run the docker image. The image is based on Debian and Clang, and can

\textsuperscript{250} https://gitlab.kitware.com/cmake/community/wikis/doc/ctest/Testing-With-CTest

\textsuperscript{264} https://circleci.com
\textsuperscript{265} https://www.docker.com
\textsuperscript{266} https://www.docker.com
be found on Docker Hub\footnote{https://hub.docker.com/r/stellargroup/build_env/}. To start a container using the HPX build environment, run:

```
docker run --interactive --tty stellargroup/build_env:latest bash
```

You are now in an environment where all the HPX build and runtime dependencies are present. You can install additional packages according to your own needs. Please see the Docker Documentation\footnote{https://docs.docker.com/} for more information on using Docker\footnote{https://www.docker.com}.

**Warning:** All changes made within the container are lost when the container is closed. If you want files to persist (e.g., the HPX source tree) after closing the container, you can bind directories from the host system into the container (see Docker Documentation (Bind mounts)\footnote{https://docs.docker.com/storage/bind-mounts/}).

## 2.9.6 Documentation

This documentation is built using Sphinx\footnote{http://www.sphinx-doc.org}, and an automatically generated API reference using Doxygen\footnote{https://www.doxygen.org} and Breathe\footnote{https://breathe.readthedocs.io/en/latest}.

We always welcome suggestions on how to improve our documentation, as well as pull requests with corrections and additions.

### Building documentation

Please see the documentation prerequisites section for details on what you need in order to build the HPX documentation. Enable building of the documentation by setting `HPX_WITH_DOCUMENTATION=ON` during CMake\footnote{https://www.cmake.org} configuration. To build the documentation, build the `docs` target using your build tool. The default output format is HTML documentation. You can choose alternative output formats (single-page HTML, PDF, and man) with the `HPX_WITH_DOCUMENTATION_OUTPUT_FORMATS` CMake option.

**Note:** If you add new source files to the Sphinx documentation, you have to run CMake again to have the files included in the build.

### Style guide

The documentation is written using reStructuredText. These are the conventions used for formatting the documentation:

- Use, at most, 80 characters per line.
- Top-level headings use over- and underlines with `=.`.
- Sub-headings use only underlines with characters in decreasing level of importance: `=`, `-`, and `.`.
- Use sentence case in headings.
- Refer to common terminology using `:term:`Component`

\footnotetext[267]{https://hub.docker.com/r/stellargroup/build_env/}
\footnotetext[268]{https://docs.docker.com/}
\footnotetext[269]{https://www.docker.com}
\footnotetext[270]{https://docs.docker.com/storage/bind-mounts/}
\footnotetext[271]{http://www.sphinx-doc.org}
\footnotetext[272]{https://www.doxygen.org}
\footnotetext[273]{https://breathe.readthedocs.io/en/latest}
\footnotetext[274]{https://www.cmake.org}
• Indent content of directives (.. directive::) by three spaces.
• For C++ code samples at the end of paragraphs, use :: and indent the code sample by 4 spaces.
  – For other languages (or if you don’t want a colon at the end of the paragraph), use .. code-block::
    language and indent by three spaces as with other directives.
• Use .. list-table:: to wrap tables with a lot of text in cells.

**API documentation**

The source code is documented using Doxygen. If you add new API documentation either to existing or new source files, make sure that you add the documented source files to the doxygen_dependencies variable in docs/CMakeLists.txt.

### 2.9.7 Module structure

This section explains the structure of an HPX module.

The tool `create_library_skeleton.py`\(^{275}\) can be used to generate a basic skeleton. To create a library skeleton, run the tool in the `libs` subdirectory with the module name as an argument:

```
./create_library_skeleton <lib_name>
```

This creates a skeleton with the necessary files for an HPX module. It will not create any actual source files. The structure of this skeleton is as follows:

- `<lib_name>/`
  - README.rst
  - CMakeLists.txt
  - cmake
  - docs/
    * index.rst
  - examples/
    * CMakeLists.txt
  - include/
    * hpx/
      · `<lib_name>`
  - src/
    * CMakeLists.txt
  - tests/
    * CMakeLists.txt
    * unit/
      · CMakeLists.txt
      · regressions/

\(^{275}\) [https://github.com/STEllAR-GROUP/hpx/blob/master/libs/create_library_skeleton.py](https://github.com/STEllAR-GROUP/hpx/blob/master/libs/create_library_skeleton.py)
A README.rst should be always included which explains the basic purpose of the library and a link to the generated documentation.

A main CMakeLists.txt is created in the root directory of the module. By default it contains a call to add_hpx_module which takes care of most of the boilerplate required for a module. You only need to fill in the source and header files in most cases.

add_hpx_module requires a module name. Optional flags are:

**Optional single-value arguments are:**

- INSTALL_BINARIES: Install the resulting library.

**Optional multi-value arguments are:**

- SOURCES: List of source files.
- HEADERS: List of header files.
- COMPAT_HEADERS: List of compatibility header files.
- DEPENDENCIES: Libraries that this module depends on, such as other modules.
- CMAKE_SUBDIRS: List of subdirectories to add to the module.

The include directory should contain only headers that other libraries need. For each of those headers, an automatic header test to check for self containment will be generated. Private headers should be placed under the src directory. This allows for clear separation. The cmake subdirectory may include additional CMake scripts needed to generate the respective build configurations.

Compatibility headers (forwarding headers for headers whose location is changed when creating a module, if moving them from the main library) should be placed in an include_compatibility directory. This directory is not created by default.

Documentation is placed in the docs folder. A empty skeleton for the index is created, which is picked up by the main build system and will be part of the generated documentation. Each header inside the include directory will automatically be processed by Doxygen and included into the documentation. If a header should be excluded from the API reference, a comment // sphinx:undocumented needs to be added.

Tests are placed in suitable subdirectories of tests.

When in doubt, consult existing modules for examples on how to structure the module.

**Finding circular dependencies**

Our CI will perform a check to see if there are circular dependencies between modules. In cases where it’s not clear what is causing the circular dependency, running the cpp-dependencies tool manually can be helpful. It can give you detailed information on exactly which files are causing the circular dependency. If you do not have the cpp-dependencies tool already installed, one way of obtaining it is by using our docker image. This way you will have exactly the same environment as on the CI. See Using docker for development for details on how to use the docker image.

To produce the graph produced by CI run the following command (HPX_SOURCE is assumed to hold the path to the HPX source directory):

```
276 https://www.cmake.org
277 https://github.com/tomtom-international/cpp-dependencies
```
This will produce a dot file in the current directory. You can inspect this manually with a text editor. You can also convert this to an image if you have graphviz installed:

dot circular_dependencies.dot -Tsvg -o circular_dependencies.svg

This produces an svg file in the current directory which shows the circular dependencies. Note that if there are no cycles the image will be empty.

You can use cpp-dependencies to print the include paths between two modules.

cpp-dependencies --dir $HPX_SOURCE/libs --shortest <from> <to>

prints all possible paths from the module <from> to the module <to>. For example, as most modules depend on config, the following should give you a long list of paths from algorithms to config:

cpp-dependencies --dir $HPX_SOURCE/libs --shortest algorithms config

The following should report that it can’t find a path between the two modules:

cpp-dependencies --dir $HPX_SOURCE/libs --shortest config algorithms

### 2.10 Releases

#### 2.10.1 HPX V1.6.0 (Feb 17, 2021)

**General changes**

This release continues the focus on C++20 conformance with multiple new algorithms adapted to be C++20 conformance and becoming customization point objects (CPOs). We have also added experimental support for HIP, allowing previous CUDA features to now be compiled with hipcc and run on AMD GPUs.

- The following algorithms have been adapted to be C++20 conformant: adjacent_find, includes, inplace_merge, is_heap, is_heap_until, is_partitioned, is_sorted, is_sorted_until, merge, set_difference, set_intersection, set_symmetric_difference, set_union.

- Experimental HIP support can be enabled by compiling HPX with hipcc. All CUDA functionality in HPX can now be used with HIP. The HIP functionality is for the time being exposed through the same API as the CUDA functionality, i.e. no changes are required in user code. The CUDA, and now HIP, functionality is in the hpx::cuda namespace.

- We have added partial_sort based on Francisco Tapia’s implementation.

- hpx::init and hpx::start gained new overloads taking an hpx::init_params struct in 1.5.0. All overloads not taking an hpx::init_params are now deprecated.

- We have added an experimental fork_join_executor. This executor can be used for OpenMP-style fork-join parallelism, where the latency of a parallel region is important for performance.

- The parallel_executor now uses a hierarchical spawning scheme for bulk execution, which improves data locality and performance.

- hpx::dataflow can now be used with executors that inject additional parameters into the call of the user-provided function.
• We have added experimental support for properties as proposed in P2220\textsuperscript{278}. Currently the only supported property is the scheduling hint on parallel_executor.

• hpx::util::annotated_function can now be passed a dynamically generated std::string.

• In moving functionality to new namespaces, old names have been deprecated. A deprecation warning will be issued if you are using deprecated functionality, with instructions on how to correct or ignore the warning.

• We have removed all support for C and Fortran from our build system.

• We have further reduced the use of Boost types within HPX (boost::system::error_code and boost::detail::spinlock).

• We have enabled more warnings in our CI builds (unused variables and unused typedefs).

Breaking changes

• hpxMP support has been completely removed.

• The verbs parcelport has been removed.

• The following compatibility options have been disabled by default: HPX\_WITH\_ACTION\_BASE\_COMPATIBILITY, HPX\_WITH\_REGISTER\_THREAD\_COMPATIBILITY, HPX\_WITH\_PROMISE\_ALIAS\_COMPATIBILITY, HPX\_WITH\_UNSCOPED\_ENUM\_COMPATIBILITY, HPX\_PROGRAM\_OPTIONS\_WITH\_BOOST\_PROGRAM\_OPTIONS\_COMPATIBILITY, HPX\_WITH\_EMBEDDED\_THREAD\_POOLS\_COMPATIBILITY, HPX\_WITH\_THREAD\_POOL\_OS\_EXECUTOR\_COMPATIBILITY, HPX\_WITH\_THREAD\_EXECUTORS\_COMPATIBILITY, HPX\_THREAD\_AWARE\_TIMER\_COMPATIBILITY, HPX\_WITH\_POOL\_EXECUTOR\_COMPATIBILITY. Unless noted here, the above functionalities do not come with replacements. Unscoped enumerations have been replaced by scoped enumerations. Previously deprecated unscoped enumerations are disabled by HPX\_WITH\_UNSCOPED\_ENUM\_COMPATIBILITY. Newly deprecated unscoped enumerations have been given deprecation warnings and replaced by scoped enumerations. hpx::promise has been replaced with hpx::distributed::promise. hpx::program_options is a drop-in replacement for boost::program_options. hpx::execution::parallel_executor now has constructors which take a thread pool, covering the use case of hpx::threads::executors::pool_executor. A pool can be supplied with hpx::resource::get_thread_pool.

Closed issues

• Issue #5148\textsuperscript{279} - runtime_support.hpp does not work with newer cling

• Issue #5147\textsuperscript{280} - Wrong results with parallel reduce

• Issue #5129\textsuperscript{281} - Missing specialization for std::hash<hpx::thread::id>

• Issue #5126\textsuperscript{282} - Use std::string for task annotations

• Issue #5115\textsuperscript{283} - Don’t expect hwloc to always report Cores

• Issue #5113\textsuperscript{284} - Handle threadmanager exceptions during startup

• Issue #5112\textsuperscript{285} - libatomic problems causing unexpected fails

2.10. Releases

1453
• Issue #5089 - Remove non-BSL files
• Issue #5088 - Unwrapping problem
• Issue #5087 - Remove hpxMP support
• Issue #5077 - PAPI counters are not accessible when HPX is installed
• Issue #5075 - Make the structs in all \texttt{iter\_sent.hpp} lower case
• Issue #5067 - Bug \texttt{string\_util/split.hpp}
• Issue #5049 - Change back the hipcc jenkins config to the fury partition on rostam
• Issue #5038 - Not all examples link in the latest HPX master
• Issue #5035 - Build with \texttt{HPX\_WITH\_EXAMPLES} fails
• Issue #5019 - Broken help string for hpx
• Issue #5016 - \texttt{hpx::parallel::fill} fails compiling
• Issue #5014 - Rename all .cc to .cpp and .hh to .hpp
• Issue #4988 - MPI is not finalized if running with only one locality
• Issue #4978 - Change feature test macros to expand to zero/one
• Issue #4949 - Crash when not enabling TCP parcelport
• Issue #4933 - Improve test coverage for unused variable warnings etc.
• Issue #4878 - HPX mpi async might call \texttt{MPI\_FINALIZE} before app calls it
• Issue #4127 - Local runtime entry-points

Closed pull requests

• PR #5178 - Fix parallel \texttt{remove/remove\_copy/transform} namespace references in docs
• PR #5169 - Attempt to get Piz Daint jenkins setup running after maintenance
• PR #5168 - Remove include of itself
• PR #5167 - Fixing deprecation warnings that slipped through the net

• PR #5159[^308] - Update APEX tag to 2.3.1
• PR #5154[^309] - Splitting unit tests on circleci to avoid timeouts
• PR #5151[^310] - Use C++20 on clang-newest Jenkins CI configuration
• PR #5149[^311] - Rename 'module' symbols to avoid keyword conflict
• PR #5145[^312] - Adjust handling of CUDA/HP options in CMake
• PR #5142[^313] - Store annotated_function annotations as std::strings
• PR #5140[^314] - Scheduler mode
• PR #5139[^315] - Fix path problem in pre-commit hook, add summary commit line
• PR #5138[^316] - Add program options variable map to resource partitioner init
• PR #5137[^317] - Remove the use of boost::throw_exception
• PR #5136[^318] - Make sure codespell checks run on CircleCI
• PR #5132[^319] - Fixing spelling errors
• PR #5131[^320] - Mark counting_iterator member functions as HPX_HOST_DEVICE
• PR #5130[^321] - Adding specialization for std::hash<hpx::thread::id>
• PR #5128[^322] - Fixing environment handling for FreeBSD
• PR #5127[^323] - Fix typo in fibonacci documentation
• PR #5123[^324] - Reduce vector sizes in partial sort benchmarks when running in debug mode
• PR #5122[^325] - Making sure exceptions during runtime initialization are correctly reported
• PR #5121[^326] - Working around hwloc limitation on certain platforms
• PR #5120[^327] - Fixing compatibility warnings in hpx::transform implementation
• PR #5119[^328] - Use sequential_find and friends from separate detail header
• PR #5116[^329] - Fix compilation with timer pool off
• PR #5114[^330] - Fix 5112 - make sure libatomic is used when needed

• PR #5109331 - Remove default runtime mode argument from init overload, again
• PR #5108332 - Refactor iter_sent.hpp to make structs lowercase
• PR #5107333 - Relax dataflow internals
• PR #5106334 - Change initialization of property CPOs to satisfy older nvcc versions
• PR #5104335 - Fix regeneration of two files that trigger unnecessary rebuilds
• PR #5103336 - Remove default runtime mode argument from start/init overloads
• PR #5102337 - Untie deprecated thread enums from the CMake option
• PR #5101338 - Update APEX tag for 1.6.0
• PR #5100339 - Bump minimum required Boost version to 1.66 and update CI configurations
• PR #5098340 - Minor fixes to public API listing
• PR #5097341 - Remove hpxMP support
• PR #5096342 - Remove fractals examples
• PR #5095343 - Use all AMD nodes again on rostam
• PR #5094344 - Attempt to remove macOS workaround for GH actions environment
• PR #5093345 - Remove verbs parcelport
• PR #5091346 - Avoid moving from lvalues
• PR #5090347 - Adopt C++20 std::endian
• PR #5085348 - Update daint CI to use Boost 1.75.0
• PR #5084349 - Disable compatibility options for 1.6.0 release
• PR #5083350 - Remove duplicated call to the limiting_executor in future_overhead test
• PR #5079351 - Add checks to make sure that MPI/CUDA polling is enabled/not disabled too early
• PR #5078352 - Add install lib directory to list of component search paths
• PR #5076353 - Fix a typo in the jenkins clang-newest cmake config

2.10. Releases
- PR #4979\(^{422}\) - Actually enable unity builds on Jenkins
- PR #4977\(^{423}\) - Cleaning up `debug::print` functionalities
- PR #4976\(^{424}\) - Remove indirection layer in `at_index_impl`
- PR #4975\(^{425}\) - Remove indirection layer in `at_index_impl`
- PR #4973\(^{426}\) - Avoid warnings/errors for older gcc complaining about multi-line comments
- PR #4970\(^{427}\) - Making set algorithms conform to C++20
- PR #4969\(^{428}\) - Moving `is_execution_policy` and friends into namespace `hpx`
- PR #4968\(^{429}\) - Enable deprecation warnings for 1.6.0 and move any functionality to `hpx` namespace
- PR #4967\(^{430}\) - Define deprecation macros conditionally
- PR #4966\(^{431}\) - Add `clang-format` and `cmake-format` version prints
- PR #4965\(^{432}\) - Making `is_heap` and `is_heap_until` conforming to C++20
- PR #4964\(^{433}\) - Adding parallel `make_heap`
- PR #4962\(^{434}\) - Fix external timer function pointer exports
- PR #4960\(^{435}\) - Fixing folder names for module tests and examples
- PR #4959\(^{436}\) - Adding communications set
- PR #4958\(^{437}\) - Deprecate tuple and timing functionality in `hpx::util`
- PR #4957\(^{438}\) - Fixing unity build option for parcelports
- PR #4953\(^{439}\) - Fixing MSVC problems after recent restructurings
- PR #4952\(^{440}\) - Make `parallel_executor` use `thread_pool_executor` spawning mechanism
- PR #4948\(^{441}\) - Clean up old artifacts better and more aggressively on Jenkins
- PR #4947\(^{442}\) - Add HIP support for AMD GPUs
- PR #4945\(^{443}\) - Enable `HPX_WITH_UNITY_BUILD` option on one of the Jenkins configurations
- PR #4943\(^{444}\) - Move public `hpx::parallel::execution` functionality to `hpx::execution`

• PR #4622 - Sanitizer fixes

2.10.2 HPX V1.5.1 (Sep 30, 2020)

General changes

This is a patch release. It contains the following changes:

• Remove restriction on suspending runtime with multiple localities, users are now responsible for synchronizing work between localities before suspending.
• Fixes several compilation problems and warnings.
• Adds notes in the documentation explaining how to cite HPX.

Closed issues

• Issue #4971 - Parallel sort fails to compile with C++20
• Issue #4950 - Build with HPX_WITH_PARCELPORT_ACTION_COUNTERS ON fails
• Issue #4940 - Codespell report for “HPX” (on fossies.org)
• Issue #4937 - Allow suspension of runtime for multiple localities

- PR #4941 \(^{465}\) - Adding some explanation to README about how to cite HPX
- PR #4939 \(^{466}\) - Small changes

2.10.3 HPX V1.5.0 (Sep 02, 2020)

General changes

The main focus of this release is on APIs and C++20 conformance. We have added many new C++20 features and adapted multiple algorithms to be fully C++20 conformant. As part of the modularization we have begun specifying the public API of HPX in terms of headers and functionality, and aligning it more closely to the C++ standard. All non-distributed modules are now in place, along with an experimental option to completely disable distributed features in HPX. We have also added experimental asynchronous MPI and CUDA executors. Lastly this release introduces CMake targets for depending projects, performance improvements, and many bug fixes.

- We have added the C++20 features `hpx::jthread` and `hpx::stop_token`. `hpx::condition_variable_any` now exposes new functions supporting `hpx::stop_token`.
- We have added `hpx::stable_sort` based on Francisco Tapia’s implementation.
- We have adapted existing synchronization primitives to be fully conformant C++20: `hpx::barrier`, `hpx::latch`, `hpx::counting_semaphore`, and `hpx::binary_semaphore`.
- We have started using customization point objects (CPOs) to make the corresponding algorithms fully conformant to C++20 as well as to make algorithm extension easier for the user. `all_of/any_of/none_of, copy, count, destroy, equal, fill, find, for_each, generate, mismatch, move, reduce, transform_reduce` are using those CPOs (all in namespace `hpx`). We also have adapted their corresponding `hpx::ranges` versions to be conforming to C++20 in this release.
- We have adapted support for `co_await` to C++20, in addition to `hpx::future` it now also supports `hpx::shared_future`. We have also added allocator support for futures returned by `co_return`. It is no longer in the experimental namespace.
- We added serialization support for `std::variant` and `std::tuple`.

---

\(^{465}\) https://github.com/STEllAR-GROUP/hpx/pull/4944
\(^{466}\) https://github.com/STEllAR-GROUP/hpx/pull/4941
- `result_of` and `is_callable` are now deprecated and replaced by `invoke_result` and `is_invocable` to conform to C++20.

- We continued with the modularization, making it easier for us to add the new experimental `HPX_WITH_DISTRIBUTED_RUNTIME` CMake option (see below). An significant amount of headers have been deprecated. We adapted the namespaces and headers we could to be closer to the standard ones (Public API). Depending code should still compile, however warnings are now generated instructing to change the include statements accordingly.

- It is now possible to have a basic CUDA support including a helper function to get a future from a CUDA stream and target handling. They are available under the `hpx::cuda::experimental` namespace and they can be enabled with the `-DHPX_WITH_ASYNC_CUDA=ON` CMake option.

- We added a new `hpx::mpi::experimental` namespace for getting futures from an asynchronous MPI call and a new minimal MPI executor `hpx::mpi::experimental::executor`. These can be enabled with the `-DHPX_WITH_ASYNC_MPI=ON` CMake option.

- A polymorphic executor has been implemented to reduce compile times as a function accepting executors can potentially be instantiated only once instead of multiple times with different executors. It accepts the function signature as a template argument. It needs to be constructed from any other executor. Please note, that the function signatures that can be scheduled using `then_execute`, `bulk_sync_execute`, `bulk_async_execute` and `bulk_then_execute` are slightly different (See the comment in PR #4514 for more details).

- The underlying executor of `block_executor` has been updated to a newer one.

- We have added a parameter to `auto_chunk_size` to control the amount of iterations to measure.

- All executor parameter hooks can now be exposed through the executor itself. This will allow to deprecate the `.with()` functionality on execution policies in the future. This is also a first step towards simplifying our executor APIs in preparation for the upcoming C++23 executors (senders/receivers).

- We have moved all of the existing APIs related to resiliency into the namespace `hpx::resiliency::experimental`. Please note this is a breaking change without backwards-compatibility option. We have converted all of those APIs to be based on customization point objects. Two new executors have been added to enable easy integration of the existing resiliency features with other facilities (like the parallel algorithms): `replay_executor` and `replicate_executor`.

- We have added performance counters type information (aggregating, monotonically increasing, average count, average timer, etc.).

- HPX threads are now re-scheduled on the same worker thread they were suspended on to avoid cache misses from moving from one thread to the other. This behavior doesn’t prevent the thread from being stolen, however.

- We have added a new configuration option `hpx.exception_verbosity` to allow to control the level of verbosity of the exceptions (3 levels available).

- `broadcast_to, broadcast_from, scatter_to and scatter_from` have been added to the collectives, modernization of `gather_here` and `gather_there` with futures taken by rvalue references. See the breaking change on `all_to_all` in the next section. None of the collectives need supporting macros anymore (e.g. specifying the data types used for a collective operation using `HPX_REGISTER_ALLGATHER` and similar is not needed anymore).

- New API functions have been added: a) to get the number of cores which are idle (hpx::get_idle_core_count) and b) returning a bitmask representing the currently idle cores (hpx::get_idle_core_mask).

- We have added an experimental option to only enable the local runtime, you can disable the distributed runtime with `HPX_WITH_DISTRIBUTED_RUNTIME=OFF`. You can also enable the local runtime by using the

467 https://github.com/STEllAR-GROUP/hpx/pull/4514
We fixed task annotations for actions.

- The alias `hpx::promise` to `hpx::lcos::promise` is now deprecated. You can use `hpx::lcos::promise` directly instead. `hpx::promise` will refer to the local-only promise in the future.

- We have added a `prepare_checkpoint` API function that calculates the amount of necessary buffer space for a particular set of arguments checkpointed.

- We have added `hpx::upgrade_lock` and `hpx::upgrade_to_unique_lock`, which make `hpx::shared_mutex` (and similar) usable in more flexible ways.

- We have changed the CMake targets exposed to the user, it now includes `HPX::hpx`, `HPX::wrap_main` (int main as the first `HPX` thread of the application, see `Starting the HPX runtime`), `HPX::plugin`, `HPX::component`. The CMake variables `HPX_INCLUDE_DIRS` and `HPX_LIBRARIES` are deprecated and will be removed in a future release, you should now link directly to the `HPX::hpx` CMake target.

- A new example is demonstrating how to create and use a wrapping executor (`quickstart/executor_with_thread_hooks.cpp`)

- A new example is demonstrating how to disable thread stealing during the execution of parallel algorithms (`quickstart/disable_thread_stealing_executor.cpp`)

- We now require for our CMake build system configuration files to be formatted using cmake-format.

- We have removed more dependencies on various Boost libraries.

- We have added an experimental option enabling unity builds of HPX using the `-DHPX_WITH_UNITY_BUILD=On` CMake option.

- Many bug fixes.

Breaking changes

- `HPX` now requires a C++14 capable compiler. We have set the `HPX` C++ standard automatically to C++14 and if it needs to be set explicitly, it should be specified through the `CMAKE_CXX_STANDARD` setting as mandated by CMake. The `HPX_WITH_CXX*` variables are now deprecated and will be removed in the future.

- Building and using HPX is now supported only when using CMake V3.13 or later, Boost V1.64 or newer, and when compiling with clang V5, gcc V7, or VS2019, or later. Other compilers might still work but have not been tested thoroughly.

- We have added a `hpx::init_params` struct to pass parameters for `HPX` initialization e.g. the resource partitioner callback to initialize thread pools (`Using the resource partitioner`).

- The `all_to_all` algorithm is renamed to `all_gather`, and the new `all_to_all` algorithm is not compatible with the old one.

- We have moved all of the existing APIs related to resiliency into the namespace `hpx::resiliency::experimental`.

• PR #4889\(^{592}\) - Restore old behaviour of not requiring linking to \texttt{hpx\_wrap} when \texttt{HPX\_WITH\_DYNAMIC\_HPX\_MAIN=OFF}
• PR #4887\(^{593}\) - Making sure remotely thrown (non-hpx) exceptions are properly marshaled back to invocation site
• PR #4885\(^{594}\) - Adapting \texttt{hpx::find} and \texttt{friends} to C++20
• PR #4884\(^{595}\) - Adapting mismatch to C++20
• PR #4883\(^{596}\) - Adapting \texttt{hpx::equal} to be conforming to C++20
• PR #4882\(^{597}\) - Fixing exception handling for \texttt{hpx::copy} and adding missing tests
• PR #4881\(^{598}\) - Adds different runtime exception when registering thread with the HPX runtime
• PR #4876\(^{599}\) - Adding example demonstrating how to disable thread stealing during the execution of parallel algorithms
• PR #4874\(^{600}\) - Adding non-policy tests to \texttt{all\_of}, \texttt{any\_of}, and \texttt{none\_of}

• PR #4873 - Set CUDA compute capability on rostam Jenkins builds
• PR #4872 - Force partitioned vector scan tests to run serially
• PR #4870 - Making move conforming with C++20
• PR #4869 - Making destroy and destroy_n conforming to C++20
• PR #4868 - Fix miscellaneous header problems
• PR #4867 - Add CPOs for for_each
• PR #4865 - Adapting count and count_if to be conforming to C++20
• PR #4864 - Release notes 1.5.0
• PR #4863 - adding libcds-hpx tag to prepare for hpx1.5 release
• PR #4862 - Adding version specific deprecation options
• PR #4861 - Limiting executor improvements
• PR #4860 - Making fill and fill_n compatible with C++20
• PR #4859 - Adapting all_of, any_of, and none_of to C++20
• PR #4858 - Improve libCDS integration
• PR #4856 - Correct typos in the documentation of the hpx performance counters
• PR #4857 - Removing obsolete code
• PR #4856 - Adding test that derives component from two other components
• PR #4855 - Fix mpi_ring test in distributed mode by ensuring all ranks run hpx_main
• PR #4854 - Converting resiliency APIs to tag_invoke based CPOs
• PR #4853 - Enable use of future_overhead test when DISTRIBUTED_RUNTIME is OFF
• PR #4852 - Fixing ‘error prone’ constructs as reported by Codacy
• PR #4851 - Disable Boost.Asio concepts support
• PR #4850 - Fix PAPI counters

2.10. Releases
- PR #4843 - Remove dependency on various Boost headers
- PR #4841 - Rearrange public API headers
- PR #4840 - Fixing TSS problems during thread termination
- PR #4839 - Fix async_cuda build problems when distributed runtime is disabled
- PR #4837 - Restore compatibility for old (now deprecated) copy algorithms
- PR #4836 - Adding CPOs for hpx::reduce
- PR #4835 - Remove using util::result_of from namespace hpx
- PR #4834 - Fixing the calculation of the number of idle cores and the corresponding idle masks
- PR #4832 - Allow thread function destructors to yield
- PR #4831 - Fixing assertion in split_gids and memory leaks in 1d_stencil_7
- PR #4830 - Making sure MPI_CXX_COMPILE_FLAGS is interpreted as a sequence of options
- PR #4827 - Update documentation on using HPX::wrap_main
- PR #4826 - Update clang-newest configuration to use clang 10
- PR #4825 - Add Jenkins configuration for rostam
- PR #4825 - Move all CUDA functionality to hpx::cuda::experimental namespace
- PR #4824 - Add support for building master/release branches to Jenkins configuration
- PR #4821 - Implement customization point for hpx::copy and hpx::ranges::copy
- PR #4819 - Allow finding Boost components before finding HPX
- PR #4817 - Adding range version of stable sort
- PR #4815 - Fix a wrong #ifdef for IO/TIMER pools causing build errors
- PR #4814 - Replace hpx::function_nonser with std::function in error module
- PR #4809 - Foreach adapt
- PR #4808 - Make internal algorithms functions const
• PR #4807 - Add Jenkins configuration for running on Piz Daint
• PR #4806 - Update documentation links to new domain name
• PR #4805 - Applying changes that resolve time complexity issues in sort
• PR #4803 - Adding implementation of stable_sort
• PR #4802 - Fix datapar header paths
• PR #4801 - Replace boost::shared_array<T> with std::shared_ptr<T> if supported
• PR #4799 - Fixing #include paths in compatibility headers
• PR #4798 - Include the main module header (fixes partially #4488)
• PR #4797 - Change cmake targets
• PR #4794 - Removing 128bit integer emulation
• PR #4793 - Make sure global variable is handled properly
• PR #4792 - Replace enable_if with HPX_CONCEPT_REQUIRES_ and add is_sentinel_for constraint
• PR #4790 - Move deprecation warnings from base template to template specializations for result_of etc. structs
• PR #4789 - Fix hangs during assertion handling and distributed runtime construction
• PR #4788 - Fixing inclusive transform scan algorithm to properly handle initial value
• PR #4786 - Fixing barrier test
• PR #4784 - Fixing deleter argument bindings in serialize_buffer
• PR #4783 - Add coveralls badge
• PR #4782 - Make header tests parallel again
• PR #4780 - Remove outdated comment about hpx::stop in documentation
• PR #4776 - debug print improvements
• PR #4775 - Checkpoint cleanup
• PR #4771 - Fix compilation with HPX_WITH_NETWORKING=OFF

668 https://github.com/STEllAR-GROUP/hpx/pull/4775
669 https://github.com/STEllAR-GROUP/hpx/pull/4771
• PR #4767 - Remove all force linking leftovers
• PR #4765 - Fix 1d stencil index calculation
• PR #4764 - Force some tests to run serially
• PR #4763 - Update pointees in compatibility headers
• PR #4761 - Fix running and building of execution module tests on CircleCI
• PR #4760 - Storing hpx_options in global property to speed up summary report
• PR #4759 - Reduce memory requirements for our main shared state
• PR #4757 - Fix mimalloc linking on Windows
• PR #4756 - Fix compilation issues
• PR #4755 - Re-adding API functions that were lost during merges
• PR #4754 - Revert “Create coverage reports and upload them to codecov.io”
• PR #4753 - Fixing possible race condition during termination detection
• PR #4750 - Deprecate result_of and friends
• PR #4748 - Create coverage reports and upload them to codecov.io
• PR #4747 - Changing #include for MPI parcelport
• PR #4745 - Add is_sentinel_for trait implementation and test
• PR #4743 - Fix init_globally example after runtime mode changes
• PR #4742 - Update SUPPORT.md
• PR #4741 - Fixing a warning generated for unity builds with msvc
• PR #4740 - Rename local_lcos and basic_execution modules
• PR #4739 - Undeprecate a couple of hpx/modulename.hpp headers
• PR #4738 - Conditionally test schedulers in thread_stacksize_current test
• PR #4734 - Fixing a bunch of codacy warnings
• PR #4733 - Add experimental unity build option to CMake configuration
• PR #4730 - Fixing compilation problems with unordered map
• PR #4729 - Fix APEX build
• PR #4727 - Fix missing runtime includes for distributed runtime
• PR #4726 - Add more API headers
• PR #4725 - Add more compatibility headers for deprecated module headers
• PR #4724 - Fix 4723
• PR #4721 - Attempt to fixing migration tests
• PR #4717 - Make the compatibility headers macro conditional
• PR #4716 - Add hpx/runtime.hpp and hpx/distributed/runtime.hpp API headers
• PR #4714 - Add hpx/future.hpp header
• PR #4713 - Remove hpx/runtime/threads_fwd.hpp and hpx/util_fwd.hpp
• PR #4711 - Make module deprecation warnings overridable
• PR #4710 - Add compatibility headers and other fixes after module header renaming
• PR #4708 - Add termination handler for parallel algorithms
• PR #4707 - Use hp::function_nonser instead of std::function internally
• PR #4706 - Move header file to module
• PR #4705 - Fix incorrect behaviour of cmake-format check
• PR #4704 - Fix resource tests
• PR #4701 - Fix missing includes for future::then specializations
• PR #4700 - Removing obsolete memory component
• PR #4699 - Add short descriptions to modules missing documentation
• PR #4696 - Rename generated modules headers

https://github.com/STEllAR-GROUP/hpx/pull/4696
• PR #4693 - Overhauling thread_mapper for public consumption
• PR #4688 - Fix thread stack size handling
• PR #4687 - Adding all_gather and fixing all_to_all
• PR #4684 - Miscellaneous compilation fixes
• PR #4683 - Fix HPX_WITH_DYNAMIC_HPX_MAIN=OFF
• PR #4682 - Fix compilation of pack_traversal_rebind_container.hpp
• PR #4681 - Add missing hpx/execution.hpp includes for future::then
• PR #4678 - Typeless communicator
• PR #4677 - Forcing registry option to be accepted without checks.
• PR #4676 - Adding scatter_to/scatter_from collective operations
• PR #4673 - Fix PAPI counters compilation
• PR #4671 - Deprecate hpx::promise alias to hpx::lcos::promise
• PR #4670 - Explicitly instantiate get_exception
• PR #4667 - Add stopValue in Sentinel struct instead of Iterator
• PR #4666 - Add release build on Windows to GitHub actions
• PR #4664 - Creating itt_notify module.
• PR #4663 - Mpi fixes
• PR #4659 - Making sure declarations match definitions in register_locks implementation
• PR #4655 - Fixing task annotations for actions
• PR #4653 - Making sure APEX is linked into every application, if needed
• PR #4651 - Update get_function_annotation.hpp
• PR #4646 - Runtime type

PR #4645 - Add a few more API headers
• PR #4644 - Fixing support for mpirun (and similar)
• PR #4643 - Fixing the fix for get_idle_core_count() API
• PR #4638 - Remove HPX_API_EXPORT missed in previous cleanup
• PR #4636 - Adding C++20 barrier
• PR #4635 - Adding C++20 latch API
• PR #4634 - Adding C++20 counting semaphore API
• PR #4633 - Unify execution parameters customization points
• PR #4632 - Adding missing bulk_sync_execute wrapper to example executor
• PR #4631 - Updates to documentation; grammar edits.
• PR #4630 - Updates to documentation; moved hyperlink
• PR #4624 - Export set_self_ptr in thread_data.hpp instead of with forward declarations where used
• PR #4623 - Clean up export macros
• PR #4621 - Trigger an error for older boost versions on power architectures
• PR #4617 - Ignore user-set compatibility header options if the module does not have compatibility headers
• PR #4616 - Fix cmake-format warning
• PR #4615 - Add handler for serializing custom exceptions
• PR #4614 - Fix error message when HPX_IGNORE_CMAKE_BUILD_TYPE_COMPATIBILITY=OFF
• PR #4613 - Make partitioner constructor private
• PR #4611 - Making auto_chunk_size execute the given function using the given executor
• PR #4610 - Making sure the thread-local lock registration data is moving to the core the suspended HPX thread is resumed on
• PR #4609 - Adding an API function that exposes the number of idle cores
• PR #4608 - Fixing moodycamel namespace
• PR #4607 - Moving winsocket initialization to core library

https://github.com/STEllAR-GROUP/hpx/pull/4607
• PR #4606\textsuperscript{762} - Local runtime module etc.
• PR #4604\textsuperscript{763} - Add config_registry module
• PR #4603\textsuperscript{764} - Deal with distributed modules in their respective CMakeLists.txt
• PR #4602\textsuperscript{765} - Small module fixes
• PR #4598\textsuperscript{766} - Making sure current_executor and service_executor functions are linked into the core library
• PR #4597\textsuperscript{767} - Adding broadcast_to/broadcast_from to collectives module
• PR #4596\textsuperscript{768} - Fix performance regression in block_executor
• PR #4595\textsuperscript{769} - Making sure main.cpp is built as a library if HPX\_WITH\_DYNAMIC\_MAIN=OFF
• PR #4592\textsuperscript{770} - Futures module
• PR #4591\textsuperscript{771} - Adapting co\_await support for C++20
• PR #4590\textsuperscript{772} - Adding missing exception test for for\_loop()
• PR #4587\textsuperscript{773} - Move traits headers to hpx/modulename/traits directory
• PR #4586\textsuperscript{774} - Remove Travis CI config
• PR #4585\textsuperscript{775} - Update macOS test blacklist
• PR #4584\textsuperscript{776} - Attempting to fix missing symbols in stack trace
• PR #4583\textsuperscript{777} - Fixing bad static\_cast
• PR #4582\textsuperscript{778} - Changing download url for Windows prerequisites to circumvent bandwidth limitations
• PR #4581\textsuperscript{779} - Adding missing using placeholder::\_X
• PR #4579\textsuperscript{780} - Move get\_stack\_size\_name and related functions
• PR #4575\textsuperscript{781} - Excluding unconditional definition of class backtrace from global header
• PR #4574\textsuperscript{782} - Changing return type of hardware\_concurrency() to unsigned int
• PR #4570\textsuperscript{783} - Move tests to modules
• PR #4564\textsuperscript{784} - Reshuffle internal targets and add HPX::hpX\_no\_wrap\_main target

• PR #4563\textsuperscript{785} - fix CMake option typo
• PR #4562\textsuperscript{786} - Unregister lock earlier to avoid holding it while suspending
• PR #4561\textsuperscript{787} - Adding test macros supporting custom output stream
• PR #4560\textsuperscript{788} - Making sure hash\_any::operator() is linked into core library
• PR #4559\textsuperscript{789} - Fixing compilation if HPX\_WITH\_THREAD\_BACKTRACE\_ON\_SUSPENSION=On
• PR #4557\textsuperscript{790} - Improve spinlock implementation to perform better in high-contention situations
• PR #4553\textsuperscript{791} - Fix a runtime\_ptr problem at shutdown when apex is enabled
• PR #4552\textsuperscript{792} - Add configuration option for making exceptions less noisy
• PR #4551\textsuperscript{793} - Clean up thread creation parameters
• PR #4549\textsuperscript{794} - Test FetchContent build on GitHub actions
• PR #4548\textsuperscript{795} - Fix stack size
• PR #4545\textsuperscript{796} - Fix header tests
• PR #4544\textsuperscript{797} - Fix a typo in sanitizer build
• PR #4541\textsuperscript{798} - Add API to check if a thread pool exists
• PR #4540\textsuperscript{799} - Making sure MPI support is enabled if MPI futures are used but networking is disabled
• PR #4538\textsuperscript{800} - Move channel documentation examples to examples directory

2.10. Releases
• PR #4291 - Add format support for std::tm
• PR #4290 - Simplify compatible tuples check
• PR #4288 - A lightweight take on boost::lexical_cast
• PR #4287 - Forking boost::lexical_cast as a new module
• PR #4277 - MPI_futures
• PR #4270 - Refactor future implementation
• PR #4265 - Threading module
• PR #4259 - Module naming base
• PR #4251 - Local workrequesting scheduler
• PR #4250 - Inline execution of scoped tasks, if possible
• PR #4247 - Add execution in module headers
• PR #4246 - Expose CMake targets officially
• PR #4239 - Doc updates miscellaneous (partially completed during Google Season of Docs)
• PR #4233 - Remove project() from modules + fix CMAKE_SOURCE_DIR issue
• PR #4231 - Module local lcos
• PR #4207 - Command line handling module
• PR #4206 - Runtime configuration module
• PR #4141 - Doc updates examples local to remote (partially completed during Google Season of Docs)
• PR #4091 - Split runtime into local and distributed parts
• PR #4017 - Require C++14
2.10.4 HPX V1.4.1 (Feb 12, 2020)

General changes

This is a bugfix release. It contains the following changes:

- Fix compilation issues on Windows, macOS, FreeBSD, and with gcc 10
- Install missing pdb files on Windows
- Allow running tests using an installed version of HPX
- Skip MPI finalization if HPX has not initialized MPI
- Give a hard error when attempting to use IO counters on Windows

Closed issues

- Issue #4320\(^{966}\) - HPX 1.4.0 does not compile with gcc 10
- Issue #4336\(^{967}\) - Building HPX 1.4.0 with IO Counters breaks (Windows)
- Issue #4334\(^{968}\) - HPX Debug and RelWithDebInfo builds on Windows not installing .pdb files
- Issue #4322\(^{969}\) - Undefine VT1 and VT2 after boost includes

2.10.5 HPX V1.4.0 (January 15, 2020)

General changes

- We have added the collectives `all_to_all` and `all_reduce`.
- We have added APIs for resiliency, which allows replication and replay for failed tasks. See the documentation for more details.
- Components can now be checkpointed.
- Performance improvements to schedulers and coroutines. A significant change is the addition of stackless coroutines. These are to be used for tasks that do not need to be suspended and can reduce overheads noticeably in applications with short tasks. A stackless coroutine can be created with the new stack size `thread_stacksize_nostack`.
- We have added an implementation of `unique_any`, which is a non-copyable version of `any`.
- The `shared_priority_queue_scheduler` has been improved. It now has lower overheads than the default scheduler in many situations. Unlike the default scheduler it fully supports NUMA scheduling hints. Enable it with the command line option `--hpx:queuing=shared-priority`. This scheduler should still be considered experimental, but its use is encouraged in real applications to help us make it production ready.
- We have added the performance counters `background-receive-duration` and `background-receive-overhead` for inspecting the time and overhead spent on receiving parcels in the background.
- Compilation time has been further improved when `HPX_WITH_NETWORKING=OFF`.
- We no longer require compiled Boost dependencies in certain configurations. This requires at least Boost 1.70, compiling on x86 with GCC 9, clang (libc++) 9, or VS2019 in C++17 mode. The dependency on Boost.Filesystem can explicitly be turned on with `HPX_FILESYSTEM_WITH_BOOST_FILESYSTEM_COMPATIBILITY=ON` (it is off by default if the standard library supports `std::filesystem`). Boost.ProgramOptions has been copied into the HPX repository. We have a compatibility layer for users who must explicitly use Boost.ProgramOptions instead of the ProgramOptions provided by HPX. To remove the dependency `HPX_PROGRAM_OPTIONS_WITH_BOOST_PROGRAM_OPTIONS_COMPATIBILITY` must be explicitly set to OFF. This option will be removed in a future release. We have also removed several other header-only dependencies on Boost.
- It is now possible to use the process affinity mask set by tools like `numactl` and various batch environments with the command line option `--hpx:use-process-mask`. Enabling this option implies `--hpx:ignore-batch-env`.
- It is now possible to create standalone thread pools without starting the runtime. See the `standalone_thread_pool_executor.cpp` test in the execution module for an example.
- Tasks annotated with `hpx::util::annotated_function` now have their correct name when using APEX to generate OTF2 files.
- Cloning of APEX was defective in previous releases (it required manual intervention to check out the correct tag or branch). This has been fixed.
- The option `HPX_WITH_MORE_THAN_64_THREADS` is now ignored and will be removed in a future release. The value is instead derived directly from `HPX_WITH_MAX_CPU_COUNT` option.
- We have deprecated compiling in C++11 mode. The next release will require a C++14 capable compiler.
- We have deprecated support for the Vc library. This option will be replaced with SIMD support from the standard library in a future release.
• We have significantly refactored our CMake setup. This is intended to be a non-breaking change and will allow for using HPX through CMake targets in the future.

• We have continued modularizing the HPX library. In the process we have rearranged many header files into module-specific directories. All moved headers have compatibility headers which forward from the old location to the new location, together with a deprecation warning. The compatibility headers will eventually be removed.

• We now enforce formatting with clang-format on the majority of our source files.

• We have added SPDX license tags to all files.

• Many bugfixes.

Breaking changes

• The HPX\_WITH\_THREAD\_COMPATIBILITY option and the associated compatibility layer has been removed.

• The HPX\_WITH\_INCLUSIVE\_SCAN\_COMPATIBILITY option and the associated compatibility layer has been removed.

• The HPX\_WITH\_UNWRAPPED\_COMPATIBILITY option and the associated compatibility layer has been removed.

2.10. Releases

1495
• PR #4160\(^{1130}\) - Using target_link_libraries for cmake versions >= 3.12
• PR #4159\(^{1131}\) - Make sure HPX_WITH_NATIVE_TLS is forwarded to dependent projects
• PR #4158\(^{1132}\) - Adding allocator imported target as a dependency of allocator module
• PR #4157\(^{1133}\) - Add hpx_memory as a dependency of parcelport plugins
• PR #4156\(^{1134}\) - Stackless coroutines now can refer to themselves (through get_self() and friends)
• PR #4154\(^{1135}\) - Added CMake policy CMP0060 for HPX applications.
• PR #4153\(^{1136}\) - add header iomanip to tests and tool
• PR #4152\(^{1137}\) - Casting MPI tag value
• PR #4149\(^{1138}\) - Add back private m_desc member variable in program_options module
• PR #4147\(^{1139}\) - Resource partitioner and threadmanager modules
• PR #4146\(^{1140}\) - Google Season of Docs updates to documentation; creating hpx projects
• PR #4145\(^{1141}\) - Adding basic support for stackless threads
• PR #4143\(^{1142}\) - Exclude test_client_1950 from all target
• PR #4142\(^{1143}\) - Add a new thread_pool_executor
• PR #4140\(^{1144}\) - Google Season of Docs updates to documentation; why hpx
• PR #4139\(^{1145}\) - Remove runtime includes from coroutines module
• PR #4138\(^{1146}\) - Forking boost::intrusive_ptr and adding it as hpx::intrusive_ptr
• PR #4137\(^{1147}\) - Fixing TSS destruction
• PR #4136\(^{1148}\) - HPX.Compute modules
• PR #4133\(^{1149}\) - Fix block_executor
• PR #4131\(^{1150}\) - Applying fixes based on reports from PVS Studio
• PR #4130\(^{1151}\) - Adding missing header to build system
• PR #4129\(^{1152}\) - Fixing compilation if HPX_WITH_DATAPAR_VC is enabled

\(^{1151}\) https://github.com/STEllAR-GROUP/hpx/pull/4130
\(^{1152}\) https://github.com/STEllAR-GROUP/hpx/pull/4129
• PR #4128 - Renaming `moveonly_any` to `unique_any`
• PR #4126 - Attempt to fix `basic_any` constructor for gcc 7
• PR #4125 - Changing `extra_archive_data` implementation
• PR #4124 - Don’t link to Boost.System unless required
• PR #4122 - Add kernel launch helper utility (+saxpy demo) and merge in octotiger changes
• PR #4121 - Fixing migration test if networking is disabled.
• PR #4120 - Google Season of Docs updates to documentation; hpx build system v1
• PR #4119 - Making sure `chunk_size` and `max_chunk` are actually applied to parallel algorithms if specified
• PR #4117 - Make CircleCI formatting check store diff
• PR #4116 - Fix automatically setting C++ standard
• PR #4114 - Module serialization
• PR #4113 - Module datastructures
• PR #4111 - Fixing performance regression introduced earlier
• PR #4110 - Adding missing SPDX tags
• PR #4109 - Overload for start without entry point/argv.
• PR #4108 - Making sure C++ standard is properly detected and propagated
• PR #4106 - use std::round for guaranteed rounding without errors
• PR #4104 - Extend `scheduler_mode` with new `work_stealing` and `task assignment modes`
• PR #4103 - Add this to lambda capture list
• PR #4102 - Add spdx license and check
• PR #4099 - Module coroutines
• PR #4098 - Fix append module path in module CMakeLists template
• PR #4097 - Function tests
• PR #4096 \(^{1176}\) - Removing return of \texttt{thread\_result\_type} from functions not needing them
• PR #4095 \(^{1177}\) - Stop-gap measure until cmake overhaul is in place
• PR #4094 \(^{1178}\) - Deprecate \texttt{HPX\_WITH\_MORE\_THAN\_64\_THREADS}
• PR #4093 \(^{1179}\) - Fix initialization of \texttt{global\_num\_tasks} in \texttt{parallel\_executor}
• PR #4092 \(^{1180}\) - Add support for mi-malloc
• PR #4090 \(^{1181}\) - Execution context
• PR #4089 \(^{1182}\) - Make counters in coroutines optional
• PR #4087 \(^{1183}\) - Making \texttt{hpx::util::any} compatible with C++17
• PR #4084 \(^{1184}\) - Making sure destination array for \texttt{std::transform} is properly resized
• PR #4083 \(^{1185}\) - Adapting \texttt{thread\_queue\_mc} to behave even if no 128bit atomics are available
• PR #4082 \(^{1186}\) - Fix compilation on GCC 5
• PR #4081 \(^{1187}\) - Adding option allowing to force using Boost.FileSystem
• PR #4080 \(^{1188}\) - Updating module dependencies
• PR #4079 \(^{1189}\) - Add missing tests for \texttt{iterator\_support} module
• PR #4078 \(^{1190}\) - Disable parcel-layer if networking is disabled
• PR #4077 \(^{1191}\) - Add missing include that causes build fails
• PR #4076 \(^{1192}\) - Enable compatibility headers for functional module
• PR #4075 \(^{1193}\) - Coroutines module
• PR #4073 \(^{1194}\) - Use \texttt{configure\_file} for generated files in modules
• PR #4071 \(^{1195}\) - Fixing MPI detection for PMIx
• PR #4070 \(^{1196}\) - Fix macOS builds
• PR #4069 \(^{1197}\) - Moving more facilities to the collectives module
• PR #4068 \(^{1198}\) - Adding main HPX \#include directory to modules

\(^{1176}\) https://github.com/STEllAR-GROUP/hpx/pull/4096
\(^{1177}\) https://github.com/STEllAR-GROUP/hpx/pull/4095

\(^{1195}\) https://github.com/STEllAR-GROUP/hpx/pull/4071
\(^{1196}\) https://github.com/STEllAR-GROUP/hpx/pull/4070
\(^{1197}\) https://github.com/STEllAR-GROUP/hpx/pull/4069
\(^{1198}\) https://github.com/STEllAR-GROUP/hpx/pull/4068
• PR #4066 - Switching the use of `message(STATUS "...")` to `hpx_info`
• PR #4065 - Move Boost.Filesystem handling to filesystem module
• PR #4064 - Fix program_options test with older boost versions
• PR #4062 - The `cpu_features` tool fails to compile on anything but x86 architectures
• PR #4061 - Add `clang-format` checking step for modules
• PR #4060 - Making sure `HPX_IDLE_BACKOFF_TIME_MAX` is always defined (even if its unused)
• PR #4059 - Renaming module `hpx_parallel_executors` into `hpx_execution`
• PR #4058 - Do not build networking tests when networking disabled
• PR #4057 - Printing configuration summary for modules as well
• PR #4055 - Google Season of Docs updates to documentation; hpx build systems
• PR #4054 - Add troubleshooting section to manual
• PR #4051 - Add more variations to `future_overhead` test
• PR #4050 - Creating plugin module
• PR #4049 - Move missing modules tests
• PR #4047 - Add boost/filesystem headers to inspect deprecated headers
• PR #4045 - Module functional
• PR #4043 - Fix preconditions and error messages for suspension functions
• PR #4041 - Pass `HPX_STANDARD` on to dependent projects via `HPXConfig.cmake`
• PR #4040 - Program options module
• PR #4039 - Moving non-serializable `any (any_nonser)` to datastructures module
• PR #4038 - Adding MPark’s variant (V1.4.0) to HPX
• PR #4037 - Adding resiliency module
• PR #4036 - Add C++17 filesystem compatibility header

1220 https://github.com/STEllAR-GROUP/hpx/pull/4037
1221 https://github.com/STEllAR-GROUP/hpx/pull/4036
• PR #4035 - Fixing support for mpirun
• PR #4028 - CMake to target based directives
• PR #4027 - Remove GitLab CI configuration
• PR #4026 - Threading refactoring
• PR #4025 - Refactoring thread queue configuration options
• PR #4024 - Fix padding calculation in cache_aligned_data.hpp
• PR #4023 - Fixing Codacy issues
• PR #4022 - Make sure process mask option is passed to affinity_data
• PR #4021 - Warn about compiling in C++11 mode
• PR #4020 - Module concurrency
• PR #4019 - Module topology
• PR #4018 - Update deprecated header in thread_queue_mc.hpp
• PR #4015 - Avoid overwriting artifacts
• PR #4014 - Future overheads
• PR #4013 - Update URL to test output conversion script
• PR #4012 - Fix CUDA compilation
• PR #4011 - Fixing cyclic dependencies between modules
• PR #4010 - Ignore stable tag on CircleCI
• PR #4009 - Check circular dependencies in a circle ci step
• PR #4008 - Extend cache aligned data to handle tuple-like data
• PR #4007 - Fixing migration for components that have actions returning a client
• PR #4006 - Move is_value_proxy.hpp to algorithms module
• PR #4004 - Shorten CTest timeout on CircleCI
• PR #4003 - Refactoring to remove (internal) dependencies
• PR #4001 - Exclude tests from all target
• PR #4000 - Module errors
• PR #3999 - Enable support for compatibility headers for logging module
• PR #3998 - Add process thread binding option
• PR #3997 - Export handle_assert function
• PR #3996 - Attempt to solve issue where -latomic does not support 128bit atomics
• PR #3993 - Make sure __LINE__ is an unsigned
• PR #3991 - Fix dependencies and flags for header tests
• PR #3990 - Documentation tags fixes
• PR #3988 - Adding missing solution folder for format module test
• PR #3987 - Move runtime-dependent functions out of command line handling
• PR #3986 - Fix CMake configuration with PAPI on
• PR #3985 - Module timing
• PR #3984 - Fix default behaviour of paths in add_hpx_component
• PR #3982 - Parallel executors module
• PR #3981 - Segmented algorithms module
• PR #3980 - Module logging
• PR #3979 - Module util
• PR #3978 - Fix clang-tidy step on CircleCI
• PR #3977 - Fixing solution folders for moved components
• PR #3976 - Module format
• PR #3975 - Enable deprecation warnings on CircleCI
• PR #3974 - Fix typos in documentation
• PR #3973 - Fix compilation with GCC 9
• PR #3972 - Add condition to clone apex + use of new cmake var APEX_ROOT
• PR #3971 - Add testing module
• PR #3968 - Remove unneeded file in hardware module
• PR #3967 - Remove leftover PIC settings from main CMakeLists.txt
• PR #3966 - Add missing export option in add_hpx_module
• PR #3965 - Change current_function_helper back to non-constexpr
• PR #3964 - Fixing merge problems
• PR #3962 - Add a trait for std::array for unwrapping
• PR #3961 - Making hpx::util::tuple<Ts...> and std::tuple<Ts...> convertible
• PR #3960 - fix compilation with CUDA 10 and GCC 6
• PR #3959 - Fix C++11 incompatibility
• PR #3957 - Algorithms module
• PR #3956 - [HPX_AddModule] Fix lower name var to upper
• PR #3955 - Fix CMake configuration with examples off and tests on
• PR #3954 - Move components to separate subdirectory in root of repository
• PR #3952 - Update papi.cpp
• PR #3951 - Exclude modules header tests from all target
• PR #3950 - Adding all_reduce facility to collectives module
• PR #3949 - This adds a configuration file that will cause for stale issues to be automatically closed
• PR #3948 - Fixing ALPS environment
• PR #3947 - Add major compiler version check for building hpx as a binary package

1290 https://github.com/STEllAR-GROUP/hpx/pull/3947

Chapter 2. What’s so special about HPX?
- PR #3946 - [Modules] Move the location of the generated headers
- PR #3945 - Simplify tests and examples cmake
- PR #3943 - Remove example module
- PR #3942 - Add NOEXPORT option to add_hpx_{component,library}
- PR #3938 - Use https for CDash submissions
- PR #3937 - Add HPX_WITH_BUILD_BINARY_PACKAGE to the compiler check (refs #3935)
- PR #3936 - Fixing installation of binaries on windows
- PR #3934 - Add set function for sliding_semaphore max_difference
- PR #3933 - Remove cudadevrt from compile/link flags as it breaks downstream projects
- PR #3932 - Fixing 3929
- PR #3931 - Adding all_to_all
- PR #3930 - Add test demonstrating the use of broadcast with component actions
- PR #3928 - fixed number of tasks and number of threads for heterogeneous slurm environments
- PR #3927 - Moving Cache module’s tests into separate solution folder
- PR #3926 - Move unit tests to cache module
- PR #3925 - Move version check to config module
- PR #3924 - Add schedule hint executor parameters
- PR #3923 - Allow aligning objects bigger than the cache line size
- PR #3922 - Add Windows builds with Travis CI
- PR #3921 - Add ccls cache directory to gitignore
- PR #3920 - Fix git_external fetching of tags
- PR #3905 - Correct rostambod url. Fix typo in doc
- PR #3904 - Fix bug in context_base.hpp

https://github.com/STEllAR-GROUP/hpx/pull/3905
https://github.com/STEllAR-GROUP/hpx/pull/3904
• PR #3903 - Adding new performance counters
• PR #3902 - Add `add_hpx_module` function
• PR #3901 - Factoring out container remapping into a separate trait
• PR #3900 - Making sure errors during command line processing are properly reported and will not cause assertions
• PR #3899 - Remove old compatibility bases from `make_action`
• PR #3898 - Make parameter size be of type `size_t`
• PR #3897 - Making sure all tests are disabled if `HPX_WITH_TESTS=OFF`
• PR #3895 - Add documentation for `annotated_function`
• PR #3894 - Working around VS2019 problem with `make_action`
• PR #3892 - Avoid MSVC compatibility warning in internal allocator
• PR #3891 - Removal of the default intel config include
• PR #3888 - Fix `async_customization` dataflow example and Clarify what’s being tested
• PR #3887 - Add Doxygen documentation
• PR #3882 - Minor docs fixes

2.10.6 \textit{HPX} V1.3.0 (May 23, 2019)

**General changes**

- Performance improvements: the schedulers have significantly reduced overheads from removing false sharing and the parallel executor has been updated to create fewer futures.
- \texttt{HPX} now defaults to not turning on networking when running on one locality. This means that you can run multiple instances on the same system without adding command line options.
- Multiple issues reported by Clang sanitizers have been fixed.
- We have added (back) single-page HTML documentation and PDF documentation.
- We have started modularizing the \texttt{HPX} library. This is useful both for developers and users. In the long term users will be able to consume only parts of the \texttt{HPX} libraries if they do not require all the functionality that \texttt{HPX} currently provides.
- We have added an implementation of \texttt{function\_\_ref}.
- The \texttt{barrier} and \texttt{latch} classes have gained a few additional member functions.

\textsuperscript{1337} https://github.com/STEllAR-GROUP/hpx/pull/3869
\textsuperscript{1338} https://github.com/STEllAR-GROUP/hpx/pull/3868
\textsuperscript{1339} https://github.com/STEllAR-GROUP/hpx/pull/3845
\textsuperscript{1340} https://github.com/STEllAR-GROUP/hpx/pull/3839
\textsuperscript{1341} https://github.com/STEllAR-GROUP/hpx/pull/3832
\textsuperscript{1342} https://github.com/STEllAR-GROUP/hpx/pull/3799
\textsuperscript{1343} https://github.com/STEllAR-GROUP/hpx/pull/3701
\textsuperscript{1344} https://github.com/STEllAR-GROUP/hpx/pull/3496
\textsuperscript{1345} https://github.com/STEllAR-GROUP/hpx/pull/3192
\textsuperscript{1346} https://github.com/STEllAR-GROUP/hpx/pull/3159
Breaking changes

- Executable and library targets are now created without the _exe and _lib suffix respectively. For example, the target 1d_stencil_1_exe is now simply called 1d_stencil_1.

- We have removed the following deprecated functionality: queue, scoped_unlock, and support for input iterators in algorithms.

- We have turned off the compatibility layer for unwrapped by default. The functionality will be removed in the next release. The option can still be turned on using the CMake option HPX_WITH_UNWRAPPED_SUPPORT. Likewise, inclusive_scan compatibility overloads have been turned off by default. They can still be turned on with HPX_WITH_INCLUSIVE_SCAN_COMPATIBILITY.

- The minimum compiler and dependency versions have been updated. We now support GCC from version 5 onwards, Clang from version 4 onwards, and Boost from version 1.61.0 onwards.

- The headers for preprocessor macros have moved as a result of the functionality being moved to a separate module. The old headers are deprecated and will be removed in a future version of HPX. You can turn off the warnings by setting HPX_PREPROCESSOR_WITH_DEPRECATION_WARNINGS=OFF or turn off the compatibility headers completely with HPX_PREPROCESSOR_WITH_COMPATIBILITY_HEADERS=OFF.

• PR #3790 - Remove deprecated options for 1.3.0 release
• PR #3789 - Remove Boost filesystem compatibility header
• PR #3788 - Disabled even more spots that should not execute if networking is disabled
• PR #3787 - Bump minimal boost supported version to 1.61.0
• PR #3786 - Bump minimum required versions for 1.3.0 release
• PR #3785 - Explicitly set number of jobs for all ninja invocations on CircleCI
• PR #3784 - Fix leak and address sanitizer problems
• PR #3783 - Disabled even more spots that should not execute if networking is disabled
• PR #3782 - Cherry-picked tuple and thread init data fixes from #3701
• PR #3781 - Fix generic context coroutines after lazy stack allocation changes
• PR #3780 - Rename hello world examples
• PR #3776 - Sort algorithms now use the supplied chunker to determine the required minimal chunk size
• PR #3775 - Disable Boost auto-linking
• PR #3774 - Tag and push stable builds
• PR #3773 - Enable migration of polymorphic components
• PR #3771 - Fix link to stackoverflow in documentation
• PR #3770 - Replacing `constexpr if` in brace-serialization code

- PR #3769\(^{1475}\) - Fix SIGSEGV handler
- PR #3768\(^{1476}\) - Adding flags to scheduler allowing to control thread stealing and idle back-off
- PR #3767\(^{1477}\) - Fix help formatting in hpxrun.py
- PR #3765\(^{1478}\) - Fix a couple of bugs in the thread test
- PR #3764\(^{1479}\) - Workaround for SFINAE regression in msvc14.2
- PR #3762\(^{1480}\) - Prevent MSVC from prematurely instantiating things
- PR #3761\(^{1481}\) - Update python scripts to work with python 3
- PR #3760\(^{1482}\) - Fix callable vtable for GCC4.9
- PR #3759\(^{1483}\) - Rename PAGE_SIZE to PAGE_SIZE__ because AppleClang
- PR #3755\(^{1484}\) - Making sure locks are not held during suspension
- PR #3754\(^{1485}\) - Disable more code if networking is not available/not enabled
- PR #3752\(^{1486}\) - Move util::format implementation to source file
- PR #3751\(^{1487}\) - Fixing problems with lcos::barrier and iostreams
- PR #3750\(^{1488}\) - Change error message to take into account use_guard_page setting
- PR #3749\(^{1489}\) - Fix lifetime problem in run_as_hpx_thread
- PR #3748\(^{1490}\) - Fixed unusable behavior of the clang code analyzer.
- PR #3747\(^{1491}\) - Added PMIX_RANK to the defaults of HPX_WITH_PARCELPORT_MPI_ENV.
- PR #3745\(^{1492}\) - Introduced cache_aligned_data and cache_line_data helper structure
- PR #3742\(^{1493}\) - Remove more unused functionality from util/logging
- PR #3740\(^{1494}\) - Fix includes in partitioned vector tests
- PR #3739\(^{1495}\) - More fixes to make sure that std::flush really flushes all output
- PR #3737\(^{1496}\) - Fix potential shutdown problems
- PR #3736\(^{1497}\) - Fix guided_pool_executor after dataflow changes caused compilation fail

- PR #3734 - Limiting executor
- PR #3732 - More constrained bound constructors
- PR #3730 - Attempt to fix deadlocks during component loading
- PR #3729 - Add latch member function count_up and reset, requested by hpxMP
- PR #3728 - Send even empty buffers on hpx::endl and hpx::flush
- PR #3727 - Adding example demonstrating how to customize the memory management for a component
- PR #3726 - Adding support for passing command line options through the HPX_COMMANDLINE_OPTIONS environment variable
- PR #3725 - Document known broken OpenMPI builds
- PR #3716 - Add barrier reset function, requested by hpxMP for reusing barrier
- PR #3715 - More work on functions and vtables
- PR #3714 - Generate single-page HTML, PDF, manpage from documentation
- PR #3713 - Updating default APEX version to 2.1.2
- PR #3712 - Update release procedure
- PR #3711 - Fix the C++11 build, after #3704
- PR #3709 - Move some component_registry functionality to source file
- PR #3708 - Ignore all locks while handling assertions
- PR #3707 - Remove obsolete hpx runtime executable
- PR #3705 - Fix and simplify make_ready_future overload sets
- PR #3704 - Reduce use of binders
- PR #3703 - Ini
- PR #3702 - Fixing CUDA compiler errors
- PR #3700 - Added barrier::increment function to increase total number of thread
- PR #3697 - One more attempt to fix migration...

2.10. Releases
• PR #3694 - Fixing component migration
• PR #3693 - Print thread state when getting disallowed value in set_thread_state
• PR #3692 - Only disable constexpr with clang-cuda, not nvcc+gcc
• PR #3691 - Link with libsupc++ if needed for thread_local
• PR #3690 - Remove thousands separators in set_operations_3442 to comply with C++11
• PR #3688 - Decouple serialization from function vtables
• PR #3687 - Fix a couple of test failures
• PR #3686 - Make sure tests.unit.build are run after install on CircleCI
• PR #3685 - Revise quickstart CMakeLists.txt explanation
• PR #3684 - Provide concept emulation for Ranges-TS concepts
• PR #3683 - Ignore uninitialized chunks
• PR #3682 - Ignore uninitialized chunks. Check proper indices.
• PR #3681 - Ignore uninitialized chunks. Check proper range indices
• PR #3679 - Simplify basic action implementations
• PR #3678 - Making sure HPX_HAVE_LIBATOMIC is unset before checking
• PR #3677 - Fix generated full version number to be usable in expressions
• PR #3674 - Reduce functional utilities call depth
• PR #3672 - Change new build system to use existing macros related to pseudo dependencies
• PR #3669 - Remove indirection in function_ref when thread description is disabled
• PR #3668 - Unbreaking async_*cb* tests
• PR #3667 - Generate version.hpp
• PR #3665 - Enabling MPI parcelport for gitlab runners
• PR #3664 - Making clang-tidy work properly again

1543 https://github.com/STEllAR-GROUP/hpx/pull/3664
• PR #3662\textsuperscript{1544} - Attempt to fix exception handling
• PR #3661\textsuperscript{1545} - Move lcos::latch to source file
• PR #3660\textsuperscript{1546} - Fix accidentally explicit gid_type default constructor
• PR #3659\textsuperscript{1547} - Parallel executor latch
• PR #3658\textsuperscript{1548} - Fixing execution_parameters
• PR #3657\textsuperscript{1549} - Avoid dangling references in wait_all
• PR #3656\textsuperscript{1550} - Avoiding lifetime problems with sync_put_parcel
• PR #3655\textsuperscript{1551} - Fixing nullptr dereference inside of function
• PR #3652\textsuperscript{1552} - Attempt to fix thread_map_type definition with C++11
• PR #3651\textsuperscript{1553} - Allowing for end iterator being different from begin iterator
• PR #3649\textsuperscript{1554} - Added architecture identification to cmake to be able to detect timestamp support
• PR #3645\textsuperscript{1555} - Enabling sanitizers on gitlab runner
• PR #3644\textsuperscript{1556} - Attempt to tackle timeouts during startup
• PR #3642\textsuperscript{1557} - Cleanup parallel partitioners
• PR #3640\textsuperscript{1558} - Dataflow now works with functions that return a reference
• PR #3637\textsuperscript{1559} - Merging the executor-enabled overloads of shared_future<>::then
• PR #3633\textsuperscript{1560} - Replace deprecated boost endian macros
• PR #3632\textsuperscript{1561} - Add instructions on getting HPX to documentation
• PR #3631\textsuperscript{1562} - Simplify parcel creation
• PR #3630\textsuperscript{1563} - Small additions and fixes to release procedure
• PR #3629\textsuperscript{1564} - Modular pp
• PR #3627\textsuperscript{1565} - Implement util::function_ref
• PR #3626\textsuperscript{1566} - Fix cancelable_action_client example

• PR #3625 - Added automatic serialization for simple structs (see #3034)
• PR #3624 - Updating the default order of priority for thread_description
• PR #3621 - Update copyright year and other small formatting fixes
• PR #3620 - Adding support for gitlab runner
• PR #3619 - Store debug logs and core dumps on CircleCI
• PR #3618 - Various optimizations
• PR #3617 - Fix link to the gpg key (#2)
• PR #3615 - Fix unused variable warnings with networking off
• PR #3614 - Restructuring counter data in scheduler to reduce false sharing
• PR #3613 - Adding support for gitlab runners
• PR #3610 - Don’t wait for stop_condition in main thread
• PR #3609 - Add inline keyword to invalid_thread_id definition for nvcc
• PR #3607 - Adding configuration key that allows one to explicitly add a directory to the component search path
• PR #3606 - Add nvcc to exclude constexpr since is it not supported by nvcc
• PR #3605 - Add inline to definition of checkpoint stream operators to fix link error
• PR #3604 - Use format for string formatting
• PR #3603 - Improve the error message for using to less MAX_CPU_COUNT
• PR #3602 - Improve the error message for to small values of MAX_CPU_COUNT
• PR #3601 - Parallel executor aggregated
• PR #3599 - Making sure networking is disabled for default one-locality-runs
• PR #3596 - Store thread exit functions in forward_list instead of deque to avoid allocations
• PR #3590 - Fix typo/mistake in thread queue cleanup_terminated
• PR #3588 - Fix formatting errors in launching_and_configuring_hpx_applications.rst

- PR #3586\textsuperscript{1590} - Make bind propagate value category
- PR #3585\textsuperscript{1591} - Extend Cmake for building hpx as distribution packages (refs #3575)
- PR #3584\textsuperscript{1592} - Untangle function storage from object pointer
- PR #3582\textsuperscript{1593} - Towards Modularized HPX
- PR #3580\textsuperscript{1594} - Remove extra || in merge.hpp
- PR #3577\textsuperscript{1595} - Partially revert “Remove vtable empty flag”
- PR #3576\textsuperscript{1596} - Make sure empty startup/shutdown functions are not being used
- PR #3574\textsuperscript{1597} - Make sure \texttt{DATAPAR} settings are conveyed to depending projects
- PR #3573\textsuperscript{1598} - Make sure HPX is usable with latest released version of Vc (V1.4.1)
- PR #3572\textsuperscript{1599} - Adding test ensuring ticket 3565 is fixed
- PR #3571\textsuperscript{1600} - Make empty \texttt{[unique_]function vtable non-dependent}
- PR #3566\textsuperscript{1601} - Fix compilation with dynamic bitset for CPU masks
- PR #3563\textsuperscript{1602} - Drop \texttt{util::[unique_]function target_type}
- PR #3562\textsuperscript{1603} - Removing the target suffixes
- PR #3561\textsuperscript{1604} - Replace executor traits return type deduction (keep non-SFINAE)
- PR #3557\textsuperscript{1605} - Replace the last usages of boost::atomic
- PR #3556\textsuperscript{1606} - Replace boost::scoped_array with std::unique_ptr
- PR #3552\textsuperscript{1607} - (Re)move APEX readme
- PR #3548\textsuperscript{1608} - Replace boost::scoped_ptr with std::unique_ptr
- PR #3547\textsuperscript{1609} - Remove last use of Boost.Signals2
- PR #3544\textsuperscript{1610} - Post 1.2.0 version bumps
- PR #3543\textsuperscript{1611} - added Ubuntu dependency list to readme
- PR #3531\textsuperscript{1612} - Warnings, warnings…

2.10.7 HPX V1.2.1 (Feb 19, 2019)

General changes

This is a bugfix release. It contains the following changes:

- Fix compilation on ARM, s390x and 32-bit architectures.
- Fix a critical bug in the future implementation.
- Fix several problems in the CMake configuration which affects external projects.
- Add support for Boost 1.69.0.

Closed issues

- Issue #3638 - Build HPX 1.2 with boost 1.69
- Issue #3635 - Non-deterministic crashing on Stampede2

2.10.8 HPX V1.2.0 (Nov 12, 2018)

General changes

Here are some of the main highlights and changes for this release:

- Thanks to the work of our Google Summer of Code student, Nikunj Gupta, we now have a new implementation of hpx_main.hpp on supported platforms (Linux, BSD and MacOS). This is intended to be a less fragile drop-in replacement for the old implementation relying on preprocessor macros. The new implementation does not require changes if you are using the CMake\(^{1641}\) or pkg-config. The old behaviour can be restored by setting HPX_WITH_DYNAMIC_HPX_MAIN=OFF during CMake\(^{1642}\) configuration. The implementation on Windows is unchanged.

- We have added functionality to allow passing scheduling hints to our schedulers. These will allow us to create executors that for example target a specific NUMA domain or allow for HPX threads to be pinned to a particular worker thread.

- We have significantly improved the performance of our futures implementation by making the shared state atomic.

\(^{1641}\) https://www.cmake.org
\(^{1642}\) https://www.cmake.org
We have replaced Boostbook by Sphinx for our documentation. This means the documentation is easier to navigate with built-in search and table of contents. We have also added a quick start section and restructured the documentation to be easier to follow for new users.

We have added a new option to the --hpx:threads command line option. It is now possible to use cores to tell HPX to only use one worker thread per core, unlike the existing option all which uses one worker thread per processing unit (processing unit can be a hyperthread if hyperthreads are available). The default value of --hpx:threads has also been changed to cores as this leads to better performance in most cases.

All command line options can now be passed alongside configuration options when initializing HPX. This means that some options that were previously only available on the command line can now be set as configuration options.

HPXMP is a portable, scalable, and flexible application programming interface using the OpenMP specification that supports multi-platform shared memory multiprocessing programming in C and C++. HPXMP can be enabled within HPX by setting DHPX_WITH_HPXMP=ON during CMake configuration.

Two new performance counters were added for measuring the time spent doing background work. /threads/time/background-work-duration returns the time spent doing background on a given thread or locality, while /threads/time/background-overhead returns the fraction of time spent doing background work with respect to the overall time spent running the scheduler. The new performance counters are disabled by default and can be turned on by setting HPX_WITH_BACKGROUND_THREAD_COUNTERS=ON during CMake configuration.

The idling behaviour of HPX has been tweaked to allow for faster idling. This is useful in interactive applications where the HPX worker threads may not have work all the time. This behaviour can be tweaked and turned off as before with HPX_WITH_THREAD_MANAGER_IDLE_BACKOFF=OFF during CMake configuration.

It is now possible to register callback functions for HPX worker thread events. Callbacks can be registered for starting and stopping worker threads, and for when errors occur.

Breaking changes

The implementation of hpx_main.hpp has changed. If you are using custom Makefiles you will need to make changes. Please see the documentation on using Makefiles for more details.

The default value of --hpx:threads has changed from all to cores. The new option cores only starts one worker thread per core.

We have dropped support for Boost 1.56 and 1.57. The minimal version of Boost we now test is 1.58.

Our boost::format-based formatting implementation has been revised and replaced with a custom implementation. This changes the formatting syntax and requires changes if you are relying on hpx::util::format or hpx::util::format_to. The pull request for this change contains more information: PR #3266.

The following deprecated options have now been completely removed: HPX_WITH_ASYNC_FUNCTION_COMPATIBILITY, HPX_WITH_LOCAL_DATAFLOW, HPX_WITH_GENERIC_EXECUTION_POLICY, HPX_WITH_BOOST_CHRONO_COMPATIBILITY, HPX_WITH_EXECUTOR_COMPATIBILITY, HPX_WITH_EXECUTION_POLICY_COMPATIBILITY, and HPX_WITH_TRANSFORM_REDUCE_COMPATIBILITY.

Chapter 2. What’s so special about HPX?
• PR #3406\textsuperscript{1783} - Adding thread local allocator and use it for future shared states
• PR #3405\textsuperscript{1784} - Adding DHPX\_HAVE\_THREAD\_LOCAL\_STORAGE=ON to builds
• PR #3404\textsuperscript{1785} - fixing multiple definition of main() in linux
• PR #3402\textsuperscript{1786} - Allow debug option to be enabled only for Linux systems with dynamic main on
• PR #3401\textsuperscript{1787} - Fix cuda_future_helper.h when compiling with C++11
• PR #3400\textsuperscript{1788} - Fix floating point exception scheduler_base idle backoff
• PR #3398\textsuperscript{1789} - Atomic future state
• PR #3397\textsuperscript{1790} - Fixing code for older gcc versions
• PR #3396\textsuperscript{1791} - Allowing to register thread event functions (start/stop/error)
• PR #3394\textsuperscript{1792} - Fix small mistake in primary\_namespace\_server.cpp
• PR #3393\textsuperscript{1793} - Explicitly instantiate configured schedulers
• PR #3392\textsuperscript{1794} - Add performance counters background overhead and background work duration
• PR #3391\textsuperscript{1795} - Adapt integration of HPXMP to latest build system changes
• PR #3390\textsuperscript{1796} - Make AGAS measurements optional
• PR #3389\textsuperscript{1797} - Fix deadlock during shutdown
• PR #3388\textsuperscript{1798} - Add several functionalities allowing to optimize synchronous action invocation
• PR #3387\textsuperscript{1799} - Add cmake option to opt out of fail-compile tests
• PR #3386\textsuperscript{1800} - Adding support for boost::container::small_vector to dataflow
• PR #3385\textsuperscript{1801} - Adds Debug option for hpx initializing from main
• PR #3384\textsuperscript{1802} - This hopefully fixes two tests that occasionally fail
• PR #3383\textsuperscript{1803} - Making sure thread local storage is enable for hpxMP
• PR #3382\textsuperscript{1804} - Fix usage of HPX\_CAPTURE together with default value capture [=]
• PR #3381\textsuperscript{1805} - Replace undefined instantiations of uniform\_int\_distribution

• PR #3228\(^{1900}\) - Allow suspension also on static schedulers
• PR #3163\(^{1901}\) - libfabric parcelport w/o HPX_PARCELPORT_LIBFABRIC_ENDPOINT_RDM
• PR #3036\(^{1902}\) - Switching to CircleCI 2.0

2.10.9 HPX V1.1.0 (Mar 24, 2018)

General changes

Here are some of the main highlights and changes for this release (in no particular order):

• We have changed the way HPX manages the processing units on a node. We do not longer implicitly bind all available cores to a single thread pool. The user has now full control over what processing units are bound to what thread pool, each with a separate scheduler. It is now also possible to create your own scheduler implementation and control what processing units this scheduler should use. We added the `hpx::resource::partitioner` that manages all available processing units and assigns resources to the used thread pools. Thread pools can be now be suspended/resumed independently. This functionality helps in running HPX concurrently to code that is directly relying on OpenMP\(^{1903}\) and/or MPI\(^{1904}\).

• We have continued to implement various parallel algorithms. HPX now almost completely implements all of the parallel algorithms as specified by the C++17 Standard\(^{1905}\). We have also continued to implement these algorithms for the distributed use case (for segmented data structures, such as `hpx::partitioned_vector`).

• Added a compatibility layer for `std::thread`, `std::mutex`, and `std::condition_variable` allowing for the code to use those facilities where available and to fall back to the corresponding Boost facilities otherwise. The CMake\(^{1906}\) configuration option `DHPX_WITH_THREAD_COMPATIBILITY=On` can be used to force using the Boost equivalents.

• The parameter sequence for the `hpx::parallel::transform_inclusive_scan` overload taking one iterator range has changed (again) to match the changes this algorithm has undergone while being moved to C++17. The old overloads can be still enabled at configure time by passing `DHPX_WITH_TRANSFORM_REDUCE_COMPATIBILITY=On` to CMake\(^{1907}\).

• The parameter sequence for the `hpx::parallel::inclusive_scan` overload taking one iterator range has changed to match the changes this algorithm has undergone while being moved to C++17. The old overloads can be still enabled at configure time by passing `DHPX_WITH_INCLUSIVE_SCAN_COMPATIBILITY=On` to CMake.

• Added a helper facility `hpx::local_new` which is equivalent to `hpx::new_` except that it creates components locally only. As a consequence, the used component constructor may accept non-serializable argument types and/or non-const references or pointers.

• Removed the (broken) component type `hpx::lcos::queue<T>`. The old type is still available at configure time by passing `DHPX_WITH_QUEUE_COMPATIBILITY=On` to CMake.

\(^{1904}\) https://en.wikipedia.org/wiki/Message_Passing_Interface
\(^{1905}\) http://www.open-std.org/jtc1/sc22/wg21
\(^{1906}\) https://www.cmake.org
\(^{1907}\) https://www.cmake.org
• The parallel algorithms adopted for C++17 restrict the iterator categories usable with those to at least forward iterators. Our implementation of the parallel algorithms was supporting input iterators (and output iterators) as well by simply falling back to sequential execution. We have now made our implementations conforming by requiring at least forward iterators. In order to enable the old behavior use the compatibility option -DHPX_WITH_ALGORITHM_INPUT_ITERATOR_SUPPORT=On on the CMake\textsuperscript{1908} command line.

• We have added the functionalities allowing for LCOs being implemented using (simple) components. Before LCOs had to always be implemented using managed components.

• User defined components don’t have to be default-constructible anymore. Return types from actions don’t have to be default-constructible anymore either. Our serialization layer now in general supports non-default-constructible types.

• We have added a new launch policy \texttt{hpx::launch::lazy} that allows one to defer the decision on what launch policy to use to the point of execution. This policy is initialized with a function (object) that – when invoked – is expected to produce the desired launch policy.

Breaking changes

• We have dropped support for the gcc compiler version V4.8. The minimal gcc version we now test on is gcc V4.9. The minimally required version of CMake\textsuperscript{1909} is now V3.3.2.

• We have dropped support for the Visual Studio 2013 compiler version. The minimal Visual Studio version we now test on is Visual Studio 2015.5.

• We have dropped support for the Boost V1.51-V1.54. The minimal version of Boost we now test is Boost V1.55.

• We have dropped support for the \texttt{hpx::util::unwrapped} API. \texttt{hpx::util::unwrapped} will stay functional to some degree, until it finally gets removed in a later version of HPX. The functional usage of \texttt{hpx::util::unwrapped} should be changed to the new \texttt{hpx::util::unwrapping} function whereas the immediate usage should be replaced to \texttt{hpx::util::unwrap}.

• The performance counter names referring to properties as exposed by the threading subsystem have changes as those now additionally have to specify the thread-pool. See the corresponding documentation for more details.

• The overloads of \texttt{hpx::async} that invoke an action do not perform implicit unwrapping of the returned future anymore in case the invoked function does return a future in the first place. In this case \texttt{hpx::async} now returns a \texttt{hpx::future\langle future\langle T\rangle\rangle} making its behavior conforming to its local counterpart.

• We have replaced the use of \texttt{boost::exception_ptr} in our APIs with the equivalent \texttt{std::exception_ptr}. Please change your codes accordingly. No compatibility settings are provided.

• We have removed the compatibility settings for \texttt{HPX_WITH_COLOCATED_BACKWARDS_COMPATIBILITY} and \texttt{HPX_WITH_COMPONENT_GET_GID_COMPATIBILITY} as their life-cycle has reached its end.

• We have removed the experimental thread schedulers hierarchy_scheduler, periodic_priority_scheduler and throttling_scheduler in an effort to clean up and consolidate our thread schedulers.

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release.

- PR #3250\(^{1910}\) - Apex refactoring with guids
- PR #3249\(^{1911}\) - Updating People.qbk
- PR #3246\(^{1912}\) - Assorted fixes for CUDA
- PR #3245\(^{1913}\) - Apex refactoring with guids
- PR #3242\(^{1914}\) - Modify task counting in thread_queue.hpp
- PR #3240\(^{1915}\) - Fixed typos
- PR #3238\(^{1916}\) - Readding accidentally removed std::abort
- PR #3237\(^{1917}\) - Adding Pipeline example
- PR #3236\(^{1918}\) - Fixing memory_block
- PR #3233\(^{1919}\) - Make schedule_thread take suspended threads into account
- Issue #3226\(^{1920}\) - memory_block is breaking, signaling SIGSEGV on a thread on creation and freeing
- PR #3225\(^{1921}\) - Applying quick fix for hwloc-2.0
- Issue #3224\(^{1922}\) - HPX counters crashing the application
- PR #3223\(^{1923}\) - Fix returns when setting config entries
- Issue #3222\(^{1924}\) - Errors linking libhpx.so
- Issue #3221\(^{1925}\) - HPX on Mac OS X with HWLoc 2.0.0 fails to run
- PR #3216\(^{1926}\) - Reorder a variadic array to satisfy VS 2017 15.6
- PR #3214\(^{1927}\) - Changed prerequisites.qbk to avoid confusion while building boost
- PR #3213\(^{1928}\) - Relax locks for thread suspension to avoid holding locks when yielding
- PR #3212\(^{1929}\) - Fix check in sequenced_executor test
- PR #3211\(^{1930}\) - Use preinit_array to set argc/argv in init_globally example

• Issue #3182 - bulk_then_execute has unexpected return type/does not compile
• Issue #3181 - hwloc 2.0 breaks topo class and cannot be used
• Issue #3180 - Schedulers that don’t support suspend/resume are unusable
• PR #3179 - Various minor changes to support FLeCSI
• PR #3178 - Fix #3124
• PR #3177 - Removed allgather
• PR #3176 - Fixed Documentation for “using_hpx_pkgconfig”
• PR #3174 - Add hpx::iostreams::ostream overload to format_to
• PR #3172 - Fix lifo queue backend
• PR #3171 - adding the missing unset() function to cpu_mask() for case of more than 64 threads
• PR #3170 - Add cmake flag -DHPX_WITH_FAULT_TOLERANCE=ON (OFF by default)
• PR #3169 - Adapted parallel::{count|count_if} for Ranges TS (see #1668)
• PR #3168 - Changing used namespace for seq execution policy
• Issue #3167 - Update GSoC projects
• Issue #3166 - Application (Octotiger) gets stuck on hpx::finalize when only using one thread
• Issue #3165 - Compilation of parallel algorithms with HPX_WITH_DATAPAR is broken
• PR #3164 - Fixing component migration
• PR #3162 - regex_from_pattern: escape regex special characters to avoid misinterpretation
• Issue #3161 - Building HPX with hwloc 2.0 fails
• PR #3160 - Fixing the handling of quoted command line arguments.
• PR #3158 - Fixing a race with timed suspension (second attempt)
• PR #3157 - Revert “Fixing a race with timed suspension”
• PR #3156 - Fixing serialization of classes with incompatible serialize signature

• PR #3106 - Add cmake test for std::decay_t to fix cuda build
• PR #3105 - Fixing refcount for async traversal frame
• PR #3104 - Local execution of direct actions is now actually performed directly
• PR #3103 - Adding support for generic counter_raw_values performance counter type
• Issue #3102 - Introduce generic performance counter type returning an array of values
• PR #3101 - Revert “Adapting stack overhead limit for gcc 4.9”
• PR #3100 - Fix #3068 (condition_variable deadlock)
• PR #3099 - Fixing lock held during suspension in papi counter component
• PR #3098 - Unbreak broadcast_wait_for_2822 test
• PR #3097 - Adapting stack overhead limit for gcc 4.9
• PR #3096 - fix detection of cxx11_std_atomic
• PR #3095 - Add ciso646 header to get _LIBCPP_VERSION for testing inplace merge
• PR #3094 - Relax atomic operations on performance counter values
• PR #3093 - Short-circuit all_of/any_of/none_of instantiations
• PR #3092 - Take advantage of C++14 lambda capture initialization syntax, where possible
• PR #3091 - Remove more references to Boost from logging code
• PR #3090 - Unify use of yield/yield_k
• PR #3089 - Fix a strange thing in parallel::detail::handle_exception. (Fix #2834.)
• Issue #3088 - A strange thing in parallel::sort.
• PR #3087 - Fixing assertion in default_distribution_policy
• PR #3086 - Implement parallel::remove and parallel::remove_if
• PR #3085 - Addressing breaking changes in Boost V1.66
• PR #3084 - Ignore build warnings round 2

2.10. Releases
• PR #3083 - Fix typo HPX_WITH_MM_PREFECTH
• PR #3081 - Pre-decay template arguments early
• PR #3080 - Suspend thread pool
• PR #3079 - Ignore build warnings
• PR #3078 - Don’t test inplace_merge with libc++
• PR #3076 - Fixing 3075: Part 1
• PR #3074 - Fix more build warnings
• PR #3073 - Suspend thread cleanup
• PR #3072 - Change existing symbol_namespace::iterate to return all data instead of invoking a callback
• PR #3071 - Fixing pack_traversal_async test
• PR #3070 - Fix dynamic_counters_loaded_1508 test by adding dependency to memory_component
• PR #3069 - Fix scheduling loop exit
• Issue #3068 - hpx::lcos::condition_variable could be suspect to deadlocks
• PR #3067 - #ifdef out random_shuffle deprecated in later c++
• PR #3066 - Make coalescing test depend on coalescing library to ensure it gets built
• PR #3065 - Workaround for minimal_timed_async_executor_test compilation failures, attempts to copy a deferred call (in unevaluated context)
• PR #3064 - Fixing wrong condition in wrapper_heap
• PR #3062 - Fix exception handling for execution::seq
• PR #3061 - Adapt MSVC C++ mode handling to VS15.5
• PR #3060 - Fix compiler problem in MSVC release mode
• PR #3059 - Fixing #2931
• Issue #3058 - minimal_timed_async_executor_test_exe fails to compile on master (d6f505c)
• PR #3057 - Fix stable_merge_2964 compilation problems

2068 https://github.com/STEllAR-GROUP/hpx/pull/3057
- PR #3056 - Fix some build warnings caused by unused variables/unnecessary tests
- PR #3055 - Update documentation for running tests
- Issue #3054 - Assertion failure when using bulk hpx::new_ in asynchronous mode
- PR #3052 - Do not bind test running to cmake test build rule
- PR #3051 - Fix HPX-Qt interaction in Qt example.
- Issue #3048 - nqueen example fails occasionally
- PR #3047 - Fixing #3044
- PR #3046 - Add OS thread suspension
- PR #3042 - PyCicle - first attempt at a build toold for checking PR’s
- PR #3041 - Fix a problem about asynchronous execution of parallel::merge and parallel::partition.
- PR #3040 - Fix a mistake about exception handling in asynchronous execution of scan_partitioner.
- PR #3039 - Consistently use executors to schedule work
- PR #3038 - Fixing local direct function execution and lambda actions perfect forwarding
- PR #3035 - Make parallel unit test names match build target/folder names
- PR #3033 - Fix setting of default build type
- Issue #3032 - Fix partitioner arg copy found in #2982
- Issue #3031 - Errors linking libhpx.so due to missing references (master branch, commit 6679a8882)
- PR #3030 - Revert “implement executor then interface with && forwarding reference”
- PR #3029 - Run CI inspect checks before building
- PR #3028 - Added range version of parallel::move
- Issue #3027 - Implement all scheduling APIs in terms of executors
- PR #3026 - implement executor then interface with && forwarding reference
- PR #3025 - Fix typo uninitialized to uninitialized

• PR #3024 - Inspect fixes
• PR #3023 - P0356 Simplified partial function application
• PR #3022 - Master fixes
• PR #3021 - Segfault fix
• PR #3020 - Disable command-line aliasing for applications that use user_main
• PR #3019 - Adding enable_elasticity option to pool configuration
• PR #3018 - Fix stack overflow detection configuration in header files
• PR #3017 - Speed up local action execution
• PR #3016 - Unify stack-overflow detection options, remove reference to libsigsegv
• PR #3015 - Speeding up accessing the resource partitioner and the topology info
• Issue #3014 - HPX does not compile on POWER8 with gcc 5.4
• Issue #3013 - hello_world occasionally prints multiple lines from a single OS-thread
• PR #3012 - Silence warning about casting away qualifiers in itt_notify.hpp
• PR #3011 - Fix cpuset leak in hwloc_topology_info.cpp
• PR #3010 - Remove useless decay_copy
• PR #3009 - Fixing 2996
• PR #3008 - Remove unused internal function
• PR #3007 - Fixing wrapper_heap alignment problems
• Issue #3006 - hwloc memory leak
• PR #3004 - Silence C4251 (needs to have dll-interface) for future_data_void
• Issue #3003 - Suspension of runtime
• PR #3001 - Attempting to avoid data races in async_traversal while evaluating dataflow()
• PR #3000 - Adding hpx::util::optional as a first step to replace experimental::optional
• PR #2998 - Cleanup up and Fixing component creation and deletion
• Issue #2996 - Build fails with HPX_WITH_HWLOC=OFF
• PR #2995 - Push more future_data functionality to source file
• PR #2994 - WIP: Fix throttle test
• PR #2993 - Making sure –hpx:help does not throw for required (but missing) arguments
• PR #2992 - Adding non-blocking (on destruction) service executors
• Issue #2991 - run_as_os_thread locks up
• Issue #2990 - --help will not work until all required options are provided
• PR #2989 - Improve error messages caused by misuse of dataflow
• PR #2988 - Improve error messages caused by misuse of .then
• Issue #2987 - stack overflow detection producing false positives
• PR #2986 - Deduplicate non-dependent thread_info logging types
• PR #2985 - Adapted parallel::{all_of|any_of|none_of} for Ranges TS (see #1668)
• PR #2984 - Refactor one_size_heap code to simplify code
• PR #2983 - Fixing local_new_component
• PR #2982 - Clang tidy
• PR #2981 - Simplify allocator rebinding in pack traversal
• PR #2979 - Fixing integer overflows
• PR #2978 - Implement parallel::inplace_merge
• Issue #2977 - Make hwloc compulsory instead of optional
• PR #2976 - Making sure client_base instance that registered the component does not unregister it when being destructed
• PR #2975 - Change version of pulled APEX to master
• PR #2974 - Fix domain not being freed at the end of scheduling loop

2.10. Releases
• PR #2973 - Fix small typos
• PR #2972 - Adding uintstd.h header
• PR #2971 - Fall back to creating local components using local_new
• PR #2970 - Improve is_tuple_like trait
• PR #2960 - Fix HPX_WITH_MORE_THAN_64_THREADS default value
• PR #2968 - Cleaning up dataflow overload set
• PR #2967 - Make parallel::merge is stable. (Fix #2964.)
• PR #2966 - Fixing a couple of held locks during exception handling
• PR #2965 - Adding missing include
• Issue #2964 - parallel merge is not stable
• PR #2962 - Making sure any function object passed to dataflow is released after being invoked
• PR #2961 - Partially reverting #2891
• PR #2960 - Attempt to fix the gcc 4.9 problem with the async pack traversal
• Issue #2959 - Program terminates during error handling
• Issue #2958 - HPX_PLAIN_ACTION breaks due to missing include
• PR #2957 - Fixing errors generated by mixing different attribute syntaxes
• Issue #2956 - Mixing attribute syntaxes leads to compiler errors
• Issue #2955 - Fix OS-Thread throttling
• PR #2953 - Making sure any hpx.os_threads=N supplied through a –hpx::config file is taken into account
• PR #2952 - Removing wrong call to cleanup_terminated_locked
• PR #2951 - Revert “Make sure the function vtables are initialized before use”
• PR #2950 - Fix a namespace compilation error when some schedulers are disabled
• Issue #2949 - master branch giving lockups on shutdown

2.10. Releases
• Issue #2822\textsuperscript{2275} - Yet another issue with wait\_for similar to #2796
• PR #2821\textsuperscript{2276} - Fix bugs and improve that about HPX\_HAVE\_CXX11\_AUTO\_RETURN\_VALUE of CMake
• PR #2820\textsuperscript{2277} - Support C++11 in benchmark codes of parallel::partition and parallel::partition\_copy
• PR #2819\textsuperscript{2278} - Fix compile errors in unit test of container version of parallel::partition
• Issue #2818\textsuperscript{2279} - A strange thing in parallel::util::detail::handle\_local\_exceptions
• Issue #2815\textsuperscript{2280} - HPX fails to compile with HPX\_WITH\_CUDA=ON and the new CUDA 9.0 RC
• Issue #2814\textsuperscript{2281} - Using ‘\texttt{gmakeN}’ after ‘\texttt{cmake}’ produces error in src/CMakeFiles/hpx.dir/runtime/agas/addressing\_service.cpp.o
• PR #2813\textsuperscript{2282} - Properly support \texttt{[[noreturn]]} attribute if available
• Issue #2812\textsuperscript{2283} - Compilation fails with gcc 7.1.1
• PR #2811\textsuperscript{2284} - Adding hpx::launch::lazy and support for async, dataflow, and future::then
• PR #2810\textsuperscript{2285} - Add option allowing to disable deprecation warning
• PR #2809\textsuperscript{2286} - Disable throttling scheduler if HWLOC is not found/used
• PR #2808\textsuperscript{2287} - Fix compile errors on some environments of parallel::partition
• Issue #2807\textsuperscript{2288} - Difficulty building with \texttt{HPX\_WITH\_HWLOC=Off}
• PR #2806\textsuperscript{2289} - Partitioned vector
• PR #2805\textsuperscript{2290} - Serializing collections with non-default constructible data
• PR #2802\textsuperscript{2291} - Fix FreeBSD 11
• Issue #2801\textsuperscript{2292} - Rate limiting techniques in io\_service
• Issue #2800\textsuperscript{2293} - New Launch Policy: async\_if
• PR #2799\textsuperscript{2294} - Fix a unit test failure on GCC in tuple\_cat
• PR #2798\textsuperscript{2295} - bump minimum required cmake to 3.0 in test
• PR #2797\textsuperscript{2296} - Making sure future::wait\_for et.al. work properly for action results
• Issue #2796\textsuperscript{2297} - wait\_for does always in “deferred” state for calls on remote localities

\textsuperscript{2297} https://github.com/STEllAR-GROUP/hpx/issues/2796
• Issue #2795 - Serialization of types without default constructor
• PR #2794 - Fixing test for partitioned_vector iteration
• PR #2792 - Implemented segmented find and its variations for partitioned vector
• PR #2791 - Circumvent scary warning about placement new
• PR #2790 - Fix OSX build
• PR #2789 - Resource partitioner
• PR #2788 - Adapt parallel::is_heap and parallel::is_heap_until to Ranges TS
• PR #2787 - Unwrap hotfixes
• PR #2786 - Update CMake Minimum Version to 3.3.2 (refs #2565)
• Issue #2785 - Issues with masks and cpuset
• PR #2784 - Error with reduce and transform reduce fixed
• PR #2783 - StackOverflow integration with libsigsegv
• PR #2782 - Replace boost::atomic with std::atomic (where possible)
• PR #2781 - Check for and optionally use [[deprecated]] attribute
• PR #2780 - Adding empty (but non-trivial) destructor to circumvent warnings
• PR #2779 - Exception info tweaks
• PR #2778 - Implement parallel::partition
• PR #2777 - Improve error handling in gather_here/gather_there
• PR #2776 - Fix a bug in compiler version check
• PR #2775 - Fix compilation when HPX_WITH_LOGGING is OFF
• PR #2774 - Removing dependency on Boost.Date_Time
• PR #2773 - Add sync_images() method to spmd_block class
• PR #2772 - Adding documentation for PAPI counters

2.10. Releases
• PR #2771 - Removing boost preprocessor dependency
• PR #2770 - Adding test, fixing deadlock in config registry
• PR #2769 - Remove some other warnings and errors detected by clang 5.0
• Issue #2768 - Is there iterator tag for HPX?
• PR #2767 - Improvements to continuation annotation
• PR #2765 - gcc split stack support for HPX threads #620
• PR #2764 - Fix some uses of begin/end, remove unnecessary includes
• PR #2763 - Bump minimal Boost version to 1.55.0
• PR #2762 - hpx::partitioned_vector serializer
• PR #2761 - Adding configuration summary to cmake output and –hpx:info
• PR #2760 - Removing 1d_hydro example as it is broken
• PR #2758 - Remove various warnings detected by clang 5.0
• Issue #2757 - In case of a “raw thread” is needed per core for implementing parallel algorithm, what is good practice in HPX?
• PR #2756 - Allowing for LCOs to be simple components
• PR #2755 - Removing make_index_pack_unrolled
• PR #2754 - Implement parallel::unique_copy
• PR #2753 - Fixing detection of [[fallthrough]] attribute
• PR #2752 - New thread priority names
• PR #2751 - Replace boost::exception with proposed exception_info
• PR #2750 - Replace boost::iterator_range
• PR #2749 - Fixing hdf5 examples
• Issue #2748 - HPX fails to build with enabled hdf5 examples
• Issue #2747 - Inherited task priorities break certain DAG optimizations

2342 https://github.com/STEllAR-GROUP/hpx/issues/2748
2343 https://github.com/STEllAR-GROUP/hpx/issues/2747
• Issue #2746 - HPX segfaulting with valgrind
• PR #2745 - Adding extended arithmetic performance counters
• PR #2744 - Adding ability to statistics counters to reset base counter
• Issue #2743 - Statistics counter does not support resetting
• PR #2742 - Making sure Vc V2 builds without additional HPX configuration flags
• PR #2741 - Deprecate unwrapped and implement unwrap and unwrapping
• PR #2740 - Coroutine stackoverflow detection for linux/posix; Issue #2408
• PR #2739 - Add files via upload
• PR #2738 - Appveyor support
• PR #2737 - Fixing 2735
• Issue #2736 - 1d_hydro example doesn’t work
• Issue #2735 - partitioned_vector_subview test failing
• PR #2734 - Add C++11 range utilities
• PR #2733 - Adapting iterator requirements for parallel algorithms
• PR #2732 - Integrate C++ Co-arrays
• PR #2731 - Adding on_migrated event handler to migratable component instances
• Issue #2729 - Add on_migrated() event handler to migratable components
• Issue #2728 - Why Projection is needed in parallel algorithms?
• PR #2727 - Cmake files for StackOverflow Detection
• PR #2726 - CMake for Stack Overflow Detection
• PR #2725 - Implemented segmented algorithms for partitioned vector
• PR #2724 - Fix examples in Action documentation
• PR #2723 - Enable lcos::channel<T>::register_as

https://github.com/STEllAR-GROUP/hpx/pull/2724
https://github.com/STEllAR-GROUP/hpx/pull/2723
- Issue #2722\textsuperscript{2367} - channel register\_as() failing on compilation
- PR #2721\textsuperscript{2368} - Mind map
- PR #2720\textsuperscript{2369} - reorder forward declarations to get rid of C++14-only auto return types
- PR #2719\textsuperscript{2370} - Add documentation for partitioned\_vector and add features in pack.hpp
- Issue #2718\textsuperscript{2371} - Some forward declarations in execution\_fwd.hpp aren’t C++11-compatible
- PR #2717\textsuperscript{2372} - Config support for fallback attribute
- PR #2716\textsuperscript{2373} - Implement parallel:\:partition\_copy
- PR #2715\textsuperscript{2374} - initial import of icu string serializer
- PR #2714\textsuperscript{2375} - initial import of valarray serializer
- PR #2713\textsuperscript{2376} - Remove slashes before CMAKE\_FILES\_DIRECTORY variables
- PR #2712\textsuperscript{2377} - Fixing wait for 1751
- PR #2711\textsuperscript{2378} - Adjust code for minimal supported GCC having being bumped to 4.9
- PR #2710\textsuperscript{2379} - Adding code of conduct
- PR #2709\textsuperscript{2380} - Fixing UB in destroy tests
- PR #2708\textsuperscript{2381} - Add inline to prevent multiple definition issue
- Issue #2707\textsuperscript{2382} - Multiple defined symbols for task\_block.hpp in VS2015
- PR #2706\textsuperscript{2383} - Adding .clang-format file
- PR #2704\textsuperscript{2384} - Add a synchronous mapping API
- Issue #2703\textsuperscript{2385} - Request: Add the .clang-format file to the repository
- Issue #2702\textsuperscript{2386} - STEllAR-GROUP/Vc slower than VCv1 possibly due to wrong instructions generated
- Issue #2701\textsuperscript{2387} - Datapar with STEllAR-GROUP/Vc requires obscure flag
- Issue #2700\textsuperscript{2388} - Naming inconsistency in parallel algorithms
- Issue #2699\textsuperscript{2389} - Iterator requirements are different from standard in parallel copy\_if.

\textsuperscript{2389} https://github.com/STEllAR-GROUP/hpx/issues/2699
• PR #2698 - Properly releasing parcelport write handlers
• Issue #2697 - Compile error in addressing_service.cpp
• Issue #2696 - Building and using HPX statically: undefined references from runtime_support_server.cpp
• Issue #2695 - Executor changes cause compilation failures
• PR #2694 - Refining C++ language mode detection for MSVC
• PR #2693 - P0443 r2
• PR #2692 - Partially reverting changes to parcel_wait
• Issue #2689 - HPX build fails when HPX_WITH_CUDA is enabled
• PR #2688 - Make Cuda Clang builds pass
• PR #2687 - Add an is_tuple_like trait for sequenceable type detection
• PR #2686 - Allowing throttling scheduler to be used without idle backoff
• PR #2685 - Add support of std::array to hpx::util::tuple_size and tuple_element
• PR #2684 - Adding new statistics performance counters
• PR #2683 - Replace boost::exception_ptr with std::exception_ptr
• Issue #2682 - HPX does not compile with HPX_WITH_THREAD_MANAGER_IDLE_BACKOFF=OFF
• PR #2681 - Attempt to fix problem in managed_component_base
• PR #2680 - Fix bad size during archive creation
• Issue #2679 - Mismatch between size of archive and container
• Issue #2678 - In parallel algorithm, other tasks are executed to the end even if an exception occurs in any task.
• PR #2677 - Adding include check for std::addressof
• PR #2676 - Adding parallel::destroy and destroy_n
• PR #2675 - Making sure statistics counters work as expected
• PR #2674 - Turning assertions into exceptions

2.10. Releases
• PR #2673 - Inhibit direct conversion from future<future<T>> -> future<void>
• PR #2672 - C++17 invoke forms
• PR #2671 - Adding uninitialized_value_construct and uninitialized_value_construct_n
• PR #2670 - Integrate spmd multidimensional views for partitioned_vectors
• PR #2669 - Adding uninitialized_default_construct and uninitialized_default_construct_n
• PR #2668 - Fixing documentation index
• Issue #2667 - Ambiguity of nested hpx::future<void>'s
• Issue #2666 - Statistics Performance counter is not working
• PR #2664 - Adding uninitialized_move and uninitialized_move_n
• Issue #2663 - Seg fault in managed_component::get_base_gid, possibly cause by util::reinitializable_static
• Issue #2662 - Crash in managed_component::get_base_gid due to problem with util::reinitializable_static
• PR #2661 - Hide the detail namespace in doxygen per default
• PR #2660 - Add documentation to hpx::util::unwrapped and hpx::util::unwrapped2
• PR #2659 - Improve integration with vcpkg
• PR #2658 - Unify access_data trait for use in both, serialization and de-serialization
• PR #2657 - Removing hpx::lcos::queue<T>
• PR #2656 - Reduce MAX_TERMINATED_THREADS default, improve memory use on manycore cpus
• PR #2655 - Maintenance for emulate-deleted macros
• PR #2654 - Implement parallel is_heap and is_heap_until
• PR #2653 - Drop support for VS2013
• PR #2652 - This patch makes sure that all parcels in a batch are properly handled
• PR #2649 - Update docs (Table 18) - move transform to end
• Issue #2647 - hpx::parcelset::detail::parcel_data::has_continuation_is uninitialized

Chapter 2. What’s so special about HPX?
• Issue #2644<sup>2436</sup> - Some .vcxproj in the HPX.sln fail to build
• Issue #2641<sup>2437</sup> - hpx::lcos::queue should be deprecated
• PR #2640<sup>2438</sup> - A new throttling policy with public APIs to suspend/resume
• PR #2639<sup>2439</sup> - Fix a tiny typo in tutorial.
• Issue #2638<sup>2440</sup> - Invalid return type ‘void’ of constexpr function
• PR #2636<sup>2441</sup> - Add and use HPX_MSVC_WARNING_PRAGMA for #pragma warning
• PR #2633<sup>2442</sup> - Distributed define_spmd_block
• PR #2632<sup>2443</sup> - Making sure container serialization uses size-compatible types
• PR #2631<sup>2444</sup> - Add lcos::local::one_element_channel
• PR #2629<sup>2445</sup> - Move unordered_map out of parcelport into hpx/concurrent
• PR #2628<sup>2446</sup> - Making sure that shutdown does not hang
• PR #2627<sup>2447</sup> - Fix serialization
• PR #2626<sup>2448</sup> - Generate cmake_variables.qbk and cmake_toolchains.qbk outside of the source tree
• PR #2625<sup>2449</sup> - Supporting -std=cpp+17 flag
• PR #2624<sup>2450</sup> - Fixing a small cmake typo
• PR #2623<sup>2451</sup> - Update CMake minimum required version to 3.0.2 (closes #2621)
• Issue #2621<sup>2452</sup> - Compiling hpx master fails with /usr/bin/ld: final link failed: Bad value
• PR #2620<sup>2453</sup> - Remove warnings due to some captured variables
• PR #2619<sup>2454</sup> - LF multiple parcels
• PR #2618<sup>2455</sup> - Some fixes to libfabric that didn’t get caught before the merge
• PR #2617<sup>2456</sup> - Adding hpx::local_new
• PR #2616<sup>2457</sup> - Documentation: Extract all entities in order to autolink functions correctly
• Issue #2615<sup>2458</sup> - Documentation: Linking functions is broken

2.10. Releases

1557
• PR #2614[^2459] - Adding serialization for std::deque
• PR #2613[^2460] - We need to link with boost.thread and boost.chrono if we use boost.context
• PR #2612[^2461] - Making sure for_loop_n(par, . . . ) is actually executed in parallel
• PR #2611[^2462] - Add documentation to invoke_fused and friends NFC
• PR #2610[^2463] - Added reduction templates using an identity value
• PR #2608[^2464] - Fixing some unused vars in inspect
• PR #2607[^2465] - Fixed build for mingw
• PR #2606[^2466] - Supporting generic context for boost >= 1.61
• PR #2605[^2467] - Parcelport libfabric3
• PR #2604[^2468] - Adding allocator support to promise and friends
• PR #2603[^2469] - Barrier hang
• PR #2602[^2470] - Changes to scheduler to steal from one high-priority queue
• Issue #2601[^2471] - High priority tasks are not executed first
• PR #2600[^2472] -Compat fixes
• PR #2599[^2473] - Compatibility layer for threading support
• PR #2598[^2474] - V1.1
• PR #2597[^2475] - Release V1.0
• PR #2596[^2476] - First attempt to introduce spmd_block in hpx
• PR #2586[^2477] -local_segment in segmented_iterator_traits
• Issue #2584[^2478] - Add allocator support to promise, packaged_task and friends
• PR #2576[^2479] - Add missing dependencies of cuda based tests
• PR #2575[^2480] - Remove warnings due to some captured variables
• Issue #2574[^2481] - MSVC 2015 Compiler crash when building HPX

• Issue #2568 - Remove throttle_scheduler as it has been abandoned
• Issue #2566 - Add an inline versioning namespace before 1.0 release
• Issue #2565 - Raise minimal cmake version requirement
• PR #2556 - Fixing scan partitioner
• PR #2546 - Broadcast async
• Issue #2543 - make install fails due to a non-existing .so file
• PR #2495 - wait_or_add_new returning thread_id_type
• Issue #2480 - Unable to register new performance counter
• Issue #2471 - no type named 'fcontext_t' in namespace
• Issue #2456 - Re-implement hpx::util::unwrapped
• Issue #2455 - Add more arithmetic performance counters
• PR #2454 - Fix a couple of warnings and compiler errors
• PR #2453 - Timed executor support
• PR #2447 - Implementing new executor API (P0443)
• Issue #2439 - Implement executor proposal
• Issue #2408 - Stack overflow detection for linux, e.g. based on libsigsegv
• PR #2377 - Add a customization point for put_parcel so we can override actions
• Issue #2368 - HPX_ASSERT problem
• Issue #2324 - Change default number of threads used to the maximum of the system
• Issue #2266 - hpx_0.9.99 make tests fail
• PR #2195 - Support for code completion in VIM
• Issue #2137 - Hpx does not compile over osx
• Issue #2092 - make tests should just build the tests

• Issue #2026\[2505\] - Build HPX with Apple’s clang
• Issue #1932\[2506\] - hpx with PBS fails on multiple localities
• PR #1914\[2507\] - Parallel heap algorithm implementations WIP
• Issue #1598\[2508\] - Disconnecting a locality results in segfault using heartbeat example
• Issue #1404\[2509\] - unwrapped doesn’t work with movable only types
• Issue #1400\[2510\] - hpx::util::unwrapped doesn’t work with non-future types
• Issue #1205\[2511\] - TSS is broken
• Issue #1126\[2512\] - vector<future<T>> does not work gracefully with dataflow, when_all and unwrapped
• Issue #1056\[2513\] - Thread manager cleanup
• Issue #863\[2514\] - Futures should not require a default constructor
• Issue #856\[2515\] - Allow runtimemode_connect to be used with security enabled
• Issue #726\[2516\] - Valgrind
• Issue #701\[2517\] - Add RCR performance counter component
• Issue #528\[2518\] - Add support for known failures and warning count/comparisons to hpx_run_tests.py

2.10.10 HPX V1.0.0 (Apr 24, 2017)

General changes

Here are some of the main highlights and changes for this release (in no particular order):

• Added the facility hpx::split_future which allows one to convert a future<tuple<Ts...>> into a tuple<future<Ts>...>. This functionality is not available when compiling HPX with VS2012.

• Added a new type of performance counter which allows one to return a list of values for each invocation. We also added a first counter of this type which collects a histogram of the times between parcels being created.

• Added new LCOs: hpx::lcos::channel and hpx::lcos::local::channel which are very similar to the well known channel constructs used in the Go language.

• Added new performance counters reporting the amount of data handled by the networking layer on a action-by-action basis (please see PR #2289\[2519\] for more details).

• Added a new facility hpx::lcos::barrier, replacing the equally named older one. The new facility has a slightly changed API and is much more efficient. Most notable, the new facility exposes a (global) function hpx::lcos::synchronize() which represents a global barrier across all localities.
• We have started to add support for vectorization to our parallel algorithm implementations. This support depends on using an external library, currently either Vc Library or boost_simdl. Please see Issue #2333 for a list of currently supported algorithms. This is an experimental feature and its implementation and/or API might change in the future. Please see this blog-post for more information.

• The parameter sequence for the hpx::parallel::transform_reduce overload taking one iterator range has changed to match the changes this algorithm has undergone while being moved to C++17. The old overload can be still enabled at configure time by specifying DHPX_WITH_TRANSFORM_REDUCE_COMPATIBILITY=On to CMake.

• The algorithm hpx::parallel::inner_product has been renamed to hpx::parallel::transform_reduce to match the changes this algorithm has undergone while being moved to C++17. The old inner_product names can be still enabled at configure time by specifying DHPX_WITH_TRANSFORM_REDUCE_COMPATIBILITY=On to CMake.

• Added versions of hpx::get_ptr taking client side representations for component instances as their parameter (instead of a global id).

• Added the helper utility hpx::performance_counters::performance_counter_set helping to encapsulate a set of performance counters to be managed concurrently.

• All execution policies and related classes have been renamed to be consistent with the naming changes applied for C++17. All policies now live in the namespace hpx::parallel::execution. The old names can be still enabled at configure time by specifying DHPX_WITH_EXECUTION_POLICY_COMPATIBILITY=On to CMake.

• The thread scheduling subsystem has undergone a major refactoring which results in significant performance improvements. We have also improved the performance of creating hpx::future and of various facilities handling those.

• We have consolidated all of the code in HPX.Compute related to the integration of CUDA. hpx::partitioned_vector has been enabled to be usable with hpx::compute::vector which allows one to place the partitions on one or more GPU devices.

• Added new performance counters exposing various internals of the thread scheduling subsystem, such as the current idle- and busy-loop counters and instantaneous scheduler utilization.

• Extended and improved the use of the ITTNotify hooks allowing to collect performance counter data and function annotation information from within the Intel Amplifier tool.

**Breaking changes**

• We have dropped support for the gcc compiler versions V4.6 and 4.7. The minimal gcc version we now test on is gcc V4.8.

• We have removed (default) support for boost::chrono in interfaces, uses of it have been replaced with std::chrono. This facility can be still enabled at configure time by specifying DHPX_WITH_BOOST_CHRONO_COMPATIBILITY=On to CMake.

• The parameter sequence for the hpx::parallel::transform_reduce overload taking one iterator range has changed to match the changes this algorithm has undergone while being moved to C++17.

• The algorithm hpx::parallel::inner_product has been renamed to hpx::parallel::transform_reduce to match the changes this algorithm has undergone while being moved to C++17.

2520 https://github.com/STEllAR-GROUP/hpx/issues/2333
• the build options `HPX_WITH_COLOCATED_BACKWARDS_COMPATIBILITY` and `HPX_WITH_COMPONENT_GET_GID_COMPATIBILITY` are now disabled by default. Please change your code still depending on the deprecated interfaces.

**Bug fixes (closed tickets)**

Here is a list of the important tickets we closed for this release.

- **PR #2596**: Adding apex data
- **PR #2595**: Remove obsolete file
- **Issue #2594**: `FindOpenCL.cmake` mismatch with the official cmake module
- **PR #2592**: First attempt to introduce `spmd_block` in `hpx`
- **Issue #2591**: Feature request: continuation (then) which does not require the callable object to take a `future<R>` as parameter
- **PR #2588**: Daint fixes
- **PR #2587**: Fixing transfer (continuation) action::schedule
- **PR #2585**: Work around MSVC having an ICE when compiling with `-Ob2`
- **PR #2583**: changing 7zip command to 7za in `roll_release.sh`
- **PR #2582**: First attempt to introduce `spmd_block` in `hpx`
- **PR #2581**: Enable annotated function for parallel algorithms
- **PR #2580**: First attempt to introduce `spmd_block` in `hpx`
- **PR #2579**: Make thread NICE level setting an option
- **PR #2578**: Implementing `enqueue` instead of busy wait when no sender is available
- **PR #2577**: Retrieve `-std=c++11` consistent `nvcc` flag
- **PR #2576**: Add missing dependencies of cuda based tests
- **PR #2575**: Remove warnings due to some captured variables
- **PR #2573**: Attempt to resolve `resolve_locality`
- **PR #2572**: Adding APEX hooks to background thread

Chapter 2. What’s so special about HPX?
- Issue #2517 - Race condition during Parcel Coalescing Handler creation
- Issue #2516 - HPX locks up when using at least 256 localities
- Issue #2515 - error: Install cannot find “/lib/hpx/libparcel_coalescing.so.0.9.99” but I can see that file
- PR #2514 - Making sure that all continuations of a shared_future are invoked in order
- PR #2513 - Fixing locks held during suspension
- PR #2512 - MPI Parcelport improvements and fixes related to the background work changes
- PR #2511 - Fixing bit-wise (zero-copy) serialization
- Issue #2509 - Linking errors in hwloc_topology
- PR #2508 - Added documentation for debugging with core files
- PR #2506 - Fixing background work invocations
- PR #2505 - Fix tuple serialization
- Issue #2504 - Ensure continuations are called in the order they have been attached
- PR #2503 - Adding serialization support for Vc v2 (datapar)
- PR #2502 - Resolve various, minor compiler warnings
- PR #2501 - Some other fixes around cuda examples
- Issue #2500 - nvcc / cuda clang issue due to a missing -DHPX_WITH_CUDA flag
- PR #2499 - Adding support for std::array to wait_all and friends
- PR #2498 - Execute background work as HPX thread
- PR #2497 - Fixing configuration options for spinlock-deadlock detection
- PR #2496 - Accounting for different compilers in CrayKNL toolchain file
- PR #2494 - Adding component base class which ties a component instance to a given executor
- PR #2493 - Enable controlling amount of pending threads which must be available to allow thread stealing
- PR #2492 - Adding new command line option –hpx:print-counter-reset
• PR #2491 - Resolve ambiguities when compiling with APEX
• PR #2490 - Resuming threads waiting on future with higher priority
• Issue #2489 - nvcc issue because -std=c++11 appears twice
• PR #2488 - Adding performance counters exposing the internal idle and busy-loop counters
• PR #2487 - Allowing for plain suspend to reschedule thread right away
• PR #2486 - Only flag HPX code for CUDA if HPX_WITH_CUDA is set
• PR #2485 - Making thread-queue parameters runtime-configurable
• PR #2484 - Added atomic counter for parcel-destinations
• PR #2483 - Added priority-queue lifo scheduler
• PR #2482 - Changing scheduler to steal only if more than a minimal number of tasks are available
• PR #2481 - Extending command line option --hpckeep-counter-destination to support value 'none'
• PR #2479 - Added option to disable signal handler
• PR #2478 - Making sure the sine performance counter module gets loaded only for the corresponding example
• Issue #2477 - Breaking at a throw statement
• PR #2476 - Annotated function
• PR #2475 - Ensure that using %osthread% during logging will not throw for non-hpx threads
• PR #2474 - Remove now superficial non_direct actions from base_lco and friends
• PR #2473 - Refining support for ITTNotify
• PR #2472 - Some fixes around hpx compute
• Issue #2470 - redefinition of boost::detail::spinlock
• Issue #2469 - Dataflow performance issue
• PR #2468 - Perf docs update
• PR #2466 - Guarantee to execute remote direct actions on HPX-thread

Chapter 2. What’s so special about HPX?
• PR #2465^2633 - Improve demo: Async copy and fixed device handling
• PR #2464^2634 - Adding performance counter exposing instantaneous scheduler utilization
• PR #2463^2635 - Downcast to future<void>
• PR #2462^2636 - Fixed usage of ITT-Notify API with Intel Amplifier
• PR #2461^2637 - Cublas demo
• PR #2460^2638 - Fixing thread bindings
• PR #2459^2639 - Make -std=c++11 nvcc flag consistent for in-build and installed versions
• Issue #2457^2640 - Segmentation fault when registering a partitioned vector
• PR #2452^2641 - Properly releasing global barrier for unhandled exceptions
• PR #2451^2642 - Fixing long shutdown times
• PR #2450^2643 - Attempting to fix initialization errors on newer platforms (Boost V1.63)
• PR #2449^2644 - Replace BOOST_COMPILER_FENCE with an HPX version
• PR #2448^2645 - This fixes a possible race in the migration code
• PR #2445^7 - Fixing dataflow et.al. for futures or future-ranges wrapped into ref()
• PR #2444^2647 - Fix segfaults
• PR #2443^2648 - Issue 2442
• Issue #2442^2649 - Mismatch between #if/#endif and namespace scope brackets in this_thread_executers.hpp
• Issue #2441^2650 - undeclared identifier BOOST_COMPILER_FENCE
• PR #2440^2651 - Knl build
• PR #2438^2652 - Datapar backend
• PR #2437^2653 - Adapt algorithm parameter sequence changes from C++17
• PR #2436^2654 - Adapt execution policy name changes from C++17
• Issue #2435^2655 - Trunk broken, undefined reference to hpx::thread::interrupt(hpx::thread::id, bool)

2.10. Releases
• PR #2434 - More fixes to resource manager
• PR #2433 - Added versions of hpx::get_ptr taking client side representations
• PR #2432 - Warning fixes
• PR #2431 - Adding facility representing set of performance counters
• PR #2430 - Fix parallel_executor thread spawning
• PR #2429 - Fix attribute warning for gcc
• Issue #2427 - Seg fault running octo-tiger with latest HPX commit
• Issue #2426 - Bug in 9592f5c0bc29806fce0dbe73f35b6ca7e027edcb causes immediate crash in Octo-tiger
• PR #2425 - Fix nvcc errors due to constexpr specifier
• Issue #2424 - Async action on component present on hpx::find_here is executing synchronously
• PR #2423 - Fix nvcc errors due to constexpr specifier
• PR #2422 - Implementing hpx::this_thread thread data functions
• PR #2421 - Adding benchmark for wait_all
• Issue #2420 - Returning object of a component client from another component action fails
• PR #2419 - Infiniband parcelport
• Issue #2418 - gcc + nvcc fails to compile code that uses partitioned_vector
• PR #2417 - Fixing context switching
• PR #2416 - Adding fixes and workarounds to allow compilation with nvcc/msvc (VS2015up3)
• PR #2415 - Fix errors coming from hpx compute examples
• PR #2414 - Fixing msvc12
• PR #2413 - Enable cuda/nvcc or cuda/clang when using add_hpx_executable()
• PR #2412 - Fix issue in HPX_SetupTarget.cmake when cuda is used
• PR #2411 - This fixes the core compilation issues with MSVC12

https://github.com/STEllAR-GROUP/hpx/pull/2412
https://github.com/STEllAR-GROUP/hpx/pull/2411
• Issue #2410 - undefined reference to opal_hwloc191_hwloc_.....
• PR #2409 - Fixing locking for channel and receive_buffer
• PR #2407 - Solving #2402 and #2403
• PR #2406 - Improve guards
• PR #2405 - Enable parallel::for_each for iterators returning proxy types
• PR #2404 - Forward the explicitly given result_type in the hpx invoke
• Issue #2403 - datapar_execution + zip iterator: lambda arguments aren’t references
• Issue #2402 - datapar algorithm instantiated with wrong type #2402
• PR #2401 - Added support for imported libraries to HPX_Libraries.cmake
• PR #2400 - Use CMake policy CMP0060
• Issue #2399 - Error trying to push back vector of futures to vector
• PR #2398 - Allow config #defines to be written out to custom config/defines.hpp
• Issue #2397 - CMake generated config defines can cause tedious rebuilds category
• Issue #2396 - BOOST_ROOT paths are not used at link time
• PR #2395 - Fix target_link_libraries() issue when HPX Cuda is enabled
• Issue #2394 - Template compilation error using HPX_WITH_DATAPAR_LIBFLATARRAY
• PR #2393 - Fixing lock registration for recursive mutex
• PR #2392 - Add keywords in target_link_libraries in hpx_setup_target
• PR #2391 - Clang goroutines
• Issue #2390 - Adapt execution policy name changes from C++17
• PR #2389 - Chunk allocator and pool are not used and are obsolete
• PR #2388 - Adding functionalities to datapar needed by octotiger
• PR #2387 - Fixing race condition for early parcels

https://github.com/STEllAR-GROUP/hpx/pull/2388
https://github.com/STEllAR-GROUP/hpx/pull/2387
• Issue #2386 - Lock registration broken for recursive_mutex
• PR #2385 - Datapar zip iterator
• PR #2384 - Fixing race condition in for_loop_reduction
• PR #2383 - Continuations
• PR #2382 - add LibFlatArray-based backend for datapar
• PR #2381 - remove unused typedef to get rid of compiler warnings
• PR #2380 - Tau cleanup
• PR #2379 - Can send immediate
• PR #2378 - Renaming copy_helper/copy_n_helper/move_helper/move_n_helper
• Issue #2376 - Boost trunk’s spinlock initializer fails to compile
• PR #2375 - Add support for minimal thread local data
• PR #2374 - Adding API functions set_config_entry_callback
• PR #2373 - Add a simple utility for debugging that gives suspended task backtraces
• PR #2372 - Barrier Fixes
• Issue #2370 - Can’t wait on a wrapped future
• PR #2369 - Fixing stable_partition
• PR #2368 - Fixing find_prefixes for Windows platforms
• PR #2367 - Testing for experimental/optional only in C++14 mode
• PR #2364 - Adding set_config_entry
• PR #2363 - Fix papi
• PR #2362 - Adding missing macros for new non-direct actions
• PR #2361 - Improve cmake output to help debug compiler incompatibility check
• PR #2360 - Fixing race condition in condition_variable

[2724] https://github.com/STEllAR-GROUP/hpx/pull/2360
• PR #2359 - Fixing shutdown when parcels are still in flight
• Issue #2357 - failed to insert console_print_action into typename_to_id_t registry
• PR #2356 - Fixing return type of get_iterator_tuple
• PR #2355 - Fixing compilation against Boost 1 62
• PR #2354 - Adding serialization for mask_type if CPU_COUNT > 64
• PR #2353 - Adding hooks to tie in APEX into the parcel layer
• Issue #2352 - Compile errors when using intel 17 beta (for KNL) on edison
• PR #2351 - Fix function vtable get_function_address implementation
• Issue #2350 - Build failure - master branch (4de09f5) with Intel Compiler v17
• PR #2349 - Enabling zero-copy serialization support for std::vector
• PR #2348 - Adding test to verify #2334 is fixed
• PR #2347 - Bug fixes for hpx.compute and hpx::lcos::channel
• PR #2346 - Removing cmake “find” files that are in the APEX cmake Modules
• PR #2345 - Implemented parallel::stable_partition
• PR #2344 - Making hpx::lcos::channel usable with basename registration
• PR #2343 - Fix a couple of examples that failed to compile after recent api changes
• Issue #2342 - Enabling APEX causes link errors
• PR #2341 - Removing cmake “find” files that are in the APEX cmake Modules
• PR #2340 - Implemented all existing datapar algorithms using Boost.SIMD
• PR #2339 - Fixing 2338
• PR #2338 - Possible race in sliding semaphore
• PR #2337 - Adjust osu_latency test to measure window_size parcels in flight at once
• PR #2336 - Allowing remote direct actions to be executed without spawning a task

• PR #2335 - Making sure multiple components are properly initialized from arguments
• Issue #2334 - Cannot construct component with large vector on a remote locality
• PR #2332 - Fixing hpx::lcos::local::barrier
• PR #2331 - Updating APEX support to include OTF2
• PR #2330 - Support for data-parallelism for parallel algorithms
• Issue #2329 - Coordinate settings in cmake
• PR #2328 - fix LibGeoDecomp builds with HPX + GCC 5.3.0 + CUDA 8RC
• PR #2326 - Making scan_partitioner work (for now)
• Issue #2325 - Constructing a vector of components only correctly initializes the first component
• PR #2322 - Fix problems that bubbled up after merging #2278
• PR #2321 - Scalable barrier
• PR #2320 - Std flag fixes
• Issue #2319 - -std=c++14 and -std=++1y with Intel can’t build recent Boost builds due to insufficient C++14 support; don’t enable these flags by default for Intel
• PR #2318 - Improve handling of –hpx:bind=<bind-spec>
• PR #2317 - Making sure command line warnings are printed once only
• PR #2316 - Fixing command line handling for default bind mode
• PR #2315 - Set id_retrieved if set_id is present
• Issue #2314 - Warning for requested/allocated thread discrepancy is printed twice
• Issue #2313 - --hpx:print-bind doesn’t work with --hpx:pu-step
• Issue #2312 - –hpx:bind range specifier restrictions are overly restrictive
• Issue #2311 - hpx_0.9.99 out of project build fails
• PR #2310 - Simplify function registration
• PR #2309 - Spelling and grammar revisions in documentation (and some code)
• PR #2306\textsuperscript{771} - Correct minor typo in the documentation
• PR #2305\textsuperscript{772} - Cleaning up and fixing parcel coalescing
• PR #2304\textsuperscript{773} - Inspect checks for stream related includes
• PR #2303\textsuperscript{774} - Add functionality allowing to enumerate threads of given state
• PR #2301\textsuperscript{775} - Algorithm overloads fix for VS2013
• PR #2300\textsuperscript{776} - Use \texttt{<cstdint>}, add inspect checks
• PR #2299\textsuperscript{777} - Replace boost::\texttt{[c]ref} with std::\texttt{[c]ref}, add inspect checks
• PR #2297\textsuperscript{778} - Fixing compilation with no hw\_loc
• PR #2296\textsuperscript{779} - Hpx compute
• PR #2295\textsuperscript{780} - Making sure for\_loop(execution::par, 0, N, \ldots) is actually executed in parallel
• PR #2294\textsuperscript{781} - Throwing exceptions if the runtime is not up and running
• PR #2293\textsuperscript{782} - Removing unused parcel port code
• PR #2292\textsuperscript{783} - Refactor function vtables
• PR #2291\textsuperscript{784} - Fixing 2286
• PR #2290\textsuperscript{785} - Simplify algorithm overloads
• PR #2289\textsuperscript{786} - Adding performance counters reporting parcel related data on a per-action basis
• Issue #2288\textsuperscript{787} - Remove dormant parcelports
• Issue #2286\textsuperscript{788} - adjustments to parcel handling to support parcelports that do not need a connection cache
• PR #2285\textsuperscript{789} - add CMake option to disable package export
• PR #2283\textsuperscript{790} - Add more inspect checks for use of deprecated components
• Issue #2282\textsuperscript{791} - Arithmetic exception in executor static chunker
• Issue #2281\textsuperscript{792} - For loop doesn’t parallelize
• PR #2280\textsuperscript{793} - Fixing 2277: build failure with PAPI

• PR #2276 - Compile time launch policies
• PR #2275 - Replace boost::chrono with std::chrono in interfaces
• PR #2274 - Replace most uses of Boost.Assign with initializer list
• PR #2273 - Fixed typos
• PR #2272 - Inspect checks
• PR #2270 - Adding test verifying -lhpex.os_threads=all
• PR #2269 - Added inspect check for now obsolete boost type traits
• PR #2268 - Moving more code into source files
• Issue #2267 - Add inspect support to deprecate Boost.TypeTraits
• PR #2265 - Adding channel LCO
• PR #2264 - Make support for std::ref mandatory
• PR #2263 - Constrain tuple_member forwarding constructor
• Issue #2262 - Test hpex.os_threads=all
• Issue #2261 - OS X: Error: no matching constructor for initialization of ‘hpex::lcos::local::condition_variable_any’
• Issue #2260 - Make support for std::ref mandatory
• PR #2259 - Remove most of Boost.MPL, Boost.EnableIf and Boost.TypeTraits
• PR #2258 - Fixing #2256
• PR #2257 - Fixing launch process
• Issue #2256 - Actions are not registered if not invoked
• PR #2255 - Coalescing histogram
• PR #2254 - Silence explicit initialization in copy-constructor warnings

2.10. Releases
General changes

As the version number of this release hints, we consider this release to be a preview for the upcoming HPX V1.0. All of the functionalities we set out to implement for V1.0 are in place; all of the features we wanted to have exposed are ready. We are very happy with the stability and performance of HPX and we would like to present this release to the community in order for us to gather broad feedback before releasing V1.0. We still expect for some minor details to change, but on the whole this release represents what we would like to have in a V1.0.

Overall, since the last release we have had almost 1600 commits while closing almost 400 tickets. These numbers reflect the incredible development activity we have seen over the last couple of months. We would like to express a big ‘Thank you!’ to all contributors and those who helped to make this release happen.

The most notable addition in terms of new functionality available with this release is the full implementation of object migration (i.e. the ability to transparently move HPX components to a different compute node). Additionally, this release of HPX cleans up many minor issues and some API inconsistencies.

Here are some of the main highlights and changes for this release (in no particular order):

- We have fixed a couple of issues in AGAS and the parcel layer which have caused hangs, segmentation faults at exit, and a slowdown of applications over time. Fixing those has significantly increased the overall stability and performance of distributed runs.

- We have started to add parallel algorithm overloads based on the C++ Extensions for Ranges (N4560) proposal. This also includes the addition of projections to the existing algorithms. Please see Issue #1668 for a list of algorithms which have been adapted to N4560.

- We have implemented index-based parallel for-loops based on a corresponding standardization proposal (P0075R1). Please see Issue #2016 for a list of available algorithms.

- We have added implementations for more parallel algorithms as proposed for the upcoming C++ 17 Standard. See Issue #1141 for an overview of which algorithms are available by now.

- We have started to implement a new prototypical functionality with HPX.Compute which uniformly exposes some of the higher level APIs to heterogeneous architectures (currently CUDA). This functionality is an early preview and should not be considered stable. It may change considerably in the future.

- We have pervasively added (optional) executor arguments to all API functions which schedule new work. Executors are now used throughout the code base as the main means of executing tasks.
• Added `hpx::make_future<R>(future<T> &&)` allowing to convert a future of any type T into a future of any other type R, either based on default conversion rules of the embedded types or using a given explicit conversion function.

• We finally finished the implementation of transparent migration of components to another locality. It is now possible to trigger a migration operation without ‘stopping the world’ for the object to migrate. HPX will make sure that no work is being performed on an object before it is migrated and that all subsequently scheduled work for the migrated object will be transparently forwarded to the new locality. Please note that the global id of the migrated object does not change, thus the application will not have to be changed in any way to support this new functionality. Please note that this feature is currently considered experimental. See Issue #559^{2851} and PR #1966^{2852} for more details.

• The `hpx::dataflow` facility is now usable with actions. Similarly to `hpx::async`, actions can be specified as an explicit template argument (`hpx::dataflow<Action>(target, ...)`) or as the first argument (`hpx::dataflow(Action(), target, ...)`). We have also enabled the use of distribution policies as the target for dataflow invocations. Please see Issue #1265^{2853} and PR #1912^{2854} for more information.

• Adding overloads of `gather_here` and `gather_there` to accept the plain values of the data to gather (in addition to the existing overloads expecting futures).

• We have cleaned up and refactored large parts of the code base. This helped reducing compile and link times of HPX itself and also of applications depending on it. We have further decreased the dependency of HPX on the Boost libraries by replacing part of those with facilities available from the standard libraries.

• Wherever possible we have removed dependencies of our API on Boost by replacing those with the equivalent facility from the C++11 standard library.

• We have added new performance counters for parcel coalescing, file-IO, the AGAS cache, and overall scheduler time. Resetting performance counters has been overhauled and fixed.

• We have introduced a generic client type `hpx::components::client<>` and added support for using it with `hpx::async`. This removes the necessity to implement specific client types for every component type without losing type safety. This deemphasizes the need for using the low level `hpx::id_type` for referencing (possibly remote) component instances. The plan is to deprecate the direct use of `hpx::id_type` in user code in the future.

• We have added a special iterator which supports automatic prefetching of one or more arrays for speeding up loop-like code (see `hpx::parallel::util::make_prefetcher_context()`).

• We have extended the interfaces exposed from executors (as proposed by N4406^{2855}) to accept an arbitrary number of arguments.

### Breaking changes

• In order to move the dataflow facility to namespace `hpx` we added a definition of `hpx::dataflow` which might create ambiguities in existing codes. The previous definition of this facility (`hpx::lcos::local::dataflow`) has been deprecated and is available only if the constant `-DHPX_WITH_LOCAL_DATAFLOW_COMPATIBILITY=On` to CMake^{2856} is defined at configuration time. Please explicitly qualify all uses of the dataflow facility if you enable this compatibility setting and encounter ambiguities.

---

^{2851} https://github.com/STEllAR-GROUP/hpx/issues/559
^{2852} https://github.com/STEllAR-GROUP/hpx/pull/1966
^{2853} https://github.com/STEllAR-GROUP/hpx/issues/1265
^{2854} https://github.com/STEllAR-GROUP/hpx/pull/1912
^{2855} http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2015/n4406.pdf
^{2856} https://www.cmake.org
• The adaptation of the C++ Extensions for Ranges (N4560) proposal imposes some breaking changes related to the return types of some of the parallel algorithms. Please see Issue #1668 for a list of algorithms which have already been adapted.

• The facility `hpx::lcos::make_future_void()` has been replaced by `hpx::make_future<void>()`.

• We have removed support for Intel V13 and gcc 4.4.x.

• We have removed (default) support for the generic `hpx::parallel::execution_policy` because it was removed from the Parallelism TS (`_cpp11_n4104_`) while it was being added to the upcoming C++17 Standard. This facility can be still enabled at configure time by specifying `-DHPX_WITH GENERIC_EXECUTION_POLICY=On` to CMake.

• Uses of `boost::shared_ptr` and related facilities have been replaced with `std::shared_ptr` and friends. Uses of `boost::unique_lock`, `boost::lock_guard` etc. have also been replaced by the equivalent (and equally named) tools available from the C++11 standard library.

• Facilities that used to expect an explicit `boost::unique_lock` now take an `std::unique_lock`. Additionally, `condition_variable` no longer aliases `condition_variable_any`; its interface now only works with `std::unique_lock<local::mutex>`.

• Uses of `boost::function`, `boost::bind`, `boost::tuple` have been replaced by the corresponding facilities in HPX (`hpx::util::function`, `hpx::util::bind`, and `hpx::util::tuple`, respectively).

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release.

- PR #2250 - change default chunker of parallel executor to static one
- PR #2247 - HPX on ppc64le
- PR #2244 - Fixing MSVC problems
- PR #2238 - Fixing small typos
- PR #2237 - Fixing small typos
- PR #2234 - Fix broken add test macro when extra args are passed in
- PR #2231 - Fixing possible race during future awaiting in serialization
- PR #2230 - Fix stream nvcc
- PR #2229 - Fixed run_as_hpx_thread
- PR #2228 - On prefetching_test branch : adding prefetching_iterator and related tests used for prefetching containers within lambda functions

Chapter 2. What’s so special about HPX?
• PR #2227 - Support for HPXCL's opencl::event
• PR #2226 - Preparing for release of V0.9.99
• PR #2225 - fix issue when compiling components with hpccxx
• PR #2224 - Compute alloc fix
• PR #2223 - Simplify promise
• PR #2222 - Replace last uses of boost::function by util::function_nonser
• PR #2221 - Fix config tests
• PR #2220 - Fixing gcc 4.6 compilation issues
• PR #2219 - nullptr support for [unique_]function
• PR #2218 - Introducing clang tidy
• PR #2216 - Replace NULL with nullptr
• Issue #2214 - Let inspect flag use of NULL, suggest nullptr instead
• PR #2213 - Require support for nullptr
• PR #2212 - Properly find jemalloc through pkg-config
• PR #2211 - Disable a couple of warnings reported by Intel on Windows
• PR #2210 - Fixed host::block_allocator::bulk_construct
• PR #2209 - Started to clean up new sort algorithms, made things compile for sort_by_key
• PR #2208 - A couple of fixes that were exposed by a new sort algorithm
• PR #2207 - Adding missing includes in /hpx/include/serialization.hpp
• PR #2206 - Call package_action::get_future before package_action::apply
• PR #2205 - The indirect_packaged_task::operator() needs to be run on a HPX thread
• PR #2204 - Variadic executor parameters
• PR #2203 - Delay-initialize members of partitioned iterator
• PR #2202 - Added segmented fill for hpx::vector
• Issue #2201 - Null Thread id encountered on partitioned_vector
• PR #2200 - Fix hangs
• PR #2199 - Deprecating hpx/traits.hpp
• PR #2198 - Making explicit inclusion of external libraries into build
• PR #2197 - Fix typo in QT CMakeLists
• PR #2196 - Fixing a gcc warning about attributes being ignored
• PR #2194 - Fixing partitioned_vector_spmd_foreach example
• Issue #2193 - partitioned_vector_spmd_foreach seg faults
• PR #2192 - Support Boost.Thread v4
• PR #2191 - HPX.Compute prototype
• PR #2190 - Spawning operation on new thread if remaining stack space becomes too small
• PR #2189 - Adding callback taking index and future to when_each
• PR #2188 - Adding new example demonstrating receive_buffer
• PR #2187 - Mask 128-bit ints if CUDA is being used
• PR #2186 - Make startup & shutdown functions unique_function
• PR #2185 - Fixing logging output not to cause hang on shutdown
• PR #2184 - Allowing component clients as action return types
• Issue #2183 - Enabling logging output causes hang on shutdown
• Issue #2182 - 1d_stencil seg fault
• Issue #2181 - Setting small stack size does not change default
• PR #2180 - Changing default bind mode to balanced
• PR #2179 - adding prefetching_iterator and related tests used for prefetching containers within lambda functions

- PR #2177 - Fixing 2176
- Issue #2176 - Launch process test fails on OSX
- PR #2175 - Fix unbalanced config/warnings includes, add some new ones
- PR #2174 - Fix test categorization: regression not unit
- Issue #2172 - Different performance results
- Issue #2171 - “negative entry in reference count table” running octotiger on 32 nodes on queenbee
- Issue #2170 - Error while compiling on Mac + boost 1.60
- PR #2169 - Fixing problems with is_bitwise_serializable
- Issue #2167 - startup & shutdown function should accept unique_function
- Issue #2166 - Simple receive_buffer example
- PR #2165 - Fix wait all
- PR #2164 - Fix wait all
- PR #2163 - Fix some typos in config tests
- PR #2162 - Improve #includes
- PR #2160 - Add inspect check for missing #include <list>
- PR #2159 - Add missing finalize call to stop test hanging
- PR #2158 - Algo fixes
- PR #2157 - Stack check
- Issue #2156 - OSX reports stack space incorrectly (generic context coroutines)
- Issue #2155 - Race condition suspected in runtime
- PR #2154 - Replace boost::detail::atomic_count with the new util::atomic_count
- PR #2153 - Fix stack overflow on OSX
- PR #2152 - Define is_bitwise_serializable as is_trivially_copyable when available

https://github.com/STEllAR-GROUP/hpx/pull/2152
• PR #2151\textsuperscript{2938} - Adding missing `<cstring>` for std::mem* functions
• Issue #2150\textsuperscript{2939} - Unable to use component clients as action return types
• PR #2149\textsuperscript{2940} - std::memmove copies bytes, use bytes*sizeof(type) when copying larger types
• PR #2146\textsuperscript{2941} - Adding customization point for parallel copy/move
• PR #2145\textsuperscript{2942} - Applying changes to address warnings issued by latest version of PVS Studio
• Issue #2148\textsuperscript{2943} - hpx::parallel::copy is broken after trivially copyable changes
• PR #2144\textsuperscript{2944} - Some minor tweaks to compute prototype
• PR #2143\textsuperscript{2945} - Added Boost version support information over OSX platform
• PR #2142\textsuperscript{2946} - Fixing memory leak in example
• PR #2141\textsuperscript{2947} - Add missing specializations in execution policies
• PR #2139\textsuperscript{2948} - This PR fixes a few problems reported by Clang’s Undefined Behavior sanitizer
• PR #2138\textsuperscript{2949} - Revert “Adding fedora docs”
• PR #2136\textsuperscript{2950} - Removed double semicolon
• PR #2135\textsuperscript{2951} - Add deprecated #include check for hpx_fwd.hpp
• PR #2134\textsuperscript{2952} - Resolved memory leak in stencil_8
• PR #2133\textsuperscript{2953} - Replace uses of boost pointer containers
• PR #2132\textsuperscript{2954} - Removing unused typedef
• PR #2131\textsuperscript{2955} - Add several include checks for std facilities
• PR #2130\textsuperscript{2956} - Fixing parcel compression, adding test
• PR #2129\textsuperscript{2957} - Fix invalid attribute warnings
• Issue #2128\textsuperscript{2958} - hpx::init seems to segfault
• PR #2127\textsuperscript{2959} - Making executor_traits N-ary
• PR #2126\textsuperscript{2960} - GCC 4.6 fails to deduce the correct type in lambda

• PR #2125 - Making parcel coalescing test actually test something
• Issue #2124 - Make a testcase for parcel compression
• Issue #2123 - hpx/hpx/runtime/applier_fwd.hpp - Multiple defined types
• Issue #2122 - Exception in primary_namespace::resolve_free_list
• Issue #2121 - Possible memory leak in 1d_stencil_8
• PR #2120 - Fixing 2119
• Issue #2119 - reduce_by_key compilation problems
• Issue #2118 - Premature unwrapping of boost::ref’ed arguments
• PR #2117 - Added missing initializer on last constructor for thread_description
• PR #2116 - Use a lightweight bind implementation when no placeholders are given
• PR #2115 - Replace boost::shared_ptr with std::shared_ptr
• PR #2114 - Adding hook functions for executor_parameter_traits supporting timers
• Issue #2113 - Compilation error with gcc version 4.9.3 (MacPorts gcc49 4.9.3_0)
• PR #2112 - Replace uses of safe_bool with explicit operator bool
• Issue #2111 - Compilation error on QT example
• Issue #2110 - Compilation error when passing non-future argument to unwrapped continuation in dataflow
• Issue #2109 - Warning while compiling hpx
• Issue #2109 - Stack trace of last bug causing issues with octotiger
• Issue #2108 - Stack trace of last bug causing issues with octotiger
• PR #2107 - Making sure that a missing parcel_coalescing module does not cause startup exceptions
• PR #2106 - Stop using hpx_fwd.hpp
• Issue #2105 - coalescing plugin handler is not optional any more
• Issue #2104 - Make executor_traits N-nary

2.10. Releases
• Issue #2103 - Build error with octotiger and hpx commit e657426d
• PR #2102 - Combining thread data storage
• PR #2101 - Added repartition version of 1d stencil that uses any performance counter
• PR #2100 - Drop obsolete TR1 result_of protocol
• PR #2098 - Replace uses of boost::bind with util::bind
• PR #2097 - Deprecated inspect checks
• PR #2096 - Reduce by key, extends #1141
• PR #2095 - Moving local cache from external to hpx/util
• PR #2094 - Bump minimum required Boost to 1.50.0
• PR #2093 - Add include checks for several Boost utilities
• Issue #2091 - ./.local_cache.hpp(89): error #303: explicit type is missing (“int” assumed)
• PR #2095 - Fix for Raspberry pi build
• PR #2090 - Fix storage size for util::function<>
• PR #2089 - Fix #2088
• Issue #2088 - More verbose output from cmake configuration
• PR #2087 - Making sure init_globally always executes hpx_main
• Issue #2086 - Race condition with recent HPX
• PR #2085 - Adding #include checker
• PR #2084 - Replace boost lock types with standard library ones
• PR #2083 - Simplify packaged task
• PR #2082 - Upgrading APEX version for testing
• PR #2081 - Cleanup exception headers
• PR #2080 - Make call_once variadic

- Issue #2079\textsuperscript{3007} - With GNU C++, line 85 of hpx/config/version.hpp causes link failure when linking application
- Issue #2078\textsuperscript{3008} - Simple test fails with \_GLIBCXX\_DEBUG defined
- PR #2079\textsuperscript{3009} - Instantiate board in nqueen client
- PR #2076\textsuperscript{3010} - Moving coalescing registration to TUs
- PR #2075\textsuperscript{3011} - Fixed some documentation typos
- PR #2074\textsuperscript{3012} - Adding flush-mode to message handler flush
- PR #2073\textsuperscript{3013} - Fixing performance regression introduced lately
- PR #2072\textsuperscript{3014} - Refactor local::condition\_variable
- PR #2071\textsuperscript{3015} - Timer based on boost::asio::deadline\_timer
- PR #2070\textsuperscript{3016} - Refactor tuple based functionality
- PR #2069\textsuperscript{3017} - Fixed typos
- Issue #2068\textsuperscript{3018} - Seg fault with octotiger
- PR #2067\textsuperscript{3019} - Algorithm cleanup
- PR #2066\textsuperscript{3020} - Split credit fixes
- PR #2065\textsuperscript{3021} - Rename HPX\_MOVABLE\_BUT\_NOT\_COPYABLE to HPX\_MOVABLE\_ONLY
- PR #2064\textsuperscript{3022} - Fixed some typos in docs
- PR #2063\textsuperscript{3023} - Adding example demonstrating template components
- Issue #2062\textsuperscript{3024} - Support component templates
- PR #2061\textsuperscript{3025} - Replace some uses of lexical\_cast\langle string\rangle with C++11 std::to\_string
- PR #2060\textsuperscript{3026} - Replace uses of boost::noncopyable with HPX\_NON\_COPYABLE
- PR #2059\textsuperscript{3027} - Adding missing for\_loop algorithms
- PR #2058\textsuperscript{3028} - Move several definitions to more appropriate headers
- PR #2057\textsuperscript{3029} - Simplify assert\_owns\_lock and ignore\_while\_checking

• PR #2056 - Replacing std::result_of with util::result_of
• PR #2055 - Fix process launching/connecting back
• PR #2054 - Add a forwarding coroutine header
• PR #2053 - Replace uses of boost::unordered_map with std::unordered_map
• PR #2052 - Rewrite tuple unwrap
• PR #2050 - Replace uses of BOOST_SCOPED_ENUM with C++11 scoped enums
• PR #2049 - Attempt to narrow down split_credit problem
• PR #2048 - Fixing gcc startup hangs
• PR #2047 - Fixing when_xxx and wait_xxx for MSVC12
• PR #2046 - Adding persistent_auto_chunk_size and related tests for for_each
• PR #2045 - Fixing HPX_HAVE_THREAD_BACKTRACE_DEPTH build time configuration
• PR #2044 - Adding missing service executor types
• PR #2043 - Removing ambiguous definitions for is_future_range and future_range_traits
• PR #2042 - Clarify that HPX builds can use (much) more than 2GB per process
• PR #2041 - Changing future_iterator_traits to support pointers
• Issue #2040 - Improve documentation memory usage warning?
• PR #2039 - Coroutine cleanup
• PR #2038 - Fix cmake policy CMP0042 warning MACOSX_RPATH
• PR #2037 - Avoid redundant specialization of [unique]function_nonser
• PR #2036 - nvcc dies with an internal error upon pushing/popping warnings inside templates
• Issue #2035 - Use a less restrictive iterator definition in hpx::lcos::detail::future_iterator_traits
• PR #2034 - Fixing compilation error with thread queue wait time performance counter
• Issue #2033 - Compilation error when compiling with thread queue waittime performance counter
• Issue #2032[^2032] - Ambiguous template instantiation for is_future_range and future_range_traits.
• PR #2031[^2031] - Don’t restart timer on every incoming parcel
• PR #2030[^2030] - Unify handling of execution policies in parallel algorithms
• PR #2029[^2029] - Make pkg-config .pc files use .dylib on OSX
• PR #2028[^2028] - Adding process component
• PR #2023[^2023] - Fixing errors related to older boost versions and parameter pack expansions in lambdas
• Issue #2022[^2022] - gmake fail: “No rule to make target /usr/lib46/libboost_context-mt.so”
• PR #2021[^2021] - Added Sudoku example
• Issue #2020[^2020] - Make errors related to init_globally.cpp example while building HPX out of the box
• PR #2019[^2019] - Fixed some compilation and cmake errors encountered in nqueen example
• PR #2018[^2018] - For loop algorithms
• PR #2017[^2017] - Non-recursive at_index implementation
• Issue #2016[^2016] - Add index-based for-loops
• Issue #2015[^2015] - Change default bind-mode to balanced
• PR #2014[^2014] - Fixed dataflow if invoked action returns a future
• PR #2013[^2013] - Fixing compilation issues with external example
• PR #2012[^2012] - Added Sierpinski Triangle example
• Issue #2011[^2011] - Compilation error while running sample hello_world_component code
• PR #2010[^2010] - Segmented move implemented for hpx::vector
• Issue #2009[^2009] - pkg-config order incorrect on 14.04 / GCC 4.8

• Issue #2008 - Compilation error in dataflow of action returning a future
• PR #2007 - Adding new performance counter exposing overall scheduler time
• PR #2006 - Function includes
• PR #2005 - Adding an example demonstrating how to initialize HPX from a global object
• PR #2004 - Fixing 2000
• PR #2003 - Adding generation parameter to gather to enable using it more than once
• PR #2002 - Turn on position independent code to solve link problem with hpx_init
• Issue #2001 - Gathering more than once segfaults
• Issue #2000 - Undefined reference to hpx::assertion_failed
• Issue #1999 - Seg fault in hpx::lcos::base_lco_with_value<*>::set_value_nonvirt() when running octo-tiger
• PR #1998 - Detect unknown command line options
• PR #1997 - Extending thread description
• PR #1996 - Adding natvis files to solution (MSVC only)
• Issue #1995 - Command line handling does not produce error
• PR #1994 - Possible missing include in test_utils.hpp
• PR #1993 - Add missing LANGUAGES tag to a hpx_add_compile_flag_if_available() call in CMakeLists.txt
• PR #1992 - Fixing shared_executor_test
• PR #1991 - Making sure the winsock library is properly initialized
• PR #1990 - Fixing bind_test placeholder ambiguity coming from boost-1.60
• PR #1989 - Performance tuning
• PR #1987 - Make configurable size of internal storage in util::function
• PR #1986 - AGAS Refactoring+1753 Cache mods
• PR #1985 - Adding missing task_block::run() overload taking an executor

- PR #19843099 - Adding an optimized LRU Cache implementation (for AGAS)
- PR #19833100 - Avoid invoking migration table look up for all objects
- PR #19813101 - Replacing uintptr_t (which is not defined everywhere) with std::size_t
- PR #19803102 - Optimizing LCO continuations
- PR #19793103 - Fixing Cori
- PR #19783104 - Fix test check that got broken in hasty fix to memory overflow
- PR #19773105 - Refactor action traits
- PR #19763106 - Fixes typo in README.rst
- PR #19753107 - Reduce size of benchmark timing arrays to fix test failures
- PR #19743108 - Add action to update data owned by the partitioned_vector component
- PR #19723109 - Adding partitioned_vector SPMD example
- PR #19713110 - Fixing 1965
- PR #19703111 - Papi fixes
- PR #19693112 - Fixing continuation recursions to not depend on fixed amount of recursions
- PR #19683113 - More segmented algorithms
- Issue #19673114 - Simplify component implementations
- PR #19663115 - Migrate components
- Issue #19643116 - fatal error: ‘boost/lockfree/detail/branch_hints.hpp’ file not found
- Issue #19623117 - parallel:copy_if has race condition when used on in place arrays
- PR #19633118 - Fixing Static Parcelport initialization
- PR #19613119 - Fix function target
- Issue #19603120 - Papi counters don’t reset
- PR #19593121 - Fixing 1958

2.10. Releases
• PR #1911\textsuperscript{3168} - Adding first batch of container algorithms
• PR #1910\textsuperscript{3169} - Keep cmake_module_path
• PR #1906\textsuperscript{3170} - Fix mpirun with pbs
• PR #1908\textsuperscript{3171} - Changing parallel::sort to return the last iterator as proposed by N4560
• PR #1907\textsuperscript{3172} - Adding a minimum version for Open MPI
• PR #1906\textsuperscript{3173} - Updates to the Release Procedure
• PR #1905\textsuperscript{3174} - Fixing #1903
• PR #1904\textsuperscript{3175} - Making sure std containers are cleared before serialization loads data
• Issue #1903\textsuperscript{3176} - When running octotiger, I get: assertion '(*new_gids_)[gid].size() == 1' failed: HPX(assertion\_failure)
• Issue #1902\textsuperscript{3177} - Immediate crash when running hpx/octotiger with _GLIBCXX_DEBUG defined.
• PR #1901\textsuperscript{3178} - Making non-serializable classes non-serializable
• Issue #1900\textsuperscript{3179} - Two possible issues with std::list serialization
• PR #1899\textsuperscript{3180} - Fixing a problem with credit splitting as revealed by #1898
• Issue #1898\textsuperscript{3181} - Accessing component from locality where it was not created segfaults
• PR #1897\textsuperscript{3182} - Changing parallel::sort to return the last iterator as proposed by N4560
• Issue #1896\textsuperscript{3183} - version 1.0?
• Issue #1895\textsuperscript{3184} - Warning comment on numa\_allocator is not very clear
• PR #1894\textsuperscript{3185} - Add support for compilers that have thread\_local
• PR #1893\textsuperscript{3186} - Fixing 1890
• PR #1892\textsuperscript{3187} - Adds typed future\_type for executor\_traits
• PR #1891\textsuperscript{3188} - Fix wording in certain parallel algorithm docs
• Issue #1890\textsuperscript{3189} - Invoking papi counters give segfault
• PR #1889\textsuperscript{3190} - Fixing problems as reported by clang-check

• Issue #553252 - Uniform syntax for enums should be implemented

2.10.12 HPX V0.9.11 (Nov 11, 2015)

Our main focus for this release was the design and development of a coherent set of higher-level APIs exposing various types of parallelism to the application programmer. We introduced the concepts of an executor, which can be used to customize the where and when of execution of tasks in the context of parallelizing codes. We extended all APIs related to managing parallel tasks to support executors which gives the user the choice of either using one of the predefined executor types or to provide its own, possibly application specific, executor. We paid very close attention to align all of these changes with the existing C++ Standards documents or with the ongoing proposals for standardization.

This release is the first after our change to a new development policy. We switched all development to be strictly performed on branches only, all direct commits to our main branch (master) are prohibited. Any change has to go through a peer review before it will be merged to master. As a result the overall stability of our code base has significantly increased, the development process itself has been simplified. This change manifests itself in a large number of pull-requests which have been merged (please see below for a full list of closed issues and pull-requests).

2.10. Releases
All in all for this release, we closed almost 100 issues and merged over 290 pull-requests. There have been over 1600 commits to the master branch since the last release.

**General changes**

- We are moving into the direction of unifying managed and simple components. As such, the classes `hpx::components::component` and `hpx::components::component_base` have been added which currently just forward to the currently existing simple component facilities. The examples have been converted to only use those two classes.

- Added integration with the CircleCI\(^{3253}\) hosted continuous integration service. This gives us constant and immediate feedback on the health of our master branch.

- The compiler configuration subsystem in the build system has been reimplemented. Instead of using Boost.Config we now use our own lightweight set of cmake scripts to determine the available language and library features supported by the used compiler.

- The API for creating instances of components has been consolidated. All component instances should be created using the `hpx::new_` only. It allows one to instantiate both, single component instances and multiple component instances. The placement of the created components can be controlled by special distribution policies. Please see the corresponding documentation outlining the use of `hpx::new_`.

- Introduced four new distribution policies which can be used with many API functions which traditionally expected to be used with a locality id. The new distribution policies are:
  - `hpx::components::default_distribution_policy` which tries to place multiple component instances as evenly as possible.
  - `hpx::components::colocating_distribution_policy` which will refer to the locality where a given component instance is currently placed.
  - `hpx::components::binpacking_distribution_policy` which will place multiple component instances as evenly as possible based on any performance counter.
  - `hpx::components::target_distribution_policy` which allows one to represent a given locality in the context of a distribution policy.

- The new distribution policies can now be also used with `hpx::async`. This change also deprecates `hpx::async_colocated(id, ...)`. It now is replaced by a distribution policy: `hpx::async(hpx::colocated(id), ...)`.\(^{3254}\)

- The `hpx::vector` and `hpx::unordered_map` data structures can now be used with the new distribution policies as well.

- The parallel facility `hpx::parallel::task_region` has been renamed to `hpx::parallel::task_block` based on the changes in the corresponding standardization proposal N4411\(^{3254}\).

- Added extensions to the parallel facility `hpx::parallel::task_block` allowing to combine a task_block with an execution policy. This implies a minor breaking change as the `hpx::parallel::task_block` is now a template.

- Added new LCOs: `hpx::lcos::latch` and `hpx::lcos::local::latch` which semantically conform to the proposed `std::latch` (see N4399\(^{3255}\)).

- Added performance counters exposing data related to data transferred by input/output (filesystem) operations (thanks to Maciej Brodowicz).

---

\(^{3253}\) https://circleci.com/gh/STEllAR-GROUP/hpx
\(^{3254}\) http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2015/n4411.pdf
\(^{3255}\) http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2015/n4399.html
• Added performance counters allowing to track the number of action invocations (local and remote invocations).
• Added new command line options –hp:print-counter-at and –hp:reset-counters.
• The `hpx::vector` component has been renamed to `hpx::partitioned_vector` to make it explicit that the underlying memory is not contiguous.
• Introduced a completely new and uniform higher-level parallelism API which is based on executors. All existing parallelism APIs have been adapted to this. We have added a large number of different executor types, such as a numa-aware executor, a this-thread executor, etc.
• Added support for the MingW toolchain on Windows (thanks to Eric Lemanissier).
• HPX now includes support for APEX, (Autonomic Performance Environment for eXascale). APEX is an instrumentation and software adaptation library that provides an interface to TAU profiling / tracing as well as runtime adaptation of HPX applications through policy definitions. For more information and documentation, please see https://github.com/khuck/xpress-apex. To enable APEX at configuration time, specify `--HPX_WITH_APEX=On`. To also include support for TAU profiling, specify `--HPX_WITH_TAU=On` and specify the `--DTAU_ROOT`, `--DTAU_ARCH`, and `--DTAU_OPTIONS` cmake parameters.
• We have implemented many more of the Using parallel algorithms. Please see Issue #1141 \(^{3256}\) for the list of all available parallel algorithms (thanks to Daniel Bourgeois and John Biddiscombe for contributing their work).

**Breaking changes**

• We are moving into the direction of unifying managed and simple components. In order to stop exposing the old facilities, all examples have been converted to use the new classes. The breaking change in this release is that performance counters are now a `hpx::components::component_base` instead of `hpx::components::managed_component_base`.
• We removed the support for stackless threads. It turned out that there was no performance benefit when using stackless threads. As such, we decided to clean up our codebase. This feature was not documented.
• The CMake project name has changed from ‘hpx’ to ‘HPX’ for consistency and compatibility with naming conventions and other CMake projects. Generated config files go into `<prefix>/lib/cmake/HPX` and not `<prefix>/lib/cmake/hpx`.
• The macro `HPX_REGISTER_MINIMAL_COMPONENT_FACTORY` has been deprecated. Please use `HPX_REGISTER_COMPONENT` instead. The old macro will be removed in the next release.
• The obsolete `distributing_factory` and `binpacking_factory` components have been removed. The corresponding functionality is now provided by the `hpx::new_` API function in conjunction with the `hpx::default_layout` and `hpx::binpacking` distribution policies (`hpx::components::default_distribution_policy` and `hpx::components::binpacking_distribution_policy`).
• The API function `hpx::new_colocated` has been deprecated. Please use the consolidated API `hpx::new_` in conjunction with the new `hpx::colocated` distribution policy (`hpx::components::colocating_distribution_policy`) instead. The old API function will still be available for at least one release of HPX if the configuration variable `HPX_WITH_COLOCA TED_BACKWARDS_COMPATIBILITY` is enabled.
• The API function `hpx::async_colocated` has been deprecated. Please use the consolidated API `hpx::async` in conjunction with the new `hpx::colocated` distribution policy (`hpx::components::colocating_distribution_policy`) instead. The old API function will still be available for at least one release of HPX if the configuration variable `HPX_WITH_COLOCA TED_BACKWARDS_COMPATIBILITY` is enabled.

\(^{3256}\) https://github.com/STEllAR-GROUP/hpx/issues/1141
• The obsolete remote_object component has been removed.

• Replaced the use of Boost.Serialization with our own solution. While the new version is mostly compatible with Boost.Serialization, this change requires some minor code modifications in user code. For more information, please see the corresponding announcement[^3257] on the hpx-users@stellar.cct.lsu.edu mailing list.

• The names used by cmake to influence various configuration options have been unified. The new naming scheme relies on all configuration constants to start with `HPX_WITH_...`, while the preprocessor constant which is used at build time starts with `HPX_HAVE_...`. For instance, the former cmake command line `-DHPX_MALLOC=...` now has to be specified a `-DHPX_WITH_MALLOC=...` and will cause the preprocessor constant `HPX_HAVE_MALLOC` to be defined. The actual name of the constant (i.e. `malloc`) has not changed. Please see the corresponding documentation for more details ([CMake variables used to configure HPX](http://thread.gmane.org/gmane.comp.lib.hpx.devel/196)).

• The `get_gid()` functions exposed by the component base classes `hpx::components::server::simple_component_base`, `hpx::components::server::managed_component_base`, and `hpx::components::server::fixed_component_base` have been replaced by two new functions: `get_unmanaged_id()` and `get_id()`. To enable the old function name for backwards compatibility, use the cmake configuration option `HPX_WITH_COMPONENT_GET_GID_COMPATIBILITY=On`.

• All functions which were named `get_gid()` but were returning `hpx::id_type` have been renamed to `get_id()`. To enable the old function names for backwards compatibility, use the cmake configuration option `HPX_WITH_COMPONENT_GET_GID_COMPATIBILITY=On`.

### Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release.

- PR #1855[^3258] - Completely removing external/endian
- PR #1854[^3259] - Don’t pollute CMAKE_CXX_FLAGS through find_package()
- PR #1853[^3260] - Updating CMake configuration to get correct version of TAU library
- PR #1852[^3261] - Fixing Performance Problems with MPI Parcelport
- PR #1851[^3262] - Fixing hpx_add_link_flag() and hpx_remove_link_flag()
- PR #1850[^3263] - Fixing 1836, adding parallel::sort
- PR #1849[^3264] - Fixing configuration for use of more than 64 cores
- PR #1848[^3265] - Change default APEX version for release
- PR #1847[^3266] - Fix client_base::then on release
- PR #1846[^3267] - Removing broken lcos::local::channel from release
- PR #1845[^3268] - Adding example demonstrating a possible safe-object implementation to release

• PR #1844 - Removing stubs from accumulator examples
• PR #1843 - Don’t pollute CMAKE_CXX_FLAGS through find_package()
• PR #1841 - Fixing client_base<>:then
• PR #1840 - Adding example demonstrating a possible safe-object implementation
• PR #1838 - Update version rc1
• PR #1837 - Removing broken lcos::local::channel
• PR #1835 - Adding explicit move constructor and assignment operator to hpx::lcos::promise
• PR #1834 - Making hpx::lcos::promise move-only
• PR #1833 - Adding fedora docs
• Issue #1832 - hpx::lcos::promise<> must be move-only
• PR #1831 - Fixing resource manager gcc5.2
• PR #1830 - Fix intel13
• PR #1829 - Unbreaking thread test
• PR #1828 - Fixing #1620
• PR #1827 - Fixing a memory management issue for the Parquet application
• Issue #1826 - Memory management issue in hpx::lcos::promise
• PR #1825 - Adding hpx::components::component and hpx::components::component_base
• PR #1823 - Adding git commit id to circleci build
• PR #1822 - Applying fixes suggested by clang 3.7
• PR #1821 - Hyperlink fixes
• PR #1820 - added parallel multi-locality sanity test
• PR #1819 - Fixing #1667
• Issue #1817 - Hyperlinks generated by inspect tool are wrong
• PR #1816 - Support hpxrx
• PR #1814 - Fix async to dispatch to the correct locality in all cases
• Issue #1813 - async(launch::..., action(), ...) always invokes locally
• PR #1812 - fixed syntax error in CMakeLists.txt
• PR #1811 - Agas optimizations
• PR #1810 - drop superfluous typedefs
• PR #1809 - Allow HPX to be used as an optional package in 3rd party code
• PR #1808 - Fixing #1723
• PR #1807 - Making sure resolve_localities does not hang during normal operation
• Issue #1806 - Spinlock no longer movable and deletes operator ‘=’, breaks MiniGhost
• Issue #1804 - register_with_basename causes hangs
• PR #1801 - Enhanced the inspect tool to take user directly to the problem with hyperlinks
• Issue #1800 - Problems compiling application on smic
• PR #1799 - Fixing cv exceptions
• PR #1798 - Documentation refactoring & updating
• PR #1797 - Updating the activeharmony CMake module
• PR #1796 - Fixing cv
• PR #1795 - Fix connect with hpx::runtime_mode_connect
• PR #1793 - fix a wrong use of HPX_MAX_CPU_COUNT instead of HPX_HAVE_MAX_CPU_COUNT
• PR #1792 - Allow for default constructed parcel instances to be moved
• PR #1791 - Fix connect with hpx::runtime_mode_connect
• Issue #1790 - assertion action_.get() failed: HPX(assertion_failure) when running Octotiger with pull request 1786
• PR #1789 - Fixing discover_counter_types API function

3314 https://github.com/STEllAR-GROUP/hpx/pull/1789
• Issue #1788 - connect with hpx::runtime_mode_connect
• Issue #1787 - discover_counter_types not working
• PR #1786 - Changing addressing_service to use std::unordered_map instead of std::map
• PR #1785 - Fix is_iterator for container algorithms
• PR #1784 - Adding new command line options:
• PR #1783 - Minor changes for APEX support
• PR #1782 - Drop legacy forwarding action traits
• PR #1781 - Attempt to resolve the race between cv::wait_xxx and cv::notify_all
• PR #1780 - Removing serialize_sequence
• PR #1779 - Fixed #1501: hwloc configuration options are wrong for MIC
• PR #1778 - Removing ability to enable/disable parcel handling
• PR #1777 - Completely removing stackless threads
• PR #1776 - Cleaning up util/plugin
• PR #1775 - Agas fixes
• PR #1774 - Action invocation count
• PR #1773 - replaced MSVC variable with WIN32
• PR #1772 - Fixing Problems in MPI parcelport and future serialization.
• PR #1771 - Fixing intel 13 compiler errors related to variadic template parameters for lcos::when_tests
• PR #1770 - Forwarding decay to std::
• PR #1769 - Add more characters with special regex meaning to the existing patch
• PR #1768 - Adding test for receive_buffer
• PR #1767 - Making sure that uptime counter throws exception on any attempt to be reset
• PR #1766 - Cleaning up code related to throttling scheduler

2.10. Releases
• PR #1765\textsuperscript{3338} - Restricting thread\_data to creating only with intrusive\_pointers
• PR #1764\textsuperscript{3339} - Fixing 1763
• Issue #1763\textsuperscript{3340} - UB in thread\_data::operator delete
• PR #1762\textsuperscript{3341} - Making sure all serialization registries/factories are unique
• PR #1761\textsuperscript{3342} - Fixed #1751: hpx::future::wait\_for fails a simple test
• PR #1758\textsuperscript{3343} - Fixing #1757
• Issue #1757\textsuperscript{3344} - pinning not correct using –hpx:bind
• Issue #1756\textsuperscript{3345} - compilation error with MinGW
• PR #1755\textsuperscript{3346} - Making output serialization const-correct
• Issue #1753\textsuperscript{3347} - HPX performance degrades with time since execution begins
• Issue #1752\textsuperscript{3348} - Error in AGAS
• Issue #1751\textsuperscript{3349} - hpx::future::wait\_for fails a simple test
• PR #1750\textsuperscript{3350} - Removing hpx\_fwd.hpp includes
• PR #1749\textsuperscript{3351} - Simplify result\_of and friends
• PR #1747\textsuperscript{3352} - Removed superfluous code from message\_buffer.hpp
• PR #1746\textsuperscript{3353} - Tuple dependencies
• Issue #1745\textsuperscript{3354} - Broken when\_some which takes iterators
• PR #1744\textsuperscript{3355} - Refining archive interface
• PR #1743\textsuperscript{3356} - Fixing when\_all when only a single future is passed
• PR #1742\textsuperscript{3357} - Config includes
• PR #1741\textsuperscript{3358} - Os executors
• Issue #1740\textsuperscript{3359} - hpx::promise has some problems
• PR #1739\textsuperscript{3360} - Parallel composition with generic containers

• Issue #1738 - After building program and successfully linking to a version of hpx DHPX_DIR seems to be ignored
• Issue #1737 - Uptime problems
• PR #1736 - added convenience c-tor and begin()/end() to serialize_buffer
• PR #1735 - Config includes
• PR #1734 - Fixed #1688: Add timer counters for tfunc_total and exec_total
• Issue #1733 - Add unit test for hpx/lcos/local/receive_buffer.hpp
• PR #1732 - Renaming get_os_thread_count
• PR #1731 - Basename registration
• Issue #1730 - Use after move of thread_init_data
• PR #1729 - Rewriting channel based on new gate component
• PR #1728 - Fixing #1722
• PR #1727 - Fixing compile problems with apply_colocated
• PR #1726 - Apex integration
• PR #1725 - fixed test timeouts
• PR #1724 - Renaming vector
• Issue #1723 - Drop support for intel compilers and gcc 4.4. based standard libs
• Issue #1722 - Add support for detecting non-ready futures before serialization
• PR #1721 - Unifying parallel executors, initializing from launch policy
• PR #1720 - dropped superfluous typedef
• Issue #1718 - Windows 10 x64, VS 2015 - Unknown CMake command “add_hpx_pseudo_target”.
• PR #1717 - Timed executor traits for thread-executors
• PR #1716 - serialization of arrays didn’t work with non-pod types. fixed
• PR #1715 - List serialization

https://github.com/STEllAR-GROUP/hpx/pull/1692
• Issue #1691 - is_executor template specification fails for inherited executors
• PR #1690 - added macro for non-intrusive serialization of classes without a default c-tor
• PR #1689 - Replace value_or_error with custom storage, unify future_data state
• Issue #1688 - Add timer counters for tfunc_total and exec_total
• PR #1687 - Fixed interval timer
• PR #1686 - Fixing cmake warnings about not existing pseudo target dependencies
• PR #1685 - Converting partitioners to use bulk async execute
• PR #1683 - Adds a tool for inspect that checks for character limits
• PR #1682 - Change project name to (uppercase) HPX
• PR #1681 - Counter shortnames
• PR #1680 - Extended Non-intrusive Serialization to Ease Usage for Library Developers
• PR #1679 - Working on 1544: More executor changes
• PR #1678 - Transpose fixes
• PR #1677 - Improve Boost compatibility check
• PR #1676 - 1d stencil fix
• Issue #1675 - hpx project name is not HPX
• PR #1674 - Fixing the MPI parcelport
• PR #1673 - added move semantics to map/vector deserialization
• PR #1672 - Vs2015 await
• PR #1671 - Adapt transform for #1668
• PR #1670 - Started to work on #1668
• PR #1669 - Add this_thread_executors
• Issue #1667 - Apple build instructions in docs are out of date

3429 https://github.com/STEllAR-GROUP/hpx/issues/1667
• PR #1666
  Apex integration
• PR #1665
  Fixes an error with the whitespace check that showed the incorrect location of the error
• Issue #1664
  Inspect tool found incorrect endline whitespace
• PR #1663
  Improve use of locks
• Issue #1662
  Possible exception source in coalescing_message_handler
• PR #1661
  Added support for 128bit number serialization
• PR #1660
  Serialization 128bits
• PR #1659
  Implemented inner_product and adjacent_diff algos
• PR #1658
  Add serialization for std::set (as there is for std::vector and std::map)
• PR #1657
  Use of shared_ptr in io_service_pool changed to unique_ptr
• Issue #1656
  1dStencil codes all have wrong factor
• PR #1654
  When using runtime_mode_connect, find the correct localhost public ip address
• PR #1653
  Fixing 1617
• PR #1652
  Remove traits::action_may_require_id_splitting
• PR #1651
  Fixed performance counters related to AGAS cache timings
• PR #1650
  Remove leftovers of traits::type_size
• PR #1649
  Shorten target names on Windows to shorten used path names
• PR #1648
  Fixing problems introduced by merging #1623 for older compilers
• PR #1647
  Simplify running automatic builds on Windows
• Issue #1646
  Cache insert and update performance counters are broken
• Issue #1644
  Remove leftovers of traits::type_size
• Issue #1643
  Remove traits::action_may_require_id_splitting
• PR #1642
  Adds spell checker to the inspect tool for qbk and doxygen comments
• PR #1640 - First step towards fixing 688
• PR #1639 - Re-apply remaining changes from limit_dataflow_recursion branch
• PR #1638 - This fixes possible deadlock in the test ignore_while_locked_1485
• PR #1637 - Fixing hpx::wait_all() invoked with two vector<future<T>>
• PR #1636 - Partially re-apply changes from limit_dataflow_recursion branch
• PR #1635 - Adding missing test for #1572
• PR #1634 - Revert “Limit recursion-depth in dataflow to a configurable constant”
• PR #1633 - Add command line option to ignore batch environment
• PR #1631 - hpx::cos::queue exhibits strange behavior
• PR #1630 - Fixed endline_whitespace_check.cpp to detect lines with only whitespace
• Issue #1629 - Inspect trailing whitespace checker problem
• PR #1628 - Removed meaningless const qualifiers. Minor icpc fix.
• PR #1627 - Fixing the queue LCO and add example demonstrating its use
• PR #1626 - Deprecating get_gid(), add get_id() and get_unmanaged_id()
• PR #1625 - Allowing to specify whether to send credits along with message
• Issue #1624 - Lifetime issue
• Issue #1623 - hpx::wait_all() invoked with two vector<future<T>> fails
• PR #1622 - Executor partitioners
• PR #1621 - Clean up coroutines implementation
• Issue #1620 - Revert #1535
• PR #1619 - Fix result type calculation for hpx::make_continuation
• PR #1618 - Fixing RDTSC on Xeon/Phi
• Issue #1617 - hpx cmake not working when run as a subproject

2.10. Releases
• Issue #1616 - cmake problem resulting in RDTSC not working correctly for Xeon Phi creates very strange results for duration counters
• Issue #1615 - hpx::make_continuation requires input and output to be the same
• PR #1614 - Fixed remove copy test
• Issue #1613 - Dataflow causes stack overflow
• PR #1612 - Modified foreach partitioner to use bulk execute
• PR #1611 - Limit recursion-depth in dataflow to a configurable constant
• PR #1610 - Increase timeout for CircleCI
• PR #1609 - Refactoring thread manager, mainly extracting thread pool
• PR #1608 - Fixed running multiple localities without localities parameter
• PR #1607 - More algorithm fixes to adjacentfind
• Issue #1606 - Running without localities parameter binds to bogus port range
• Issue #1605 - Too many serializations
• PR #1604 - Changes the HPX image into a hyperlink
• PR #1601 - Fixing problems with remove_copy algorithm tests
• PR #1600 - Actions with ids cleanup
• PR #1599 - Duplicate binding of global ids should fail
• PR #1598 - Fixing array access
• PR #1597 - Improved the reliability of connecting/disconnecting localities
• Issue #1596 - Duplicate id binding should fail
• PR #1595 - Fixing more cmake config constants
• PR #1594 - Fixing preprocessor constant used to enable C++11 chrono
• PR #1593 - Adding operator() for hpx::launch
• Issue #1592 - Error (typo) in the docs
• Issue #1590 - CMake fails when CMAKE_BINARY_DIR contains `+`.
• Issue #1589 - Disconnecting a locality results in segfault using heartbeat example
• PR #1588 - Fix doc string for config option HPX_WITH_EXAMPLES
• PR #1586 - Fixing 1493
• PR #1583 - Additional Check for Inspect Tool to detect Endline Whitespace
• Issue #1584 - Clean up coroutines implementation
• PR #1583 - Adding a check for end line whitespace
• PR #1582 - Attempt to fix assert firing after scheduling loop was exited
• PR #1581 - Fixed adjacentfind_binary test
• PR #1580 - Prevent some of the internal cmake lists from growing indefinitely
• PR #1579 - Removing type_size trait, replacing it with special archive type
• Issue #1578 - Remove demangle_helper
• PR #1577 - Get ptr problems
• Issue #1576 - Refactor async, dataflow, and future::then
• PR #1575 - Fixing tests for parallel rotate
• PR #1574 - Cleaning up schedulers
• PR #1573 - Fixing thread pool executor
• PR #1572 - Fixing number of configured localities
• PR #1571 - Reimplement decay
• PR #1570 - Refactoring async, apply, and dataflow APIs
• PR #1569 - Changed range for mach-o library lookup
• PR #1568 - Mark decltype support as required
• PR #1567 - Removed const from algorithms

• Issue #1566 - CMAKE Configuration Test Failures for clang 3.5 on debian
• PR #1565 - Dylib support
• PR #1564 - Converted partitioners and some algorithms to use executors
• PR #1563 - Fix several #includes for Boost.Preprocessor
• PR #1562 - Adding configuration option disabling/enabling all message handlers
• PR #1561 - Removed all occurrences of boost::move replacing it with std::move
• Issue #1560 - Leftover HPX_REGISTER_ACTION_DECLARATION_2
• PR #1559 - Revisit async/apply SFINAE conditions
• PR #1558 - Removing type_size trait, replacing it with special archive type
• PR #1557 - Executor algorithms
• PR #1556 - Remove the necessity to specify archive flags on the receiving end
• PR #1555 - Removing obsolete Boost.Serialization macros
• PR #1554 - Properly fix HPX_DEFINE_*_ACTION macros
• PR #1553 - Fixed algorithms relying on copy_if implementation
• PR #1552 - Pxs - Modifying FindOrangeFS.cmake based on OrangeFS 2.9.X
• Issue #1550 - Passing plain identifier inside HPX_DEFINE_plain_ACTION_1
• PR #1549 - Fixing intel14/libstdc++4.4
• PR #1548 - Moving raw_ptr to detail namespace
• PR #1547 - Adding support for executors to future.then
• PR #1546 - Executor traits result types
• PR #1545 - Integrate executors with dataflow
• PR #1544 - Fix potential zero-copy for primarynamespace::bulk_service_async et.al.
• PR #1543 - Merging HPX0.9.10 into pxfs branch
• PR #1542 - PXfs - Modifying FindOrangeFS.cmake based on OrangeFS 2.9.X
• PR #1541 - Removed stale cmake tests, unused since the great cmake refactoring
• PR #1540 - Fix idle-rate on platforms without TSC
• PR #1539 - Reporting situation if zero-copy-serialization was performed by a parcel generated from a plain apply/async
• PR #1538 - Changed return type of bulk executors and added test
• Issue #1537 - Incorrect cpuid config tests
• PR #1536 - Changed return type of bulk executors and added test
• PR #1535 - Make sure promise::get_gid() can be called more than once
• PR #1534 - Fixed async_callback with bound callback
• PR #1533 - Updated the link in the documentation to a publically-accessible URL
• PR #1532 - Make sure sync primitives are not copyable nor movable
• PR #1531 - Fix unwrapped issue with future ranges of void type
• PR #1530 - Serialization complex
• Issue #1529 - Unwrapped issue with future<void>
• Issue #1528 - HPX does not build with Boost 1.58.0
• PR #1526 - Added support for boost.multi_array serialization
• PR #1525 - Properly handle deferred futures, fixes #1506
• PR #1524 - Making sure invalid action argument types generate clear error message
• Issue #1522 - Need serialization support for boost multi array
• Issue #1521 - Remote async and zero-copy serialization optimizations don’t play well together
• PR #1520 - Fixing UB whil registering polymorphic classes for serialization
• PR #1519 - Making detail::condition_variable safe to use
• PR #1518 - Fix when_some bug missing indices in its result
• Issue #1517 - Typo may affect CMake build system tests

• PR #1516 - Fixing Posix context
• PR #1513 - Fixing Posix context
• PR #1514 - Correct problems with loading dynamic components
• PR #1513 - Fixing intel glibc
• Issue #1508 - memory and papi counters do not work
• Issue #1507 - Unrecognized Command Line Option Error causing exit status 0
• Issue #1506 - Properly handle deferred futures
• PR #1503 - Adding #include - would not compile without this
• Issue #1502 - boost::filesystem::exists throws unexpected exception
• Issue #1501 - hwloc configuration options are wrong for MIC
• PR #1504 - Making sure boost::filesystem::exists() does not throw
• PR #1500 - Exit application on --hpx:version/-v and --hpx:info
• PR #1498 - Extended task block
• PR #1497 - Unique ptr serialization
• PR #1496 - Unique ptr serialization (closed)
• PR #1495 - Switching circleci build type to debug
• Issue #1494 - --hpx:version/-v does not exit after printing version information
• Issue #1493 - add an hpx_ prefix to libraries and components to avoid name conflicts
• Issue #1492 - Define and ensure limitations for arguments to async/apply
• PR #1489 - Enable idle rate counter on demand
• PR #1488 - Made sure detail::condition_variable can be safely destroyed
• PR #1487 - Introduced default (main) template implementation for ignore_while_checking
• PR #1486 - Add HPX inspect tool
- Issue #1485 - ignore_while_locked doesn’t support all Lockable types
- PR #1484 - Docker image generation
- PR #1483 - Move external endian library into HPX
- PR #1482 - Actions with integer type ids
- Issue #1481 - Sync primitives safe destruction
- Issue #1480 - Move external/boost/endian into hpx/util
- Issue #1478 - Boost inspect violations
- PR #1479 - Adds serialization for arrays; some further/minor fixes
- PR #1477 - Fixing problems with the Intel compiler using a GCC 4.4 std library
- PR #1476 - Adding hpx::lcos::latch and hpx::lcos::local::latch
- Issue #1475 - Boost inspect violations
- PR #1473 - Fixing action move tests
- Issue #1471 - Sync primitives should not be movable
- PR #1470 - Removing hpx::util::polymorphic_factory
- PR #1469 - Fixed container creation
- Issue #1467 - HPX application fail during finalization
- Issue #1466 - HPX doesn’t pick up Torque’s nodefile on SuperMIC
- Issue #1464 - HPX option for pre and post bootstrap performance counters
- PR #1463 - Replacing async_colocated(id, ...) with async(colocated(id), ...)
- PR #1462 - Consolidated task_region with N4411
- PR #1461 - Consolidate inconsistent CMake option names
- Issue #1460 - Which malloc is actually used? or at least which one is HPX built with
- Issue #1459 - Make cmake configure step fail explicitly if compiler version is not supported
• Issue #1458 - Update parallel::task_region with N4411
• PR #1456 - Consolidating new_<>()
• Issue #1455 - Replace async_colocated(id, ...) with async(colocated(id), ...)
• PR #1454 - Removed harmful std::moves from return statements
• PR #1453 - Use range-based for-loop instead of Boost.Foreach
• PR #1452 - C++ feature tests
• PR #1451 - When serializing, pass archive flags to traits::get_type_size
• Issue #1450 - traits::get_type_size needs archive flags to enable zero_copy optimizations
• Issue #1449 - “couldn’t create performance counter” - AGAS
• Issue #1448 - Replace distributing factories with new_<T[]>(...)
• PR #1447 - Removing obsolete remote_object component
• PR #1446 - Hpx serialization
• PR #1445 - Removing superfluous typedefs
• Issue #1437 - hpx::init() should strip HPX-related flags from argv
• Issue #1436 - Add strong scaling option to htxs
• PR #1435 - Adding async_cb, async_continue_cb, and async_colocated_cb
• PR #1434 - Added missing install rule, removed some dead CMake code
• PR #1433 - Add GitExternal and SubProject cmake scripts from eyescale/cmake repo
• Issue #1432 - Add command line flag to disable thread pinning

Chapter 2. What’s so special about HPX?
- PR #1431 - Fix #1423
- Issue #1430 - Inconsistent CMake option names
- Issue #1429 - Configure setting HPX_HAVE_PARCELPORT_MPI is ignored
- PR #1428 - Fixes #1419 (closed)
- PR #1427 - Adding stencil_iterator and transform_iterator
- PR #1426 - Fixes #1419
- PR #1425 - During serialization memory allocation should honour allocator chunk size
- Issue #1424 - chunk allocation during serialization does not use memory pool/allocator chunk size
- Issue #1423 - Remove HPX_STD_UNIQUE_PTR
- Issue #1422 - hpx::threads=all allocates too many os threads
- PR #1420 - added .travis.yml
- Issue #1419 - Unify enums: hpx::runtime::state and hpx::state
- PR #1416 - Adding travis builder
- Issue #1414 - Correct directory for dispatch_gcc46.hpp iteration
- Issue #1410 - Set operation algorithms
- Issue #1389 - Parallel algorithms relying on scan partitioner break for small number of elements
- Issue #1325 - Exceptions thrown during parcel handling are not handled correctly
- Issue #1315 - Errors while running performance tests
- Issue #1309 - hpx::vector partitions are not easily extendable by applications
- PR #1300 - Added serialization/de-serialization to examples.tuplespace
- Issue #1251 - hpx::threads::get_thread_count doesn’t consider pending threads
- Issue #1008 - Decrease in application performance overtime; occasional spikes of major slowdown
- Issue #1001 - Zero copy serialization raises assert
• Issue #721 - Make HPX usable for Xeon Phi
• Issue #524 - Extend scheduler to support threads which can’t be stolen

2.10.13  HPX V0.9.10 (Mar 24, 2015)

General changes

This is the 12th official release of HPX. It coincides with the 7th anniversary of the first commit to our source code repository. Since then, we have seen over 12300 commits amounting to more than 220000 lines of C++ code.

The major focus of this release was to improve the reliability of large scale runs. We believe to have achieved this goal as we now can reliably run HPX applications on up to ~24k cores. We have also shown that HPX can be used with success for symmetric runs (applications using both, host cores and Intel Xeon/Phi coprocessors). This is a huge step forward in terms of the usability of HPX. The main focus of this work involved isolating the causes of the segmentation faults at start up and shut down. Many of these issues were discovered to be the result of the suspension of threads which hold locks.

A very important improvement introduced with this release is the refactoring of the code representing our parcel-port implementation. Parcel-ports can now be implemented by 3rd parties as independent plugins which are dynamically loaded at runtime (static linking of parcel-ports is also supported). This refactoring also includes a massive improvement of the performance of our existing parcel-ports. We were able to significantly reduce the networking latencies and to improve the available networking bandwidth. Please note that in this release we disabled the ibverbs and ipc parcel ports as those have not been ported to the new plugin system yet (see Issue #839).

Another corner stone of this release is our work towards a complete implementation of __cpp11_n4104__ (Working Draft, Technical Specification for C++ Extensions for Parallelism). This document defines a set of parallel algorithms to be added to the C++ standard library. We now have implemented about 75% of all specified parallel algorithms (see [link hpx.manual.parallel.parallel_algorithms Parallel Algorithms] for more details). We also implemented some extensions to __cpp11_n4104__ allowing to invoke all of the algorithms asynchronously.

This release adds a first implementation of hpx::vector which is a distributed data structure closely aligned to the functionality of std::vector. The difference is that hpx::vector stores the data in partitions where the partitions can be distributed over different localities. We started to work on allowing to use the parallel algorithms with hpx::vector. At this point we have implemented only a few of the parallel algorithms to support distributed data structures (like hpx::vector) for testing purposes (see Issue #1338 for a documentation of our progress).

Breaking changes

With this release we put a lot of effort into changing the code base to be more compatible to C++11. These changes have caused the following issues for backward compatibility:

• Move to Variadics- All of the API now uses variadic templates. However, this change required to modify the argument sequence for some of the exiting API functions (hpx::async_continue, hpx::apply_continue, hpx::when_each, hpx::wait_each, synchronous invocation of actions).

• Changes to Macros- We also removed the macros HPX_STD_FUNCTION and HPX_STD_TUPLE. This shouldn’t affect any user code as we replaced HPX_STD_FUNCTION with hpx::util::function_nonser which was the default expansion used for this macro. All HPX API functions which expect a hpx::util::function_nonser (or a hpx::util::unique_function_nonser) can now be transparently called with a compatible

3660 https://github.com/STEllAR-GROUP/hpx/issues/721
3661 https://github.com/STEllAR-GROUP/hpx/issues/524
3662 https://github.com/STEllAR-GROUP/hpx/issues/839
3663 https://github.com/STEllAR-GROUP/hpx/issues/1338
std::function instead. Similarly, HPX_STD_TUPLE was replaced by its default expansion as well: hpx::util::tuple.

- Changes to hpx::unique_future- hpx::unique_future, which was deprecated in the previous release for hpx::future is now completely removed from HPX. This completes the transition to a completely standards conforming implementation of hpx::future.

- Changes to Supported Compilers. Finally, in order to utilize more C++11 semantics, we have officially dropped support for GCC 4.4 and MSVC 2012. Please see our Prerequisites page for more details.

### Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release.

- Issue #1402 - Internal shared_future serialization copies
- Issue #1399 - Build takes unusually long time...
- Issue #1398 - Tests using the scan partitioner are broken on at least gcc 4.7 and intel compiler
- Issue #1397 - Completely remove hpx::unique_future
- Issue #1396 - Parallel scan algorithms with different initial values
- Issue #1395 - Race Condition - 1d_stencil_8 - SuperMIC
- Issue #1394 - “suspending thread while at least one lock is being held” - 1d_stencil_8 - SuperMIC
- Issue #1393 - SEGFAULT in 1d_stencil_8 on SuperMIC
- Issue #1392 - Fixing #1168
- Issue #1391 - Parallel Algorithms for scan partitioner for small number of elements
- Issue #1387 - Failure with more than 4 localities
- Issue #1386 - Dispatching unhandled exceptions to outer user code
- Issue #1385 - Adding Copy algorithms, fixing parallel::copy_if
- Issue #1384 - Fixing 1325
- Issue #1383 - Fixed #504: Refactor Dataflow LCO to work with futures, this removes the dataflow component as it is obsolete
- Issue #1382 - is_sorted, is_sorted_until and is_partitioned algorithms
- Issue #1381 - fix for CMake versions prior to 3.1

2.10. Releases

1619
• Issue #1333 - Distributed transform reduce
• Issue #1332 - Variadic templates support for actions
• Issue #1331 - Some ambiguous calls of map::erase have been prevented by adding additional check in locality constructor.
• Issue #1330 - Defining Plain Actions does not work as described in the documentation
• Issue #1329 - Distributed vector cleanup
• Issue #1328 - Sync docs and comments with code in hello_world example
• Issue #1327 - Typos in docs
• Issue #1326 - Documentation and code diverged in Fibonacci tutorial
• Issue #1325 - Exceptions thrown during parcel handling are not handled correctly
• Issue #1324 - fixed bandwidth calculation
• Issue #1323 - mmap() failed to allocate thread stack due to insufficient resources
• Issue #1322 - HPX fails to build aa182cf
• Issue #1321 - Limiting size of outgoing messages while coalescing parcels
• Issue #1320 - passing a future with launch::deferred in remote function call causes hang
• Issue #1319 - An exception when tries to specify number high priority threads with abp-priority
• Issue #1318 - Unable to run program with abp-priority and numa-sensitivity enabled
• Issue #1317 - N4071 Search/Search_n finished, minor changes
• Issue #1316 - Add config option to make -lhpx.run_hpx_main!=1 the default
• Issue #1314 - Variadic support for async and apply
• Issue #1313 - Adjust when_any/some to the latest proposed interfaces
• Issue #1312 - Fixing #857: hpx::naming::locality leaks parcelport specific information into the public interface
• Issue #1311 - Distributed get'er/set'er_values for distributed vector
• Issue #1310^3749 - Crashing in hpx::parcelset::policies::mpi::connection_handler::handle_messages() on Super-MIC
• Issue #1308^3750 - Unable to execute an application with –hpx:threads
• Issue #1307^3751 - merge_graph linking issue
• Issue #1306^3752 - First batch of variadic templates support
• Issue #1305^3753 - Create a compiler wrapper
• Issue #1304^3754 - Provide a compiler wrapper for hpx
• Issue #1303^3755 - Drop support for GCC44
• Issue #1302^3756 - Fixing #1297
• Issue #1301^3757 - Compilation error when tried to use boost range iterators with wait_all
• Issue #1298^3758 - Distributed vector
• Issue #1297^3759 - Unable to invoke component actions recursively
• Issue #1294^3760 - HDF5 build error
• Issue #1275^3761 - The parcelport implementation is non-optimal
• Issue #1267^3762 - Added classes and unit tests for local_file, orangefs_file and pxfs_file
• Issue #1264^3763 - Error “assertion ‘!m_fun’ failed” randomly occurs when using TCP
• Issue #1254^3764 - thread binding seems to not work properly
• Issue #1220^3765 - parallel::copy_if is broken
• Issue #1217^3766 - Find a better way of fixing the issue patched by #1216
• Issue #1168^3767 - Starting HPX on Cray machines using aprun isn’t working correctly
• Issue #1085^3768 - Replace startup and shutdown barriers with broadcasts
• Issue #981^3769 - With SLURM, –hpx:threads=8 should not be necessary
• Issue #857^3770 - hpx::naming::locality leaks parcelport specific information into the public interface
• Issue #850^3771 - “flush” not documented

• Issue #763\textsuperscript{3772} - Create buildbot instance that uses std::bind as HPX_STD_BIND
• Issue #680\textsuperscript{3773} - Convert parcel ports into a plugin system
• Issue #582\textsuperscript{3774} - Make exception thrown from HPX threads available from hpx::init
• Issue #504\textsuperscript{3775} - Refactor Dataflow LCO to work with futures
• Issue #196\textsuperscript{3776} - Don’t store copies of the locality network metadata in the gva table

2.10.14 HPX V0.9.9 (Oct 31, 2014, codename Spooky)

General changes

We have had over 1500 commits since the last release and we have closed over 200 tickets (bugs, feature requests, pull requests, etc.). These are by far the largest numbers of commits and resolved issues for any of the HPX releases so far. We are especially happy about the large number of people who contributed for the first time to HPX.

• We completed the transition from the older (non-conforming) implementation of hpx::future to the new and fully conforming version by removing the old code and by renaming the type hpx::unique_future to hpx::future. In order to maintain backwards compatibility with existing code which uses the type hpx::unique_future we support the configuration variable HPX_UNIQUE_FUTURE_ALIAS. If this variable is set to ON while running cmake it will additionally define a template alias for this type.

• We rewrote and significantly changed our build system. Please have a look at the new (now generated) documentation here: HPX build system. Please revisit your build scripts to adapt to the changes. The most notable changes are:
  – HPX\_NO\_INSTALL is no longer necessary.
  – For external builds, you need to set HPX\_DIR instead of HPX\_ROOT as described here: Using HPX with CMake-based projects.
  – IDEs that support multiple configurations (Visual Studio and XCode) can now be used as intended. that means no build dir.
  – Building HPX statically (without dynamic libraries) is now supported (-DHPX\_STATIC\_LINKING=On).
  – Please note that many variables used to configure the build process have been renamed to unify the naming conventions (see the section CMake variables used to configure HPX for more information).
  – This also fixes a long list of issues, for more information see Issue #1204\textsuperscript{3777}.

• We started to implement various proposals to the C++ Standardization committee related to parallelism and concurrency, most notably N4409\textsuperscript{3778} (Working Draft, Technical Specification for C++ Extensions for Parallelism), N4411\textsuperscript{3779} (Task Region Rev. 3), and N4313\textsuperscript{3780} (Working Draft, Technical Specification for C++ Extensions for Concurrency).

\textsuperscript{3779} http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2015/n4411.pdf
\textsuperscript{3780} http://www.open-std.org/jtc1/sc22/wg21/docs/papers/2014/n4313.html
• We completely remodeled our automatic build system to run builds and unit tests on various systems and compilers. This allows us to find most bugs right as they were introduced and helps to maintain a high level of quality and compatibility. The newest build logs can be found at *HPX Buildbot Website*.

**Bug fixes (closed tickets)**

Here is a list of the important tickets we closed for this release.

- **Issue #1296** - Rename make_error_future to make_exceptional_future, adjust to N4123
- **Issue #1295** - building issue
- **Issue #1293** - Transpose example
- **Issue #1292** - Wrong abs() function used in example
- **Issue #1291** - non-synchronized shift operators have been removed
- **Issue #1290** - RDTSCP is defined as true for Xeon Phi build
- **Issue #1289** - Fixing 1288
- **Issue #1288** - Add new performance counters
- **Issue #1287** - Hierarchy scheduler broken performance counters
- **Issue #1286** - Algorithm cleanup
- **Issue #1285** - Broken Links in Documentation
- **Issue #1284** - Uninitialized copy
- **Issue #1283** - missing boost::scoped_ptr includes
- **Issue #1282** - Update documentation of build options for schedulers
- **Issue #1281** - reset idle rate counter
- **Issue #1280** - Bug when executing on Intel MIC
- **Issue #1279** - Add improved when_all/wait_all
- **Issue #1278** - Implement improved when_all/wait_all
- **Issue #1277** - feature request: get access to argc argv and variables_map

• Issue #1276 - Remove merging map
• Issue #1274 - Weird (wrong) string code in papi.cpp
• Issue #1273 - Sequential task execution policy
• Issue #1272 - Avoid CMake name clash for Boost.Thread library
• Issue #1271 - Updates on HPX Test Units
• Issue #1270 - hpx/util/safe_lexical_cast.hpp is added
• Issue #1269 - Added default value for “LIB” cmake variable
• Issue #1268 - Memory Counters not working
• Issue #1266 - FindHPX.cmake is not installed
• Issue #1263 - apply_remote test takes too long
• Issue #1262 - Chrono cleanup
• Issue #1261 - Need make install for papi counters and this builds all the examples
• Issue #1260 - Documentation of Stencil example claims
• Issue #1259 - Avoid double-linking Boost on Windows
• Issue #1257 - Adding additional parameter to create_thread
• Issue #1256 - added buildbot changes to release notes
• Issue #1255 - Cannot build MiniGhost
• Issue #1253 - hpx::thread defects
• Issue #1252 - HPX_PREFIX is too fragile
• Issue #1250 - switch_to_fiber_emulation does not work properly
• Issue #1249 - Documentation is generated under Release folder
• Issue #1248 - Fix usage of hpx::generic_coroutine_context and get tests passing on powerpc
• Issue #1247 - Dynamic linking error

https://github.com/STEllAR-GROUP/hpx/issues/1247
• Issue #1246³⁸²⁴ - Make cpuid.cpp C++11 compliant
• Issue #1245³⁸²⁵ - HPX fails on startup (setting thread affinity mask)
• Issue #1244³⁸²⁶ - HPX_WITH_RDTSC configure test fails, but should succeed
• Issue #1243³⁸²⁷ - CTest dashboard info for CSCS CDash drop location
• Issue #1242³⁸²⁸ - Mac fixes
• Issue #1241³⁸²⁹ - Failure in Distributed with Boost 1.56
• Issue #1240³⁸³⁰ - fix a race condition in examples.diskperf
• Issue #1239³⁸³¹ - fix wait_each in examples.diskperf
• Issue #1238³⁸³² - Fixed #1237: hpx::util::portable_binary_iarchive failed
• Issue #1237³⁸³³ - hpx::util::portable_binary_iarchive faileds
• Issue #1235³⁸³⁴ - Fixing clang warnings and errors
• Issue #1234³⁸³⁵ - TCP runs fail: Transport endpoint is not connected
• Issue #1233³⁸³⁶ - Making sure the correct number of threads is registered with AGAS
• Issue #1232³⁸³⁷ - Fixing race in wait_xxx
• Issue #1231³⁸³⁸ - Parallel minmax
• Issue #1230³⁸³⁹ - Distributed run of 1d_stencil_8 uses less threads than spec. & sometimes gives errors
• Issue #1229³⁸⁴⁰ - Unstable number of threads
• Issue #1228³⁸⁴¹ - HPX link error (cmake / MPI)
• Issue #1226³⁸⁴² - Warning about struct/class thread_counters
• Issue #1225³⁸⁴³ - Adding parallel::replace etc
• Issue #1224³⁸⁴⁴ - Extending dataflow to pass through non-future arguments
• Issue #1223³⁸⁴⁵ - Remaining find algorithms implemented, N4071
• Issue #1222³⁸⁴⁶ - Merging all the changes

2.10. Releases 1625
• Issue #1221 - No error output when using mpirun with hpx
• Issue #1219 - Adding new AGAS cache performance counters
• Issue #1216 - Fixing using futures (clients) as arguments to actions
• Issue #1215 - Error compiling simple component
• Issue #1214 - Stencil docs
• Issue #1213 - Using more than a few dozen MPI processes on SuperMike results in a seg fault before getting to hpx_main
• Issue #1212 - Parallel rotate
• Issue #1211 - Direct actions cause the future’s shared_state to be leaked
• Issue #1210 - Refactored local::promise to be standard conformant
• Issue #1209 - Improve command line handling
• Issue #1208 - Adding parallel::reverse and parallel::reverse_copy
• Issue #1207 - Add copy_backward and move_backward
• Issue #1206 - N4071 additional algorithms implemented
• Issue #1204 - Cmake simplification and various other minor changes
• Issue #1203 - Implementing new launch policy for (local) async: hpx::launch::fork.
• Issue #1202 - Failed assertion in connection_cache.hpp
• Issue #1201 - pkg-config doesn’t add mpi link directories
• Issue #1200 - Error when querying time performance counters
• Issue #1199 - Library path is now configurable (again)
• Issue #1198 - Error when querying performance counters
• Issue #1197 - Tests fail with intel compiler
• Issue #1196 - Silence several warnings
• Issue #1195 - Rephrase initializers to work with VC++ 2012
• Issue #1194 Simplify parallel algorithms
• Issue #1193 Adding parallel::equal
• Issue #1192 HPX(out_of_memory) on including <hpx/hpx.hpp>
• Issue #1191 Fixing #1189
• Issue #1190 Chrono cleanup
• Issue #1189 Deadlock .. somewhere? (probably serialization)
• Issue #1188 Removed future::get_status()
• Issue #1187 Fixed FindOpenCL to find current AMD APP SDK
• Issue #1186 Tweaking future unwrapping
• Issue #1185 Extended parallel::reduce
• Issue #1184 future::unwrap hangs for launch::deferred
• Issue #1183 Adding all_of, any_of, and none_of and corresponding documentation
• Issue #1182 hpx::cout defect
• Issue #1179 hpx::async does not work for member function pointers when called on types with self-defined unary operator*
• Issue #1178 Implemented variadic hpx::util::zip_iterator
• Issue #1177 MPI parcelport defect
• Issue #1176 HPX_DEFINE_COMPONENT_CONST_ACTION_TPL does not have a 2-argument version
• Issue #1175 Create util::zip_iterator working with util::tuple<>
• Issue #1174 Error Building HPX on linux, root_certificate_authority.cpp
• Issue #1173 hpx::cout output lost
• Issue #1172 HPX build error with Clang 3.4.2
• Issue #1171 CMAKE_INSTALL_PREFIX ignored
• Issue #1170 Close hpx_benchmarks repository on Github

3892 https://github.com/STEllAR-GROUP/hpx/issues/1170
• Issue #1169 - Buildbot emails have syntax error in url
• Issue #1167 - Merge partial implementation of standards proposal N3960
• Issue #1166 - Fixed several compiler warnings
• Issue #1165 - cmake warns: “tests.regressions.actions” does not exist
• Issue #1164 - Want my own serialization of hpx::future
• Issue #1162 - Segfault in hello_world example
• Issue #1161 - Use HPX_ASSERT to aid the compiler
• Issue #1160 - Do not put -DNDEBUG into hpx_application.pc
• Issue #1159 - Support Clang 3.4.2
• Issue #1158 - Fixed #1157: Rename when_n/wait_n, add when_xxx_n/wait_xxx_n
• Issue #1157 - Rename when_n/wait_n, add when_xxx_n/wait_xxx_n
• Issue #1156 - Force inlining fails
• Issue #1155 - changed header of printout to be compatible with python csv module
• Issue #1154 - Fixing iostreams
• Issue #1153 - Standard manipulators (like std::endl) do not work with hpx::ostream
• Issue #1152 - Functions revamp
• Issue #1151 - Suppressing cmake 3.0 policy warning for CMP0026
• Issue #1150 - Client Serialization error
• Issue #1149 - Segfault on Stampede
• Issue #1148 - Refactoring mini-ghost
• Issue #1147 - N3960 copy_if and copy_n implemented and tested
• Issue #1146 - Stencil print
• Issue #1145 - N3960 hpx::parallel::copy implemented and tested

• Issue #1144 - OpenMP examples 1d_stencil do not build
• Issue #1143 - 1d_stencil OpenMP examples do not build
• Issue #1142 - Cannot build HPX with gcc 4.6 on OS X
• Issue #1140 - Fix OpenMP lookup, enable usage of config tests in external CMake projects.
• Issue #1139 - hpx/hpx/config/compiler_specific.hpp
• Issue #1138 - clean up pkg-config files
• Issue #1137 - Improvements to create binary packages
• Issue #1136 - HPX_GCC_VERSION not defined on all compilers
• Issue #1135 - Avoiding collision between winsock2.h and windows.h
• Issue #1134 - Making sure, that hpx::finalize can be called from any locality
• Issue #1133 - 1d stencil examples
• Issue #1132 - Refactor unique_function implementation
• Issue #1131 - Unique function
• Issue #1129 - Some fixes to the Build system on OS X
• Issue #1128 - Action future args
• Issue #1127 - Executor causes segmentation fault
• Issue #1124 - Adding new API functions: register_id_with_basename, unregister_id_with basename, find_ids_from_basename; adding test
• Issue #1123 - Reduce nesting of try-catch construct in encode_parcel?.
• Issue #1122 - Client base fixes
• Issue #1121 - Update hpxrun.py.in
• Issue #1120 - HTTS2 tests compile errors on v110 (VS2012)
• Issue #1119 - Remove references to boost::atomic in accumulator example
• Issue #1118 - Only build test thread_pool_executor_1114_test if HPX_LOCAL_SCHEDULER is set

2.10. Releases
• Issue #1117\textsuperscript{3939} - local\_queue\_executor linker error on vc110
• Issue #1116\textsuperscript{3940} - Disabled performance counter should give runtime errors, not invalid data
• Issue #1115\textsuperscript{3941} - Compile error with Intel C++ 13.1
• Issue #1114\textsuperscript{3942} - Default constructed executor is not usable
• Issue #1113\textsuperscript{3943} - Fast compilation of logging causes ABI incompatibilities between different NDEBUG values
• Issue #1112\textsuperscript{3944} - Using thread\_pool\_executors causes segfault
• Issue #1111\textsuperscript{3945} - hpx::threads::get\_thread\_data always returns zero
• Issue #1110\textsuperscript{3946} - Remove unnecessary null pointer checks
• Issue #1109\textsuperscript{3947} - More tests adjustments
• Issue #1108\textsuperscript{3948} - Clarify build rules for “libboost\_atomic-mt.so”?
• Issue #1107\textsuperscript{3949} - Remove unnecessary null pointer checks
• Issue #1106\textsuperscript{3950} - network\_storage benchmark improvements, adding legends to plots and tidying layout
• Issue #1105\textsuperscript{3951} - Add more plot outputs and improve instructions doc
• Issue #1104\textsuperscript{3952} - Complete quoting for parameters of some CMake commands
• Issue #1103\textsuperscript{3953} - Work on test/scripts
• Issue #1102\textsuperscript{3954} - Changed minimum requirement of window install to 2012
• Issue #1101\textsuperscript{3955} - Changed minimum requirement of window install to 2012
• Issue #1100\textsuperscript{3956} - Changed readme to no longer specify using MSVC 2010 compiler
• Issue #1099\textsuperscript{3957} - Error returning futures from component actions
• Issue #1098\textsuperscript{3958} - Improve storage test
• Issue #1097\textsuperscript{3959} - data\_actions quickstart example calls missing function decorate\_action of data\_get\_action
• Issue #1096\textsuperscript{3960} - MPI parcelport broken with new zero copy optimization
• Issue #1095\textsuperscript{3961} - Warning C4005: _WIN32_WINNT: Macro redefinition
• Issue #1094 - Syntax error for -DHPX_UNIQUE_FUTURE_ALIAS in master
• Issue #1093 - Syntax error for -DHPX_UNIQUE_FUTURE_ALIAS
• Issue #1092 - Rename unique_future<> back to future<>
• Issue #1091 - Inconsistent error message
• Issue #1090 - On windows 8.1 the examples crashed if using more than one os thread
• Issue #1089 - Components should be allowed to have their own executor
• Issue #1088 - Add possibility to select a network interface for the ibverbs parcelport
• Issue #1087 - ibverbs and ipc parcelport uses zero copy optimization
• Issue #1083 - Make shell examples copyable in docs
• Issue #1082 - Implement proper termination detection during shutdown
• Issue #1081 - Implement thread_specific_ptr for hpx::threads
• Issue #1072 - make install not working properly
• Issue #1070 - Complete quoting for parameters of some CMake commands
• Issue #1059 - Fix more unused variable warnings
• Issue #1051 - Implement when_each
• Issue #973 - Would like option to report hwloc bindings
• Issue #970 - Bad flags for Fortran compiler
• Issue #941 - Create a proper user level context switching class for BG/Q
• Issue #935 - Build error with gcc 4.6 and Boost 1.54.0 on hpx trunk and 0.9.6
• Issue #934 - Want to build HPX without dynamic libraries
• Issue #927 - Make hpx/lcos/reduce.hpp accept futures of id_type
• Issue #926 - All unit tests that are run with more than one thread with CTest/hpx_run_test should configure hpx.os_threads
• Issue #925 - regression_dataflow_791 needs to be brought in line with HPX standards

3983 https://github.com/STEllAR-GROUP/hpx/issues/926
3984 https://github.com/STEllAR-GROUP/hpx/issues/925
- Issue #899 - Fix race conditions in regression tests
- Issue #879 - Hung test leads to cascading test failure; make tests should support the MPI parcelport
- Issue #865 - future<T> and friends shall work for movable only Ts
- Issue #847 - Dynamic libraries are not installed on OS X
- Issue #816 - First Program tutorial pull request
- Issue #799 - Wrap lexical_cast to avoid exceptions
- Issue #720 - broken configuration when using cmake on Ubuntu
- Issue #622 - --hpx:hpx and --hpx:debug-hpx-log is nonsensical
- Issue #525 - Extend barrier LCO test to run in distributed
- Issue #515 - Multi-destination version of hpx::apply is broken
- Issue #509 - Push Boost.Atomic changes upstream
- Issue #503 - Running HPX applications on Windows should not require setting %PATH%
- Issue #461 - Add a compilation sanity test
- Issue #456 - hpx_run_tests.py should log output from tests that timeout
- Issue #454 - Investigate threadmanager performance
- Issue #345 - Add more versatile environmental/cmake variable support to hpx_find_* CMake macros
- Issue #209 - Support multiple configurations in generated build files
- Issue #190 - hpx::cout should be a std::ostream
- Issue #189 - iostreams component should use startup/shutdown functions
- Issue #183 - Use Boost.ICL for correctness in AGAS
- Issue #44 - Implement real futures
2.10.15  HPX V0.9.8 (Mar 24, 2014)

We have had over 800 commits since the last release and we have closed over 65 tickets (bugs, feature requests, etc.). With the changes below, HPX is once again leading the charge of a whole new era of computation. By intrinsically breaking down and synchronizing the work to be done, HPX insures that application developers will no longer have to fret about where a segment of code executes. That allows coders to focus their time and energy to understanding the data dependencies of their algorithms and thereby the core obstacles to an efficient code. Here are some of the advantages of using HPX:

- **HPX** is solidly rooted in a sophisticated theoretical execution model – ParalleX
- **HPX** exposes an API fully conforming to the C++11 and the draft C++14 standards, extended and applied to distributed computing. Everything programmers know about the concurrency primitives of the standard C++ library is still valid in the context of **HPX**.
- It provides a competitive, high performance implementation of modern, future-proof ideas which gives an smooth migration path from today’s mainstream techniques
- There is no need for the programmer to worry about lower level parallelization paradigms like threads or message passing; no need to understand pthreads, MPI, OpenMP, or Windows threads, etc.
- There is no need to think about different types of parallelism such as tasks, pipelines, or fork-join, task or data parallelism.
- The same source of your program compiles and runs on Linux, BlueGene/Q, Mac OS X, Windows, and Android.
- The same code runs on shared memory multi-core systems and supercomputers, on handheld devices and Intel® Xeon Phi™ accelerators, or a heterogeneous mix of those.

General changes

- A major API breaking change for this release was introduced by implementing hpx::future and hpx::shared_future fully in conformance with the C++11 Standard\(^{4006}\). While hpx::shared_future is new and will not create any compatibility problems, we revised the interface and implementation of the existing hpx::future. For more details please see the mailing list archive\(^{4007}\).
  To avoid any incompatibilities for existing code we named the type which implements the std::future interface as hpx::unique_future. For the next release this will be renamed to hpx::future, making it full conforming to C++11 Standard\(^{4008}\).
- A large part of the code base of HPX has been refactored and partially re-implemented. The main changes were related to
  - The threading subsystem: these changes significantly reduce the amount of overheads caused by the schedulers, improve the modularity of the code base, and extend the variety of available scheduling algorithms.
  - The parcel subsystem: these changes improve the performance of the HPX networking layer, modularize the structure of the parcelports, and simplify the creation of new parcelports for other underlying networking libraries.
  - The API subsystem: these changes improved the conformance of the API to C++11 Standard, extend and unify the available API functionality, and decrease the overheads created by various elements of the API.
  - The robustness of the component loading subsystem has been improved significantly, allowing to more portably and more reliably register the components needed by an application as startup. This additionally speeds up general application initialization.

\(^{4006}\) [http://www.open-std.org/jtc1/sc22/wg21](http://www.open-std.org/jtc1/sc22/wg21)
\(^{4008}\) [http://www.open-std.org/jtc1/sc22/wg21](http://www.open-std.org/jtc1/sc22/wg21)
• We added new API functionality like `hpx::migrate` and `hpx::copy_component` which are the basic building blocks necessary for implementing higher level abstractions for system-wide load balancing, runtime-adaptive resource management, and object-oriented checkpointing and state-management.

• We removed the use of C++11 move emulation (using Boost.Move), replacing it with C++11 rvalue references. This is the first step towards using more and more native C++11 facilities which we plan to introduce in the future.

• We improved the reference counting scheme used by HPX which helps managing distributed objects and memory. This improves the overall stability of HPX and further simplifies writing real world applications.

• The minimal Boost version required to use HPX is now V1.49.0.

• This release coincides with the first release of HPXPI (V0.1.0), the first implementation of the XPI specification.

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release.

• Issue #1086 - Expose internal boost::shared_array to allow user management of array lifetime
• Issue #1083 - Make shell examples copyable in docs
• Issue #1080 - /threads/{locality#*/total}/count/cumulative broken
• Issue #1079 - Build problems on OS X
• Issue #1078 - Improve robustness of component loading
• Issue #1077 - Fix a missing enum definition for ‘take’ mode
• Issue #1076 - Merge Jb master
• Issue #1075 - Unknown CMake command “add_hpx_pseudo_target”
• Issue #1074 - Implement `apply_continue_callback` and `apply_colocated_callback`
• Issue #1073 - The new `apply_colocated` and `async_colocated` functions lead to automatic registered functions
• Issue #1071 - Remove `deferred_packaged_task`
• Issue #1069 - `serialize_buffer` with allocator fails at destruction
• Issue #1068 - Coroutine include and forward declarations missing
• Issue #1067 - Add allocator support to `util::serialize_buffer`

• Issue #1066 - Allow for MPI_Init being called before HPX launches
• Issue #1065 - AGAS cache isn’t used/populated on worker localities
• Issue #1064 - Reorder includes to ensure ws2 includes early
• Issue #1063 - Add hpx::runtime::suspend and hpx::runtime::resume
• Issue #1062 - Fix async_continue to properly handle return types
• Issue #1061 - Implement async_colocated and apply_colocated
• Issue #1060 - Implement minimal component migration
• Issue #1058 - Remove HPX_UTIL_TUPLE from code base
• Issue #1057 - Add performance counters for threading subsystem
• Issue #1055 - Thread allocation uses two memory pools
• Issue #1053 - Work stealing flawed
• Issue #1052 - Fix a number of warnings
• Issue #1049 - Fixes for TLS on OSX and more reliable test running
• Issue #1048 - Fixing after 588 hang
• Issue #1047 - Use port ‘0’ for networking when using one locality
• Issue #1046 - Composable guard test is broken when having more than one thread
• Issue #1045 - Security missing headers
• Issue #1044 - Native TLS on FreeBSD via __thread
• Issue #1043 - async et.al. compute the wrong result type
• Issue #1042 - async et.al. implicitly unwrap reference_wrappers
• Issue #1041 - Remove redundant costly Kleene stars from regex searches
• Issue #1040 - CMake script regex match patterns has unnecessary kleenes
• Issue #1039 - Remove use of Boost.Move and replace with std::move and real rvalue refs
• Issue #1038 - Bump minimal required Boost to 1.49.0
• Issue #1037 - Implicit unwrapping of futures in async broken
• Issue #1036 - Scheduler hangs when user code attempts to “block” OS-threads
• Issue #1035 - Idle-rate counter always reports 100% idle rate
• Issue #1034 - Symbolic name registration causes application hangs
• Issue #1033 - Application options read in from an options file generate an error message
• Issue #1032 - `hpx::id_type` local reference counting is wrong
• Issue #1031 - Negative entry in reference count table
• Issue #1030 - Implement `condition_variable`
• Issue #1029 - Deadlock in thread scheduling subsystem
• Issue #1028 - HPX-thread cumulative count performance counters report incorrect value
• Issue #1027 - Expose `hpx::thread_interrupted` error code as a separate exception type
• Issue #1026 - Exceptions thrown in asynchronous calls can be lost if the value of the future is never queried
• Issue #1025 - `future::wait_for/wait_until` do not remove callback
• Issue #1024 - Remove dependence to boost assert and create `hpx assert`
• Issue #1023 - Segfaults with tcmalloc
• Issue #1022 - prerequisites link in readme is broken
• Issue #1020 - HPX Deadlock on external synchronization
• Issue #1019 - Convert using `BOOST_ASSERT` to `HPX_ASSERT`
• Issue #1018 - compiling bug with gcc 4.8.1
• Issue #1017 - Possible crash in `io_pool` executor
• Issue #1016 - Crash at startup
• Issue #1014 - Implement Increment/Decrement Merging

• Issue #1013 - Add more logging channels to enable greater control over logging granularity
• Issue #1012 - `--hpx:debug-hpx-log` and `--hpx:debug-agas-log` lead to non-thread safe writes
• Issue #1011 - After installation, running applications from the build/staging directory no longer works
• Issue #1010 - Mergeable decrement requests are not being merged
• Issue #1009 - `--hpx:list-symbolic-names` crashes
• Issue #1007 - Components are not properly destroyed
• Issue #1006 - Segfault/hang in set_data
• Issue #1003 - Performance counter naming issue
• Issue #982 - Race condition during startup
• Issue #912 - OS X: component type not found in map
• Issue #663 - Create a buildbot slave based on Clang 3.2/OSX
• Issue #636 - Expose `this_locality::apply<act>(p1, p2);` for local execution
• Issue #197 - Add `--console=address` option for PBS runs
• Issue #175 - Asynchronous AGAS API

2.10.16 HPX V0.9.7 (Nov 13, 2013)

We have had over 1000 commits since the last release and we have closed over 180 tickets (bugs, feature requests, etc.).

General changes

• Ported HPX to BlueGene/Q
• Improved HPX support for Xeon/Phi accelerators
• Reimplemented `hpx::bind`, `hpx::tuple`, and `hpx::function` for better performance and better compliance with the C++11 Standard. Added `hpx::mem_fn`.
• Reworked `hpx::when_all` and `hpx::when_any` for better compliance with the ongoing C++ standardization effort, added heterogeneous version for those functions. Added `hpx::when_any_swapped`.
• Added `hpx::copy` as a precursor for a migrate functionality
• Added `hpx::get_ptr` allowing to directly access the memory underlying a given component
• Added the `hpx::lcos::broadcast`, `hpx::lcos::reduce`, and `hpx::lcos::fold` collective operations

• Added `hpx::get_locality_name` allowing to retrieve the name of any of the localities for the application.

• Added support for more flexible thread affinity control from the HPX command line, such as new modes for `--hpx:bind` (balanced, scattered, compact), improved default settings when running multiple localities on the same node.

• Added experimental executors for simpler thread pooling and scheduling. This API may change in the future as it will stay aligned with the ongoing C++ standardization efforts.

• Massively improved the performance of the HPX serialization code. Added partial support for zero copy serialization of array and bitwise-copyable types.

• General performance improvements of the code related to threads and futures.

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release.

• Issue #1005\(^{4084}\) - Allow one to disable array optimizations and zero copy optimizations for each parcelport

• Issue #1004\(^{4085}\) - Generate new HPX logo image for the docs

• Issue #1002\(^{4086}\) - If MPI parcelport is not available, running HPX under mpirun should fail

• Issue #1001\(^{4087}\) - Zero copy serialization raises assert

• Issue #1000\(^{4088}\) - Can’t connect to a HPX application running with the MPI parcelport from a non MPI parcelport locality

• Issue #999\(^{4089}\) - Optimize `hpx::when_n`

• Issue #998\(^{4090}\) - Fixed const-correctness

• Issue #997\(^{4091}\) - Making `serialize_buffer::data()` type save

• Issue #996\(^{4092}\) - Memory leak in `hpx::lcos::promise`

• Issue #995\(^{4093}\) - Race while registering pre-shutdown functions

• Issue #994\(^{4094}\) - thread_rescheduling regression test does not compile

• Issue #992\(^{4095}\) - Correct comments and messages

• Issue #991\(^{4096}\) - `setcap cap_sys_rawio=ep` for power profiling causes an HPX application to abort

• Issue #989\(^{4097}\) - Jacobi hangs during execution

\(^{4097}\) [https://github.com/STEllAR-GROUP/hpx/issues/989](https://github.com/STEllAR-GROUP/hpx/issues/989)
• Issue #988 - multiple_init test is failing
• Issue #986 - Can’t call a function called “init” from “main” when using `<hpx/hpx_main.hpp>`
• Issue #984 - Reference counting tests are failing
• Issue #983 - thread_suspension_executor test fails
• Issue #980 - Terminating HPX threads don’t leave stack in virgin state
• Issue #979 - Static scheduler not in documents
• Issue #978 - Preprocessing limits are broken
• Issue #977 - Make tests.regressions.lcos.future_hang_on_get shorter
• Issue #976 - Wrong library order in pkgconfig
• Issue #975 - Please reopen #963
• Issue #974 - Option pu-offset ignored in fixing_588 branch
• Issue #972 - Cannot use MKL with HPX
• Issue #969 - Non-existent INI files requested on the command line via `--hpx:config` do not cause warnings or errors.
• Issue #968 - Cannot build examples in fixing_588 branch
• Issue #967 - Command line description of `--hpx:queuing` seems wrong
• Issue #966 - `--hpx:print-bind` physical core numbers are wrong
• Issue #965 - Deadlock when building in Release mode
• Issue #963 - Not all worker threads are working
• Issue #962 - Problem with SLURM integration
• Issue #961 - `--hpx:print-bind` outputs incorrect information
• Issue #960 - Fix cut and paste error in documentation of `get_thread_priority`
• Issue #959 - Change link to boost.atomic in documentation to point to boost.org
• Issue #958 - Undefined reference to intrusive_ptr_release

4120 https://github.com/STEllAR-GROUP/hpx/issues/958
• Issue #957 - Make tuple standard compliant
• Issue #956 - Segfault with a3382fb
• Issue #955 - --hpx:node and --hpx:nodefiles do not work with foreign nodes
• Issue #954 - Make order of arguments for hpx::async and hpx::broadcast consistent
• Issue #953 - Cannot use MKL with HPX
• Issue #952 - register_[pre_]shutdown_function never throw
• Issue #951 - Assert when number of threads is greater than hardware concurrency
• Issue #948 - HPX_HAVE_GENERIC_CONTEXT_COROUTINES conflicts with HPX_HAVE_FIBER_BASED_COROUTINES
• Issue #947 - Need MPI_THREAD_MULTIPLE for backward compatibility
• Issue #946 - HPX does not call MPI_Finalize
• Issue #945 - Segfault with hpx::lcos::broadcast
• Issue #944 - OS X: assertion pu_offset_ < hardware_concurrency failed
• Issue #943 - #include <hpx/hpx_main.hpp> does not work
• Issue #942 - Make the BG/Q work with -O3
• Issue #940 - Use separator when concatenating locality name
• Issue #939 - Refactor MPI parcelport to use MPI_Wait instead of multiple MPI_Test calls
• Issue #938 - Want to officially access client_base::gid_
• Issue #937 - client_base::gid_ should be private``
• Issue #936 - Want doxygen-like source code index
• Issue #935 - Build error with gcc 4.6 and Boost 1.54.0 on hpx trunk and 0.9.6
• Issue #933 - Cannot build HPX with Boost 1.54.0
• Issue #932 - Components are destructed too early
• Issue #931 - Make HPX work on BG/Q

Chapter 2. What’s so special about HPX?
• Issue #930⁻¹⁴⁴ - make git-docs is broken
• Issue #929⁻¹⁴⁵ - Generating index in docs broken
• Issue #928⁻¹⁴⁶ - Optimize `hpx::util::static_` for C++11 compilers supporting magic statics
• Issue #924⁻¹⁴⁷ - Make `kill_process_tree` (in process.py) more robust on Mac OSX
• Issue #923⁻¹⁴⁸ - Correct BLAS and RNPL cmake tests
• Issue #922⁻¹⁴⁹ - Cannot link against BLAS
• Issue #921⁻¹⁵⁰ - Implement `hpx::mem_fn`
• Issue #920⁻¹⁵¹ - Output locality with `--hpx:print-bind`
• Issue #919⁻¹⁵² - Correct grammar; simplify boolean expressions
• Issue #918⁻¹⁵³ - Link to hello_world.cpp is broken
• Issue #917⁻¹⁵⁴ - adapt cmake file to new boostbook version
• Issue #916⁻¹⁵⁵ - fix problem building documentation with xsltproc >= 1.1.27
• Issue #915⁻¹⁵⁶ - Add another TBBMalloc library search path
• Issue #914⁻¹⁵⁷ - Build problem with Intel compiler on Stampede (TACC)
• Issue #913⁻¹⁵⁸ - fix error messages in fibonacci examples
• Issue #911⁻¹⁵⁹ - Update OS X build instructions
• Issue #910⁻¹⁶⁰ - Want like to specify MPI_ROOT instead of compiler wrapper script
• Issue #909⁻¹⁶¹ - Warning about void* arithmetic
• Issue #908⁻¹⁶² - Buildbot for MIC is broken
• Issue #906⁻¹⁶³ - Can’t use `--hpx:bind=balanced` with multiple MPI processes
• Issue #905⁻¹⁶⁴ - `--hpx:bind` documentation should describe full grammar
• Issue #904⁻¹⁶⁵ - Add `hpx::lcos::fold` and `hpx::lcos::inverse_fold` collective operation
• Issue #903⁻¹⁶⁶ - Add `hpx::when_any_swapped()`
• Issue #902\(^{1167}\) - Add hpx::lcos::reduce collective operation
• Issue #901\(^{1168}\) - Web documentation is not searchable
• Issue #900\(^{1169}\) - Web documentation for trunk has no index
• Issue #898\(^{1170}\) - Some tests fail with GCC 4.8.1 and MPI parcel port
• Issue #897\(^{1171}\) - HWLOC causes failures on Mac
• Issue #896\(^{1172}\) - pu-offset leads to startup error
• Issue #895\(^{1173}\) - hpx::get_locality_name not defined
• Issue #894\(^{1174}\) - Race condition at shutdown
• Issue #893\(^{1175}\) - --hpx:print-bind switches std::cout to hexadecimal mode
• Issue #892\(^{1176}\) - hwloc_topology_load can be expensive – don’t call multiple times
• Issue #891\(^{1177}\) - The documentation for get_locality_name is wrong
• Issue #890\(^{1178}\) - --hpx:print-bind should not exit
• Issue #889\(^{1179}\) - --hpx:debug-hpx-log=FILE does not work
• Issue #888\(^{1180}\) - MPI parcelport does not exit cleanly for --hpx:print-bind
• Issue #887\(^{1181}\) - Choose thread affinities more cleverly
• Issue #886\(^{1182}\) - Logging documentation is confusing
• Issue #885\(^{1183}\) - Two threads are slower than one
• Issue #884\(^{1184}\) - is_callable failing with member pointers in C++11
• Issue #883\(^{1185}\) - Need help with is_callable_test
• Issue #882\(^{1186}\) - tests.regressions.lcos.future_hang_on_get does not terminate
• Issue #881\(^{1187}\) - tests/regressions/block_matrix/matrix.hh won’t compile with GCC 4.8.1
• Issue #880\(^{1188}\) - HPX does not work on OS X
• Issue #878\(^{1189}\) - future::unwrap triggers assertion

\(^{1189}\) https://github.com/STEllAR-GROUP/hpx/issues/878
• Issue #877 - “make tests” has build errors on Ubuntu 12.10
• Issue #876 - tcmalloc is used by default, even if it is not present
• Issue #875 - global_fixture is defined in a header file
• Issue #874 - Some tests take very long
• Issue #873 - Add block-matrix code as regression test
• Issue #872 - HPX documentation does not say how to run tests with detailed output
• Issue #871 - All tests fail with “make test”
• Issue #870 - Please explicitly disable serialization in classes that don’t support it
• Issue #868 - boost_any test failing
• Issue #867 - Reduce the number of copies of hpx::function arguments
• Issue #866 - Futures should not require a default constructor
• Issue #865 - value_or_error shall not default construct its result
• Issue #864 - HPX_UNUSED macro
• Issue #863 - Add functionality to copy construct a component
• Issue #862 - hpx::endl should flush
• Issue #861 - Create hpx::get_ptr<> allowing to access component implementation
• Issue #859 - Implement hpx::INVOKE
• Issue #858 - hpx/hpx.hpp does not include hpx/include/iostreams.hpp
• Issue #857 - Feature request: null future
• Issue #855 - Feature request: Locality names
• Issue #854 - hpx::cout output does not appear on screen
• Issue #853 - All tests fail on OS X after installing
• Issue #852 - Update OS X build instructions

2.10. Releases
• Issue #846
  Update hpx_external_example
• Issue #845
  Issues with having both debug and release modules in the same directory
• Issue #844
  Create configuration header
• Issue #843
  Tests should use CTest
• Issue #842
  Remove buffer_pool from MPI parcelport
• Issue #841
  Add possibility to broadcast an index with hpx::cos::broadcast
• Issue #838
  Simplify util::tuple
• Issue #837
  Adopt boost::tuple tests for util::tuple
• Issue #836
  Adopt boost::function tests for util::function
• Issue #835
  Tuple interface missing pieces
• Issue #833
  Partially preprocessing files not working
• Issue #832
  Native papi counters do not work with wild cards
• Issue #831
  Arithmetics counter fails if only one parameter is given
• Issue #830
  Convert hpx::util::function to use new scheme for serializing its base pointer
• Issue #829
  Consistently use decay<T> instead of remove_const< remove_reference<T>>
• Issue #828
  Update future implementation to N3721 and N3722
• Issue #827
  Enable MPI parcelport for bootstrapping whenever application was started using mpirun
• Issue #826
  Support command line option --hpx::print-bind even if --hpx::bind was not used
• Issue #825
  Memory counters give segfault when attempting to use thread wild cards or numbers only total works
• Issue #824
  Enable lambda functions to be used with hpx::async/hpx::apply
• Issue #823
  Using a hashing filter
• Issue #822
  Silence unused variable warning
• Issue #821
  Detect if a function object is callable with given arguments

Chapter 2. What’s so special about HPX?
- Issue #820\footnote{https://github.com/STEllAR-GROUP/hpx/issues/820} - Allow wildcards to be used for performance counter names
- Issue #819\footnote{https://github.com/STEllAR-GROUP/hpx/issues/819} - Make the AGAS symbolic name registry distributed
- Issue #818\footnote{https://github.com/STEllAR-GROUP/hpx/issues/818} - Add future::then() overload taking an executor
- Issue #817\footnote{https://github.com/STEllAR-GROUP/hpx/issues/817} - Fixed typo
- Issue #815\footnote{https://github.com/STEllAR-GROUP/hpx/issues/815} - Create an lco that is performing an efficient broadcast of actions
- Issue #814\footnote{https://github.com/STEllAR-GROUP/hpx/issues/814} - Papi counters cannot specify thread## to get the counts for all threads
- Issue #813\footnote{https://github.com/STEllAR-GROUP/hpx/issues/813} - Scoped unlock
- Issue #811\footnote{https://github.com/STEllAR-GROUP/hpx/issues/811} - simple_central_tuplespace_client run error
- Issue #810\footnote{https://github.com/STEllAR-GROUP/hpx/issues/810} - ostream error when << any objects
- Issue #809\footnote{https://github.com/STEllAR-GROUP/hpx/issues/809} - Optimize parcel serialization
- Issue #808\footnote{https://github.com/STEllAR-GROUP/hpx/issues/808} - HPX applications throw exception when executed from the build directory
- Issue #807\footnote{https://github.com/STEllAR-GROUP/hpx/issues/807} - Create performance counters exposing overall AGAS statistics
- Issue #795\footnote{https://github.com/STEllAR-GROUP/hpx/issues/795} - Create timed make_ready_future
- Issue #794\footnote{https://github.com/STEllAR-GROUP/hpx/issues/794} - Create heterogeneous when_all/when_any/etc.
- Issue #721\footnote{https://github.com/STEllAR-GROUP/hpx/issues/721} - Make HPX usable for Xeon Phi
- Issue #694\footnote{https://github.com/STEllAR-GROUP/hpx/issues/694} - CMake should complain if you attempt to build an example without its dependencies
- Issue #692\footnote{https://github.com/STEllAR-GROUP/hpx/issues/692} - SLURM support broken
- Issue #683\footnote{https://github.com/STEllAR-GROUP/hpx/issues/683} - python/hpx/process.py imports epoll on all platforms
- Issue #619\footnote{https://github.com/STEllAR-GROUP/hpx/issues/619} - Automate the doc building process
- Issue #600\footnote{https://github.com/STEllAR-GROUP/hpx/issues/600} - GTC performance broken
- Issue #577\footnote{https://github.com/STEllAR-GROUP/hpx/issues/577} - Allow for zero copy serialization/networking
- Issue #551\footnote{https://github.com/STEllAR-GROUP/hpx/issues/551} - Change executable names to have debug postfix in Debug builds
- Issue #544\footnote{https://github.com/STEllAR-GROUP/hpx/issues/544} - Write a custom .lib file on Windows pulling in hpx_init and hpx.dll, phase out hpx_init
• Issue #534\textsuperscript{4259} - \texttt{hpx::init} should take functions by \texttt{std::function} and should accept all forms of \texttt{hpx_main}

• Issue #508\textsuperscript{4260} - FindPackage fails to set FOO_LIBRARY_DIR

• Issue #506\textsuperscript{4261} - Add cmake support to generate ini files for external applications

• Issue #470\textsuperscript{4262} - Changing build-type after configure does not update boost library names

• Issue #453\textsuperscript{4263} - Document \texttt{hpx_run_tests.py}

• Issue #445\textsuperscript{4264} - Significant performance mismatch between MPI and HPX in SMP for allgather example

• Issue #443\textsuperscript{4265} - Make docs viewable from build directory

• Issue #421\textsuperscript{4266} - Support multiple HPX instances per node in a batch environment like PBS or SLURM

• Issue #316\textsuperscript{4267} - Add message size limitation

• Issue #249\textsuperscript{4268} - Clean up locking code in big boot barrier

• Issue #136\textsuperscript{4269} - Persistent CMake variables need to be marked as cache variables

2.10.17 \textit{HPX} V0.9.6 (Jul 30, 2013)

We have had over 1200 commits since the last release and we have closed roughly 140 tickets (bugs, feature requests, etc.).

General changes

The major new features in this release are:

• We further consolidated the API exposed by \textit{HPX}. We aligned our APIs as much as possible with the existing \texttt{C++11 Standard}\textsuperscript{4270} and related proposals to the \texttt{C++ standardization committee} (such as \texttt{N3632}\textsuperscript{4271} and \texttt{N3857}\textsuperscript{4272}).

• We implemented a first version of a distributed AGAS service which essentially eliminates all explicit AGAS network traffic.

• We created a native ibverbs parcelport allowing to take advantage of the superior latency and bandwidth characteristics of Infiniband networks.

• We successfully ported \textit{HPX} to the Xeon Phi platform.

• Support for the SLURM scheduling system was implemented.

• Major efforts have been dedicated to improving the performance counter framework, numerous new counters were implemented and new APIs were added.
• We added a modular parcel compression system allowing to improve bandwidth utilization (by reducing the overall size of the transferred data).

• We added a modular parcel coalescing system allowing to combine several parcels into larger messages. This reduces latencies introduced by the communication layer.

• Added an experimental executors API allowing to use different scheduling policies for different parts of the code. This API has been modelled after the Standards proposal N3562\(^\text{4273}\). This API is bound to change in the future, though.

• Added minimal security support for localities which is enforced on the parcelport level. This support is preliminary and experimental and might change in the future.

• We created a parcelport using low level MPI functions. This is in support of legacy applications which are to be gradually ported and to support platforms where MPI is the only available portable networking layer.

• We added a preliminary and experimental implementation of a tuple-space object which exposes an interface similar to such systems described in the literature (see for instance The Linda Coordination Language\(^\text{4274}\)).

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release. This is again a very long list of newly implemented features and fixed issues.

• Issue #806\(^\text{4275}\) - make (all) in examples folder does nothing
• Issue #805\(^\text{4276}\) - Adding the introduction and fixing DOCBOOK dependencies for Windows use
• Issue #804\(^\text{4277}\) - Add stackless (non-suspendable) thread type
• Issue #803\(^\text{4278}\) - Create proper serialization support functions for util::tuple
• Issue #800\(^\text{4279}\) - Add possibility to disable array optimizations during serialization
• Issue #798\(^\text{4280}\) - HPX_LIMIT does not work for local dataflow
• Issue #797\(^\text{4281}\) - Create a parcelport which uses MPI
• Issue #796\(^\text{4282}\) - Problem with Large Numbers of Threads
• Issue #793\(^\text{4283}\) - Changing dataflow test case to hang consistently
• Issue #792\(^\text{4284}\) - CMake Error
• Issue #791\(^\text{4285}\) - Problems with local::dataflow
• Issue #790\(^\text{4286}\) - wait_for() doesn’t compile
• Issue #789\(^\text{4287}\) - HPX with Intel compiler segfaults

\(^{4286}\) https://github.com/STEllAR-GROUP/hpx/issues/790
\(^{4287}\) https://github.com/STEllAR-GROUP/hpx/issues/789
• Issue #788\textsuperscript{4288} - Intel compiler support
• Issue #787\textsuperscript{4289} - Fixed SFINAEd specializations
• Issue #786\textsuperscript{4290} - Memory issues during benchmarking.
• Issue #785\textsuperscript{4291} - Create an API allowing to register external threads with HPX
• Issue #784\textsuperscript{4292} - util::plugin is throwing an error when a symbol is not found
• Issue #783\textsuperscript{4293} - How does hpx:bind work?
• Issue #782\textsuperscript{4294} - Added quotes around STRING REPLACE potentially empty arguments
• Issue #781\textsuperscript{4295} - Make sure no exceptions propagate into the thread manager
• Issue #780\textsuperscript{4296} - Allow arithmetics performance counters to expand its parameters
• Issue #779\textsuperscript{4297} - Test case for 778
• Issue #778\textsuperscript{4298} - Swapping futures segfaults
• Issue #777\textsuperscript{4299} - hpx::lcos::details::when_xxx don’t restore completion handlers
• Issue #776\textsuperscript{4300} - Compiler chokes on dataflow overload with launch policy
• Issue #775\textsuperscript{4301} - Runtime error with local dataflow (copying futures?)
• Issue #774\textsuperscript{4302} - Using local dataflow without explicit namespace
• Issue #773\textsuperscript{4303} - Local dataflow with unwrap: functor operators need to be const
• Issue #772\textsuperscript{4304} - Allow (remote) actions to return a future
• Issue #771\textsuperscript{4305} - Setting HPX\_LIMIT gives huge boost MPL errors
• Issue #770\textsuperscript{4306} - Add launch policy to (local) dataflow
• Issue #769\textsuperscript{4307} - Make compile time configuration information available
• Issue #768\textsuperscript{4308} - Const correctness problem in local dataflow
• Issue #767\textsuperscript{4309} - Add launch policies to async
• Issue #766\textsuperscript{4310} - Mark data structures for optimized (array based) serialization

• Issue #765 - Align hpx::any with N3508: Any Library Proposal (Revision 2)
• Issue #764 - Align hpx::future with newest N3558: A Standardized Representation of Asynchronous Operations
• Issue #762 - added a human readable output for the ping pong example
• Issue #761 - Ambiguous typename when constructing derived component
• Issue #760 - Simple components can not be derived
• Issue #759 - make install doesn’t give a complete install
• Issue #758 - Stack overflow when using locking_hook<>
• Issue #757 - copy paste error; unsupported function overloading
• Issue #756 - GTCX runtime issue in Gordon
• Issue #755 - Papi counters don’t work with reset and evaluate API’s
• Issue #753 - cmake bugfix and improved component action docs
• Issue #752 - hpx simple component docs
• Issue #750 - Add hpx::util::any
• Issue #749 - Thread phase counter is not reset
• Issue #748 - Memory performance counter are not registered
• Issue #747 - Create performance counters exposing arithmetic operations
• Issue #745 - apply_callback needs to invoke callback when applied locally
• Issue #744 - CMake fixes
• Issue #743 - Problem Building github version of HPX
• Issue #742 - Remove HPX_STD_BIND
• Issue #741 - assertion ‘px != 0’ failed: HPX(assertion_failure) for low numbers of OS threads
• Issue #739 - Performance counters do not count to the end of the program or evaluation
• Issue #738 - Dedicated AGAS server runs don’t work; console ignores -a option.

https://github.com/STEllAR-GROUP/hpx/issues/739
https://github.com/STEllAR-GROUP/hpx/issues/738
• Issue #737 - Missing bind overloads
• Issue #736 - Performance counter wildcards do not always work
• Issue #735 - Create native ibverbs parcelport based on rdma operations
• Issue #734 - Threads stolen performance counter total is incorrect
• Issue #733 - Test benchmarks need to be checked and fixed
• Issue #732 - Build fails with Mac, using mac ports clang-3.3 on latest git branch
• Issue #731 - Add global start/stop API for performance counters
• Issue #730 - Performance counter values are apparently incorrect
• Issue #729 - Unhandled switch
• Issue #728 - Serialization of hpx::util::function between two localities causes seg faults
• Issue #727 - Memory counters on Mac OS X
• Issue #725 - Restore original thread priority on resume
• Issue #724 - Performance benchmarks do not depend on main HPX libraries
• Issue #723 - [teletype]–hpx:nodefile=$PBS_NODEFILE`  works; –hpx:nodefile=$PBS_NODEFILE does not.[c++]
• Issue #722 - Fix binding const member functions as actions
• Issue #719 - Create performance counter exposing compression ratio
• Issue #718 - Add possibility to compress parcel data
• Issue #717 - strip_credit_from_gid has misleading semantics
• Issue #716 - Non-option arguments to programs run using pbsdsh must be before --hpx:node, contrary to directions
• Issue #715 - Re-thrown exceptions should retain the original call site
• Issue #714 - failed assertion in debug mode
• Issue #713 - Add performance counters monitoring connection caches

https://github.com/STEllAR-GROUP/hpx/issues/713
• Issue #712\[4356\] - Adjust parcel related performance counters to be connection type specific
• Issue #711\[4357\] - configuration failure
• Issue #710\[4358\] - Error “timed out while trying to find room in the connection cache” when trying to start multiple localities on a single computer
• Issue #709\[4359\] - Add new thread state ‘staged’ referring to task descriptions
• Issue #708\[4360\] - Detect/mitigate bad non-system installs of GCC on Redhat systems
• Issue #707\[4361\] - Many examples do not link with Git HEAD version
• Issue #706\[4362\] - \texttt{hpx::init} removes portions of non-option command line arguments before last = sign
• Issue #705\[4363\] - Create rolling average and median aggregating performance counters
• Issue #704\[4364\] - Create performance counter to expose thread queue waiting time
• Issue #703\[4365\] - Add support to HPX build system to find librctool.a and related headers
• Issue #699\[4366\] - Generalize instrumentation support
• Issue #698\[4367\] - compilation failure with hwloc absent
• Issue #697\[4368\] - Performance counter counts should be zero indexed
• Issue #696\[4369\] - Distributed problem
• Issue #695\[4370\] - Bad perf counter time printed
• Issue #693\[4371\] - \texttt{--help} doesn’t print component specific command line options
• Issue #692\[4372\] - SLURM support broken

General changes

This release is continuing along the lines of code and API consolidation, and overall usability improvements. We dedicated much attention to performance and we were able to significantly improve the threading and networking subsystems.

We successfully ported HPX to the Android platform. HPX applications now not only can run on mobile devices, but we support heterogeneous applications running across architecture boundaries. At the Supercomputing Conference 2012 we demonstrated connecting Android tablets to simulations running on a Linux cluster. The Android tablet was used to query performance counters from the Linux simulation and to steer its parameters.

We successfully ported HPX to Mac OSX (using the Clang compiler). Thanks to Pyry Jahkola for contributing the corresponding patches. Please see the section How to install HPX on OS X (Mac) for more details.

We made a special effort to make HPX usable in highly concurrent use cases. Many of the HPX API functions which possibly take longer than 100 microseconds to execute now can be invoked asynchronously. We added uniform
support for composing futures which simplifies to write asynchronous code. HPX actions (function objects encapsu-
lating possibly concurrent remote function invocations) are now well integrated with all other API facilities such like
\texttt{hpx::bind}.

All of the API has been aligned as much as possible with established paradigms. HPX now mirrors many of the
facilities as defined in the C++11 Standard, such as \texttt{hpx::thread}, \texttt{hpx::function}, \texttt{hpx::future}, etc.

A lot of work has been put into improving the documentation. Many of the API functions are documented now,
concepts are explained in detail, and examples are better described than before. The new documentation index enables
finding information with lesser effort.

This is the first release of HPX we perform after the move to Github\footnote{https://github.com/STEllAR-GROUP/hpx/}. This step has enabled a wider participation
from the community and further encourages us in our decision to release HPX as a true open source library (HPX is
licensed under the very liberal Boost Software License\footnote{https://www.boost.org/LICENSE_1_0.txt}).

**Bug fixes (closed tickets)**

Here is a list of the important tickets we closed for this release. This is by far the longest list of newly implemented
features and fixed issues for any of HPX' releases so far.

- Issue \#666\footnote{https://github.com/STEllAR-GROUP/hpx/issues/666} - Segfault on calling \texttt{hpx::finalize} twice
- Issue \#665\footnote{https://github.com/STEllAR-GROUP/hpx/issues/665} - Adding declaration \texttt{num_of_cores}
- Issue \#662\footnote{https://github.com/STEllAR-GROUP/hpx/issues/662} - \texttt{pkgconfig} is building wrong
- Issue \#660\footnote{https://github.com/STEllAR-GROUP/hpx/issues/660} - Need uninterrupt function
- Issue \#659\footnote{https://github.com/STEllAR-GROUP/hpx/issues/659} - Move our logging library into a different namespace
- Issue \#658\footnote{https://github.com/STEllAR-GROUP/hpx/issues/658} - Dynamic performance counter types are broken
- Issue \#657\footnote{https://github.com/STEllAR-GROUP/hpx/issues/657} - HPX v0.9.5 (RC1) \texttt{hello_world} example segfaulting
- Issue \#656\footnote{https://github.com/STEllAR-GROUP/hpx/issues/656} - Define the affinity of parcel-pool, io-pool, and timer-pool threads
- Issue \#654\footnote{https://github.com/STEllAR-GROUP/hpx/issues/654} - Integrate the Boost auto\_index tool with documentation
- Issue \#653\footnote{https://github.com/STEllAR-GROUP/hpx/issues/653} - Make HPX build on OS X + Clang + libc++
- Issue \#651\footnote{https://github.com/STEllAR-GROUP/hpx/issues/651} - Add fine-grained control for thread pinning
- Issue \#650\footnote{https://github.com/STEllAR-GROUP/hpx/issues/650} - Command line no error message when using \texttt{-hpx:(anything)}
- Issue \#645\footnote{https://github.com/STEllAR-GROUP/hpx/issues/645} - Command line aliases don't work in \texttt{[teletype]\`` @file`` [c++]}]
- Issue \#644\footnote{https://github.com/STEllAR-GROUP/hpx/issues/644} - Terminated threads are not always properly cleaned up

\textsuperscript{4415} \textsuperscript{4416} \textsuperscript{4417} \textsuperscript{4418} \textsuperscript{4419} \textsuperscript{4420} \textsuperscript{4421} \textsuperscript{4422} \textsuperscript{4423} \textsuperscript{4424} \textsuperscript{4425} \textsuperscript{4426} \textsuperscript{4427} \textsuperscript{4428} \textsuperscript{4429} \textsuperscript{4430}
• Issue #640[4431] - `future_data<T>::set_on_completed_` used without locks
• Issue #638[4432] - hpx build with intel compilers fails on linux
• Issue #637[4433] - --copy-dt-needed-entries breaks with gold
• Issue #635[4434] - Boost V1.53 will add Boost.Lockfree and Boost.Atomic
• Issue #633[4435] - Re-add examples to final 0.9.5 release
• Issue #632[4436] - Example thread_aware_timer is broken
• Issue #631[4437] - FFT application throws error in parcellayer
• Issue #630[4438] - Event synchronization example is broken
• Issue #629[4439] - Waiting on futures hangs
• Issue #628[4440] - Add an HPX_ALWAYS_ASSERT macro
• Issue #625[4441] - Port coroutines context switch benchmark
• Issue #621[4442] - New INI section for stack sizes
• Issue #618[4443] - pkg_config support does not work with a HPX debug build
• Issue #617[4444] - hpx/external/logging/boost/logging/detail/cache_before_init.hpp:139:67: error: `get_thread_id` was not declared in this scope
• Issue #616[4445] - Change wait_xxx not to use locking
• Issue #615[4446] - Revert visibility ‘fix’ (fb0b6b8245dad1127b0c25ebaf9386b3945cca9)
• Issue #614[4447] - Fix Dataflow linker error
• Issue #613[4448] - find_here should throw an exception on failure
• Issue #612[4449] - Thread phase doesn’t show up in debug mode
• Issue #611[4450] - Make stack guard pages configurable at runtime (initialization time)
• Issue #610[4451] - Co-Locate Components
• Issue #609[4452] - future_overhead
• Issue #608[4453] - --hpx:list-counter-infos problem

• Issue #607\(^{4454}\) - Update Boost.Context based backend for coroutines
• Issue #606\(^{4455}\) - 1D_wave_equation is not working
• Issue #605\(^{4456}\) - Any C++ function that has serializable arguments and a serializable return type should be remotable
• Issue #604\(^{4457}\) - Connecting localities isn’t working anymore
• Issue #603\(^{4458}\) - Do not verify any ini entries read from a file
• Issue #602\(^{4459}\) - Rename argument_size to type_size/ added implementation to get parcel size
• Issue #599\(^{4460}\) - Enable locality specific command line options
• Issue #598\(^{4461}\) - Need an API that accesses the performance counter reporting the system uptime
• Issue #597\(^{4462}\) - compiling on ranger
• Issue #595\(^{4463}\) - I need a place to store data in a thread self pointer
• Issue #594\(^{4464}\) - 32/64 interoperability
• Issue #593\(^{4465}\) - Warn if logging is disabled at compile time but requested at runtime
• Issue #592\(^{4466}\) - Add optional argument value to --hpx:list-counters and --hpx:list-counter-infos
• Issue #591\(^{4467}\) - Allow for wildcards in performance counter names specified with --hpx:print-counter
• Issue #590\(^{4468}\) - Local promise semantic differences
• Issue #589\(^{4469}\) - Create API to query performance counter names
• Issue #587\(^{4470}\) - Add get_num_localities and get_num_threads to AGAS API
• Issue #586\(^{4471}\) - Adjust local AGAS cache size based on number of localities
• Issue #585\(^{4472}\) - Error while using counters in HPX
• Issue #584\(^{4473}\) - counting argument size of actions, initial pass.
• Issue #581\(^{4474}\) - Remove RemoteResult template parameter for future<>
• Issue #580\(^{4475}\) - Add possibility to hook into actions
• Issue #578\footnote{https://github.com/STEllAR-GROUP/hpx/issues/578} - Use angle brackets in HPX error dumps
• Issue #576\footnote{https://github.com/STEllAR-GROUP/hpx/issues/576} - Exception incorrectly thrown when \texttt{--help} is used
• Issue #575\footnote{https://github.com/STEllAR-GROUP/hpx/issues/575} - HPX(bad_component_type) with gcc 4.7.2 and boost 1.51
• Issue #574\footnote{https://github.com/STEllAR-GROUP/hpx/issues/574} - `--hpx:connect` command line parameter not working correctly
• Issue #571\footnote{https://github.com/STEllAR-GROUP/hpx/issues/571} - `hpx::wait()` (callback version) should pass the future to the callback function
• Issue #570\footnote{https://github.com/STEllAR-GROUP/hpx/issues/570} - `hpx::wait` should operate on `boost::arrays` and `std::lists`
• Issue #569\footnote{https://github.com/STEllAR-GROUP/hpx/issues/569} - Add a logging sink for Android
• Issue #568\footnote{https://github.com/STEllAR-GROUP/hpx/issues/568} - 2-argument version of `HPX_DEFINE_COMPONENT_ACTION`
• Issue #567\footnote{https://github.com/STEllAR-GROUP/hpx/issues/567} - Connecting to a running HPX application works only once
• Issue #565\footnote{https://github.com/STEllAR-GROUP/hpx/issues/565} - HPX doesn’t shutdown properly
• Issue #564\footnote{https://github.com/STEllAR-GROUP/hpx/issues/564} - Partial preprocessing of new component creation interface
• Issue #563\footnote{https://github.com/STEllAR-GROUP/hpx/issues/563} - Add `hpx::start/hpx::stop` to avoid blocking main thread
• Issue #562\footnote{https://github.com/STEllAR-GROUP/hpx/issues/562} - All command line arguments swallowed by hpx
• Issue #561\footnote{https://github.com/STEllAR-GROUP/hpx/issues/561} - Boost.Tuple is not move aware
• Issue #558\footnote{https://github.com/STEllAR-GROUP/hpx/issues/558} - `boost::shared_ptr<>` style semantics/syntax for client classes
• Issue #556\footnote{https://github.com/STEllAR-GROUP/hpx/issues/556} - Creation of partially preprocessed headers should be enabled for Boost newer than V1.50
• Issue #555\footnote{https://github.com/STEllAR-GROUP/hpx/issues/555} - `BOOST_FORCEINLINE` does not name a type
• Issue #554\footnote{https://github.com/STEllAR-GROUP/hpx/issues/554} - Possible race condition in thread `get_id()`
• Issue #552\footnote{https://github.com/STEllAR-GROUP/hpx/issues/552} - Move enable client_base
• Issue #550\footnote{https://github.com/STEllAR-GROUP/hpx/issues/550} - Add stack size category ‘huge’
• Issue #549\footnote{https://github.com/STEllAR-GROUP/hpx/issues/549} - ShenEOS run seg-faults on single or distributed runs
• Issue #545\footnote{https://github.com/STEllAR-GROUP/hpx/issues/545} - `AUTOGLOB` broken for `add_hpx_component`
• Issue #542\footnote{https://github.com/STEllAR-GROUP/hpx/issues/542} - `FindHPX_HDF5` still searches multiple times
- Issue #541 - Quotes around application name in hpx::init
- Issue #539 - Race condition occurring with new lightweight threads
- Issue #535 - hpx_run_tests.py exits with no error code when tests are missing
- Issue #530 - Thread description in logs
- Issue #523 - Make thread objects more lightweight
- Issue #521 - hpx::error_code is not usable for lightweight error handling
- Issue #520 - Add full user environment to HPX logs
- Issue #519 - Build succeeds, running fails
- Issue #517 - Add a guard page to linux coroutine stacks
- Issue #516 - hpx::thread::detach suspends while holding locks, leads to hang in debug
- Issue #514 - Preprocessed headers for <hpx/apply.hpp> don’t compile
- Issue #513 - Buildbot configuration problem
- Issue #512 - Implement action based stack size customization
- Issue #511 - Move action priority into a separate type trait
- Issue #510 - trunk broken
- Issue #507 - No matching function for call to boost::scoped_ptr<hpx::threads::topology>::scoped_ptr(hpx::threads::linux_topology*)
- Issue #505 - undefined_symbol regression test currently failing
- Issue #502 - Adding OpenCL and OCLM support to HPX for Windows and Linux
- Issue #501 - find_package(HPX) sets cmake output variables
- Issue #500 - wait_any/wait_all are badly named
- Issue #499 - Add support for disabling pbs support in pbs runs
- Issue #498 - Error during no-cache runs
- Issue #496 - Add partial preprocessing support to cmake
• Issue #495  - Support HPX modules exporting startup/shutdown functions only
• Issue #494  - Allow modules to specify when to run startup/shutdown functions
• Issue #493  - Avoid constructing a string in make_success_code
• Issue #492  - Performance counter creation is no longer synchronized at startup
• Issue #491  - Performance counter creation is no longer synchronized at startup
• Issue #490  - Sheneos on_completed_bulk seg fault in distributed
• Issue #489  - compiling issue with g++44
• Issue #488  - Adding OpenCL and OCLM support to HPX for the MSVC platform
• Issue #487  - FindHPX.cmake problems
• Issue #485  - Change distributing_factory and binpacking_factory to use bulk creation
• Issue #484  - Change HPX_DONT_USE_PREPROCESSED_FILES to HPX_USE_PREPROCESSED_FILES
• Issue #483  - Memory counter for Windows
• Issue #479  - strange errors appear when requesting performance counters on multiple nodes
• Issue #477  - Create (global) timer for multi-threaded measurements
• Issue #472  - Add partial preprocessing using Wave
• Issue #471  - Segfault stack traces don’t show up in release
• Issue #468  - External projects need to link with internal components
• Issue #462  - Startup/shutdown functions are called more than once
• Issue #458  - Consolidate hpx:util::high_resolution_timer and hpx::util::high_resolution_clock
• Issue #457  - index out of bounds in allgather_and_gate on 4 cores or more
• Issue #448  - Make HPX compile with clang
• Issue #447  - ‘make tests’ should execute tests on local installation
• Issue #446  - Remove SVN-related code from the codebase
• Issue #444 - race condition in smp
• Issue #441 - Patched Boost.Serialization headers should only be installed if needed
• Issue #439 - Components using `HPX_REGISTER_STARTUP_MODULE` fail to compile with MSVC
• Issue #436 - Verify that no locks are being held while threads are suspended
• Issue #435 - Installing HPX should not clobber existing Boost installation
• Issue #434 - Logging external component failed (Boost 1.50)
• Issue #433 - Runtime crash when building all examples
• Issue #432 - Dataflow hangs on 512 cores/64 nodes
• Issue #430 - Problem with distributing factory
• Issue #424 - File paths referring to XSL-files need to be properly escaped
• Issue #417 - Make dataflow LCOs work out of the box by using partial preprocessing
• Issue #413 - `hpx_svnversion.py` fails on Windows
• Issue #412 - Make `hpx::error_code` equivalent to `hpx::exception`
• Issue #398 - HPX clobbers out-of-tree application specific CMake variables (specifically `CMAKE_BUILD_TYPE`)
• Issue #394 - Remove code generating random port numbers for network
• Issue #378 - ShenEOS scaling issues
• Issue #354 - Create a coroutines wrapper for Boost.Context
• Issue #349 - Commandline option `--localities=N/-1N` should be necessary only on AGAS locality
• Issue #343 - Add auto_index support to cmake based documentation toolchain
• Issue #318 - Network benchmarks
• Issue #317 - Implement network performance counters
• Issue #310 - Duplicate logging entries
• Issue #230 - Add compile time option to disable thread debugging info
• Issue #171\textsuperscript{4568} - Add an INI option to turn off deadlock detection independently of logging
• Issue #170\textsuperscript{4569} - OSHL internal counters are incorrect
• Issue #103\textsuperscript{4570} - Better diagnostics for multiple component/action registrations under the same name
• Issue #48\textsuperscript{4571} - Support for Darwin (Xcode + Clang)
• Issue #21\textsuperscript{4572} - Build fails with GCC 4.6

2.10.19 \textit{HPX V0.9.0} (Jul 5, 2012)

We have had roughly 800 commits since the last release and we have closed approximately 80 tickets (bugs, feature requests, etc.).

General changes

• Significant improvements made to the usability of \textit{HPX} in large-scale, distributed environments.
• Renamed \texttt{hpx::lcos::packaged\_task} to \texttt{hpx::lcos::packaged\_action} to reflect the semantic differences to a \texttt{packaged\_task} as defined by the C++11 Standard\textsuperscript{4573}.
• \textit{HPX} now exposes \texttt{hpx::\_thread} which is compliant to the C++11 \texttt{std::thread} type except that it (purely locally) represents an \textit{HPX} thread. This new type does not expose any of the remote capabilities of the underlying \textit{HPX}-thread implementation.
• The type \texttt{hpx::lcos::\_future} is now compliant to the C++11 \texttt{std::future<>} type. This type can be used to synchronize both, local and remote operations. In both cases the control flow will ‘return’ to the future in order to trigger any continuation.
• The types \texttt{hpx::lcos::local::promise} and \texttt{hpx::lcos::local::packaged\_task} are now compliant to the C++11 \texttt{std::promise<>} and \texttt{std::packaged\_task<>} types. These can be used to create a future representing local work only. Use the types \texttt{hpx::lcos::promise} and \texttt{hpx::lcos::packaged\_action} to wrap any (possibly remote) action into a future.
• \texttt{hpx::\_thread} and \texttt{hpx::lcos::\_future} are now cancelable.
• Added support for sequential and logic composition of \texttt{hpx::lcos::\_futures}. The member function \texttt{hpx::\_lcos::\_future::when} permits futures to be sequentially composed. The helper functions \texttt{hpx::wait\_all}, \texttt{hpx::wait\_any}, and \texttt{hpx::wait\_n} can be used to wait for more than one future at a time.
• \textit{HPX} now exposes \texttt{hpx::apply} and \texttt{hpx::async} as the preferred way of creating (or invoking) any deferred work. These functions are usable with various types of functions, function objects, and actions and provide a uniform way to spawn deferred tasks.
• \textit{HPX} now utilizes \texttt{hpx::util::bind} to (partially) bind local functions and function objects, and also actions. Remote bound actions can have placeholders as well.
• \textit{HPX} continuations are now fully polymorphic. The class \texttt{hpx::actions::forwarding\_continuation} is an example of how the user can write is own types of continuations. It can be used to execute any function as an continuation of a particular action.

\textsuperscript{4568} \url{https://github.com/STEllAR-GROUP/hpx/issues/171}
\textsuperscript{4569} \url{https://github.com/STEllAR-GROUP/hpx/issues/170}
\textsuperscript{4570} \url{https://github.com/STEllAR-GROUP/hpx/issues/103}
\textsuperscript{4571} \url{https://github.com/STEllAR-GROUP/hpx/issues/48}
\textsuperscript{4572} \url{https://github.com/STEllAR-GROUP/hpx/issues/21}
\textsuperscript{4573} \url{http://www.open-std.org/jtc1/sc22/wg21}
- Reworked the action invocation API to be fully conformant to normal functions. Actions can now be invoked using `hpx::apply`, `hpx::async`, or using the `operator()` implemented on actions. Actions themselves can now be cheaply instantiated as they do not have any members anymore.

- Reworked the lazy action invocation API. Actions can now be directly bound using `hpx::util::bind` by passing an action instance as the first argument.

- A minimal HPX program now looks like this:

```cpp
#include <hpx/hpx_init.hpp>

int hpx_main()
{
    return hpx::finalize();
}

int main()
{
    return hpx::init();
}
```

This removes the immediate dependency on the Boost.Program Options library.

**Note:** This minimal version of an HPX program does not support any of the default command line arguments (such as `--help`, or command line options related to PBS). It is suggested to always pass `argc` and `argv` to HPX as shown in the example below.

- In order to support those, but still not to depend on Boost.Program Options, the minimal program can be written as:

```cpp
#include <hpx/hpx_init.hpp>

// The arguments for hpx_main can be left off, which very similar to the
// behavior of ``main`` as defined by C++.
int hpx_main(int argc, char* argv[])
{
    return hpx::finalize();
}

int main(int argc, char* argv[])
{
    return hpx::init(argc, argv);
}
```

- Added performance counters exposing the number of component instances which are alive on a given locality.

- Added performance counters exposing then number of messages sent and received, the number of parcels sent and received, the number of bytes sent and received, the overall time required to send and receive data, and the overall time required to serialize and deserialize the data.

- Added a new component: `hpx::components::binpacking_factory` which is equivalent to the existing `hpx::components::distributing_factory` component, except that it equalizes the overall population of the components to create. It exposes two factory methods, one based on the number of existing instances of the component type to create, and one based on an arbitrary performance counter which will be queried for all relevant localities.
• Added API functions allowing to access elements of the diagnostic information embedded in the given exception: `hpx::get_locality_id`, `hpx::get_host_name`, `hpx::get_process_id`, `hpx::get_function_name`, `hpx::get_file_name`, `hpx::get_line_number`, `hpx::get_os_thread`, `hpx::get_thread_id`, and `hpx::get_thread_description`.

### Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release:

- Issue #71\(^{4576}\) - GIDs that are not serialized via `handle_gid<>` should raise an exception
- Issue #105\(^{4577}\) - Allow for `hpx::util::functions` to be registered in the AGAS symbolic namespace
- Issue #107\(^{4578}\) - Nasty threadmanger race condition (reproducible in sheneos_test)
- Issue #108\(^{4579}\) - Add millisecond resolution to HPX logs on Linux
- Issue #110\(^{4580}\) - Shutdown hang in distributed with release build
- Issue #116\(^{4581}\) - Don’t use TSS for the applier and runtime pointers
- Issue #162\(^{4582}\) - Move local synchronous execution shortcut from `hpx::function` to the applier
- Issue #172\(^{4583}\) - Cache sources in CMake and check if they change manually
- Issue #178\(^{4584}\) - Add an INI option to turn off ranged-based AGAS caching
- Issue #187\(^{4585}\) - Support for disabling performance counter deployment
- Issue #202\(^{4586}\) - Support for sending performance counter data to a specific file
- Issue #218\(^{4587}\) - `boost.coroutines` allows different stack sizes, but stack pool is unaware of this
- Issue #231\(^{4588}\) - Implement movable `boost::bind`
- Issue #232\(^{4589}\) - Implement movable `boost::function`
- Issue #236\(^{4590}\) - Allow binding `hpx::util::function` to actions
- Issue #239\(^{4591}\) - Replace `hpx::function` with `hpx::util::function`
- Issue #240\(^{4592}\) - Can’t specify RemoteResult with lcos::async
- Issue #242\(^{4593}\) - REGISTER_TEMPLATE support for plain actions
- Issue #243\(^{4594}\) - `handle_gid<>` support for `hpx::util::function`

2.10.20 **HPX V0.8.1 (Apr 21, 2012)**

This is a point release including important bug fixes for **HPX V0.8.0 (Mar 23, 2012)**.

**General changes**

- **HPX** does not need to be installed anymore to be functional.

**Bug fixes (closed tickets)**

Here is a list of the important tickets we closed for this point release:

- Issue #295 - Don’t require install path to be known at compile time.
- Issue #371 - Add hpx iostreams to standard build.
- Issue #384 - Fix compilation with GCC 4.7.
- Issue #390 - Remove keep_factory_alive startup call from ShenEOS; add shutdown call to H5close.
- Issue #393 - Thread affinity control is broken.

**Bug fixes (commits)**

Here is a list of the important commits included in this point release:

- r7642 - External: Fix backtrace memory violation.
- r7775 - Components: Fix symbol visibility bug with component startup providers. This prevents one components providers from overriding another components.
- r7778 - Components: Fix startup/shutdown provider shadowing issues.

2.10.21 **HPX V0.8.0 (Mar 23, 2012)**

We have had roughly 1000 commits since the last release and we have closed approximately 70 tickets (bugs, feature requests, etc.).

**General changes**

- Improved PBS support, allowing for arbitrary naming schemes of node-hostnames.
- Finished verification of the reference counting framework.
- Implemented decrement merging logic to optimize the distributed reference counting system.
- Restructured the LCO framework. Renamed `hpx::lcos::eager_future<>` and `hpx::lcos::lazy_future<>` into `hpx::lcos::packaged_task` and `hpx::lcos::deferred_packaged_task`. Split `hpx::lcos::promise` into `hpx::lcos::packaged_task` and `hpx::lcos::future`. Added ‘local’ futures (in namespace `hpx::lcos::local`).

---

1666 Chapter 2. What’s so special about **HPX**?
• Improved the general performance of local and remote action invocations. This (under certain circumstances) drastically reduces the number of copies created for each of the parameters and return values.

• Reworked the performance counter framework. Performance counters are now created only when needed, which reduces the overall resource requirements. The new framework allows for much more flexible creation and management of performance counters. The new sine example application demonstrates some of the capabilities of the new infrastructure.

• Added a buildbot-based continuous build system which gives instant, automated feedback on each commit to SVN.

• Added more automated tests to verify proper functioning of HPX.

• Started to create documentation for HPX and its API.

• Added documentation toolchain to the build system.

• Added dataflow LCO.

• Changed default HPX command line options to have hpx: prefix. For instance, the former option --threads is now --hpx:threads. This has been done to make ambiguities with possible application specific command line options as unlikely as possible. See the section HPX Command Line Options for a full list of available options.

• Added the possibility to define command line aliases. The former short (one-letter) command line options have been predefined as aliases for backwards compatibility. See the section HPX Command Line Options for a detailed description of command line option aliasing.

• Network connections are now cached based on the connected host. The number of simultaneous connections to a particular host is now limited. Parcels are buffered and bundled if all connections are in use.

• Added more refined thread affinity control. This is based on the external library Portable Hardware Locality (HWLOC).

• Improved support for Windows builds with CMake.

• Added support for components to register their own command line options.

• Added the possibility to register custom startup/shutdown functions for any component. These functions are guaranteed to be executed by an HPX thread.

• Added two new experimental thread schedulers: hierarchy_scheduler and periodic_priority_scheduler. These can be activated by using the command line options --hpx:queuing=hierarchy or --hpx:queuing=periodic.

Example applications

• Graph500 performance benchmark\(^\text{4643}\) (thanks to Matthew Anderson for contributing this application).

• GTC (Gyrokinetic Toroidal Code)\(^\text{4644}\): a skeleton for particle in cell type codes.

• Random Memory Access: an example demonstrating random memory accesses in a large array

• ShenEOS example\(^\text{4645}\), demonstrating partitioning of large read-only data structures and exposing an interpolation API.

• Sine performance counter demo.

• Accumulator examples demonstrating how to write and use HPX components.

\(^{4643}\) http://www.graph500.org/
\(^{4644}\) http://www.nersc.gov/research-and-development/benchmarking-and-workload-characterization/nersc-6-benchmarks/gtc/
\(^{4645}\) http://stellarcollapse.org/equationofstate
• Quickstart examples (like hello_world, fibonacci, quicksort, factorial, etc.) demonstrating simple HPX concepts which introduce some of the concepts in HPX.

• Load balancing and work stealing demos.

API changes

• Moved all local LCOs into a separate namespace hpx::lcos::local (for instance, hpx::lcos::local_mutex is now hpx::lcos::local::mutex).

• Replaced hpx::actions::function with hpx::util::function. Cleaned up related code.

• Removed hpx::traits::handle_gid and moved handling of global reference counts into the corresponding serialization code.

• Changed terminology: prefix is now called locality_id, renamed the corresponding API functions (such as hpx::get_prefix, which is now called hpx::get_locality_id).

• Adding hpx::find_remote_localities, and hpx::get_num_localities.

• Changed performance counter naming scheme to make it more bash friendly. The new performance counter naming scheme is now

  /object{parentname#parentindex/instance#index}/counter#parameters

• Added hpx::get_worker_thread_num replacing hpx::threadmanager_base::get_thread_num.

• Renamed hpx::get_num_os_threads to hpx::get_os_threads_count.

• Added hpx::threads::get_thread_count.

• Restructured the Futures sub-system, renaming types in accordance with the terminology used by the C++11 ISO standard.

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release:

• Issue #31\textsuperscript{4646} - Specialize handle_gid<> for examples and tests

• Issue #72\textsuperscript{4647} - Fix AGAS reference counting

• Issue #104\textsuperscript{4648} - heartbeat throws an exception when decrefing the performance counter it’s watching

• Issue #111\textsuperscript{4649} - throttle causes an exception on the target application

• Issue #142\textsuperscript{4650} - One failed component loading causes an unrelated component to fail

• Issue #165\textsuperscript{4651} - Remote exception propagation bug in AGAS reference counting test

• Issue #186\textsuperscript{4652} - Test credit exhaustion/splitting (e.g. prepare_gid and symbol NS)

• Issue #188\textsuperscript{4653} - Implement remaining AGAS reference counting test cases

\textsuperscript{4646} https://github.com/STEllAR-GROUP/hpx/issues/31

\textsuperscript{4653} https://github.com/STEllAR-GROUP/hpx/issues/188
• Issue #258\(^{4654}\) - No type checking of GIDs in stubs classes
• Issue #271\(^{4655}\) - Seg fault/shared pointer assertion in distributed code
• Issue #281\(^{4656}\) - CMake options need descriptive text
• Issue #283\(^{4657}\) - AGAS caching broken (gva_cache needs to be rewritten with ICL)
• Issue #285\(^{4658}\) - HPX_INSTALL root directory not the same as CMAKE_INSTALL_PREFIX
• Issue #286\(^{4659}\) - New segfault in dataflow applications
• Issue #289\(^{4660}\) - Exceptions should only be logged if not handled
• Issue #290\(^{4661}\) - c++11 tests failure
• Issue #293\(^{4662}\) - Build target for component libraries
• Issue #296\(^{4663}\) - Compilation error with Boost V1.49rc1
• Issue #298\(^{4664}\) - Illegal instructions on termination
• Issue #299\(^{4665}\) - gravity aborts with multiple threads
• Issue #301\(^{4666}\) - Build error with Boost trunk
• Issue #303\(^{4667}\) - Logging assertion failure in distributed runs
• Issue #304\(^{4668}\) - Exception ‘what’ strings are lost when exceptions from decode_parcel are reported
• Issue #306\(^{4669}\) - Performance counter user interface issues
• Issue #307\(^{4670}\) - Logging exception in distributed runs
• Issue #308\(^{4671}\) - Logging deadlocks in distributed
• Issue #309\(^{4672}\) - Reference counting test failures and exceptions
• Issue #311\(^{4673}\) - Merge AGAS remote_interface with the runtime_support object
• Issue #314\(^{4674}\) - Object tracking for id_types
• Issue #315\(^{4675}\) - Remove handle_gid and handle credit splitting in id_type serialization
• Issue #320\(^{4676}\) - applier::get_locality_id() should return an error value (or throw an exception)

• Issue #321 - Optimization for id_types which are never split should be restored
• Issue #322 - Command line processing ignored with Boost 1.47.0
• Issue #323 - Credit exhaustion causes object to stay alive
• Issue #324 - Duplicate exception messages
• Issue #326 - Integrate Quickbook with CMake
• Issue #329 - --help and --version should still work
• Issue #330 - Create pkg-config files
• Issue #337 - Improve usability of performance counter timestamps
• Issue #338 - Non-std exceptions deriving from std::exceptions in tfunc may be sliced
• Issue #339 - Decrease the number of send_pending_parcel threads
• Issue #343 - Dynamically setting the stack size doesn’t work
• Issue #351 - ‘make install’ does not update documents
• Issue #353 - Disable FIXMEs in the docs by default; add a doc developer CMake option to enable FIXMEs
• Issue #355 - ‘make’ doesn’t do anything after correct configuration
• Issue #356 - Don’t use hpx::util::static_ in topology code
• Issue #359 - Infinite recursion in hpx::tuple serialization
• Issue #361 - Add compile time option to disable logging completely
• Issue #364 - Installation seriously broken in r7443

2.10.22 HPX V0.7.0 (Dec 12, 2011)

We have had roughly 1000 commits since the last release and we have closed approximately 120 tickets (bugs, feature requests, etc.).

General changes

- Completely removed code related to deprecated AGAS V1, started to work on AGAS V2.1.
- Started to clean up and streamline the exposed APIs (see ‘API changes’ below for more details).
- Revamped and unified performance counter framework, added a lot of new performance counter instances for monitoring of a diverse set of internal HPX parameters (queue lengths, access statistics, etc.).
- Improved general error handling and logging support.
- Fixed several race conditions, improved overall stability, decreased memory footprint, improved overall performance (major optimizations include native TLS support and ranged-based AGAS caching).
- Added support for running HPX applications with PBS.
- Many updates to the build system, added support for gcc 4.5.x and 4.6.x, added C++11 support.
- Many updates to default command line options.
- Added many tests, set up buildbot for continuous integration testing.
- Better shutdown handling of distributed applications.

Example applications

- quickstart/factorial and quickstart/fibonacci, future-recursive parallel algorithms.
- quickstart/hello_world, distributed hello world example.
- quickstart/rma, simple remote memory access example.
- quickstart/quicksort, parallel quicksort implementation.
- gtc, gyrokinetic torodial code.
- bfs, breadth-first-search, example code for a graph application.
- sheneos, partitioning of large data sets.
- accumulator, simple component example.
- balancing/os_thread_num, balancing/px_thread_phase, examples demonstrating load balancing and work stealing.

API changes

- Added `hpx::find_all_localities`.
- Added `hpx::terminate` for non-graceful termination of applications.
- Added `hpx::lcos::async` functions for simpler asynchronous programming.
- Added new AGAS interface for handling of symbolic namespace (`hpx::agas::*`).
- Renamed `hpx::components::wait` to `hpx::lcos::wait`.
- Renamed `hpx::lcos::future_value` to `hpx::lcos::promise`.
- Renamed `hpx::lcos::recursive_mutex` to `hpx::lcos::local_recursive_mutex, hpx::lcos::mutex` to `hpx::lcos::local_mutex`.
- Removed support for Boost versions older than V1.38, recommended Boost version is now V1.47 and newer.
- Removed `hpx::process` (this will be replaced by a real process implementation in the future).
• Removed non-functional LCO code (hpx::lcos::dataflow, hpx::lcos::thunk, hpx::lcos::dataflow_variable).
• Removed deprecated hpx::naming::full_address.

Bug fixes (closed tickets)

Here is a list of the important tickets we closed for this release:

• Issue #28^4695 - Integrate Windows/Linux CMake code for HPX core
• Issue #32^4696 - hpx::cout() should be hpx::cout
• Issue #33^4697 - AGAS V2 legacy client does not properly handle error_code
• Issue #60^4698 - AGAS: allow for registredid to optionally take ownership of the gid
• Issue #62^4699 - adaptive1d compilation failure in Fusion
• Issue #64^4700 - Parcel subsystem doesn’t resolve domain names
• Issue #83^4701 - No error handling if no console is available
• Issue #84^4702 - No error handling if a hosted locality is treated as the bootstrap server
• Issue #90^4703 - Add general commandline option -N
• Issue #91^4704 - Add possibility to read command line arguments from file
• Issue #92^4705 - Always log exceptions/errors to the log file
• Issue #93^4706 - Log the command line/program name
• Issue #95^4707 - Support for distributed launches
• Issue #97^4708 - Attempt to create a bad component type in AMR examples
• Issue #100^4709 - factorial and factorial_get examples trigger AGAS component type assertions
• Issue #101^4710 - Segfault when hpx::process::here() is called in fibonacci2
• Issue #102^4711 - unknown_component_address in int_object_semaphore_client
• Issue #114^4712 - marduk raises assertion with default parameters
• Issue #115^4713 - Logging messages for SMP runs (on the console) shouldn’t be buffered

1672 Chapter 2. What’s so special about HPX?
- Issue #119 - marduk linking strategy breaks other applications
- Issue #121 - pbsdsh problem
- Issue #123 - marduk, dataflow and adaptive1d fail to build
- Issue #124 - Lower default preprocessing arity
- Issue #125 - Move hpx::detail::diagnostic_information out of the detail namespace
- Issue #126 - Test definitions for AGAS reference counting
- Issue #128 - Add averaging performance counter
- Issue #129 - Error with endian.hpp while building adaptive1d
- Issue #130 - Bad initialization of performance counters
- Issue #131 - Add global startup/shutdown functions to component modules
- Issue #132 - Avoid using auto_ptr
- Issue #133 - On Windows hpx.dll doesn’t get installed
- Issue #134 - HPX_LIBRARY does not reflect real library name (on Windows)
- Issue #135 - Add detection of unique_ptr to build system
- Issue #137 - Add command line option allowing to repeatedly evaluate performance counters
- Issue #139 - Logging is broken
- Issue #140 - CMake problem on windows
- Issue #141 - Move all non-component libraries into $PREFIX/lib/hpx
- Issue #143 - adaptive1d throws an exception with the default command line options
- Issue #146 - Early exception handling is broken
- Issue #147 - Sheneos doesn’t link on Linux
- Issue #149 - sheneos_test hangs
- Issue #154 - Compilation fails for r5661

https://github.com/STEllAR-GROUP/hpx/issues/154
• Issue #155\(^{4737}\) - Sine performance counters example chokes on chrono headers
• Issue #156\(^{4738}\) - Add build type to –version
• Issue #157\(^{4739}\) - Extend AGAS caching to store gid ranges
• Issue #158\(^{4740}\) - r5691 doesn’t compile
• Issue #160\(^{4741}\) - Re-add AGAS function for resolving a locality to its prefix
• Issue #168\(^{4742}\) - Managed components should be able to access their own GID
• Issue #169\(^{4743}\) - Rewrite AGAS future pool
• Issue #179\(^{4744}\) - Complete switch to request class for AGAS server interface
• Issue #182\(^{4745}\) - Sine performance counter is loaded by other examples
• Issue #185\(^{4746}\) - Write tests for symbol namespace reference counting
• Issue #191\(^{4747}\) - Assignment of read-only variable in point_geometry
• Issue #200\(^{4748}\) - Seg faults when querying performance counters
• Issue #204\(^{4749}\) - --ifnames and suffix stripping needs to be more generic
• Issue #205\(^{4750}\) - --list-* and --print-counter-* options do not work together and produce no warning
• Issue #207\(^{4751}\) - Implement decrement entry merging
• Issue #208\(^{4752}\) - Replace the spinlocks in AGAS with hpx::lcos::local_mutexes
• Issue #210\(^{4753}\) - Add an –ifprefix option
• Issue #214\(^{4754}\) - Performance test for PX-thread creation
• Issue #216\(^{4755}\) - VS2010 compilation
• Issue #222\(^{4756}\) - r6045 context_linux_x86.hpp
• Issue #223\(^{4757}\) - fibonacci hangs when changing the state of an active thread
• Issue #225\(^{4758}\) - Active threads end up in the FEB wait queue
• Issue #226\(^{4759}\) - VS Build Error for Accumulator Client

• Issue #272 - G++ unrecognized command line option
• Issue #273 - quicksort example doesn’t compile
• Issue #277 - Invalid CMake logic for Windows

2.11 Citing HPX

Please cite HPX whenever you use it for publications. Use our paper in The Journal of Open Source Software as the main citation for HPX: 4771. Use the Zenodo entry for referring to the latest version of HPX: 4772. Entries for citing specific versions of HPX can also be found at 4773.

2.12 HPX users

A list of institutions and projects using HPX can be found on the HPX Users page.

2.13 About HPX

2.13.1 History

The development of High Performance ParalleX (HPX) began in 2007. At that time, Hartmut Kaiser became interested in the work done by the ParalleX group at the Center for Computation and Technology (CCT)4775, a multi-disciplinary research institute at Louisiana State University (LSU)4776. The ParalleX group was working to develop a new and...
experimental execution model for future high performance computing architectures. This model was christened ParalleX. The first implementations of ParalleX were crude, and many of those designs had to be discarded entirely. However, over time the team learned quite a bit about how to design a parallel, distributed runtime system which implements the concepts of ParalleX.

From the very beginning, this endeavour has been a group effort. In addition to a handful of interested researchers, there have always been graduate and undergraduate students participating in the discussions, design, and implementation of HPX. In 2011 we decided to formalize our collective research efforts by creating the STE||AR group (Systems Technology, Emergent Parallelism, and Algorithm Research). Over time, the team grew to include researchers around the country and the world. In 2014, the STE||AR Group was reorganized to become the international community it is today. This consortium of researchers aims to develop stable, sustainable, and scalable tools which will enable application developers to exploit the parallelism latent in the machines of today and tomorrow. Our goal of the HPX project is to create a high quality, freely available, open source implementation of ParalleX concepts for conventional and future systems by building a modular and standards conforming runtime system for SMP and distributed application environments. The API exposed by HPX is conformant to the interfaces defined by the C++11/14 ISO standard and adheres to the programming guidelines used by the Boost collection of C++ libraries. We steer the development of HPX with real world applications and aim to provide a smooth migration path for domain scientists.

To learn more about STE||AR and ParalleX, see People and Why HPX?

### 2.13.2 People

The STE||AR Group (pronounced as stellar) stands for “Systems Technology, Emergent Parallelism, and Algorithm Research”. We are an international group of faculty, researchers, and students working at various institutions around the world. The goal of the STE||AR Group is to promote the development of scalable parallel applications by providing a community for ideas, a framework for collaboration, and a platform for communicating these concepts to the broader community.

Our work is focused on building technologies for scalable parallel applications. HPX, our general purpose C++ runtime system for parallel and distributed applications, is no exception. We use HPX for a broad range of scientific applications, helping scientists and developers to write code which scales better and shows better performance compared to more conventional programming models such as MPI.

HPX is based on ParalleX which is a new (and still experimental) parallel execution model aiming to overcome the limitations imposed by the current hardware and the techniques we use to write applications today. Our group focuses on two types of applications - those requiring excellent strong scaling, allowing for a dramatic reduction of execution time for fixed workloads and those needing highest level of sustained performance through massive parallelism. These applications are presently unable (through conventional practices) to effectively exploit a relatively small number of cores in a multi-core system. By extension, these application will not be able to exploit high-end exascale computing systems which are likely to employ hundreds of millions of such cores by the end of this decade.

Critical bottlenecks to the effective use of new generation high performance computing (HPC) systems include:

- **Starvation**: due to lack of usable application parallelism and means of managing it,
- **Overhead**: reduction to permit strong scalability, improve efficiency, and enable dynamic resource management,
- **Latency**: from remote access across system or to local memories,
- **Contention**: due to multicore chip I/O pins, memory banks, and system interconnects.

---

4778 [https://stellar-group.org](https://stellar-group.org)
4779 [https://www.boost.org/](https://www.boost.org/)
4780 [https://stellar-group.org](https://stellar-group.org)
4781 [https://stellar-group.org](https://stellar-group.org)
4782 [https://stellar-group.org](https://stellar-group.org)
The ParalleX model has been devised to address these challenges by enabling a new computing dynamic through the application of message-driven computation in a global address space context with lightweight synchronization. The work on HPX is centered around implementing the concepts as defined by the ParalleX model. HPX is currently targeted at conventional machines, such as classical Linux based Beowulf clusters and SMP nodes.

We fully understand that the success of HPX (and ParalleX) is very much the result of the work of many people. To see a list of who is contributing see our tables below.

Chapter 2. What’s so special about HPX?
Acknowledgements

Thanks also to the following people who contributed directly or indirectly to the project through discussions, pull requests, documentation patches, etc.

- Brice Goglin, for reporting and helping fix issues related to the integration of hwloc in HPX.
- Giannis Gonidelis, for his work on the ranges adaptation during the Google Summer of Code 2020.
- Auriane Reverdell (Swiss National Supercomputing Centre⁴⁸²⁰), for her tireless work on refactoring our CMake setup and modularizing HPX.
- Christopher Hinz, for his work on refactoring our CMake setup.
- Weile Wei, for fixing HPX builds with CUDA on Summit.
- Severin Strobl, for fixing our CMake setup related to linking and adding new entry points to the HPX runtime.
- Rebecca Stobaugh, for her major documentation review and contributions during and after the 2019 Google Season of Documentation.
- Jan Melech, for adding automatic serialization of simple structs.
- Austin McCartney, for adding concept emulation of the Ranges TS bidirectional and random access iterator concepts.
- Marco Diers, reporting and fixing issues related PMIx.
- Maximilian Bremer, for reporting multiple issues and extending the component migration tests.
- Piotr Mikolajczyk, for his improvements and fixes to the set and count algorithms.
- Grant Rostig, for reporting several deficiencies on our web pages.
- Jakub Golinowski, for implementing an HPX backend for OpenCV and in the process improving documentation and reporting issues.
- Mikael Simberg (Swiss National Supercomputing Centre⁴⁸²¹), for his tireless help cleaning up and maintaining HPX.
- Tianyi Zhang, for his work on HPXMP.
- Shahrzad Shirzad, for her contributions related to Phylanx.
- Christopher Ogle, for his contributions to the parallel algorithms.
- Surya Priy, for his work with statistic performance counters.
- Anushi Maheshwari, for her work on random number generation.
- Bruno Pitrus, for his work with parallel algorithms.
- Nikunj Gupta, for rewriting the implementation of hpx_main.hpp and for his fixes for tests.
- Christopher Taylor, for his interest in HPX and the fixes he provided.
- Shoshana Jakobovits, for her work on the resource partitioner.
- Denis Blank, who re-wrote our unwrapped function to accept plain values arbitrary containers, and properly deal with nested futures.
- Ajai V. George, who implemented several of the parallel algorithms.
- Taeguk Kwon, who worked on implementing parallel algorithms as well as adapting the parallel algorithms to the Ranges TS.

⁴⁸²⁰ https://www.cscs.ch
⁴⁸²¹ https://www.cscs.ch
• Zach Byerly (Louisiana State University (LSU)\textsuperscript{4822}), who in his work developing applications on top of HPX opened tickets and contributed to the HPX examples.
• Daniel Estermann, for his work porting HPX to the Raspberry Pi.
• Alireza Kheirkhahan (Louisiana State University (LSU)\textsuperscript{4823}), who built and administered our local cluster as well as his work in distributed IO.
• Abhimanyu Rawat, who worked on stack overflow detection.
• David Pfander, who improved signal handling in HPX, provided his optimization expertise, and worked on incorporating the Vc vectorization into HPX.
• Denis Demidov, who contributed his insights with VexCL.
• Khalid Hasanov, who contributed changes which allowed to run HPX on 64Bit power-pc architectures.
• Zahra Khatami (Louisiana State University (LSU)\textsuperscript{4824}), who contributed the prefetching iterators and the persistent auto chunking executor parameters implementation.
• Marcin Copik, who worked on implementing GPU support for C++AMP and HCC. He also worked on implementing a HCC backend for HPX\texttt{Compute}.
• Minh-Khanh Do, who contributed the implementation of several segmented algorithms.
• Bibek Wagle (Louisiana State University (LSU)\textsuperscript{4825}), who worked on fixing and analyzing the performance of the\texttt{parcel} coalescing plugin in HPX.
• Lukas Troska, who reported several problems and contributed various test cases allowing to reproduce the corresponding issues.
• Andreas Schaefer, who worked on integrating his library (LibGeoDecomp\textsuperscript{4826}) with HPX. He reported various problems and submitted several patches to fix issues allowing for a better integration with LibGeoDecomp\textsuperscript{4827}.
• Satyaki Upadhyay, who contributed several examples to HPX.
• Brandon Cordes, who contributed several improvements to the inspect tool.
• Harris Brakmic, who contributed an extensive build system description for building HPX with Visual Studio.
• Parsa Amini (Louisiana State University (LSU)\textsuperscript{4828}), who refactored and simplified the implementation of AGAS in HPX and who works on its implementation and optimization.
• Luis Martinez de Bartolome who implemented a build system extension for HPX integrating it with the Conan\textsuperscript{4829} C/C++ package manager.
• Vinay C Amatya (Louisiana State University (LSU)\textsuperscript{4830}), who contributed to the documentation and provided some of the HPX examples.
• Kevin Huck and Nick Chaimov (University of Oregon\textsuperscript{4831}), who contributed the integration of APEX (Autonomic Performance Environment for eXascale) with HPX.
• Francisco Jose Tapia, who helped with implementing the parallel sort algorithm for HPX.

• Patrick Diehl, who worked on implementing CUDA support for our companion library targeting GPGPUs (HPXCL\textsuperscript{4832}).

• Eric Lemanissier contributed fixes to allow compilation using the MingW toolchain.

• Nidhi Makhijani who helped cleaning up some enum consistencies in HPX and contributed to the resource manager used in the thread scheduling subsystem. She also worked on HPX in the context of the Google Summer of Code 2015.

• Larry Xiao, Devang Bacharwar, Marcin Copik, and Konstantin Kronfeldner who worked on HPX in the context of the Google Summer of Code program 2015.

• Daniel Bourgeois (Center for Computation and Technology (CCT)\textsuperscript{4833}) who contributed to HPX the implementation of several parallel algorithms (as proposed by N4313\textsuperscript{4834}).

• Anuj Sharma and Christopher Bross (Department of Computer Science 3 - Computer Architecture\textsuperscript{4835}), who worked on HPX in the context of the Google Summer of Code\textsuperscript{4836} program 2014.

• Martin Stumpf (Department of Computer Science 3 - Computer Architecture\textsuperscript{4837}), who rebuilt our contiguous testing infrastructure (see the HPX Buildbot Website\textsuperscript{4838}). Martin is also working on HPXCL\textsuperscript{4839} (mainly all work related to OpenCL\textsuperscript{4840}) and implementing an HPX backend for POCL\textsuperscript{4841}, a portable computing language solution based on OpenCL\textsuperscript{4842}.

• Grant Mercer (University of Nevada, Las Vegas\textsuperscript{4843}), who helped creating many of the parallel algorithms (as proposed by N4313\textsuperscript{4844}).

• Damond Howard (Louisiana State University (LSU)\textsuperscript{4845}), who works on HPXCL\textsuperscript{4846} (mainly all work related to CUDA\textsuperscript{4847}).

• Christoph Junghans (Los Alamos National Lab), who helped making our build system more portable.

• Antoine Tran Tan (Laboratoire de Recherche en Informatique, Paris), who worked on integrating HPX as a backend for NT2\textsuperscript{4848}. He also contributed an implementation of an API similar to Fortran co-arrays on top of HPX.

• John Biddiscombe (Swiss National Supercomputing Centre\textsuperscript{4849}), who helped with the BlueGene/Q port of HPX, implemented the parallel sort algorithm, and made several other contributions.

• Erik Schnetter (Perimeter Institute for Theoretical Physics), who greatly helped to make HPX more robust by submitting a large amount of problem reports, feature requests, and made several direct contributions.

• Mathias Gaunard (Metascale), who contributed several patches to reduce compile time warnings generated while compiling HPX.

• Andreas Buhr, who helped with improving our documentation, especially by suggesting some fixes for inconsistencies.

• Patricia Grubel (New Mexico State University4850), who contributed the description of the different HPX thread scheduler policies and is working on the performance analysis of our thread scheduling subsystem.

• Lars Viklund, whose wit, passion for testing, and love of odd architectures has been an amazing contribution to our team. He has also contributed platform specific patches for FreeBSD and MSVC12.

• Agustín Berge, who contributed patches fixing some very nasty hidden template meta-programming issues. He rewrote large parts of the API elements ensuring strict conformance with C++11/14.

• Anton Bikineev for contributing changes to make using boost::lexical_cast safer, he also contributed a thread safety fix to the iostreams module. He also contributed a complete rewrite of the serialization infrastructure replacing Boost.Serialization inside HPX.

• Pyry Jahkola, who contributed the Mac OS build system and build documentation on how to build HPX using Clang and libc++.

• Mario Mulansky, who created an HPX backend for his Boost.Odeint library, and who submitted several test cases allowing us to reproduce and fix problems in HPX.

• Rekha Raj, who contributed changes to the description of the Windows build instructions.

• Jeremy Kemp how worked on an HPX OpenMP backend and added regression tests.

• Alex Nagelberg for his work on implementing a C wrapper API for HPX.

• Chen Guo, helvihartmann, Nicholas Pezolano, and John West who added and improved examples in HPX.

• Joseph Kleinhenz, Markus Elfring, Kirill Kropivyansky, Alexander Neundorf, Bryant Lam, and Alex Hirsch who improved our CMake.

• Tapasweni Pathak, Praveen Velliengiri, Jean-Loup Tastet, Michael Levine, Aalekh Nigam, HadrienG2, Prayag Verma, Islada, Alex Myczko, and Avyav Kumar who improved the documentation.

• Jayesh Badwaik, J. F. Bastien, Christoph Garth, Christopher Hinz, Brandon Kohn, Mario Lang, Maikel Nadolski, pierrele, hendrx, Dekken, woodmeister123, xaguilar, Andrew Kemp, Dylan Stark, Matthew Anderson, Jeremy Wilke, Jiasheng Yuan, CyberDrudge, david8dixon, Maxwell Reeser, Raffaele Solca, Marco Ippolito, Jules Penuchot, Weile Wei, Severí n Strobl, Kor de Jong, albestro, Jeff Trull, Yuri Victorovich, and Gregor Dais who contributed to the general improvement of HPX.

HPX Funding Acknowledgements4851 lists current and past funding sources for HPX.
