3 Index ........................................................................ 1731
If you’re new to **HPX** you can get started with the *Quick start* guide. Don’t forget to read the *Terminology* section to learn about the most important concepts in **HPX**. The *Examples* give you a feel for how it is to write real **HPX** applications and the *Manual* contains detailed information about everything from building **HPX** to debugging it. There are links to blog posts and videos about **HPX** in *Additional material*.

If you can’t find what you’re looking for in the documentation, please:

- open an issue on GitHub\(^1\);
- contact us on IRC, the **HPX** channel on the C++ Slack\(^2\), or on our mailing list\(^3\); or
- read or ask questions tagged with **HPX** on StackOverflow\(^4\).

You can find a comprehensive list of contact options on Support for deploying and using **HPX**\(^5\).

See *Citing HPX* for details on how to cite **HPX** in publications. See **HPX users** for a list of institutions and projects using **HPX**.

There are also available a PDF version of this documentation as well as a Single HTML Page.

HPX is a C++ Standard Library for Concurrency and Parallelism. It implements all of the corresponding facilities as defined by the C++ Standard. Additionally, in HPX we implement functionalities proposed as part of the ongoing C++ standardization process. We also extend the C++ Standard APIs to the distributed case. HPX is developed by the STE||AR group (see People).

The goal of HPX is to create a high quality, freely available, open source implementation of a new programming model for conventional systems, such as classic Linux based Beowulf clusters or multi-socket highly parallel SMP nodes. At the same time, we want to have a very modular and well designed runtime system architecture which would allow us to port our implementation onto new computer system architectures. We want to use real-world applications to drive the development of the runtime system, coining out required functionalities and converging onto a stable API which will provide a smooth migration path for developers.

The API exposed by HPX is not only modeled after the interfaces defined by the C++11/14/17/20 ISO standard. It also adheres to the programming guidelines used by the Boost collection of C++ libraries. We aim to improve the scalability of today’s applications and to expose new levels of parallelism which are necessary to take advantage of the exascale systems of the future.
WHAT’S SO SPECIAL ABOUT HPX?

- HPX exposes a uniform, standards-oriented API for ease of programming parallel and distributed applications.
- It enables programmers to write fully asynchronous code using hundreds of millions of threads.
- HPX provides unified syntax and semantics for local and remote operations.
- HPX makes concurrency manageable with dataflow and future based synchronization.
- It implements a rich set of runtime services supporting a broad range of use cases.
- HPX exposes a uniform, flexible, and extendable performance counter framework which can enable runtime adaptivity.
- It is designed to solve problems conventionally considered to be scaling-impaired.
- HPX has been designed and developed for systems of any scale, from hand-held devices to very large scale systems.
- It is the first fully functional implementation of the ParalleX execution model.
- HPX is published under a liberal open-source license and has an open, active, and thriving developer community.

2.1 Quick start

The following steps will help you get started with HPX. After Installing HPX, you can check how to run a simple example Hello, World!. Writing task-based applications explains how you can get started with HPX. You can refer to our Migration guide if you use other APIs for parallelism (like OpenMP, MPI or Intel Threading Building Blocks (TBB)) and you would like to convert your code to HPX code.

2.1.1 Installing HPX

The easiest way to install HPX on your system is by choosing one of the steps below:

1. vcpgk
   You can download and install HPX using the vcpgk\(^6\) dependency manager:

   ```
   $ vcpgk install hpx
   ```

2. Spack
   Another way to install HPX is using Spack\(^7\):

---

\(^6\) https://github.com/Microsoft/vcpgk
\(^7\) https://spack.readthedocs.io/en/latest/
$ spack install hpx

3. Fedora

Installation can be done with Fedora\(^8\) as well:

$ dnf install hpx*

4. Arch Linux

HPX is available in the Arch User Repository (AUR)\(^9\) as hpx too.

More information or alternatives regarding the installation can be found in the Building HPX, a detailed guide with thorough explanation of ways to build and use HPX.

### 2.1.2 Hello, World!

To get started with this minimal example you need to create a new project directory and a file CMakeLists.txt with the contents below in order to build an executable using CMake and HPX:

```cmake
# The next step is to create a main.cpp with the contents below:
// Including 'hpx/hpx_main.hpp' instead of the usual 'hpx/hpx_init.hpp' enables
// to use the plain C-main below as the direct main HPX entry point.
#include <hpx/hpx_main.hpp>
#include <hpx/iostream.hpp>

int main()
{
    // Say hello to the world!
    hpx::cout << "Hello World!\n" << std::flush;
    return 0;
}
```

Then, in your project directory run the following:

```
$ mkdir build && cd build
$ cmake -DCMAKE_PREFIX_PATH=/path/to/hpx/installation ..
$ make all
$ ./my_hpx_program
```

```
$ ./my_hpx_program
Hello World!
```

The program looks almost like a regular C++ hello world with the exception of the two includes and hpx::cout.

---

\(^8\) [https://fedoraproject.org/wiki/DNF](https://fedoraproject.org/wiki/DNF)

\(^9\) [https://wiki.archlinux.org/title/Arch_User_Repository](https://wiki.archlinux.org/title/Arch_User_Repository)
• When you include `hpx_main.hpp` HPX makes sure that `main` actually gets launched on the HPX runtime. So while it looks almost the same you can now use futures, async, parallel algorithms and more which make use of the HPX runtime with lightweight threads.

• `hpx::cout` is a replacement for `std::cout` to make sure printing never blocks a lightweight thread. You can read more about `hpx::cout` in The HPX I/O-streams component.

Note:
• You will most likely have more than one `main.cpp` file in your project. See the section on Using HPX with CMake-based projects for more details on how to use `add_hpx_executable`.

• HPX::wrap_main is required if you are implicitly using `main()` as the runtime entry point. See Re-use the main() function as the main HPX entry point for more information.

• HPX::iostreams_component is optional for a minimal project but lets us use the HPX equivalent of `std::cout`, i.e., the HPX The HPX I/O-streams component functionality in our application.

• You do not have to let HPX take over your main function like in the example. See Starting the HPX runtime for more details on how to initialize and run the HPX runtime.

Caution: When including `hpx_main.hpp` the user-defined `main` gets renamed and the real `main` function is defined by HPX. This means that the user-defined `main` must include a return statement, unlike the real `main`. If you do not include the return statement, you may end up with confusing compile time errors mentioning `user_main` or even runtime errors.

2.1.3 Writing task-based applications

So far we haven’t done anything that can’t be done using the C++ standard library. In this section we will give a short overview of what you can do with HPX on a single node. The essence is to avoid global synchronization and break up your application into small, composable tasks whose dependencies control the flow of your application. Remember, however, that HPX allows you to write distributed applications similarly to how you would write applications for a single node (see Why HPX? and Writing distributed HPX applications).

If you are already familiar with async and futures from the C++ standard library, the same functionality is available in HPX.

The following terminology is essential when talking about task-based C++ programs:

• lightweight thread: Essential for good performance with task-based programs. Lightweight refers to smaller stacks and faster context switching compared to OS threads. Smaller overheads allow the program to be broken up into smaller tasks, which in turns helps the runtime fully utilize all processing units.

• async: The most basic way of launching tasks asynchronously. Returns a `future<T>`.

• `future<T>`: Represents a value of type `T` that will be ready in the future. The value can be retrieved with `get` (blocking) and one can check if the value is ready with `is_ready` (non-blocking).

• `shared_future<T>`: Same as `future<T>` but can be copied (similar to `std::unique_ptr` vs `std::shared_ptr`).

• continuation: A function that is to be run after a previous task has run (represented by a future). `then` is a method of `future<T>` that takes a function to run next. Used to build up dataflow DAGs (directed acyclic graphs). `shared_futures` help you split up nodes in the DAG and functions like `when_all` help you join nodes in the DAG.

The following example is a collection of the most commonly used functionality in HPX:
```
#include <hpx/algorithm.hpp>
#include <hpx/future.hpp>
#include <hpx/init.hpp>

#include <iostream>
#include <random>
#include <vector>

void final_task(hpx::future<hpx::tuple<hpx::future<double>, hpx::future<void>>>)
{
    std::cout << "in final_task" << std::endl;
}

int hpx_main()
{
    // A function can be launched asynchronously. The program will not block
    // here until the result is available.
    hpx::future<int> f = hpx::async([]() { return 42; });
    std::cout << "Just launched a task!" << std::endl;

    // Use get to retrieve the value from the future. This will block this task
    // until the future is ready, but the HPX runtime will schedule other tasks
    // if there are tasks available.
    std::cout << "f contains " << f.get() << std::endl;

    // Let's launch another task.
    hpx::future<double> g = hpx::async([]() { return 3.14; });

    // Tasks can be chained using the then method. The continuation takes the
    // future as an argument.
    hpx::future<double> result = g.then([](hpx::future<double>&& gg) {
        // This function will be called once g is ready. gg is g moved
        // into the continuation.
        return gg.get() * 42.0 * 42.0;
    });

    // You can check if a future is ready with the is_ready method.
    std::cout << "Result is ready? " << result.is_ready() << std::endl;

    // You can launch other work in the meantime. Let's sort a vector.
    std::vector<int> v(1000000);

    // We fill the vector synchronously and sequentially.
    hpx::generate(hpx::execution::seq, std::begin(v), std::end(v), &std::rand);

    // We can launch the sort in parallel and asynchronously.
    hpx::future<void> done_sorting =
        hpx::sort(hpx::execution::par( // In parallel.
                                           hpx::execution::task), // Asynchronously.
                  std::begin(v), std::end(v));

    // We launch the final task when the vector has been sorted and result is
    // ready using when_all.
}
```
auto all = hpx::when_all(result, done_sorting).then(&final_task);

// We can wait for all to be ready.
all.wait();

// all must be ready at this point because we waited for it to be ready.
std::cout << (all.is_ready() ? "all is ready!" : "all is not ready...")
<< std::endl;

return hpx::local::finalize();
}

int main(int argc, char* argv[])
{
    return hpx::local::init(hpx_main, argc, argv);
}

Try copying the contents to your main.cpp file and look at the output. It can be a good idea to go through the program step by step with a debugger. You can also try changing the types or adding new arguments to functions to make sure you can get the types to match. The type of the then method can be especially tricky to get right (the continuation needs to take the future as an argument).

Note: HPX programs accept command line arguments. The most important one is --hpx:threads=N to set the number of OS threads used by HPX. HPX uses one thread per core by default. Play around with the example above and see what difference the number of threads makes on the sort function. See Launching and configuring HPX applications for more details on how and what options you can pass to HPX.

Tip: The example above used the construction hpx::when_all(...).then(...). For convenience and performance it is a good idea to replace uses of hpx::when_all(...).then(...) with dataflow. See Dataflow for more details on dataflow.

Tip: If possible, try to use the provided parallel algorithms instead of writing your own implementation. This can save you time and the resulting program is often faster.

2.1.4 Next steps

If you haven’t done so already, reading the Terminology section will help you get familiar with the terms used in HPX. The Examples section contains small, self-contained walkthroughs of example HPX programs. The Local to remote example is a thorough, realistic example starting from a single node implementation and going stepwise to a distributed implementation.

The Manual contains detailed information on writing, building and running HPX applications.
2.2 Examples

The following sections analyze some examples to help you get familiar with the HPX style of programming. We start off with simple examples that utilize basic HPX elements and then begin to expose the reader to the more complex and powerful HPX concepts. Section Building tests and examples shows how you can build the examples.

2.2.1 Asynchronous execution

The Fibonacci sequence is a sequence of numbers starting with 0 and 1 where every subsequent number is the sum of the previous two numbers. In this example, we will use HPX to calculate the value of the n-th element of the Fibonacci sequence. In order to compute this problem in parallel, we will use a facility known as a future.

As shown in the Fig. 2.1 below, a future encapsulates a delayed computation. It acts as a proxy for a result initially not known, most of the time because the computation of the result has not completed yet. The future synchronizes the access of this value by optionally suspending any HPX-threads requesting the result until the value is available. When a future is created, it spawns a new HPX-thread (either remotely with a parcel or locally by placing it into the thread queue) which, when run, will execute the function associated with the future. The arguments of the function are bound when the future is created.

![Fig. 2.1: Schematic of a future execution.](image)

Once the function has finished executing, a write operation is performed on the future. The write operation marks the future as completed, and optionally stores data returned by the function. When the result of the delayed computation is needed, a read operation is performed on the future. If the future’s function hasn’t completed when a read operation is performed on it, the reader HPX-thread is suspended until the future is ready. The future facility allows HPX to schedule work early in a program so that when the function value is needed it will already be calculated and available. We use this property in our Fibonacci example below to enable its parallel execution.
Setup

The source code for this example can be found here: fibonacci_local.cpp.

To compile this program, go to your HPX build directory (see Building HPX for information on configuring and building HPX) and enter:

```
$ make examples.quickstart.fibonacci_local
```

To run the program type:

```
$ ./bin/fibonacci_local
```

This should print (time should be approximate):

```
fibonacci(10) == 55
elapsed time: 0.002430 [s]
```

This run used the default settings, which calculate the tenth element of the Fibonacci sequence. To declare which Fibonacci value you want to calculate, use the `--n-value` option. Additionally you can use the `--hpx:threads` option to declare how many OS-threads you wish to use when running the program. For instance, running:

```
$ ./bin/fibonacci --n-value 20 --hpx:threads 4
```

Will yield:

```
fibonacci(20) == 6765
elapsed time: 0.062854 [s]
```

Walkthrough

Now that you have compiled and run the code, let’s look at how the code works. Since this code is written in C++, we will begin with the `main()` function. Here you can see that in HPX, `main()` is only used to initialize the runtime system. It is important to note that application-specific command line options are defined here. HPX uses Boost.Program_options for command line processing. You can see that our program's `--n-value` option is set by calling the `add_options()` method on an instance of `hpx::program_options::options_description`. The default value of the variable is set to 10. This is why when we ran the program for the first time without using the `--n-value` option the program returned the 10th value of the Fibonacci sequence. The constructor argument of the description is the text that appears when a user uses the `--hpx:help` option to see what command line options are available. HPX_APPLICATION_STRING is a macro that expands to a string constant containing the name of the HPX application currently being compiled.

In HPX main() is used to initialize the runtime system and pass the command line arguments to the program. If you wish to add command line options to your program you would add them here using the instance of the Boost class `options_description`, and invoking the public member function `add_options()` (see Boost Documentation for more details). `hpx::init` calls `hpx_main()` after setting up HPX, which is where the logic of our program is encoded.

```c
int main(int argc, char* argv[]) {
    // Configure application-specific options
    hpx::program_options::options_description desc_commandline(
        "Usage: " HPX_APPLICATION_STRING " [options]";
```

10 https://www.boost.org/doc/html/program_options.html
11 https://www.boost.org/doc/
desc_commandline.add_options()("n-value",
    hpx::program_options::value<std::uint64_t>()->default_value(10),
    "n value for the Fibonacci function");

// Initialize and run HPX
hpx::local::init_params init_args;
init_args.desc_cmdline = desc_commandline;

return hpx::local::init(hpx_main, argc, argv, init_args);
}

The hpx::init function in main() starts the runtime system, and invokes hpx_main() as the first HPX-thread. Below we can see that the basic program is simple. The command line option --n-value is read in, a timer (hpx::chrono::high_resolution_timer) is set up to record the time it takes to do the computation, the fibonacci function is invoked synchronously, and the answer is printed out.

```cpp
int hpx_main(hpx::program_options::variables_map& vm)
{
    // extract command line argument, i.e. fib(N)
    std::uint64_t n = vm["n-value"].as<std::uint64_t>();

    {
        // Keep track of the time required to execute.
        hpx::chrono::high_resolution_timer t;
        std::uint64_t r = fibonacci(n);

        char const* fmt = "fibonacci({1}) == {2}\n
        elapsed time: {3} [s]\n"
        hpx::util::format_to(std::cout, fmt, n, r, t.elapsed());
    }

    return hpx::local::finalize(); // Handles HPX shutdown
}
```

The fibonacci function itself is synchronous as the work done inside is asynchronous. To understand what is happening we have to look inside the fibonacci function:

```cpp
std::uint64_t fibonacci(std::uint64_t n)
{
    if (n < 2)
        return n;

    // Invoking the Fibonacci algorithm twice is inefficient.
    // However, we intentionally demonstrate it this way to create some
    // heavy workload.

    hpx::future<std::uint64_t> n1 = hpx::async(fibonacci, n - 1);
    hpx::future<std::uint64_t> n2 = hpx::async(fibonacci, n - 2);

    return n1.get() +
            n2.get(); // wait for the Futures to return their values
}```
This block of code looks similar to regular C++ code. First, if \( n < 2 \), meaning \( n \) is 0 or 1, then we return 0 or 1 (recall the first element of the Fibonacci sequence is 0 and the second is 1). If \( n \) is larger than 1 we spawn two new tasks whose results are contained in \( n1 \) and \( n2 \). This is done using `hpx::async` which takes as arguments a function (function pointer, object or lambda) and the arguments to the function. Instead of returning a `std::uint64_t` like `fibonacci` does, `hpx::async` returns a future of a `std::uint64_t`, i.e. `hpx::future<std::uint64_t>`. Each of these futures represents an asynchronous, recursive call to `fibonacci`. After we've created the futures, we wait for both of them to finish computing, we add them together, and return that value as our result. We get the values from the futures using the `get` method. The recursive call tree will continue until \( n \) is equal to 0 or 1, at which point the value can be returned because it is implicitly known. When this termination condition is reached, the futures can then be added up, producing the \( n \)-th value of the Fibonacci sequence.

Note that calling `get` potentially blocks the calling \( HPX \)-thread, and lets other \( HPX \)-threads run in the meantime. There are, however, more efficient ways of doing this. `examples/quickstart/fibonacci_futures.cpp` contains many more variations of locally computing the Fibonacci numbers, where each method makes different tradeoffs in where asynchrony and parallelism is applied. To get started, however, the method above is sufficient and optimizations can be applied once you are more familiar with \( HPX \). The example `Dataflow` presents dataflow, which is a way to more efficiently chain together multiple tasks.

### 2.2.2 Parallel algorithms

This program will perform a matrix multiplication in parallel. The output will look something like this:

Matrix A is :

\[
\begin{bmatrix}
4 & 9 & 6 \\
1 & 9 & 8 \\
\end{bmatrix}
\]

Matrix B is :

\[
\begin{bmatrix}
4 & 9 \\
6 & 1 \\
9 & 8 \\
\end{bmatrix}
\]

Resultant Matrix is :

\[
\begin{bmatrix}
124 & 93 \\
111 & 127 \\
\end{bmatrix}
\]

**Setup**

The source code for this example can be found here: `matrix_multiplication.cpp`.

To compile this program, go to your \( HPX \) build directory (see `Building HPX` for information on configuring and building \( HPX \)) and enter:

```bash
$ make examples.quickstart.matrix_multiplication
```

To run the program type:

```bash
$ ./bin/matrix_multiplication
```

or:

```bash
$ ./bin/matrix_multiplication --n 2 --m 3 --k 2 --s 100 --l 0 --u 10
```

where the first matrix is \( n \times m \) and the second \( m \times k \), \( s \) is the seed for creating the random values of the matrices and the range of these values is \([l,u]\).
This should print:

<table>
<thead>
<tr>
<th>Matrix A is:</th>
</tr>
</thead>
<tbody>
<tr>
<td>4 9 6</td>
</tr>
<tr>
<td>1 9 8</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Matrix B is:</th>
</tr>
</thead>
<tbody>
<tr>
<td>4 9</td>
</tr>
<tr>
<td>6 1</td>
</tr>
<tr>
<td>9 8</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Resultant Matrix is:</th>
</tr>
</thead>
<tbody>
<tr>
<td>124 93</td>
</tr>
<tr>
<td>111 127</td>
</tr>
</tbody>
</table>

Notice that the numbers may be different because of the random initialization of the matrices.

Walkthrough

Now that you have compiled and run the code, let’s look at how the code works.

First, main() is used to initialize the runtime system and pass the command line arguments to the program. hpx::init calls hpx::main() after setting up HPX, which is where our program is implemented.

```c++
int main(int argc, char* argv[]) {
    using namespace hpx::program_options;
    options_description cmdline("usage: " HPX_APPLICATION_STRING " [options]");
    // clang-format off
    cmdline.add_options()
        (“n”, hpx::program_options::value<std::size_t>()->default_value(2),
         "Number of rows of first matrix")
        (“m”, hpx::program_options::value<std::size_t>()->default_value(3),
         "Number of columns of first matrix (equal to the number of rows of "
         "second matrix")")
        (“k”, hpx::program_options::value<std::size_t>()->default_value(2),
         "Number of columns of second matrix")
        (“seed,s”, hpx::program_options::value<unsigned int>(),
         "The random number generator seed to use for this run")
        (“l”, hpx::program_options::value<int>()->default_value(0),
         "Lower limit of range of values")
        (“u”, hpx::program_options::value<int>()->default_value(10),
         "Upper limit of range of values");
    // clang-format on
    hpx::local::init_params init_args;
    init_args.desc_cmdline = cmdline;
}
```

(continues on next page)
return hpx::local::init(hpx_main, argc, argv, init_args);
}

Proceeding to the hpx_main() function, we can see that matrix multiplication can be done very easily.

```cpp
int hpx_main(hpx::program_options::variables_map& vm) {
    using element_type = int;

    // Define matrix sizes
    std::size_t const rowsA = vm["n"].as<std::size_t>();
    std::size_t const colsA = vm["m"].as<std::size_t>();
    std::size_t const rowsB = colsA;
    std::size_t const colsB = vm["k"].as<std::size_t>();
    std::size_t const rowsR = rowsA;
    std::size_t const colsR = colsB;

    // Initialize matrices A and B
    std::vector<int> A(rowsA * colsA);
    std::vector<int> B(rowsB * colsB);
    std::vector<int> R(rowsR * colsR);

    // Define seed
    unsigned int seed = std::random_device{}();
    if (vm.count("seed"))
        seed = vm["seed"].as<unsigned int>();

    gen.seed(seed);
    std::cout << "using seed: " << seed << std::endl;

    // Define range of values
    int const lower = vm["l"].as<int>();
    int const upper = vm["u"].as<int>();

    // Matrices have random values in the range [lower, upper]
    std::uniform_int_distribution<element_type> dis(lower, upper);
    auto generator = std::bind(dis, gen);
    hpx::ranges::generate(A, generator);
    hpx::ranges::generate(B, generator);

    // Perform matrix multiplication
    hpx::experimental::for_loop(hpx::execution::par, 0, rowsA, [&] (auto i) {
        hpx::experimental::for_loop(0, colsB, [&] (auto j) {
            R[i * colsR + j] = 0;
            hpx::experimental::for_loop(0, rowsB, [&] (auto k) {
                R[i * colsR + j] += A[i * colsA + k] * B[k * colsB + j];
            });
        });
    });

    // Print all 3 matrices
    print_matrix(A, rowsA, colsA, "A");
}
```

2.2. Examples
First, the dimensions of the matrices are defined. If they were not given as command-line arguments, their default values are 2 x 3 for the first matrix and 3 x 2 for the second. We use standard vectors to define the matrices to be multiplied as well as the resultant matrix.

To give some random initial values to our matrices, we use `std::uniform_int_distribution`. Then, `std::bind()` is used along with `hpx::ranges::generate()` to yield two matrices A and B, which contain values in the range of [0, 10] or in the range defined by the user at the command-line arguments. The seed to generate the values can also be defined by the user.

The next step is to perform the matrix multiplication in parallel. This can be done by just using an `hpx::experimental::for_loop` combined with a parallel execution policy `hpx::execution::par` as the outer loop of the multiplication. Note that the execution of `hpx::experimental::for_loop` without specifying an execution policy is equivalent to specifying `hpx::execution::seq` as the execution policy.

Finally, the matrices A, B that are multiplied as well as the resultant matrix R are printed using the following function.

```cpp
void print_matrix(std::vector<int> const& M, std::size_t rows, std::size_t cols, char const* message) {
    std::cout << "\nMatrix " << message << " is:" << std::endl;
    for (std::size_t i = 0; i < rows; i++) {
        for (std::size_t j = 0; j < cols; j++)
            std::cout << M[i * cols + j] << " ";
        std::cout << "\n";
    }
}
```

### 2.2.3 Asynchronous execution with actions

This example extends the previous example by introducing actions: functions that can be run remotely. In this example, however, we will still only run the action locally. The mechanism to execute actions stays the same: `hpx::async`. Later examples will demonstrate running actions on remote localities (e.g. Remote execution with actions).

**Setup**

The source code for this example can be found here: fibonacci.cpp.

To compile this program, go to your HPX build directory (see Building HPX for information on configuring and building HPX) and enter:

```
$ make examples.quickstart.fibonacci
```

To run the program type:

```
```
This run used the default settings, which calculate the tenth element of the Fibonacci sequence. To declare which Fibonacci value you want to calculate, use the \texttt{--n-value} option. Additionally you can use the \texttt{--hpx:threads} option to declare how many OS-threads you wish to use when running the program. For instance, running:

```
$ ./bin/fibonacci --n-value 20 --hpx:threads 4
```

Will yield:

```
fibonacci(20) == 6765  
elapsed time: 0.233827 [s]
```

### Walkthrough

The code needed to initialize the \textit{HPX} runtime is the same as in the previous example:

```cpp
int main(int argc, char* argv[]) {
    // Configure application-specific options
    hpx::program_options::options_description desc_commandline(
        "Usage: \" HPX_APPLICATION_STRING \" [options]\"); 
    desc_commandline.add_options()("n-value", hpx::program_options::value<std::uint64_t>()->default_value(10), 
        "n value for the Fibonacci function");

    // Initialize and run HPX
    hpx::init_params init_args;
    init_args.desc_cmdline = desc_commandline;

    return hpx::init(argc, argv, init_args);
}
```

The \texttt{hpx::init} function in \texttt{main()} starts the runtime system, and invokes \texttt{hpx\_main()} as the first \textit{HPX}-thread. The command line option \texttt{--n-value} is read in, a timer (\texttt{hpx::chrono::high\_resolution\_timer}) is set up to record the time it takes to do the computation, the \texttt{fibonacci} action is invoked synchronously, and the answer is printed out.

```cpp
int hpx\_main(hpx::program\_options::variables\_map& vm) {
    // extract command line argument, i.e. fib(N)
    std::uint64\_t n = vm["n-value"].as<\texttt{std::int64\_t}>();

    { // Keep track of the time required to execute.
        hpx::chrono::high\_resolution\_timer t;
```
// Wait for fib() to return the value
fibonacci_action fib;
std::uint64_t r = fib(hpx::find_here(), n);

char const* fmt = "fibonacci({1}) == {2}\nelapsed time: {3} [s]\n";

hpx::util::format_to(std::cout, fmt, n, r, t.elapsed());

return hpx::finalize(); // Handles HPX shutdown
}

Upon a closer look we see that we’ve created a `std::uint64_t` to store the result of invoking our `fibonacci_action` `fib`. This `action` will launch synchronously (as the work done inside of the `action` will be asynchronous itself) and return the result of the Fibonacci sequence. But wait, what is an `action`? And what is this `fibonacci_action`? For starters, an `action` is a wrapper for a function. By wrapping functions, HPX can send packets of work to different processing units. These vehicles allow users to calculate work now, later, or on certain nodes. The first argument to our `action` is the location where the `action` should be run. In this case, we just want to run the `action` on the machine that we are currently on, so we use `hpx::find_here`. To further understand this we turn to the code to find where `fibonacci_action` was defined:

```cpp
// forward declaration of the Fibonacci function
std::uint64_t fibonacci(std::uint64_t n);

// This is to generate the required boilerplate we need for the remote
// invocation to work.
HPX_PLAIN_ACTION(fibonacci, fibonacci_action)
```

A plain `action` is the most basic form of `action`. Plain `actions` wrap simple global functions which are not associated with any particular object (we will discuss other types of `actions` in `Components and actions`). In this block of code the function `fibonacci()` is declared. After the declaration, the function is wrapped in an `action` in the declaration `HPX_PLAIN_ACTION`. This function takes two arguments: the name of the function that is to be wrapped and the name of the `action` that you are creating.

This picture should now start making sense. The function `fibonacci()` is wrapped in an `action` `fibonacci_action`, which was run synchronously but created asynchronous work, then returns a `std::uint64_t` representing the result of the function `fibonacci()`. Now, let’s look at the function `fibonacci()`:

```cpp
std::uint64_t fibonacci(std::uint64_t n)
{
    if (n < 2)
        return n;

    // We restrict ourselves to execute the Fibonacci function locally.
    hpx::id_type const locality_id = hpx::find_here();

    // Invoking the Fibonacci algorithm twice is inefficient.
    // However, we intentionally demonstrate it this way to create some
    // heavy workload.

    fibonacci_action fib;
    hpx::future<std::uint64_t> n1 = hpx::async(fib, locality_id, n - 1);
    hpx::future<std::uint64_t> n2 = hpx::async(fib, locality_id, n - 2);
```
This block of code is much more straightforward and should look familiar from the previous example. First, if \((n < 2)\), meaning \(n\) is 0 or 1, then we return 0 or 1 (recall the first element of the Fibonacci sequence is 0 and the second is 1). If \(n\) is larger than 1 we spawn two tasks using `hpx::async`. Each of these futures represents an asynchronous, recursive call to `fibonacci`. As previously we wait for both futures to finish computing, get the results, add them together, and return that value as our result. The recursive call tree will continue until \(n\) is equal to 0 or 1, at which point the value can be returned because it is implicitly known. When this termination condition is reached, the futures can then be added up, producing the \(n\)-th value of the Fibonacci sequence.

### 2.2.4 Remote execution with actions

This program will print out a hello world message on every OS-thread on every localility. The output will look something like this:

```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 1 on locality 1
hello world from OS-thread 0 on locality 0
hello world from OS-thread 0 on locality 1
```

#### Setup

The source code for this example can be found here: `hello_world_distributed.cpp`.

To compile this program, go to your HPX build directory (see [Building HPX](#building-hpx) for information on configuring and building HPX) and enter:

```
$ make examples.quickstart.hello_world_distributed
```

To run the program type:

```
$ ./bin/hello_world_distributed
```

This should print:

```
hello world from OS-thread 0 on locality 0
```

To use more OS-threads use the command line option `--hpx:threads` and type the number of threads that you wish to use. For example, typing:

```
$ ./bin/hello_world_distributed --hpx:threads 2
```

will yield:

```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 0
```

Notice how the ordering of the two print statements will change with subsequent runs. To run this program on multiple localities please see the section [How to use HPX applications with PBS](#how-to-use-hpx-applications-with-pbs).

### 2.2. Examples

```cpp
return n1.get() +
n2.get();    // wait for the Futures to return their values
}
```
Walkthrough

Now that you have compiled and run the code, let’s look at how the code works, beginning with main():

```cpp
// Here is the main entry point. By using the include 'hpx/hpx_main.hpp' HPX
// will invoke the plain old C-main() as its first HPX thread.
int main()
{
    // Get a list of all available localities.
    std::vector<hpx::id_type> localities = hpx::find_all_localities();

    // Reserve storage space for futures, one for each locality.
    std::vector<hpx::future<void>> futures;
    futures.reserve(localities.size());

    for (hpx::id_type const& node : localities)
    {
        // Asynchronously start a new task. The task is encapsulated in a
        // future, which we can query to determine if the task has
        // completed.
        typedef hello_world_foreman_action action_type;
        futures.push_back(hpx::async<action_type>(node));
    }

    // The non-callback version of hpx::wait_all takes a single parameter,
    // a vector of futures to wait on. hpx::wait_all only returns when
    // all of the futures have finished.
    hpx::wait_all(futures);
    return 0;
}
```

In this excerpt of the code we again see the use of futures. This time the futures are stored in a vector so that they can easily be accessed. `hpx::wait_all` is a family of functions that wait for an `std::vector<>` of futures to become ready. In this piece of code, we are using the synchronous version of `hpx::wait_all`, which takes one argument (the `std::vector<>` of futures to wait on). This function will not return until all the futures in the vector have been executed.

In asynchronous execution with actions we used `hpx::find_here` to specify the target of our actions. Here, we instead use `hpx::find_all_localities`, which returns an `std::vector<>` containing the identifiers of all the machines in the system, including the one that we are on.

As in asynchronous execution with actions our futures are set using `hpx::async<>`. The `hello_world_foreman_action` is declared here:

```cpp
// Define the boilerplate code necessary for the function 'hello_world_foreman'
// to be invoked as an HPX action.
HPX_PLAIN_ACTION(hello_world_foreman, hello_world_foreman_action)
```

Another way of thinking about this wrapping technique is as follows: functions (the work to be done) are wrapped in actions, and actions can be executed locally or remotely (e.g. on another machine participating in the computation).

Now it is time to look at the `hello_world_foreman()` function which was wrapped in the action above:

```cpp
void hello_world_foreman()
{
(continues on next page)```
// Get the number of worker OS-threads in use by this locality.
std::size_t const os_threads = hpx::get_os_thread_count();

// Populate a set with the OS-thread numbers of all OS-threads on this
// locality. When the hello world message has been printed on a particular
// OS-thread, we will remove it from the set.
std::set<std::size_t> attendance;
for (std::size_t os_thread = 0; os_thread < os_threads; ++os_thread)
    attendance.insert(os_thread);

// As long as there are still elements in the set, we must keep scheduling
// HPX-threads. Because HPX features work-stealing task schedulers, we have
// no way of enforcing which worker OS-thread will actually execute
// each HPX-thread.
while (!attendance.empty())
{
    // Each iteration, we create a task for each element in the set of
    // OS-threads that have not said "Hello world". Each of these tasks
    // is encapsulated in a future.
    std::vector<hpx::future<std::size_t>> futures;
    futures.reserve(attendance.size());
    for (std::size_t worker : attendance)
    {
        // Asynchronously start a new task. The task is encapsulated in a
        // future that we can query to determine if the task has completed.
        // We give the task a hint to run on a particular worker thread
        // (core) and suggest binding the scheduled thread to the given
        // core, but no guarantees are given by the scheduler that the task
        // will actually run on that worker thread. It will however try as
        // hard as possible to place the new task on the given worker
        // thread.
        hpx::execution::parallel_executor exec(
            hpx::threads::thread_priority::bound);

        hpx::threads::thread_schedule_hint hint(
            hpx::threads::thread_schedule_hint_mode::thread,
            static_cast<std::int16_t>(worker));

        futures.push_back(
            hpx::async(hpx::execution::experimental::with_hint(exec, hint),
                hello_world_worker, worker));
    }

    // Wait for all of the futures to finish. The callback version of the
    // hpx::wait_each function takes two arguments: a vector of futures,
    // and a binary callback. The callback takes two arguments; the first
    // is the index of the future in the vector, and the second is the
    // return value of the future. hpx::wait_each doesn't return until
    // all the futures in the vector have returned.
    hpx::spinlock mtx;
    (continues on next page)
Now, before we discuss `hello_world_foreman()`, let’s talk about the `hpx::wait_each` function. The version of `hpx::wait_each` invokes a callback function provided by the user, supplying the callback function with the result of the future.

In `hello_world_foreman()`, an `std::set<>` called `attendance` keeps track of which OS-threads have printed out the hello world message. When the OS-thread prints out the statement, the future is marked as ready, and `hpx::wait_each` in `hello_world_foreman()` will check if it is not executing on the correct OS-thread, it returns a value of -1, which causes `hello_world_foreman()` to leave the OS-thread id in `attendance`.

```cpp
std::size_t hello_world_worker(std::size_t desired) {
    // Returns the OS-thread number of the worker that is running this
    // HPX-thread.
    std::size_t current = hpx::get_worker_thread_num();
    if (current == desired) {
        // The HPX-thread has been run on the desired OS-thread.
        char const* msg = "hello world from OS-thread {1} on locality {2}\n";
        hpx::util::format_to(hpx::cout, msg, desired, hpx::get_locality_id()) << std::flush;

        return desired;
    }

    // This HPX-thread has been run by the wrong OS-thread, make the foreman
    // try again by rescheduling it.
    return std::size_t(-1);
}
```

Because HPX features work stealing task schedulers, there is no way to guarantee that an action will be scheduled on a particular OS-thread. This is why we must use a guess-and-check approach.
2.2.5 Components and actions

The accumulator example demonstrates the use of components. Components are C++ classes that expose methods as a type of HPX action. These actions are called component actions.

Components are globally named, meaning that a component action can be called remotely (e.g., from another machine). There are two accumulator examples in HPX.

In the Asynchronous execution with actions and the Remote execution with actions, we introduced plain actions, which wrapped global functions. The target of a plain action is an identifier which refers to a particular machine involved in the computation. For plain actions, the target is the machine where the action will be executed.

Component actions, however, do not target machines. Instead, they target component instances. The instance may live on the machine that we’ve invoked the component action from, or it may live on another machine.

The component in this example exposes three different functions:

- **reset()** - Resets the accumulator value to 0.
- **add(arg)** - Adds arg to the accumulators value.
- **query()** - Queries the value of the accumulator.

This example creates an instance of the accumulator, and then allows the user to enter commands at a prompt, which subsequently invoke actions on the accumulator instance.

Setup

The source code for this example can be found here: accumulator_client.cpp.

To compile this program, go to your HPX build directory (see Building HPX for information on configuring and building HPX) and enter:

```
$ make examples.accumulators.accumulator
```

To run the program type:

```
$ ./bin/accumulator_client
```

Once the program starts running, it will print the following prompt and then wait for input. An example session is given below:

```
commands: reset, add [amount], query, help, quit
> add 5
> add 10
> query
15
> add 2
> query
17
> reset
> add 1
> query
1
> quit
```
Walkthrough

Now, let’s take a look at the source code of the accumulator example. This example consists of two parts: an HPX component library (a library that exposes an HPX component) and a client application which uses the library. This walkthrough will cover the HPX component library. The code for the client application can be found here: accumulator_client.cpp.

An HPX component is represented by two C++ classes:

- **A server class** - The implementation of the component's functionality.
- **A client class** - A high-level interface that acts as a proxy for an instance of the component.

Typically, these two classes both have the same name, but the server class usually lives in different sub-namespaces (server). For example, the full names of the two classes in accumulator are:

- examples::server::accumulator (server class)
- examples::accumulator (client class)

**The server class**

The following code is from: accumulator.hpp.

All HPX component server classes must inherit publicly from the HPX component base class: hpx::components::component_base

The accumulator component inherits from hpx::components::locking_hook. This allows the runtime system to ensure that all action invocations are serialized. That means that the system ensures that no two actions are invoked at the same time on a given component instance. This makes the component thread safe and no additional locking has to be implemented by the user. Moreover, an accumulator component is a component because it also inherits from hpx::components::component_base (the template argument passed to locking_hook is used as its base class). The following snippet shows the corresponding code:

```cpp
class accumulator
  : public hpx::components::locking_hook<
    hpx::components::component_base<accumulator>>

argument_type value_;  // Our accumulator class will need a data member to store its value in, so let's declare a data member:

accumulator()
  : value_(0)
{
}
```

Next, let’s look at the three methods of this component that we will be exposing as component actions:

Here are the action types. These types wrap the methods we’re exposing. The wrapping technique is very similar to the one used in the Asynchronous execution with actions and the Remote execution with actions:

```cpp
HPX_DEFINE_COMPONENT_ACTION(accumulator, reset)
HPX_DEFINE_COMPONENT_ACTION(accumulator, add)
HPX_DEFINE_COMPONENT_ACTION(accumulator, query)
```
The last piece of code in the server class header is the declaration of the action type registration code:

```cpp
HPX_REGISTER_ACTION_DECLARATION(
    examples::server::accumulator::reset_action, accumulator_reset_action)
HPX_REGISTER_ACTION_DECLARATION(
    examples::server::accumulator::add_action, accumulator_add_action)
HPX_REGISTER_ACTION_DECLARATION(
    examples::server::accumulator::query_action, accumulator_query_action)
```

**Note:** The code above must be placed in the global namespace.

The rest of the registration code is in `accumulator.cpp`

```cpp
///////////////////////////////////////////////////////////////////////////////
// Add factory registration functionality.
HPX_REGISTER_COMPONENT_MODULE()
///////////////////////////////////////////////////////////////////////////////

typedef hpx::components::component<examples::server::accumulator>
    accumulator_type;
HPX_REGISTER_COMPONENT(accumulator_type, accumulator)
///////////////////////////////////////////////////////////////////////////////
// Serialization support for accumulator actions.
HPX_REGISTER_ACTION(
    accumulator_type::wrapped_type::reset_action, accumulator_reset_action)
HPX_REGISTER_ACTION(
    accumulator_type::wrapped_type::add_action, accumulator_add_action)
HPX_REGISTER_ACTION(
    accumulator_type::wrapped_type::query_action, accumulator_query_action)
```

**Note:** The code above must be placed in the global namespace.

### The client class

The following code is from `accumulator.hpp`.

The client class is the primary interface to a component instance. Client classes are used to create components:

```cpp
// Create a component on this locality.
examples::accumulator c = hpx::new_<examples::accumulator>(hpx::find_here());
```

and to invoke component actions:

```cpp
c.add(hpx::launch::apply, 4);
```

Clients, like servers, need to inherit from a base class, this time, `hpx::components::client_base`.

#### 2.2. Examples

25
The `accumulator` class is defined as:

```cpp
class accumulator :
  public hpx::components::client_base<accumulator, server::accumulator>
```

For readability, we typedef the base class like so:

```cpp
typedef hpx::components::client_base<accumulator, server::accumulator>
  base_type;
```

Here are examples of how to expose actions through a client class:

There are a few different ways of invoking actions:

- **Non-blocking**: For actions that don’t have return types, or when we do not care about the result of an action, we can invoke the action using fire-and-forget semantics. This means that once we have asked *HPX* to compute the action, we forget about it completely and continue with our computation. We use `hpx::post` to invoke an action in a non-blocking fashion.

  ```cpp
  void reset(hpx::launch::apply_policy)
  {
    HPX_ASSERT(this->get_id);
    typedef server::accumulator::reset_action action_type;
    hpx::post<action_type>(this->get_id);
  }
  ```

- **Asynchronous**: Futures, as demonstrated in *Asynchronous execution, Asynchronous execution with actions*, and the *Remote execution with actions*, enable asynchronous action invocation. Here’s an example from the accumulator client class:

  ```cpp
  hpx::future<argument_type> query(hpx::launch::async_policy)
  {
    HPX_ASSERT(this->get_id);
    typedef server::accumulator::query_action action_type;
    return hpx::async<action_type>(hpx::launch::async,
                                 this->get_id);
  }
  ```

- **Synchronous**: To invoke an action in a fully synchronous manner, we can simply call `hpx::async().get()` (i.e., create a future and immediately wait on it to be ready). Here’s an example from the accumulator client class:

  ```cpp
  void add(argument_type arg)
  {
    HPX_ASSERT(this->get_id);
    typedef server::accumulator::add_action action_type;
    action_type()(this->get_id(), arg);
  }
  ```

Note that `this->get_id()` references a data member of the `hpx::components::client_base` base class which identifies the server accumulator instance.

`hpx::naming::id_type` is a type which represents a global identifier in *HPX*. This type specifies the target of an action. This is the type that is returned by `hpx::find_here` in which case it represents the *locality* the code is running on.
2.2.6 Dataflow

HPX provides its users with several different tools to simply express parallel concepts. One of these tools is a local control object (LCO) called dataflow. An LCO is a type of component that can spawn a new thread when triggered. They are also distinguished from other components by a standard interface that allows users to understand and use them easily. A Dataflow, being an LCO, is triggered when the values it depends on become available. For instance, if you have a calculation X that depends on the results of three other calculations, you could set up a dataflow that would begin the calculation X as soon as the other three calculations have returned their values. Dataflows are set up to depend on other dataflows. It is this property that makes dataflow a powerful parallelization tool. If you understand the dependencies of your calculation, you can devise a simple algorithm that sets up a dependency tree to be executed. In this example, we calculate compound interest. To calculate compound interest, one must calculate the interest made in each compound period, and then add that interest back to the principal before calculating the interest made in the next period. A practical person would, of course, use the formula for compound interest:

\[ F = P(1 + i)^n \]

where \( F \) is the future value, \( P \) is the principal value, \( i \) is the interest rate, and \( n \) is the number of compound periods.

However, for the sake of this example, we have chosen to manually calculate the future value by iterating:

\[ I = Pi \]

and

\[ P = P + I \]

Setup

The source code for this example can be found here: interest_calculator.cpp.

To compile this program, go to your HPX build directory (see Building HPX for information on configuring and building HPX) and enter:

```bash
$ make examples.quickstart.interest_calculator
```

To run the program type:

```bash
$ ./bin/interest_calculator --principal 100 --rate 5 --cp 6 --time 36
```

Final amount: 134.01
Amount made: 34.0096

Walkthrough

Let us begin with main. Here we can see that we again are using Boost.Program_options to set our command line variables (see Asynchronous execution with actions for more details). These options set the principal, rate, compound period, and time. It is important to note that the units of time for cp and time must be the same.

```c++
int main(int argc, char** argv)
{
    options_description cmdline("Usage: " HPX_APPLICATION_STRING " [options]");

    cmdline.add_options()
        ("principal", value<double>()->default_value(1000), "The principal \([\$]\)"")
        ("rate", value<double>()->default_value(7), "The interest rate")
        ("cp", value<int>()->default_value(6), "The cp")
        ("time", value<int>()->default_value(36), "The time")
        ...

    // Parse the command line options
    auto desc = parse_command_line(argc, argv, cmdline);

    // Access the command line options
    double principal = desc.get<double>("principal");
    double rate = desc.get<double>("rate");
    int cp = desc.get<int>("cp");
    int time = desc.get<int>("time");

    // Calculate compound interest
    double future_value = principal * pow(1 + rate, time);
    double amount_made = future_value - principal;
}
```

(continues on next page)
"The interest rate [%]"("cp", value<int>()->default_value(12),
"The compound period [months]"("time",
value<int>()->default_value(12 * 30),
"The time money is invested [months]"
);

hpx::init_params init_args;
init_args.desc_cmdline = cmdline;

return hpx::init(argc, argv, init_args);
}

Next we look at hpx_main.

int hpx_main(variables_map& vm)
{
    {
using hpx::dataflow;
using hpx::make_ready_future;
using hpx::shared_future;
using hpx::unwrapping;
hpx::id_type here = hpx::find_here();

    double init_principal =
        vm["principal"].as<double>() ; //Initial principal
    double init_rate = vm["rate"].as<double>() ; //Interest rate
    int cp = vm["cp"].as<int>() ; //Length of a compound period
    int t = vm["time"].as<int>() ; //Length of time money is invested

    init_rate /= 100; //Rate is a % and must be converted
    t /= cp; //Determine how many times to iterate interest calculation: //How many full compound periods can fit in the time invested

    // In non-dataflow terms the implemented algorithm would look like:
    //
    // int t = 5; // number of time periods to use
    // double principal = init_principal;
    // double rate = init_rate;
    //
    // for (int i = 0; i < t; ++i)
    // {
    //     double interest = calc(principal, rate);
    //     principal = add(principal, interest);
    // }
    //
    // Please note the similarity with the code below!

    shared_future<double> principal = make_ready_future(init_principal);
    shared_future<double> rate = make_ready_future(init_rate);

    for (int i = 0; i < t; ++i)
    {
        shared_future<double> interest =

    (continues on next page)
dataflow(unwrapping(calc), principal, rate);
principal = dataflow(unwrapping(add), principal, interest);

// wait for the dataflow execution graph to be finished calculating our // overall interest
double result = principal.get();

std::cout << "Final amount: " << result << std::endl;
std::cout << "Amount made: " << result - init_principal << std::endl;
}
return hpx::finalize();

Here we find our command line variables read in, the rate is converted from a percent to a decimal, the number of calculation iterations is determined, and then our shared_futures are set up. Notice that we first place our principal and rate into shares futures by passing the variables init_principal and init_rate using hpx::make_ready_future. In this way hpx::shared_future<double> principal and rate will be initialized to init_principal and init_rate when hpx::make_ready_future<double> returns a future containing those initial values. These shared futures then enter the for loop and are passed to interest. Next principal and interest are passed to the reassignment of principal using a hpx::dataflow. A dataflow will first wait for its arguments to be ready before launching any callbacks, so add in this case will not begin until both principal and interest are ready. This loop continues for each compound period that must be calculated. To see how interest and principal are calculated in the loop, let us look at calc_action and add_action:

// Calculate interest for one period
double calc(double principal, double rate)
{
    return principal * rate;
}

// Add the amount made to the principal
double add(double principal, double interest)
{
    return principal + interest;
}

After the shared future dependencies have been defined in hpx_main, we see the following statement:

double result = principal.get();

This statement calls hpx::future::get on the shared future principal which had its value calculated by our for loop. The program will wait here until the entire dataflow tree has been calculated and the value assigned to result. The program then prints out the final value of the investment and the amount of interest made by subtracting the final value of the investment from the initial value of the investment.
2.2.7 Local to remote

When developers write code they typically begin with a simple serial code and build upon it until all of the required functionality is present. The following set of examples were developed to demonstrate this iterative process of evolving a simple serial program to an efficient, fully-distributed HPX application. For this demonstration, we implemented a 1D heat distribution problem. This calculation simulates the diffusion of heat across a ring from an initialized state to some user-defined point in the future. It does this by breaking each portion of the ring into discrete segments and using the current segment’s temperature and the temperature of the surrounding segments to calculate the temperature of the current segment in the next timestep as shown by Fig. 2.2 below.

![Heat diffusion example program flow.](image)

We parallelize this code over the following eight examples:

- Example 1
- Example 2
- Example 3
- Example 4
- Example 5
- Example 6
- Example 7
- Example 8

The first example is straight serial code. In this code we instantiate a vector \( U \) that contains two vectors of doubles as seen in the structure `stepper`.

```cpp
struct stepper
{
  // Our partition type
  typedef double partition;

  // Our data for one time step
  typedef std::vector<partition> space;

  // Our operator
  static double heat(double left, double middle, double right)
  {
    return middle + (k * dt / (dx * dx)) * (left - 2 * middle + right);
  }
}
```

(continues on next page)
// do all the work on 'nx' data points for 'nt' time steps
space do_work(std::size_t nx, std::size_t nt)
{
    // U[t][i] is the state of position i at time t.
    std::vector<space> U(2);
    for (space& s : U)
        s.resize(nx);

    // Initial conditions: f(0, i) = i
    for (std::size_t i = 0; i != nx; ++i)
        U[0][i] = double(i);

    // Actual time step loop
    for (std::size_t t = 0; t != nt; ++t)
    {
        space const& current = U[t % 2];
        space& next = U[(t + 1) % 2];

        next[0] = heat(current[nx - 1], current[0], current[1]);

        for (std::size_t i = 1; i != nx - 1; ++i)
            next[i] = heat(current[i - 1], current[i], current[i + 1]);

        next[nx - 1] = heat(current[nx - 2], current[nx - 1], current[0]);
    }

    // Return the solution at time-step 'nt'.
    return U[nt % 2];
}

Each element in the vector of doubles represents a single grid point. To calculate the change in heat distribution, the
temperature of each grid point, along with its neighbors, is passed to the function heat. In order to improve readability,
references named current and next are created which, depending on the time step, point to the first and second vector
of doubles. The first vector of doubles is initialized with a simple heat ramp. After calling the heat function with the
data in the current vector, the results are placed into the next vector.

In example 2 we employ a technique called futurization. Futurization is a method by which we can easily transform a
code that is serially executed into a code that creates asynchronous threads. In the simplest case this involves replacing
a variable with a future to a variable, a function with a future to a function, and adding a .get() at the point where a
value is actually needed. The code below shows how this technique was applied to the struct stepper.

struct stepper
{
    // Our partition type
    typedef hpx::shared_future<double> partition;

    // Our data for one time step
    typedef std::vector<partition> space;

    // Our operator
    static double heat(double left, double middle, double right)
    {

(continues on next page)
return middle + (k * dt / (dx * dx)) * (left - 2 * middle + right);
}

// do all the work on 'nx' data points for 'nt' time steps
hpx::future<space> do_work(std::size_t nx, std::size_t nt)
{
    using hpx::dataflow;
    using hpx::unwrapping;

    // U[t][i] is the state of position i at time t.
    std::vector<space> U(2);
    for (space& s : U)
        s.resize(nx);

    // Initial conditions: f(0, i) = i
    for (std::size_t i = 0; i != nx; ++i)
        U[0][i] = hpx::make_ready_future(double(i));

    auto Op = unwrapping(&stepper::heat);

    // Actual time step loop
    for (std::size_t t = 0; t != nt; ++t)
    {
        space const& current = U[t % 2];
        space& next = U[(t + 1) % 2];

        // WHEN U[t][i-1], U[t][i], and U[t][i+1] have been computed, THEN we
        // can compute U[t+1][i]
        for (std::size_t i = 0; i != nx; ++i)
        {
            next[i] =
                dataflow(hpx::launch::async, Op, current[idx(i, -1, nx)],
                         current[i], current[idx(i, +1, nx)]);
        }
    }

    // Now the asynchronous computation is running; the above for-loop does not
    // wait on anything. There is no implicit waiting at the end of each timestep;
    // the computation of each U[t][i] will begin as soon as its dependencies
    // are ready and hardware is available.

    // Return the solution at time-step 'nt'.
    return hpx::when_all(U[nt % 2]);
};

In example 2, we redefine our partition type as a shared_future and, in main, create the object result, which is a future to a vector of partitions. We use result to represent the last vector in a string of vectors created for each timestep. In order to move to the next timestep, the values of a partition and its neighbors must be passed to heat once the futures that contain them are ready. In HPX, we have an LCO (Local Control Object) named Dataflow that assists the programmer in expressing this dependency. Dataflow allows us to pass the results of a set of futures to a specified function when the futures are ready. Dataflow takes three types of arguments, one which instructs the dataflow on how to perform the function call (async or sync), the function to call (in this case Op), and futures to the arguments that will
be passed to the function. When called, dataflow immediately returns a future to the result of the specified function. This allows users to string dataflows together and construct an execution tree.

After the values of the futures in dataflow are ready, the values must be pulled out of the future container to be passed to the function heat. In order to do this, we use the HPX facility unwrapping, which underneath calls .get() on each of the futures so that the function heat will be passed doubles and not futures to doubles.

By setting up the algorithm this way, the program will be able to execute as quickly as the dependencies of each future are met. Unfortunately, this example runs terribly slow. This increase in execution time is caused by the overheads needed to create a future for each data point. Because the work done within each call to heat is very small, the overhead of creating and scheduling each of the three futures is greater than that of the actual useful work! In order to amortize the overheads of our synchronization techniques, we need to be able to control the amount of work that will be done with each future. We call this amount of work per overhead grain size.

In example 3, we return to our serial code to figure out how to control the grain size of our program. The strategy that we employ is to create “partitions” of data points. The user can define how many partitions are created and how many data points are contained in each partition. This is accomplished by creating the struct partition, which contains a member object data_, a vector of doubles that holds the data points assigned to a particular instance of partition.

In example 4, we take advantage of the partition setup by redefining space to be a vector of shared_futures with each future representing a partition. In this manner, each future represents several data points. Because the user can define how many data points are in each partition, and, therefore, how many data points are represented by one future, a user can control the grainsize of the simulation. The rest of the code is then futurized in the same manner as example 2. It should be noted how strikingly similar example 4 is to example 2.

Example 4 finally shows good results. This code scales equivalently to the OpenMP version. While these results are promising, there are more opportunities to improve the application’s scalability. Currently, this code only runs on one locality, but to get the full benefit of HPX, we need to be able to distribute the work to other machines in a cluster. We begin to add this functionality in example 5.

In order to run on a distributed system, a large amount of boilerplate code must be added. Fortunately, HPX provides us with the concept of a component, which saves us from having to write quite as much code. A component is an object that can be remotely accessed using its global address. Components are made of two parts: a server and a client class. While the client class is not required, abstracting the server behind a client allows us to ensure type safety instead of having to pass around pointers to global objects. Example 5 renames example 4’s struct partition to partition_data and adds serialization support. Next, we add the server side representation of the data in the structure partition_server. Partition_server inherits from hpx::components::component_base, which contains a server-side component boilerplate. The boilerplate code allows a component’s public members to be accessible anywhere on the machine via its Global Identifier (GID). To encapsulate the component, we create a client side helper class. This object allows us to create new instances of our component and access its members without having to know its GID. In addition, we are using the client class to assist us with managing our asynchrony. For example, our client class partition’s member function get_data() returns a future to partition_data get_data(). This struct inherits its boilerplate code from hpx::components::client_base.

In the structure stepper, we have also had to make some changes to accommodate a distributed environment. In order to get the data from a particular neighboring partition, which could be remote, we must retrieve the data from all of the neighboring partitions. These retrievals are asynchronous and the function heat_part_data, which, amongst other things, calls heat, should not be called unless the data from the neighboring partitions have arrived. Therefore, it should come as no surprise that we synchronize this operation with another instance of dataflow (found in heat_part). This dataflow receives futures to the data in the current and surrounding partitions by calling get_data() on each respective partition. When these futures are ready, dataflow passes them to the unwrapping function, which extracts the shared_array of doubles and passes them to the lambda. The lambda calls heat_part_data on the locality, which the middle partition is on.

Although this example could run distributed, it only runs on one locality, as it always uses hpx::find_here() as the target for the functions to run on.

In example 6, we begin to distribute the partition data on different nodes. This is accomplished in

2.2. Examples
We distribute the partitions evenly based on the number of localities used, which is described in the function `locidx`. Because some of the data needed to update the partition in `heat_part` could now be on a new `locality`, we must devise a way of moving data to the `locality` of the middle partition. We accomplished this by adding a switch in the function `get_data()` that returns the end element of the buffer data if it is from the left partition or the first element of the buffer if the data is from the right partition. In this way only the necessary elements, not the whole buffer, are exchanged between nodes. The reader should be reminded that this exchange of end elements occurs in the function `get_data()` and, therefore, is executed asynchronously.

Now that we have the code running in distributed, it is time to make some optimizations. The function `heat_part` spends most of its time on two tasks: retrieving remote data and working on the data in the middle partition. Because we know that the data for the middle partition is local, we can overlap the work on the middle partition with that of the possibly remote call of `get_data()`. This algorithmic change, which was implemented in example 7, can be seen below:}

```cpp
// The partitioned operator, it invokes the heat operator above on all elements // of a partition.
static partition heat_part(
    partition const& left, partition const& middle, partition const& right)
{
    using hpx::dataflow;
    using hpx::unwrapping;

    hpx::shared_future<partition_data> middle_data =
        middle.get_data(partition_server::middle_partition);

    hpx::future<partition_data> next_middle = middle_data.then(
        unwrapping([middle](partition_data const& m) -> partition_data {
            HPX_UNUSED(middle);
            // All local operations are performed once the middle data of // the previous time step becomes available.
            std::size_t size = m.size();
            partition_data next(size);
            for (std::size_t i = 1; i != size - 1; ++i)
                next[i] = heat(m[i - 1], m[i], m[i + 1]);
            return next;
        }));

    return dataflow(hpx::launch::async,
        unwrapping([left, middle, right](partition_data next, 
            partition_data const& l, partition_data const& m, 
            partition_data const& r) -> partition {
            HPX_UNUSED(left);
            HPX_UNUSED(right);

            // Calculate the missing boundary elements once the // corresponding data has become available.
            std::size_t size = m.size();
        }));
}
```
next[0] = heat(l[size - 1], m[0], m[1]);
next[size - 1] = heat(m[size - 2], m[size - 1], r[0]);

// The new partition_data will be allocated on the same locality
// as 'middle'.
return partition(middle.get_id(), std::move(next));
});
std::move(next_middle),
left.get_data(partition_server::left_partition), middle_data,
right.get_data(partition_server::right_partition));

Example 8 completes the futurization process and utilizes the full potential of HPX by distributing the program flow to multiple localities, usually defined as nodes in a cluster. It accomplishes this task by running an instance of HPX main on each locality. In order to coordinate the execution of the program, the struct stepper is wrapped into a component. In this way, each locality contains an instance of stepper that executes its own instance of the function do_work(). This scheme does create an interesting synchronization problem that must be solved. When the program flow was being coordinated on the head node, the GID of each component was known. However, when we distribute the program flow, each partition has no notion of the GID of its neighbor if the next partition is on another locality. In order to make the GIDs of neighboring partitions visible to each other, we created two buffers to store the GIDs of the remote neighboring partitions on the left and right respectively. These buffers are filled by sending the GID of newly created edge partitions to the right and left buffers of the neighboring localities.

In order to finish the simulation, the solution vectors named result are then gathered together on locality 0 and added into a vector of spaces overall_result using the HPX functions gather_id and gather_here.

Example 8 completes this example series, which takes the serial code of example 1 and incrementally morphs it into a fully distributed parallel code. This evolution was guided by the simple principles of futurization, the knowledge of grain size, and utilization of components. Applying these techniques easily facilitates the scalable parallelization of most applications.

### 2.2.8 Serializing user-defined types

In order to facilitate the sending and receiving of complex datatypes HPX provides a serialization abstraction.

Just like boost, hpx allows users to serialize user-defined types by either providing the serializer as a member function or defining the serialization as a free function.

Unlike Boost HPX doesn’t acknowledge second unsigned int parameter, it is solely there to preserve API compatibility with Boost Serialization

This tutorial was heavily inspired by Boost’s serialization concepts\(^\text{13}\).

\(^{13}\) [https://www.boost.org/doc/libs/1_79_0/libs/serialization/doc/serialization.html](https://www.boost.org/doc/libs/1_79_0/libs/serialization/doc/serialization.html)
Setup

The source code for this example can be found here: custom_serialization.cpp.

To compile this program, go to your HPX build directory (see Building HPX for information on configuring and building HPX) and enter:

```bash
$ make examples.quickstart.custom_serialization
```

To run the program type:

```bash
$ ./bin/custom_serialization
```

This should print:

```bash
Rectangle(Point(x=0,y=0),Point(x=0,y=5))
gavity.g = 9.81%
```

Serialization Requirements

In order to serialize objects in HPX, at least one of the following criteria must be met:

In the case of default constructible objects:

- The object is an empty type.
- Has a serialization function as shown in this tutorial.
- All members are accessible publicly and they can be used in structured binding contexts.

Otherwise:

- They need to have special serialization support.

Member function serialization

```cpp
struct point_member_serialization
{
    int x{0};
    int y{0};

    // Required when defining the serialization function as private
    // In this case it isn't
    // Provides serialization access to HPX
    friend class hpx::serialization::access;

    // Second argument exists solely for compatibility with boost serialize
    // it is NOT processed by HPX in any way.
    template <typename Archive>
    void serialize(Archive& ar, const unsigned int)
    {
        // clang-format off
        ar & x & y;
        // clang-format on
    }
}
```

(continues on next page)
Notice that `point_member_serialization` is defined as bitwise serializable (see Bitwise serialization for bitwise copyable data for more details). HPX is also able to recursively serialize composite classes and structs given that its members are serializable.

```cpp
struct rectangle_member_serialization
{
    point_member_serialization top_left;
    point_member_serialization lower_right;

    template <typename Archive>
    void serialize(Archive& ar, const unsigned int)
    {
        // clang-format off
        ar & top_left & lower_right;
        // clang-format on
    }
};
```

### Free function serialization

In order to decouple your models from HPX, HPX also allows for the definition of free function serializers.

```cpp
struct rectangle_free
{
    point_member_serialization top_left;
    point_member_serialization lower_right;
};

template <typename Archive>
void serialize(Archive& ar, rectangle_free& pt, const unsigned int)
{
    // clang-format off
    ar & pt.lower_right & pt.top_left;
    // clang-format on
}
```

Even if you can’t modify a class to befriend it, you can still be able to serialize your class provided that your class is default constructable and you are able to reconstruct it yourself.

```cpp
class point_class
{
    public:
        point_class(int x, int y)
            : x(x), y(y)
        {
```
```cpp
point_class() = default;

[[nodiscard]] int get_x() const noexcept
{
    return x;
}

[[nodiscard]] int get_y() const noexcept
{
    return y;
}

private:
    int x;
    int y;

};

template <typename Archive>
void load(Archive& ar, point_class& pt, const unsigned int)
{
    int x, y;
    ar >> x >> y;
    pt = point_class(x, y);
}

template <typename Archive>
void save(Archive& ar, point_class const& pt, const unsigned int)
{
    ar << pt.get_x() << pt.get_y();
}

// This tells HPX that you have split your serialize function into
// load and save
HPX_SERIALIZATION_SPLIT_FREE(point_class)
```

### Serializing non default constructable classes

Some classes don’t provide any default constructor.

```cpp
class planet_weight_calculator
{
public:
    explicit planet_weight_calculator(double g)
        : g(g)
    {
    }

    template <class Archive>
    friend void save_construct_data(}
```
Archive&, planet_weight_calculator const*, unsigned int);

[[nodiscard]] double get_g() const
{
  return g;
}

private:
  // Provides serialization access to HPX
  friend class hpx::serialization::access;
  template <class Archive>
  void serialize(Archive&, const unsigned int)
  {
    // Serialization will be done in the save_construct_data
    // Still needs to be defined
  }
  double g;
};

In this case you have to define a save_construct_data and load_construct_data in which you do the serialization yourself.

```cpp
template <class Archive>
inline void save_construct_data(Archive& ar, planet_weight_calculator const* weight_calc, const unsigned int)
{
  ar << weight_calc->g; // Do all of your serialization here
}

template <class Archive>
inline void load_construct_data(
  Archive& ar, planet_weight_calculator* weight_calc, const unsigned int)
{
  double g;
  ar >> g;
  // ::new(ptr) construct new object at given address
  hpx::construct_at(weight_calc, g);
}
```

Bitwise serialization for bitwise copyable data

When sending non arithmetic types not defined by std::is_arithmetic\textsuperscript{14}, HPX has to (de)serialize each object separately. However, if the class you are trying to send classes consists only of bitwise copyable datatypes, you may mark your class as such. Then HPX will serialize your object bitwise instead of element wise. This has enormous benefits, especially when sending a vector/array of your class. To define your class as such you need to call HPX\_IS\_BITWISE\_SERIALIZABLE(T) with your desired custom class.

\textsuperscript{14} https://en.cppreference.com/w/cpp/types/is_arithmetic

2.2. Examples
```cpp
struct point_member_serialization
{
    int x{0};
    int y{0};

    // Required when defining the serialization function as private
    // In this case it isn’t
    // Provides serialization access to HPX
    friend class hpx::serialization::access;

    // Second argument exists solely for compatibility with boost serialize
    // it is NOT processed by HPX in any way.
    template <typename Archive>
    void serialize(Archive& ar, const unsigned int)
    {
        // clang-format off
        ar & x & y;
        // clang-format on
    }
};

// Allow bitwise serialization
HPX_IS_BITWISE_SERIALIZABLE(point_member_serialization)
```

2.3 Manual

The manual is your comprehensive guide to HPX. It contains detailed information on how to build and use HPX in different scenarios.

2.3.1 Prerequisites

Supported platforms

At this time, HPX supports the following platforms. Other platforms may work, but we do not test HPX with other platforms, so please be warned.

<tr>
<td>Boost</td>
<td>1.71.0</td>
</tr>
<tr>
<td>Portable Hardware Locality (HWLOC)</td>
<td>1.5</td>
</tr>
<tr>
<td>Asio</td>
<td>1.12.0</td>
</tr>
</tbody>
</table>

The most important dependencies are Boost and Portable Hardware Locality (HWLOC). The installation of Boost is described in detail in Boost’s Getting Started document. A recent version of hwloc is required in order to support thread pinning and NUMA awareness and can be found in Hwloc Downloads.

HPX is written in 99.99% Standard C++ (the remaining 0.01% is platform specific assembly code). As such, HPX is compilable with almost any standards compliant C++ compiler. The code base takes advantage of C++ language and standard library features when available.

Note: When building Boost using gcc, please note that it is required to specify a cxxflags=-std=c++17 command line argument to b2 (bjam).

Note: In most configurations, HPX depends only on header-only Boost. Boost.Filesystem is required if the standard library does not support filesystem. The following are not needed by default, but are required in certain configurations: Boost.Chrono, Boost.DateTime, Boost.Log, Boost.LogSetup, Boost.Regex, and Boost.Thread.

24 https://www.boost.org/more/getting_started/index.html
25 https://www.open-mpi.org/software/hwloc/v1.11
Depending on the options you chose while building and installing HPX, you will find that HPX may depend on several other libraries such as those listed below.

**Note:** In order to use a high speed parcelport, we currently recommend configuring HPX to use MPI so that MPI can be used for communication between different localities. Please set the CMake variable `MPI_CXX_COMPILER` to your MPI C++ compiler wrapper if not detected automatically.

### 2.3.2 Getting HPX

Download a tarball of the latest release from HPX Downloads and unpack it or clone the repository directly using git:

```bash
$ git clone https://github.com/STEllAR-GROUP/hpx.git
```

It is also recommended that you check out the latest stable tag:

```bash
$ cd hpx
$ git checkout 1.10.0
```

### 2.3.3 Building HPX

**Basic information**

The build system for HPX is based on CMake, a cross-platform build-generator tool which is not responsible for building the project but rather generates the files needed by your build tool (GNU make, Visual Studio, etc.) for building HPX. If CMake is not already installed in your system, you can download it and install it here: CMake Downloads.

Once CMake has been run, the build process can be started. The build process consists of the following parts:

- **HPX Core libraries (target core):** This forms the basic set of HPX libraries.
- **HPX Examples (target examples):** This target is enabled by default and builds all HPX examples (disable by setting `HPX_WITH_EXAMPLES:BOOL=Off`). HPX examples are part of the all target and are included in the installation if enabled.
- **HPX Tests (target tests):** This target builds the HPX test suite and is enabled by default (disable by setting `HPX_WITH_TESTS:BOOL=OFF`). They are not built by the all target and have to be built separately.

26 https://code.google.com/p/gperftools
27 http://jemalloc.net
28 http://microsoft.github.io/mimalloc/
29 https://hpx.stellar-group.org/downloads/
30 https://www.cmake.org
31 https://www.cmake.org/cmake/resources/software.html
• **HPX Documentation** (target docs): This target builds the documentation, and is not enabled by default (enable by setting `HPX_WITH_DOCUMENTATION:BOOL=On`). For more information see [Documentation](https://uo-oaciss.github.io/apex/quickstarthpx/).

The **HPX** build process is highly configurable through CMake, and various CMake variables influence the build process. A list with the most important CMake variables can be found in the section that follows, while the complete list of available CMake variables is in **CMake options**. These variables can be used to refine the recipes that can be found at [Platform specific build recipes](https://uo-oaciss.github.io/apex/quickstarthpx/), a section that shows some basic steps on how to build **HPX** for a specific platform.

In order to use **HPX**, only the core libraries are required. In order to use the optional libraries, you need to specify them as link dependencies in your build (See [Creating HPX projects](https://uo-oaciss.github.io/apex/quickstarthpx/)).

### Most important CMake options

While building **HPX**, you are provided with multiple CMake options which correspond to different configurations. Below, there is a set of the most important and frequently used CMake options.

**HPX_WITH_MALLOC**

Use a custom allocator. Using a custom allocator tuned for multithreaded applications is very important for the performance of **HPX** applications. When debugging applications, it's useful to set this to `system`, as custom allocators can hide some memory-related bugs. Note that setting this to something other than `system` requires an external dependency.

**HPX_WITH_CUDA**

Enable support for CUDA. Use `CMAKE_CUDA_COMPILER` to set the CUDA compiler. This is a standard CMake variable, like `CMAKE_CXX_COMPILER`.

**HPX_WITH_PARCELPORT_MPI**

Enable the MPI parcelport. This enables the use of MPI for the networking operations in the **HPX** runtime. The default value is `OFF` because it’s not available on all systems and/or requires another dependency. However, it is the recommended parcelport.

**HPX_WITH_PARCELPORT_TCP**

Enable the TCP parcelport. Enables the use of TCP for networking in the runtime. The default value is `ON`. However, it’s only recommended for debugging purposes, as it is slower than the MPI parcelport.

**HPX_WITH_PARCELPORT_LCI**

Enable the LCI parcelport. This enables the use of LCI for the networking operations in the **HPX** runtime. The default value is `OFF` because it’s not available on all systems and/or requires another dependency. However, this experimental parcelport may provide better performance than the MPI parcelport. Please refer to [Using the LCI parcelport](https://uo-oaciss.github.io/apex/quickstarthpx/) for more information about the LCI parcelport.

**HPX_WITH_APEX**

Enable APEX integration. APEX[^ape] can be used to profile **HPX** applications. In particular, it provides information about individual tasks in the **HPX** runtime.

**HPX_WITH_GENERIC_CONTEXT_COROUTINES**

Enable Boost. Context for task context switching. It must be enabled for non-x86 architectures such as ARM and Power.

**HPX_WITH_MAX_CPU_COUNT**

Set the maximum CPU count supported by **HPX**. The default value is 64, and should be set to a number at least as high as the number of cores on a system including virtual cores such as hyperthreads.

**HPX_WITH_CXX_STANDARD**

Set a specific C++ standard version e.g. `HPX_WITH_CXX_STANDARD=20`. The default and minimum value is 17.

[^ape]: https://uo-oaciss.github.io/apex/quickstarthpx/
Build types

CMake can be configured to generate project files suitable for builds that have enabled debugging support or for an optimized build (without debugging support). The CMake variable used to set the build type is `CMAKE_BUILD_TYPE` (for more information see the CMake Documentation\(^3^3\)). Available build types are:

- **Debug**: Full debug symbols are available as well as additional assertions to help debugging. To enable the debug build type for the HPX API, the C++ Macro `HPX_DEBUG` is defined.
- **RelWithDebInfo**: Release build with debugging symbols. This is most useful for profiling applications.
- **Release**: Release build. This disables assertions and enables default compiler optimizations.
- **RelMinSize**: Release build with optimizations for small binary sizes.

**Important**: We currently don’t guarantee ABI compatibility between Debug and Release builds. Please make sure that applications built against HPX use the same build type as you used to build HPX. For CMake builds, this means that the `CMAKE_BUILD_TYPE` variables have to match and for projects not using CMake\(^3^4\), the `HPX_DEBUG` macro has to be set in debug mode.

Platform specific build recipes

Unix variants

Once you have the source code and the dependencies and assuming all your dependencies are in paths known to CMake, the following gets you started:

1. First, set up a separate build directory to configure the project:

   ```bash
   $ mkdir build && cd build
   ```

2. To configure the project you have the following options:

   - To build the core HPX libraries and examples, and install them to your chosen location (recommended):

     ```bash
     $ cmake -DCMAKE_INSTALL_PREFIX=/install/path ..
     ```

     **Tip**: If you want to change CMake variables for your build, it is usually a good idea to start with a clean build directory to avoid configuration problems. It is especially important that you use a clean build directory when changing between Release and Debug modes.

   - To install HPX to the default system folders, simply leave out the `CMAKE_INSTALL_PREFIX` option:

\(^3^3\) [https://cmake.org/cmake/help/latest/variable/CMAKE_BUILD_TYPE.html](https://cmake.org/cmake/help/latest/variable/CMAKE_BUILD_TYPE.html)

\(^3^4\) [https://www.cmake.org](https://www.cmake.org)

Chapter 2. What’s so special about HPX?
• If your dependencies are in custom locations, you may need to tell CMake where to find them by passing one or more options to CMake as shown below:

```
$ cmake -DBOOST_ROOT=/path/to/boost
     -DHWLOC_ROOT=/path/to/hwloc
     -DTCMALLOC_ROOT=/path/to/tcmalloc
     -DJEMALLOC_ROOT=/path/to/jemalloc
     [other CMake variable definitions]
     /path/to/source/tree
```

For instance:

```
$ cmake -DBOOST_ROOT=~/packages/boost -DHWLOC_ROOT=/packages/hwloc -DCMAKE_INSTALL_PREFIX=~/packages/hpx ~/downloads/hpx_1.5.1
```

• If you want to try HPX without using a custom allocator pass `-DHPX_WITH_MALLOC=system` to CMake:

```
$ cmake -DCMAKE_INSTALL_PREFIX=/install/path -DHPX_WITH_MALLOC=system ..
```

**Note:** Please pay special attention to the section about `HPX_WITH_MALLOC:STRING` as this is crucial for getting decent performance.

---

**Important:** If you are building HPX for a system with more than 64 processing units, you must change the CMake variable `HPX_WITH_MAX_CPU_COUNT` (to a value at least as big as the number of (virtual) cores on your system). Note that the default value is 64.

---

**Caution:** Compiling and linking HPX needs a considerable amount of memory. It is advisable that at least 2 GB of memory per parallel process is available.

---

3. Once the configuration is complete, to build the project you run:

```
$ cmake --build . --target install
```

---

### Windows

**Note:** The following build recipes are mostly user-contributed and may be outdated. We always welcome updated and new build recipes.

To build HPX under Windows 10 x64 with Visual Studio 2015:

- Download the CMake V3.18.1 installer (or latest version) from [here](https://blog.kitware.com/cmake-3-18-1-available-for-download/)
- Download the hwloc V1.11.0 (or the latest version) from [here](http://www.open-mpi.org/software/hwloc/v1.11/downloads/hwloc-win64-build-1.11.0.zip) and unpack it.
• Download the latest Boost libraries from [here](https://www.boost.org/users/download/) and unpack them.

• Build the Boost DLLs and LIBs by using these commands from Command Line (or PowerShell). Open CMD/PowerShell inside the Boost dir and type in:

```
\bootstrap.bat
```

This batch file will set up everything needed to create a successful build. Now execute:

```
\b2.exe link=shared variant=release,debug architecture=x86 address-model=64 threading=multi --build-type=complete install
```

This command will start a (very long) build of all available Boost libraries. Please, be patient.

• Open CMake-GUI.exe and set up your source directory (input field ‘Where is the source code’) to the base directory of the source code you downloaded from HPX’s GitHub pages. Here’s an example of CMake path settings, which point to the Documents/GitHub/hpx folder:

![CMake path settings](image)

Fig. 2.3: Example CMake path settings.

Inside ‘Where is the source-code’ enter the base directory of your HPX source directory (do not enter the “src” sub-directory!). Inside ‘Where to build the binaries’ you should put in the path where all the building processes will happen. This is important because the building machinery will do an “out-of-tree” build. CMake will not touch or change the original source files in any way. Instead, it will generate Visual Studio Solution Files, which will build HPX packages out of the HPX source tree.

---

37 https://www.boost.org/users/download/
• Set three new environment variables (in CMake, not in Windows environment): BOOST_ROOT, HWLOC_ROOT, ASIO_ROOT, CMAKE_INSTALL_PREFIX. The meaning of these variables is as follows:

– **BOOST_ROOT** the HPX root directory of the unpacked Boost headers/cpp files.

– **HWLOC_ROOT** the HPX root directory of the unpacked Portable Hardware Locality files.

– **ASIO_ROOT** the HPX root directory of the unpacked ASIO files. Alternatively use HPX_WITH_FETCH_ASIO with value True.

– **CMAKE_INSTALL_PREFIX** the HPX root directory where the future builds of HPX should be installed.

**Note:** HPX is a very large software collection, so it is not recommended to use the default C:\Program Files\hpx. Many users may prefer to use simpler paths without whitespace, like C:\bin\hpx or D:\bin\hpx etc.

To insert new env-vars click on “Add Entry” and then insert the name inside “Name”, select PATH as Type and put the path-name in the “Path” text field. Repeat this for the first three variables.

This is how variable insertion will look:

![Example CMake adding entry](image)

Fig. 2.4: Example CMake adding entry.

Alternatively, users could provide BOOST_LIBRARYDIR instead of BOOST_ROOT; the difference is that BOOST_LIBRARYDIR should point to the subdirectory inside Boost root where all the compiled DLLs/LIBs are. For example, BOOST_LIBRARYDIR may point to the bin.v2 subdirectory under the Boost rootdir. It is important to keep the meanings of these two variables separated from each other: BOOST_DIR points to the ROOT folder
of the Boost library. `BOOST_LIBRARYDIR` points to the subdir inside the Boost root folder where the compiled binaries are.

- Click the ‘Configure’ button of CMake-GUI. You will be immediately presented with a small window where you can select the C++ compiler to be used within Visual Studio. This has been tested using the latest v14 (a.k.a C++ 2015) but older versions should be sufficient too. Make sure to select the 64Bit compiler.

- After the generate process has finished successfully, click the ‘Generate’ button. Now, CMake will put new VS Solution files into the BUILD folder you selected at the beginning.

- Open Visual Studio and load the `HPX.sln` from your build folder.

- Go to `CMakePredefinedTargets` and build the `INSTALL` project:

![Visual Studio INSTALL target](image)

**Fig. 2.5:** Visual Studio INSTALL target.

It will take some time to compile everything, and in the end you should see an output similar to this one:
2.3.4 CMake options

In order to configure HPX, you can set a variety of options to allow CMake to generate your specific makefiles/project files. A list of the most important CMake options can be found in Most important CMake options, while this section includes the comprehensive list.

Variables that influence how HPX is built

The options are split into these categories:

- **Generic options**
- **Build Targets options**
- **Thread Manager options**
- **AGAS options**
- **Parcelport options**
- **Profiling options**
- **Debugging options**
- **Modules options**

### Generic options

- `HPX_WITH_AUTOMATIC_SERIALIZATION_REGISTRATION:BOOL`
- `HPX_WITH_BENCHMARK_SCRIPTS_PATH:PATH`
- `HPX_WITH_BUILD_BINARY_PACKAGE:BOOL`
- `HPX_WITH_CHECK_MODULE_DEPENDENCIES:BOOL`
- `HPX_WITH_COMPILER_WARNINGS:BOOL`
- `HPX_WITH_COMPILER_WARNINGS_AS_ERRORS:BOOL`
- `HPX_WITH_COMPRESSION_BZIP2:BOOL`
- `HPX_WITH_COMPRESSION_SNAPPY:BOOL`
- `HPX_WITH_COMPRESSION_ZLIB:BOOL`
- `HPX_WITH_CUDA:BOOL`
- `HPX_WITH_CXX_STANDARD:STRING`
- `HPX_WITH_DATAPAR:BOOL`
- `HPX_WITH_DATAPAR_BACKEND:STRING`
- `HPX_WITH_DATAPAR_VC_NO_LIBRARY:BOOL`
- `HPX_WITH_DEPRECATION_WARNINGS:BOOL`
- `HPX_WITH_DISABLED_SIGNAL_EXCEPTION_HANDLERS:BOOL`
- `HPX_WITH_DYNAMIC_HPX_MAIN:BOOL`
- `HPX_WITH_FAULT_TOLERANCE:BOOL`
- `HPX_WITH_FULL_RPATH:BOOL`
HPX Documentation, master

- `HPX_WITH_GCC_VERSION_CHECK:BOOL`
- `HPX_WITH_GENERIC_CONTEXT_COROUTINES:BOOL`
- `HPX_WITH_HIDDEN_VISIBILITY:BOOL`
- `HPX_WITH_HIP:BOOL`
- `HPX_WITH_HIPSYCL:BOOL`
- `HPX_WITH_LOGGING:BOOL`
- `HPX_WITH_MALLOC:STRING`
- `HPX_WITH_MODULES_AS_STATIC_LIBRARIES:BOOL`
- `HPX_WITH_NICE_THREADLEVEL:BOOL`
- `HPX_WITH_PARCEL_COALESCING:BOOL`
- `HPX_WITH_PKGCONFIG:BOOL`
- `HPX_WITH_PRECOMPILED_HEADERS:BOOL`
- `HPX_WITH_RUN_MAIN_EVERYWHERE:BOOL`
- `HPX_WITH_STACKOVERFLOW_DETECTION:BOOL`
- `HPX_WITH_STATIC_LINKING:BOOL`
- `HPX_WITH_SYCL:BOOL`
- `HPX_WITH_SYCL_FLAGS:STRING`
- `HPX_WITHUNITY_BUILD:BOOL`
- `HPX_WITH_VIM_YCM:BOOL`
- `HPX_WITHZERO_COPY_SERIALIZATION_THRESHOLD:STRING`

`HPX_WITH_AUTOMATIC_SERIALIZATION_REGISTRATION:BOOL`
Use automatic serialization registration for actions and functions. This affects compatibility between HPX applications compiled with different compilers (default ON)

`HPX_WITH_BENCHMARK_SCRIPTS_PATH:PATH`
Directory to place batch scripts in

`HPX_WITH_BUILD_BINARY_PACKAGE:BOOL`
Build HPX on the build infrastructure on any LINUX distribution (default: OFF).

`HPX_WITH_CHECK_MODULE_DEPENDENCIES:BOOL`
Verify that no modules are cross-referenced from a different module category (default: OFF)

`HPX_WITH_COMPILER_WARNINGS:BOOL`
Enable compiler warnings (default: ON)

`HPX_WITH_COMPILER_WARNINGS_AS_ERRORS:BOOL`
Turn compiler warnings into errors (default: OFF)

`HPX_WITH_COMPRESSION_BZIP2:BOOL`
Enable bzip2 compression for parcel data (default: OFF).

`HPX_WITH_COMPRESSION_SNAPPY:BOOL`
Enable snappy compression for parcel data (default: OFF).
HPX_WITH_COMPRESSION_ZLIB:BOOL
Enable zlib compression for parcel data (default: OFF).

HPX_WITH_CUDA:BOOL
Enable support for CUDA (default: OFF)

HPX_WITH_CXX_STANDARD:STRING
Set the C++ standard to use when compiling HPX itself. (default: 17)

HPX_WITH_DATAPAR:BOOL
Enable data parallel algorithm support using Vc library (default: ON)

HPX_WITH_DATAPAR_BACKEND:STRING
Define which vectorization library should be used. Options are: VC, EVE, STD_EXPERIMENTAL_SIMD, SVE; NONE

HPX_WITH_DATAPAR_VC_NO_LIBRARY:BOOL
Don’t link with the Vc static library (default: OFF)

HPX_WITH_DEPRECATION_WARNINGS:BOOL
Enable warnings for deprecated facilities. (default: ON)

HPX_WITH_DISABLED_SIGNAL_EXCEPTION_HANDLERS:BOOL
Disables the mechanism that produces debug output for caught signals and unhandled exceptions (default: OFF)

HPX_WITH_DYNAMIC_HPX_MAIN:BOOL
Enable dynamic overload of system main() (Linux and Apple only, default: ON)

HPX_WITH_FAULT_TOLERANCE:BOOL
Build HPX to tolerate failures of nodes, i.e. ignore errors in active communication channels (default: OFF)

HPX_WITH_FULL_RPATH:BOOL
Build and link HPX libraries and executables with full RPATHs (default: ON)

HPX_WITH_GCC_VERSION_CHECK:BOOL
Don’t ignore version reported by gcc (default: ON)

HPX_WITH_GENERIC_CONTEXT_COROUTINES:BOOL
Use Boost.Context as the underlying coroutines context switch implementation.

HPX_WITH_HIDDEN_VISIBILITY:BOOL
Use -fvisibility=hidden for builds on platforms which support it (default OFF)

HPX_WITH_HIP:BOOL
Enable compilation with HIPCC (default: OFF)

HPX_WITH_HIPSYCL:BOOL
Use hipsycl cmake integration (default: OFF)

HPX_WITH_LOGGING:BOOL
Build HPX with logging enabled (default: ON).

HPX_WITH_MALLOC:STRING
Define which allocator should be linked in. Options are: system, tcmalloc, jemalloc, mimalloc, tbbmalloc, and custom (default is: tcmalloc)

HPX_WITH_MODULES_AS_STATIC_LIBRARIES:BOOL
Compile HPX modules as STATIC (whole-archive) libraries instead of OBJECT libraries (Default: ON)
HPX\_WITH\_NICE\_THREADLEVEL:BOOL
   Set HPX worker threads to have high NICE level (may impact performance) (default: OFF)

HPX\_WITH\_PARCEL\_COALEScing:BOOL
   Enable the parcel coalescing plugin (default: ON).

HPX\_WITH\_PKGCONFIG:BOOL
   Enable generation of pkgconfig files (default: ON on Linux without CUDA/HIP, otherwise OFF)

HPX\_WITH\_PRECOMPILED\_HEADERS:BOOL
   Enable precompiled headers for certain build targets (experimental) (default OFF)

HPX\_WITH\_RUN\_MAIN\_EVERYWHERE:BOOL
   Run hpx\_main by default on all localities (default: OFF).

HPX\_WITH\_STACKOVERFLOW\_DETECTION:BOOL
   Enable stackoverflow detection for HPX threads/coroutines. (default: OFF, debug: ON)

HPX\_WITH\_STATIC\_LINKING:BOOL
   Compile HPX statically linked libraries (Default: OFF)

HPX\_WITH\_SYCL:BOOL
   Enable support for Sycl (default: OFF)

HPX\_WITH\_SYCL\_FLAGS:STRING
   Sycl compile flags for selecting specific targets (default: empty)

HPX\_WITH\_UNITY\_BUILD:BOOL
   Enable unity build for certain build targets (default OFF)

HPX\_WITH\_VIM\_YCM:BOOL
   Generate HPX completion file for VIM YouCompleteMe plugin

HPX\_WITH\_ZERO\_COPY\_SERIALIZATION\_THRESHOLD:STRING
   The threshold in bytes to when perform zero copy optimizations (default: 8192)

### Build Targets options

- HPX\_WITH\_ASIO\_TAG:STRING
- HPX\_WITH\_COMPILE\_ONLY\_TESTS:BOOL
- HPX\_WITH\_DISTRIBUTED\_RUNTIME:BOOL
- HPX\_WITH\_DOCUMENTATION:BOOL
- HPX\_WITH\_DOCUMENTATION\_OUTPUT\_FORMATS:STRING
- HPX\_WITH\_EXAMPLES:BOOL
- HPX\_WITH\_EXAMPLES\_HDF5:BOOL
- HPX\_WITH\_EXAMPLES\_OPENMP:BOOL
- HPX\_WITH\_EXAMPLES\_QT4:BOOL
- HPX\_WITH\_EXAMPLES\_QTHREADS:BOOL
- HPX\_WITH\_EXAMPLES\_TBB:BOOL
- HPX\_WITH\_EXECUTABLE\_PREFIX:STRING
- `HPX_WITH_FAIL_COMPILE_TESTS:BOOL`
- `HPX_WITH_FETCH_ASIO:BOOL`
- `HPX_WITH_FETCH_LCI:BOOL`
- `HPX_WITH_IO_COUNTERS:BOOL`
- `HPX_WITH_LCI_TAG:STRING`
- `HPX_WITH_PARALLEL_LINK_JOBS:STRING`
- `HPX_WITH_TESTS:BOOL`
- `HPX_WITH_TESTS_BENCHMARKS:BOOL`
- `HPX_WITH_TESTS_EXAMPLES:BOOL`
- `HPX_WITH_TESTS_EXTERNAL_BUILD:BOOL`
- `HPX_WITH_TESTS_HEADERS:BOOL`
- `HPX_WITH_TESTS_REGRESSIONS:BOOL`
- `HPX_WITH_TESTS_UNIT:BOOL`
- `HPX_WITH_TOOLS:BOOL`

`HPX_WITH_ASIO_TAG:STRING`

Asio repository tag or branch

`HPX_WITH_COMPILE_ONLY_TESTS:BOOL`

Create build system support for compile time only HPX tests (default ON)

`HPX_WITH_DISTRIBUTED_RUNTIME:BOOL`

Enable the distributed runtime (default: ON). Turning off the distributed runtime completely disallows the creation and use of components and actions. Turning this option off is experimental!

`HPX_WITH_DOCUMENTATION:BOOL`

Build the HPX documentation (default OFF).

`HPX_WITH_DOCUMENTATION_OUTPUT_FORMATS:STRING`

List of documentation output formats to generate. Valid options are html;singlehtml;latexpdf;man. Multiple values can be separated with semicolons. (default html).

`HPX_WITH_EXAMPLES:BOOL`

Build the HPX examples (default ON)

`HPX_WITH_EXAMPLES_HDF5:BOOL`

Enable examples requiring HDF5 support (default: OFF).

`HPX_WITH_EXAMPLES_OPENMP:BOOL`

Enable examples requiring OpenMP support (default: OFF).

`HPX_WITH_EXAMPLES_QT4:BOOL`

Enable examples requiring Qt4 support (default: OFF).

`HPX_WITH_EXAMPLES_QTHREADS:BOOL`

Enable examples requiring QThreads support (default: OFF).

`HPX_WITH_EXAMPLES_TBB:BOOL`

Enable examples requiring TBB support (default: OFF).
HPX WITH EXECUTABLE_PREFIX:STRING
Executable prefix (default none), ‘hpx_’ useful for system install.

HPX WITH_FAIL_COMPILE_TESTS:BOOL
Create build system support for fail compile HPX tests (default ON)

HPX WITH_FETCH_ASI0:BOOL
Use FetchContent to fetch Asio. By default an installed Asio will be used. (default: OFF)

HPX WITH_FETCH_LCI:BOOL
Use FetchContent to fetch LCI. By default an installed LCI will be used. (default: OFF)

HPX WITH IO_COUNTERS:BOOL
Enable IO counters (default: ON)

HPX WITH LCI_TAG:STRING
LCI repository tag or branch

HPX WITH_PARALLEL_LINK_JOBS:STRING
Number of Parallel link jobs while building hpx (only for Ninja as generator) (default 2)

HPX WITH_TESTS:BOOL
Build the HPX tests (default ON)

HPX WITH_TESTS_BENCHMARKS:BOOL
Build HPX benchmark tests (default: ON)

HPX WITH_TESTS_EXAMPLES:BOOL
Add HPX examples as tests (default: ON)

HPX WITH_TESTS_EXTERNAL_BUILD:BOOL
Build external cmake build tests (default: ON)

HPX WITH_TESTS_HEADERS:BOOL
Build HPX header tests (default: OFF)

HPX WITH_TESTS_REGRESSIONS:BOOL
Build HPX regression tests (default: ON)

HPX WITH_TESTS_UNIT:BOOL
Build HPX unit tests (default: ON)

HPX WITH TOOLS:BOOL
Build HPX tools (default: OFF)

Thread Manager options

• HPX COROUTINES WITH_SWAP_CONTEXT_EMULATION:BOOL
• HPX WITH COROUTINE_COUNTERS:BOOL
• HPX WITH IO_POOL:BOOL
• HPX WITH MAX CPU_COUNT:STRING
• HPX WITH MAX NUMA_DOMAIN_COUNT:STRING
• HPX WITH SCHEDULER LOCAL STORAGE:BOOL
• HPX WITH SPINLOCK DEADLOCK DETECTION:BOOL
- `HPX_WITH_SPINLOCK_POOL_NUM: STRING`
- `HPX_WITH_STACKTRACES: BOOL`
- `HPX_WITH_STACKTRACES_DEMANGLE_SYMBOLS: BOOL`
- `HPX_WITH_STACKTRACES_STATIC_SYMBOLS: BOOL`
- `HPX_WITH_THREAD_BACKTRACE_DEPTH: STRING`
- `HPX_WITH_THREAD_BACKTRACE_ON_SUSPENSION: BOOL`
- `HPX_WITH_THREAD_CREATION_AND_CLEANUP_RATES: BOOL`
- `HPX_WITH_THREAD_CUMULATIVE_COUNTS: BOOL`
- `HPX_WITH_THREAD_IDLE_RATES: BOOL`
- `HPX_WITH_THREAD_LOCAL_STORAGE: BOOL`
- `HPX_WITH_THREAD_MANAGER_IDLE_BACKOFF: BOOL`
- `HPX_WITH_THREAD_QUEUE_WAITTIME: BOOL`
- `HPX_WITH_THREAD_STACK_MMAP: BOOL`
- `HPX_WITH_THREAD_STEALING_COUNTS: BOOL`
- `HPX_WITH_THREAD_TARGET_ADDRESS: BOOL`
- `HPX_WITH_TIMER_POOL: BOOL`

`HPX_COROUTINES_WITH_SWAP_CONTEXT_EMULATION: BOOL`

Emulate SwapContext API for coroutines (Windows only, default: OFF)

`HPX_WITH_COROUTINE_COUNTERS: BOOL`

Enable keeping track of coroutine creation and rebind counts (default: OFF)

`HPX_WITH_IO_POOL: BOOL`

Disable internal IO thread pool, do not change if not absolutely necessary (default: ON)

`HPX_WITH_MAX_CPU_COUNT: STRING`

HPX applications will not use more that this number of OS-Threads (empty string means dynamic) (default: ““)

`HPX_WITH_MAX_NUMA_DOMAIN_COUNT: STRING`

HPX applications will not run on machines with more NUMA domains (default: 8)

`HPX_WITH_SCHEDULER_LOCAL_STORAGE: BOOL`

Enable scheduler local storage for all HPX schedulers (default: OFF)

`HPX_WITH_SPINLOCK_DEADLOCK_DETECTION: BOOL`

Enable spinlock deadlock detection (default: OFF)

`HPX_WITH_SPINLOCK_POOL_NUM: STRING`

Number of elements a spinlock pool manages (default: 128)

`HPX_WITH_STACKTRACES: BOOL`

Attach backtraces to HPX exceptions (default: ON)

`HPX_WITH_STACKTRACES_DEMANGLE_SYMBOLS: BOOL`

Thread stack back trace symbols will be demangled (default: ON)

`HPX_WITH_STACKTRACES_STATIC_SYMBOLS: BOOL`

Thread stack back trace will resolve static symbols (default: OFF)
HPX_WITH_THREAD_BACKTRACE_DEPTH:STRING
Thread stack back trace depth being captured (default: 20)

HPX_WITH_THREAD_BACKTRACE_ON_SUSPENSION:BOOL
Enable thread stack back trace being captured on suspension (default: OFF)

HPX_WITH_THREAD_CREATION_AND_CLEANUP_RATES:BOOL
Enable measuring thread creation and cleanup times (default: OFF)

HPX_WITH_THREAD_CUMULATIVE_COUNTS:BOOL
Enable keeping track of cumulative thread counts in the schedulers (default: ON)

HPX_WITH_THREAD_IDLE_RATES:BOOL
Enable measuring the percentage of overhead times spent in the scheduler (default: OFF)

HPX_WITH_THREAD_LOCAL_STORAGE:BOOL
Enable thread local storage for all HPX threads (default: OFF)

HPX_WITH_THREAD_MANAGER_IDLE_BACKOFF:BOOL
HPX scheduler threads do exponential backoff on idle queues (default: ON)

HPX_WITH_THREAD_QUEUE_WAITTIME:BOOL
Enable collecting queue wait times for threads (default: OFF)

HPX_WITH_THREAD_STACK_MMAP:BOOL
Use mmap for stack allocation on appropriate platforms

HPX_WITH_THREAD_STEALING_COUNTS:BOOL
Enable keeping track of counts of thread stealing incidents in the schedulers (default: OFF)

HPX_WITH_THREAD_TARGET_ADDRESS:BOOL
Enable storing target address in thread for NUMA awareness (default: OFF)

HPX_WITH_TIMER_POOL:BOOL
Disable internal timer thread pool, do not change if not absolutely necessary (default: ON)

AGAS options

• HPX_WITH_AGAS_DUMP_REFCNT_ENTRIES:BOOL

HPX_WITH_AGAS_DUMP_REFCNT_ENTRIES:BOOL
Enable dumps of the AGAS refcnt tables to logs (default: OFF)

Parcelport options

• HPX_WITH_NETWORKING:BOOL
• HPX_WITH_PARCELPORT_ACTION_COUNTERS:BOOL
• HPX_WITH_PARCELPORT_COUNTERS:BOOL
• HPX_WITH_PARCELPORT_LCI:BOOL
• HPX_WITH_PARCELPORT_LIBFABRIC:BOOL
• HPX_WITH_PARCELPORT_MPI:BOOL
• HPX_WITH_PARCELPORT_TCP:BOOL
- `HPX_WITH_PARCEL_PROFILING:BOOL`

**HPX_WITH_NETWORKING:BOOL**

Enable support for networking and multi-node runs (default: ON)

**HPX_WITH_PARCELPORT_ACTION_COUNTERS:BOOL**

Enable performance counters reporting parcelport statistics on a per-action basis.

**HPX_WITH_PARCELPORT_COUNTERS:BOOL**

Enable performance counters reporting parcelport statistics.

**HPX_WITH_PARCELPORT_LCI:BOOL**

Enable the LCI based parcelport.

**HPX_WITH_PARCELPORT_LIBFABRIC:BOOL**

Enable the libfabric based parcelport. This is currently an experimental feature

**HPX_WITH_PARCELPORT_MPI:BOOL**

Enable the MPI based parcelport.

**HPX_WITH_PARCELPORT_TCP:BOOL**

Enable the TCP based parcelport.

**HPX_WITH_PARCEL_PROFILING:BOOL**

Enable profiling data for parcels

### Profiling options

- `HPX_WITH_APEX:BOOL`
- `HPX_WITH_ITTNOTIFY:BOOL`
- `HPX_WITH_PAPI:BOOL`

**HPX_WITH_APEX:BOOL**

Enable APEX instrumentation support.

**HPX_WITH_ITTNOTIFY:BOOL**

Enable Amplifier (ITT) instrumentation support.

**HPX_WITH_PAPI:BOOL**

Enable the PAPI based performance counter.

### Debugging options

- `HPX_WITH_ATTACH_DEBUGGER_ON_TEST_FAILURE:BOOL`
- `HPX_WITH_PARALLEL_TESTS_BIND_NONE:BOOL`
- `HPX_WITH_SANITIZERS:BOOL`
- `HPX_WITH_TESTS_DEBUG_LOG:BOOL`
- `HPX_WITH_TESTS_DEBUG_LOG_DESTINATION:STRING`
- `HPX_WITH_TESTS_MAX_THREADS_PER_LOCALITY:STRING`
- `HPX_WITH_THREAD_DEBUG_INFO:BOOL`
- `HPX_WITH_THREAD_DESCRIPTION_FULL:BOOL`
• \texttt{HPX\_WITH\_THREAD\_GUARD\_PAGE}: \texttt{BOOL}
• \texttt{HPX\_WITH\_VALGRIND}: \texttt{BOOL}
• \texttt{HPX\_WITH\_VERIFY\_LOCKS}: \texttt{BOOL}
• \texttt{HPX\_WITH\_VERIFY\_LOCKS\_BACKTRACE}: \texttt{BOOL}

\texttt{HPX\_WITH\_ATTACH\_DEBUGGER\_ON\_TEST\_FAILURE}: \texttt{BOOL}

- Break the debugger if a test has failed (default: OFF)

\texttt{HPX\_WITH\_PARALLEL\_TESTS\_BIND\_NONE}: \texttt{BOOL}

- Pass \texttt{--hpx:bind=none} to tests that may run in parallel (cmake \texttt{-j} flag) (default: OFF)

\texttt{HPX\_WITH\_SANITIZERS}: \texttt{BOOL}

- Configure with sanitizer instrumentation support.

\texttt{HPX\_WITH\_TESTS\_DEBUG\_LOG}: \texttt{BOOL}

- Turn on debug logs (\texttt{--hpx:debug-hpx-log}) for tests (default: OFF)

\texttt{HPX\_WITH\_TESTS\_DEBUG\_LOG\_DESTINATION}: \texttt{STRING}

- Destination for test debug logs (default: cout)

\texttt{HPX\_WITH\_TESTS\_MAX\_THREADS\_PER\_LOCALITY}: \texttt{STRING}

- Maximum number of threads to use for tests (default: 0, use the number of threads specified by the test)

\texttt{HPX\_WITH\_THREAD\_DEBUG\_INFO}: \texttt{BOOL}

- Enable thread debugging information (default: OFF, implicitly enabled in debug builds)

\texttt{HPX\_WITH\_THREAD\_DESCRIPTION\_FULL}: \texttt{BOOL}

- Use function address for thread description (default: OFF)

\texttt{HPX\_WITH\_THREAD\_GUARD\_PAGE}: \texttt{BOOL}

- Enable thread guard page (default: ON)

\texttt{HPX\_WITH\_VALGRIND}: \texttt{BOOL}

- Enable Valgrind instrumentation support.

\texttt{HPX\_WITH\_VERIFY\_LOCKS}: \texttt{BOOL}

- Enable lock verification code (default: OFF, enabled in debug builds)

\texttt{HPX\_WITH\_VERIFY\_LOCKS\_BACKTRACE}: \texttt{BOOL}

- Enable thread stack back trace being captured on lock registration (to be used in combination with \texttt{HPX\_WITH\_VERIFY\_LOCKS=ON}, default: OFF)

\textbf{Modules options}

• \texttt{HPX\_COMMAND\_LINE\_HANDLING\_WITH\_JSON\_CONFIGURATION\_FILES}: \texttt{BOOL}
• \texttt{HPX\_DATASTRUCTURES\_WITH\_ADAPT\_STD\_TUPLE}: \texttt{BOOL}
• \texttt{HPX\_DATASTRUCTURES\_WITH\_ADAPT\_STD\_VARIANT}: \texttt{BOOL}
• \texttt{HPX\_FILESYSTEM\_WITH\_BOOST\_FILESYSTEM\_COMPATIBILITY}: \texttt{BOOL}
• \texttt{HPX\_ITERATOR\_SUPPORT\_WITH\_BOOST\_ITERATOR\_TRAVERSAL\_TAG\_COMPATIBILITY}: \texttt{BOOL}
• \texttt{HPX\_LOGGING\_WITH\_SEPARATE\_DESTINATIONS}: \texttt{BOOL}
• \texttt{HPX\_SERIALIZATION\_WITH\_ALLOW\_CONST\_TUPLE\_MEMBERS}: \texttt{BOOL}
• **HPX_SERIALIZATION_WITH_ALLOW_RAW_POINTER_SERIALIZATION**: `BOOL`  
  Enable serializing raw pointers. (default: OFF)

• **HPX_SERIALIZATION_WITH_ALL_TYPES_ARE_BITWISE_SERIALIZABLE**: `BOOL`  
  Assume all types are bitwise serializable. (default: OFF)

• **HPX_SERIALIZATION_WITH_BOOST_TYPES**: `BOOL`  
 Enable serialization of certain Boost types. (default: OFF)

• **HPX_SERIALIZATION_WITH_SUPPORTS_ENDIANESS**: `BOOL`  
  Support endian conversion on inout and output archives. (default: OFF)

• **HPX_TOPOLOGY_WITH_ADDITIONAL_HWLOC_TESTING**: `BOOL`  
  Enable HWLOC filtering that makes it report no cores, this is purely an  
  option supporting better testing - do not enable under normal circumstances. (default: OFF)

• **HPX_WITH_POWER_COUNTER**: `BOOL`  
  Enable use of performance counters based on pwr library (default: OFF)

---

**HPX_COMMAND_LINE_HANDLING_WITH_JSON_CONFIGURATION_FILES**: `BOOL`  
Enable reading JSON formatted configuration files on the command line. (default: OFF)

**HPX_DATASTRUCTURES_WITH_ADAPT_STD_TUPLE**: `BOOL`  
Enable compatibility of hpx::get with std::tuple. (default: ON)

**HPX_DATASTRUCTURES_WITH_ADAPT_STD_VARIANT**: `BOOL`  
Enable compatibility of hpx::get with std::variant. (default: OFF)

**HPX_FILESYSTEM_WITH_BOOST_FILESYSTEM_COMPATIBILITY**: `BOOL`  
Enable Boost.FileSystem compatibility. (default: OFF)

**HPX_ITERATOR_SUPPORT_WITH_BOOST_ITERATOR_TRAVERSAL_TAG_COMPATIBILITY**: `BOOL`  
Enable Boost.Iterator traversal tag compatibility. (default: OFF)

**HPX_LOGGING_WITH_SEPARATE_DESTINATIONS**: `BOOL`  
Enable separate logging channels for AGAS, timing, and parcel transport. (default: ON)

**HPX_SERIALIZATION_WITH_ALLOW_CONST_TUPLE_MEMBERS**: `BOOL`  
Enable serializing std::tuple with const members. (default: OFF)
Additional tools and libraries used by HPX

Here is a list of additional libraries and tools that are either optionally supported by the build system or are optionally required for certain examples or tests. These libraries and tools can be detected by the HPX build system.

Each of the tools or libraries listed here will be automatically detected if they are installed in some standard location. If a tool or library is installed in a different location, you can specify its base directory by appending \_ROOT to the variable name as listed below. For instance, to configure a custom directory for BOOST, specify BOOST_ROOT=/custom/boost/root.

**BOOST\_ROOT:PATH**

Specifies where to look for the Boost installation to be used for compiling HPX. Set this if CMake is not able to locate a suitable version of Boost. The directory specified here can be either the root of an installed Boost distribution or the directory where you unpacked and built Boost without installing it (with staged libraries).

**HWLOC\_ROOT:PATH**

Specifies where to look for the hwloc library. Set this if CMake is not able to locate a suitable version of hwloc. Hwloc provides platform-independent support for extracting information about the used hardware architecture (number of cores, number of NUMA domains, hyperthreading, etc.). HPX utilizes this information if available.

**PAPI\_ROOT:PATH**

Specifies where to look for the PAPI library. The PAPI library is needed to compile a special component exposing PAPI hardware events and counters as HPX performance counters. This is not available on the Windows platform.

**AMPLIFIER\_ROOT:PATH**

Specifies where to look for one of the tools of the Intel Parallel Studio product, either Intel Amplifier or Intel Inspector. This should be set if the CMake variable HPX\_USE\_ITT\_NOTIFY is set to ON. Enabling ITT support in HPX will integrate any application with the mentioned Intel tools, which customizes the generated information for your application and improves the generated diagnostics.

In addition, some of the examples may need the following variables:

**HDF5\_ROOT:PATH**

Specifies where to look for the Hierarchical Data Format V5 (HDF5) include files and libraries.

### 2.3.5 Migration guide

The Migration Guide serves as a valuable resource for developers seeking to transition their parallel computing applications from different APIs (i.e. OpenMP, Intel Threading Building Blocks (TBB)) to HPX. HPX, an advanced C++ library, offers a versatile and high-performance platform for parallel and distributed computing, providing a wide range of features and capabilities. This guide aims to assist developers in understanding the key differences between different APIs and HPX, and it provides step-by-step instructions for converting code to HPX code effectively.

Some general steps that can be used to migrate code to HPX code are the following:

1. Install HPX using the *Quick start* guide.
2. Include the HPX header files:
   
   ```
   #include <hpx/init.hpp>
   ```

3. Replace your code with HPX code using the guide that follows.
4. Use HPX-specific features and APIs:
HPX provides additional features and APIs that can be used to take advantage of the library’s capabilities. For example, you can use the HPX asynchronous execution to express fine-grained tasks and dependencies, or utilize HPX’s distributed computing features for distributed memory systems.

5. Compile and run the HPX code:

   Compile the converted code with the HPX library and run it using the appropriate HPX runtime environment.

OpenMP

The OpenMP API supports multi-platform shared-memory parallel programming in C/C++. Typically it is used for loop-level parallelism, but it also supports function-level parallelism. Below are some examples on how to convert OpenMP to HPX code:

OpenMP parallel for loop

Parallel for loop

OpenMP code:

```cpp
#pragma omp parallel for
for (int i = 0; i < n; ++i) {
    // loop body
}
```

HPX equivalent:

```cpp
#include <hpx/algorithm.hpp>

hpx::experimental::for_loop(hpx::execution::par, 0, n, [&](int i) {
    // loop body
});
```

In the above code, the OpenMP `#pragma omp parallel for` directive is replaced with `hpx::experimental::for_loop` from the HPX library. The loop body within the lambda function will be executed in parallel for each iteration.

Private variables

OpenMP code:

```cpp
int x = 0;

#pragma omp parallel for private(x)
for (int i = 0; i < n; ++i) {
    // loop body
}
```

HPX equivalent:

```cpp
#include <hpx/algorithm.hpp>

hpx::experimental::for_loop(hpx::execution::par, 0, n, [&] (int i) {
    // loop body
});
```

(continues on next page)
The variable \( x \) is declared as a local variable inside the loop body, ensuring that it is private to each thread.

**Shared variables**

OpenMP code:

```c
int x = 0;
#pragma omp parallel for shared(x)
for (int i = 0; i < n; ++i) {
    // loop body
}
```

**HPX equivalent:**

```cpp
#include <hpx/algorithm.hpp>
std::atomic<int> x = 0; // Declare 'x' as a shared variable outside the loop
hpx::experimental::for_loop(hpx::execution::par, 0, n, [&](int i) {
    // loop body
});
```

To ensure variable \( x \) is shared among all threads, you simply have to declare it as an atomic variable outside the `for_loop`.

**Number of threads**

OpenMP code:

```c
#pragma omp parallel for num_threads(2)
for (int i = 0; i < n; ++i) {
    // loop body
}
```

**HPX equivalent:**

```cpp
#include <hpx/algorithm.hpp>
#include <hpx/execution.hpp>
hpx::execution::experimental::num_cores nc(2);
hpx::experimental::for_loop(hpx::execution::par.with(nc), 0, n, [&](int i) {
    // loop body
});
```

To declare the number of threads to be used for the parallel region, you can use `hpx::execution::experimental::num_cores` and pass the number of cores (\( nc \)) to `hpx::experimental::for_loop` using `hpx::execution::par.with(nc)`. This example uses 2 threads for the parallel loop.
Reduction

OpenMP code:

```c
int s = 0;
#pragma omp parallel for reduction(+: s)
for (int i = 0; i < n; ++i) {
    s += i;
    // loop body
}
```

HPX equivalent:

```c
#include <hpx/algorithm.hpp>
#include <hpx/execution.hpp>

int s = 0;

hpx::experimental::for_loop(hpx::execution::par, 0, n, reduction(s, 0, plus<>()), [& &](int i, int& accum) {
    accum += i;
    // loop body
});
```

The reduction clause specifies that the variable \( s \) should be reduced across iterations using the \( \text{plus}<> \) operation. It initializes \( s \) to 0 at the beginning of the loop and accumulates the values of \( s \) from each iteration using the + operator. The lambda function representing the loop body takes two parameters: \( i \), which represents the loop index, and \( \text{accum} \), which is the reduction variable \( s \). The lambda function is executed for each iteration of the loop. The reduction ensures that the \( \text{accum} \) value is correctly accumulated across different iterations and threads.

Schedule

OpenMP code:

```c
int s = 0;

// static scheduling with chunk size 1000
#pragma omp parallel for schedule(static, 1000)
for (int i = 0; i < n; ++i) {
    // loop body
}
```

HPX equivalent:

```c
#include <hpx/algorithm.hpp>
#include <hpx/execution.hpp>

hpx::execution::experimental::static_chunk_size cs(1000);

hpx::experimental::for_loop(hpx::execution::par.with(cs), 0, n, [&](int i) {
    // loop body
});
```
To define the scheduling type, you can use the corresponding execution policy from `hpx::execution::experimental`, define the chunk size (cs, here declared as 1000) and pass it to the to `hpx::experimental::for_loop` using `hpx::execution::par.with(cs)`.

Accordingly, other types of scheduling are available and can be used in a similar manner:

```cpp
#include <hpx/execution.hpp>
hpx::execution::experimental::dynamic_chunk_size cs(1000);
```

```cpp
#include <hpx/execution.hpp>
hpx::execution::experimental::guided_chunk_size cs(1000);
```

```cpp
#include <hpx/execution.hpp>
hpx::execution::experimental::auto_chunk_size cs(1000);
```

**OpenMP single thread**

OpenMP code:

```cpp
{ // parallel code
    #pragma omp single
    { // single-threaded code
    } // more parallel code
}
```

**HPX equivalent**:

```cpp
#include <hpx/mutex.hpp>
hpx::mutex mtx;

{ // parallel code
    { // single-threaded code
        std::scoped_lock l(mtx);
    } // more parallel code
}
```

To make sure that only one thread accesses a specific code within a parallel section you can use `hpx::mutex` and `std::scoped_lock` to take ownership of the given mutex `mtx`. For more information about mutexes please refer to `Mutex`. 
OpenMP tasks

Simple tasks

OpenMP code:

```c
// executed asynchronously by any available thread
#pragma omp task
{
   // task code
}
```

HPX equivalent:

```cpp
#include <hpx/future.hpp>
auto future = hpx::async([](){
   // task code
});
```

or

```cpp
#include <hpx/future.hpp>

hpx::post([](){
   // task code
}); // fire and forget
```

The tasks in HPX can be defined simply by using the `async` function and passing as argument the code you wish to run asynchronously. Another alternative is to use `post` which is a fire-and-forget method.

**Tip:** If you think you will like to synchronize your tasks later on, we suggest you use `hpx::async` which provides synchronization options, while `hpx::post` explicitly states that there is no return value or way to synchronize with the function execution. Synchronization options are listed below.

Task wait

OpenMP code:

```c
#pragma omp task
{
   // task code
}
#pragma omp taskwait
// code after completion of task
```

HPX equivalent:

```cpp
#include <hpx/future.hpp>
```
The `get()` function can be used to ensure that the task created with `hpx::async` is completed before the code continues executing beyond that point.

### Multiple tasks synchronization

OpenMP code:

```c
#pragma omp task
{
    // task 1 code
}
#pragma omp task
{
    // task 2 code
}
#pragma omp taskwait
// code after completion of both tasks 1 and 2
```

HPX equivalent:

```c
#include <hpx/future.hpp>

auto future1 = hpx::async([](){
    // task 1 code
});

auto future2 = hpx::async([](){
    // task 2 code
});

auto future = hpx::when_all(future1, future2).then([](auto&&){
    // code after completion of both tasks 1 and 2
});
```

If you would like to synchronize multiple tasks, you can use the `hpx::when_all` function to define which futures have to be ready and the `then()` function to declare what should be executed once these futures are ready.
Dependencies

OpenMP code:

```c
int a = 10;
int b = 20;
int c = 0;

#pragma omp task depend(in: a, b) depend(out: c)
{
    // task code
    c = 100;
}
```

HPX equivalent:

```c
#include <hpx/future.hpp>

int a = 10;
int b = 20;
int c = 0;

// Create a future representing 'a'
auto future_a = hpx::make_ready_future(a);

// Create a future representing 'b'
auto future_b = hpx::make_ready_future(b);

// Create a task that depends on 'a' and 'b' and executes 'task_code'
auto future_c = hpx::dataflow(
    []() {
        // task code
        return 100;
    },
    future_a, future_b);

c = future_c.get();
```

If one of the arguments of `hpx::dataflow` is a future, then it will wait for the future to be ready to launch the thread. Hence, to define the dependencies of tasks you have to create futures representing the variables that create dependencies and pass them as arguments to `hpx::dataflow`. `get()` is used to save the result of the future to the desired variable.

Nested tasks

OpenMP code:

```c
#pragma omp task
{
    // Outer task code
    #pragma omp task
    {
        // Inner task code
    }

    // Outer task code
    #pragma omp task
    {
        // Inner task code
    }
```
If you have nested tasks, you can simply use nested `hpx::async` or `hpx::post` calls. The implementation is similar if you want to take care of synchronization:

OpenMP code:

```
#pragma omp taskwait
{
    // Outer task code
    #pragma omp taskwait
    {
        // Inner task code
    }
}
```

HPX equivalent:

```
#include <hpx/future.hpp>

auto future_outer = hpx::async([](){
    // Outer task code
    hpx::async([](){
        // Inner task code
    });
});

or

```
#include <hpx/future.hpp>

auto future_outer = hpx::post([](){ // fire and forget
    // Outer task code
    hpx::post([](){ // fire and forget
        // Inner task code
    });
});
```

If you have nested tasks, you can simply use nested `hpx::async` or `hpx::post` calls. The implementation is similar if you want to take care of synchronization:

OpenMP code:

```
#pragma omp taskwait
{
    // Outer task code
    #pragma omp taskwait
    {
        // Inner task code
    }
}
```

HPX equivalent:

```
#include <hpx/future.hpp>

auto future_outer = hpx::async([]() { // Outer task code
    hpx::async([]() { // Inner task code
        }).get(); // Wait for the inner task to complete
});

future_outer.get(); // Wait for the outer task to complete
```
**Task yield**

OpenMP code:

```c
#pragma omp task
{
    // code before yielding
    #pragma omp taskyield
    // code after yielding
}
```

*HPX equivalent:*

```c
#include <hpx/future.hpp>
#include <hpx/thread.hpp>

auto future = hpx::async([](){
    // code before yielding
});

// yield execution to potentially allow other tasks to run
hpx::this_thread::yield();

// code after yielding
```

After creating a task using `hpx::async`, `hpx::this_thread::yield` can be used to reschedule the execution of threads, allowing other threads to run.

**Task group**

OpenMP code:

```c
#pragma omp taskgroup
{
    #pragma omp task
    {
        // task 1 code
    }

    #pragma omp task
    {
        // task 2 code
    }
}
```

*HPX equivalent:*

```c
#include <hpx/task_group.hpp>

// Declare a task group
hpx::experimental::task_group tg;

// Run the tasks
```

(continues on next page)
To create task groups, you can use `hpx::experimental::task_group`. The function `run()` can be used to run each task within the task group, while `wait()` can be used to achieve synchronization. If you do not care about waiting for the task group to complete its execution, you can simply remove the `wait()` function.

**OpenMP sections**

OpenMP code:

```c
#pragma omp sections
{
  #pragma omp section
  // section 1 code
  #pragma omp section
  // section 2 code
} // implicit synchronization
```

HPX equivalent:

```c
#include <hpx/future.hpp>

auto future_section1 = hpx::async([](){
  // section 1 code
});
auto future_section2 = hpx::async([](){
  // section 2 code
});

// synchronization: wait for both sections to complete
hpx::wait_all(future_section1, future_section2);
```

Unlike tasks, there is an implicit synchronization barrier at the end of each `sections` directive in OpenMP. This synchronization is achieved using `hpx::wait_all` function.

**Note:** If the `nowait` clause is used in the `sections` directive, then you can just remove the `hpx::wait_all` function while keeping the rest of the code as it is.
Intel Threading Building Blocks (TBB)

Intel Threading Building Blocks (TBB) provides a high-level interface for parallelism and concurrent programming using standard ISO C++ code. Below are some examples on how to convert Intel Threading Building Blocks (TBB) to HPX code:

parallel_for

Intel Threading Building Blocks (TBB) code:

```cpp
auto values = std::vector<double>(10000);

tbb::parallel_for(tbb::blocked_range<int>(0, values.size()),
    [&](tbb::blocked_range<int> r)
    {
        for (int i=r.begin(); i<r.end(); ++i)
            {
            // loop body
            }
    });
```

HPX equivalent:

```cpp
#include <hpx/algorithm.hpp>

auto values = std::vector<double>(10000);

hpx::experimental::for_loop(hpx::execution::par, 0, values.size(),
    [&](int i) {
        // loop body
    });
```

In the above code, `tbb::parallel_for` is replaced with `hpx::experimental::for_loop` from the HPX library. The loop body within the lambda function will be executed in parallel for each iteration.

parallel_for_each

Intel Threading Building Blocks (TBB) code:

```cpp
auto values = std::vector<double>(10000);

tbb::parallel_for_each(values.begin(), values.end(),
    [&](){
        // loop body
    });
```

HPX equivalent:

```cpp
#include <hpx/algorithm.hpp>

auto values = std::vector<double>(10000);

hpx::for_each(hpx::execution::par, values.begin(), values.end(),
    [&](){
        // loop body
    });
```

(continues on next page)
By utilizing `hpx::for_each` and specifying a parallel execution policy with `hpx::execution::par`, it is possible to transform `tbb::parallel_for_each` into its equivalent counterpart in HPX.

**parallel_invoke**

Intel Threading Building Blocks (TBB) code:

```cpp
tbb::parallel_invoke(task1, task2, task3);
```

HPX equivalent:

```cpp
#include <hpx/future.hpp>
hpx::wait_all(hpx::async(task1), hpx::async(task2), hpx::async(task3));
```

To convert `tbb::parallel_invoke` to HPX, we use `hpx::async` to asynchronously execute each task, which returns a future representing the result of each task. We then pass these futures to `hpx::when_all`, which waits for all the futures to complete before returning.

**parallel_pipeline**

Intel Threading Building Blocks (TBB) code:

```cpp
tbb::parallel_pipeline(4,
    tbb::make_filter<void, int>(tbb::filter::serial_in_order,
      [](tbb::flow_control& fc) -> int {
        // Generate numbers from 1 to 10
        static int i = 1;
        if (i <= 10) {
          return i++;
        }
        else {
          fc.stop();
          return 0;
        }
      } &
    tbb::make_filter<int, int>(tbb::filter::parallel,
      [](int num) -> int {
        // Multiply each number by 2
        return num * 2;
      } &
    tbb::make_filter<int, void>(tbb::filter::serial_in_order,
      [](int num) {
        // Print the results
        std::cout << num << " ";
      })
    );
```
The line `auto range = std::views::iota(1) | std::views::take(10);` generates a range of values using the `std::views::iota` function. It starts from the value 1 and generates an infinite sequence of incrementing values. The `std::views::take(10)` function is then applied to limit the sequence to the first 10 values. The result is stored in the `range` variable.

**Hint:** A view is a lightweight object that represents a particular view of a sequence or range. It acts as a read-only interface to the original data, providing a way to query and traverse the elements without making any copies or modifications.

Views can be composed and chained together to form complex pipelines of operations. These operations are evaluated lazily, meaning that the actual computation is performed only when the result is needed or consumed.

Since views perform lazy evaluation, we use `std::vector<int> results(10);` to materialize the vector that will store the transformed values. The `hpx::ranges::transform` function is then used to perform a parallel transformation on the range. The transformed values will be written to the `results` vector.

**Hint:** Ranges enable loop fusion by combining multiple operations into a single parallel loop, eliminating waiting time and reducing overhead. Using ranges, you can express these operations as a pipeline of transformations on a sequence of elements. This pipeline is evaluated in a single pass, performing all the desired operations in parallel without the need to wait between them.

In addition, HPX enhances the benefits of range fusion by offering parallel execution policies, which can be used to optimize the execution of the fused loop across multiple threads.
**parallel_reduce**

**Reduction**

Intel Threading Building Blocks (TBB) code:

```cpp
auto values = std::vector<double>{1,2,3,4,5,6,7,8,9};
auto total = tbb::parallel_reduce(
    tbb::blocked_range<int>(0,values.size()),
    0.0,
    [&](tbb::blocked_range<int> r, double running_total) {
        for (int i=r.begin(); i<r.end(); ++i) {
            running_total += values[i];
        }
        return running_total;
    },
    std::plus<double>());
```

**HPX** equivalent:

```cpp
#include <hpx/numeric.hpp>
auto values = std::vector<double>{1,2,3,4,5,6,7,8,9};
auto total = hpx::reduce(hpx::execution::par, values.begin(), values.end(), 0, std::plus{});
```

By utilizing `hpx::reduce` and specifying a parallel execution policy with `hpx::execution::par`, it is possible to transform `tbb::parallel_reduce` into its equivalent counterpart in HPX. As demonstrated in the previous example, the management of intermediate results is seamlessly handled internally by HPX, eliminating the need for explicit consideration.

**Transformation & Reduction**

Intel Threading Building Blocks (TBB) code:

```cpp
auto values = std::vector<double>{1,2,3,4,5,6,7,8,9};
auto transform_function(double current_value){
    // transformation code
}
auto total = tbb::parallel_reduce(
    tbb::blocked_range<int>(0,values.size()),
    0.0,
    [&](tbb::blocked_range<int> r, double transformed_val) {
        for (int i=r.begin(); i<r.end(); ++i) {
            running_total += values[i];
        }
        return running_total;
    },
    std::plus<double>());
```

(continues on next page)
{  
    transformed_val += transform_function(values[i]);
}

return transformed_val;
},
std::plus<double>();

HPX equivalent:

#include <hpx/numeric.hpp>

auto values = std::vector<double>{1,2,3,4,5,6,7,8,9};

auto transform_function(double current_value)  
{
    // transformation code
}

auto total = hpx::transform_reduce(hpx::execution::par, values.begin(),
    values.end(), 0, std::plus{},
    [&](double current_value) { return transform_function(current_value); });

In situations where certain values require transformation before the reduction process, HPX provides a straightforward solution through hpx::transform_reduce. The transform_function() allows for the application of the desired transformation to each value.

parallel_scan

Intel Threading Building Blocks (TBB) code:

tbb::parallel_scan(tbb::blocked_range<size_t>(0, input.size()),
    0,
    [&input, &output](const tbb::blocked_range<size_t>& range, int& partial_sum, bool is_final_scan) {
        for(size_t i = range.begin(); i != range.end(); ++i) {
            partial_sum += input[i];
            if(is_final_scan) {
                output[i] = partial_sum;
            }
        }
        return partial_sum;
    },
    [](int left_sum, int right_sum) {  
        return left_sum + right_sum;
    });//

HPX equivalent:

#include <hpx/numeric.hpp>

hpx::inclusive_scan(hpx::execution::par, input.begin(), input.end(),
output.begin(),
[](const int & left, const int & right) { return left + right; });

**hpx::inclusive_scan with hpx::execution::par as execution policy** can be used to perform a prefix scan in parallel. The management of intermediate results is seamlessly handled internally by HPX, eliminating the need for explicit consideration. `input.begin()` and `input.end()` refer to the beginning and end of the sequence of elements the algorithm will be applied to respectively. `output.begin()` refers to the beginning of the destination, while the last argument specifies the function which will be invoked for each of the values of the input sequence.

Apart from **hpx::inclusive_scan**, HPX provides its users with **hpx::exclusive_scan**. The key difference between inclusive scan and exclusive scan lies in the treatment of the current element during the scan operation. In an inclusive scan, each element in the output sequence includes the contribution of the corresponding element in the input sequence, while in an exclusive scan, the current element in the input sequence does not contribute to the corresponding element in the output sequence.

### parallel_sort

Intel Threading Building Blocks (TBB) code:

```cpp
std::vector<int> numbers = {9, 2, 7, 1, 5, 3};
tbb::parallel_sort(numbers.begin(), numbers.end());
```

**HPX** equivalent:

```cpp
#include <hpx/algorithm.hpp>
std::vector<int> numbers = {9, 2, 7, 1, 5, 3};
hpx::sort(hpx::execution::par, numbers.begin(), numbers.end());
```

**hpx::sort** provides an equivalent functionality to **tbb::parallel_sort**. When given a parallel execution policy with **hpx::execution::par**, the algorithm employs parallel execution, allowing for efficient sorting across available threads.

### task_group

Intel Threading Building Blocks (TBB) code:

```cpp
// Declare a task group
tbb::task_group tg;

// Run the tasks
tg.run(task1);
tg.run(task2);

// Wait for the task group
tg.wait();
```

**HPX** equivalent:
```cpp
#include <hpx/task_group.hpp>

// Declare a task group
hpx::experimental::task_group tg;

// Run the tasks
tg.run(task1);
tg.run(task2);

// Wait for the task group
tg.wait();
```

HPX drew inspiration from Intel Threading Building Blocks (TBB) to introduce the `hpx::experimental::task_group` feature. Therefore, utilizing `hpx::experimental::task_group` provides an equivalent functionality to `tbb::task_group`.

### 2.3.6 Building tests and examples

#### Tests

To build the tests:

```bash
$ cmake --build . --target tests
```

To control which tests to run use `ctest`:

- To run single tests, for example a test for `for_loop`:
  ```bash
  $ ctest --output-on-failure -R tests.unit.modules.algorithms.algorithms.for_loop
  ```

- To run a whole group of tests:
  ```bash
  $ ctest --output-on-failure -R tests.unit
  ```

#### Examples

- To build (and install) all examples invoke:
  ```bash
  $ cmake -DHPX_WITH_EXAMPLES=On .
  $ make examples
  $ make install
  ```

- To build the `hello_world_1` example run:
  ```bash
  $ make hello_world_1
  ```

HPX executables end up in the `bin` directory in your build directory. You can now run `hello_world_1` and should see the following output:

```bash
$ ./bin/hello_world_1
Hello World!
```
You’ve just run an example which prints Hello World! from the HPX runtime. The source for the example is in examples/quickstart/hello_world_1.cpp. The hello_world_distributed example (also available in the examples/quickstart directory) is a distributed hello world program, which is described in Remote execution with actions. It provides a gentle introduction to the distributed aspects of HPX.

Tip: Most build targets in HPX have two names: a simple name and a hierarchical name corresponding to what type of example or test the target is. If you are developing HPX it is often helpful to run make help to get a list of available targets. For example, make help | grep hello_world outputs the following:

```
... examples.quickstart.hello_world_2
... hello_world_2
... examples.quickstart.hello_world_1
... hello_world_1
... examples.quickstart.hello_world_distributed
... hello_world_distributed
```

It is also possible to build, for instance, all quickstart examples using make examples.quickstart.

### 2.3.7 Creating HPX projects

#### Using HPX with pkg-config

##### How to build HPX applications with pkg-config

After you are done installing HPX, you should be able to build the following program. It prints Hello World! on the locality you run it on.

```cpp
#include <hpx/hpx_main.hpp>
#include <hpx/iostream.hpp>

int main()
{
    hpx::cout << "Hello World!\n" << std::flush;
    return 0;
}
```

Copy the text of this program into a file called hello_world.cpp.

Now, in the directory where you put hello_world.cpp, issue the following commands (where $HPX_LOCATION is the build directory or CMAKE_INSTALL_PREFIX you used while building HPX):

```
$ export PKG_CONFIG_PATH=$PKG_CONFIG_PATH:$HPX_LOCATION/lib/pkgconfig
$ c++ -o hello_world hello_world.cpp \
    `pkg-config --cflags --libs hpx_application` \
    -lhpx_iostreams -DHPX_APPLICATION_NAME=hello_world
```

**Important:** When using pkg-config with HPX, the pkg-config flags must go after the -o flag.
**Note:** HPX libraries have different names in debug and release mode. If you want to link against a debug HPX library, you need to use the _debug suffix for the pkg-config name. That means instead of hpx_application or hpx_component, you will have to use hpx_application_debug or hpx_component_debug. Moreover, all referenced HPX components need to have an appended d suffix. For example, instead of -lhpx_iostreams you will need to specify -lhpx_iostreams_d.

**Important:** If the HPX libraries are in a path that is not found by the dynamic linker, you will need to add the path $HPX_LOCATION/lib to your linker search path (for example LD_LIBRARY_PATH on Linux).

To test the program, type:

```bash
$ ./hello_world
```

which should print Hello World! and exit.

**How to build HPX components with pkg-config**

Let’s try a more complex example involving an HPX component. An HPX component is a class that exposes HPX actions. HPX components are compiled into dynamically loaded modules called component libraries. Here’s the source code:

**hello_world_component.cpp**

```cpp
#include <hpx/config.hpp>
#if !defined(HPX_COMPUTE_DEVICE_CODE)
#include <hpx/iostream.hpp>
#include "hello_world_component.hpp"
#include <iostream>
namespace examples { namespace server {
    void hello_world::invoke()
    {
        hpx::cout << "Hello HPX World!" << std::endl;
    }
}} // namespace examples::server
HPX_REGISTER_COMPONENT_MODULE()
typedef hpx::components::component<examples::server::hello_world>
    hello_world_type;
HPX_REGISTER_COMPONENT(hello_world_type, hello_world)
HPX_REGISTER_ACTION(
    examples::server::hello_world::invoke_action, hello_world_invoke_action)
#endif
```

**hello_world_component.hpp**

---

2.3. Manual 79
```
#pragma once

#include <hpx/config.hpp>
#if !defined(HPX_COMPUTE_DEVICE_CODE)
#include <hpx/hpx.hpp>
#include <hpx/include/actions.hpp>
#include <hpx/include/components.hpp>
#include <hpx/include/lcos.hpp>
#include <hpx/serialization.hpp>
#include <utility>

namespace examples {
namespace server {
  struct HPX_COMPONENT_EXPORT hello_world : hpx::components::component_base<hello_world> {
    void invoke();
    HPX_DEFINE_COMPONENT_ACTION(hello_world, invoke)
  };
}
} // namespace examples::server

HPX_REGISTER_ACTION_DECLARATION(
  examples::server::hello_world::invoke_action, hello_world_invoke_action)

namespace examples {
  struct hello_world : hpx::components::client_base<hello_world, server::hello_world> {
    typedef hpx::components::client_base<hello_world, server::hello_world> base_type;

    hello_world(hpx::future<hpx::id_type>&& f) : base_type(std::move(f)) {
    }

    hello_world(hpx::id_type&& f) : base_type(std::move(f)) {
    }

    void invoke() {
      hpx::async<server::hello_world::invoke_action>(this->get_id()).get();
    }
  } // namespace examples

#endif

hello_world_client.cpp
```

Chapter 2. What’s so special about HPX?
```cpp
#include <hpx/config.hpp>
#if defined(HPX_COMPUTE_HOST_CODE)
#include <hpx/wrap_main.hpp>
#include "hello_world_component.hpp"

int main()
{
    std::cout << std::endl;
    // Create a single instance of the component on this locality.
    examples::hello_world client =
        hpx::new_<examples::hello_world>(hpx::find_here());

    // Involve the component's action, which will print "Hello World!".
    client.invoke();
}

return 0;
#endif
```

Copy the three source files above into three files (called `hello_world_component.cpp`, `hello_world_component.hpp` and `hello_world_client.cpp`, respectively).

Now, in the directory where you put the files, run the following command to build the component library. (where `$HPX_LOCATION` is the build directory or `CMAKE_INSTALL_PREFIX` you used while building HPX):

```bash
$ export PKG_CONFIG_PATH=$PKG_CONFIG_PATH:$HPX_LOCATION/lib/pkgconfig
$ c++ -o libhpx_hello_world.so hello_world_component.cpp \  
`pkg-config --cflags --libs hpx_component` \  
-lhpx_iostreams -DHPX_COMPONENT_NAME=hpx_hello_world
```

Now pick a directory in which to install your HPX component libraries. For this example, we'll choose a directory named `my_hpx_libs`:

```bash
$ mkdir ~/my_hpx_libs
$ mv libhpx_hello_world.so ~/my_hpx_libs
```

**Note:** HPX libraries have different names in debug and release mode. If you want to link against a debug HPX library, you need to use the `_debug` suffix for the pkg-config name. That means instead of `hpx_application` or `hpx_component` you will have to use `hpx_application_debug` or `hpx_component_debug`. Moreover, all referenced HPX components need to have a appended _d suffix, e.g. instead of `-lhpx_iostreams` you will need to specify `-lhpx_iostreamsd`.

**Important:** If the HPX libraries are in a path that is not found by the dynamic linker. You need to add the path `$HPX_LOCATION/lib` to your linker search path (for example `LD_LIBRARY_PATH` on Linux).

Now, to build the application that uses this component (`hello_world_client.cpp`), we do:

```bash
$ export PKG_CONFIG_PATH=$PKG_CONFIG_PATH:$HPX_LOCATION/lib/pkgconfig
$ c++ -o hello_world_client hello_world_client.cpp \  
`pkg-config --cflags --libs hpx_component` \  
-lhpx_iostreams -DHPX_COMPONENT_NAME=hpx_hello_world
```

(continues on next page)
```
```
 pkg-config --cflags --libs hpx_application \
 -L${HOME}/my_hpx_libs -lhpx_hello_world -lhpx_iostreams
```

**Important:** When using pkg-config with HPX, the pkg-config flags must go after the -o flag.

Finally, you’ll need to set your LD_LIBRARY_PATH before you can run the program. To run the program, type:

```
$ export LD_LIBRARY_PATH="$LD_LIBRARY_PATH:$HOME/my_hpx_libs"
$ ./hello_world_client
```

which should print Hello HPX World! and exit.

**Using HPX with CMake-based projects**

In addition to the pkg-config support discussed on the previous pages, HPX comes with full CMake support. In order to integrate HPX into existing or new CMakeLists.txt, you can leverage the find_package command integrated into CMake. Following, is a Hello World component example using CMake.

Let’s revisit what we have. We have three files that compose our example application:

- hello_world_component.hpp
- hello_world_component.cpp
- hello_world_client.hpp

The basic structure to include HPX into your CMakeLists.txt is shown here:

```cmake
# Require a recent version of cmake
cmake_minimum_required(VERSION 3.18 FATAL_ERROR)

# This project is C++ based.
project(your_app CXX)

# Instruct cmake to find the HPX settings
find_package(HPX)
```

In order to have CMake find HPX, it needs to be told where to look for the HPXConfig.cmake file that is generated when HPX is built or installed. It is used by find_package(HPX) to set up all the necessary macros needed to use HPX in your project. The ways to achieve this are:

- Set the HPX_DIR CMake variable to point to the directory containing the HPXConfig.cmake script on the command line when you invoke CMake:

```
$ cmake -DHPX_DIR=$HPX_LOCATION/lib/cmake/HPX ...
```

where $HPX_LOCATION is the build directory or CMAKE_INSTALL_PREFIX you used when building/configuring HPX.

- Set the CMAKE_PREFIX_PATH variable to the root directory of your HPX build or install location on the command line when you invoke CMake:

```
https://www.cmake.org/cmake/help/latest/command/find_package.html
```
The difference between `CMAKE_PREFIX_PATH` and `HPX_DIR` is that CMake will add common postfixes, such as `lib/cmake/<project>`, to the `CMAKE_PREFIX_PATH` and search in these locations too. Note that if your project uses `HPX` as well as other CMake-managed projects, the paths to the locations of these multiple projects may be concatenated in the `CMAKE_PREFIX_PATH`.

- The variables above may be set in the CMake GUI or curses `ccmake` interface instead of the command line.

Additionally, if you wish to require `HPX` for your project, replace the `find_package(HPX)` line with `find_package(HPX REQUIRED)`.

You can check if `HPX` was successfully found with the `HPX_FOUND` CMake variable.

### Using CMake targets

The recommended way of setting up your targets to use `HPX` is to link to the `HPX::hpx` CMake target:

```cmake
target_link_libraries(hello_world_component PUBLIC HPX::hpx)
```

This requires that you have already created the target like this:

```cmake
add_library(hello_world_component SHARED hello_world_component.cpp)
target_include_directories(hello_world_component PUBLIC ${CMAKE_CURRENT_SOURCE_DIR})
```

When you link your library to the `HPX::hpx` CMake target, you will be able use `HPX` functionality in your library. To use `main()` as the implicit entry point in your application you must additionally link your application to the CMake target `HPX::wrap_main`. This target is automatically linked to executables if you are using the macros described below (Using macros to create new targets). See Re-use the main() function as the main HPX entry point for more information on implicitly using `main()` as the entry point.

Creating a component requires setting two additional compile definitions:

```cmake
target_compile_options(hello_world_component
    HPX_COMPONENT_NAME=hello_world
    HPX_COMPONENT_EXPORTS)
```

Instead of setting these definitions manually you may link to the `HPX::component` target, which sets `HPX_COMPONENT_NAME` to `hpx_<target_name>`, where `<target_name>` is the target name of your library. Note that these definitions should be PRIVATE to make sure these definitions are not propagated transitively to dependent targets.

In addition to making your library a component you can make it a plugin. To do so link to the `HPX::plugin` target. Similarly to `HPX::component` this will set `HPX_PLUGIN_NAME` to `hpx_<target_name>`. This definition should also be PRIVATE. Unlike regular shared libraries, plugins are loaded at runtime from certain directories and will not be found without additional configuration. Plugins should be installed into a directory containing only plugins. For example, the plugins created by `HPX` itself are installed into the `hpX` subdirectory in the library install directory (typically `lib` or `lib64`). When using the `HPX::plugin` target you need to install your plugins into an appropriate directory. You may also want to set the location of your plugin in the build directory with the `*_OUTPUT_DIRECTORY` CMake target properties to be able to load the plugins in the build directory. Once you’ve set the install or output directory of your plugin you need to tell your executable where to find it at runtime. You can do this either by setting the environment variable `HPX_COMPONENT_PATHS` or the ini setting `hpx.component_paths` (see `--hpx:ini`) to the directory containing your plugin.
Using macros to create new targets

In addition to the targets described above, *HPX* provides convenience macros to hide optional boilerplate code that may be useful for your project. The link to the targets described above. We recommend that you use the targets directly whenever possible as they tend to compose better with other targets.

The macro for adding an *HPX* component is `add_hpx_component`. It can be used in your CMakeLists.txt file like this:

```cmake
# build your application using HPX
add_hpx_component(hello_world
  SOURCES hello_world_component.cpp
  HEADERS hello_world_component.hpp
  COMPONENT_DEPENDENCIES iostreams)
```

**Note:** `add_hpx_component` adds a _component suffix to the target name. In the example above, a `hello_world_component` target will be created.

The available options to `add_hpx_component` are:

- **SOURCES**: The source files for that component
- **HEADERS**: The header files for that component
- **DEPENDENCIES**: Other libraries or targets this component depends on
- **COMPONENT_DEPENDENCIES**: The components this component depends on
- **PLUGIN**: Treats this component as a plugin-able library
- **COMPILE_FLAGS**: Additional compiler flags
- **LINK_FLAGS**: Additional linker flags
- **FOLDER**: Adds the headers and source files to this Source Group folder
- **EXCLUDE_FROM_ALL**: Do not build this component as part of the all target

After adding the component, the way you add the executable is as follows:

```cmake
# build your application using HPX
add_hpx_executable(hello_world
  SOURCES hello_world_client.cpp
  COMPONENT_DEPENDENCIES hello_world)
```

**Note:** `add_hpx_executable` automatically adds a _component suffix to dependencies specified in `COMPONENT_DEPENDENCIES`, meaning you can directly use the name given when adding a component using `add_hpx_component`.

When you configure your application, all you need to do is set the `HPX_DIR` variable to point to the installation of *HPX*.

**Note:** All library targets built with *HPX* are exported and readily available to be used as arguments to `target_link_libraries` in your targets. The *HPX* include directories are available with the `HPX_INCLUDE_DIRS` CMake variable.

---

Using the **HPX** compiler wrapper **hpxcxx**

The **hpxcxx** compiler wrapper helps to compile a **HPX** component, application, or object file, based on the arguments passed to it.

```
$ hpxcxx [--exe=<APPLICATION_NAME> | --comp=<COMPONENT_NAME> | -c] FLAGS FILES
```

The **hpxcxx** command **requires** that either an application or a component is built or `-c` flag is specified. If the build is against a debug build, the `-g` is to be specified while building.

**Optional FLAGS**

- `-l <LIBRARY> | -l<LIBRARY>`: Links `<LIBRARY>` to the build
- `-g`: Specifies that the application or component build is against a debug build
- `-rd`: Sets `release-with-debug-info` option
- `-mr`: Sets `minsize-release` option

All other flags (like `-o OUTPUT_FILE`) are directly passed to the underlying C++ compiler.

**Using macros to set up existing targets to use **HPX****

In addition to the `add_hpx_component` and `add_hpx_executable`, you can use the `hpx_setup_target` macro to have an already existing target to be used with the **HPX** libraries:

```
hpx_setup_target(target)
```

Optional parameters are:

- **EXPORT**: Adds it to the CMake export list HPXTargets
- **INSTALL**: Generates an install rule for the target
- **PLUGIN**: Treats this component as a plugin-able library
- **TYPE**: The type can be: EXECUTABLE, LIBRARY or COMPONENT
- **DEPENDENCIES**: Other libraries or targets this component depends on
- **COMPONENT_DEPENDENCIES**: The components this component depends on
- **COMPILE_FLAGS**: Additional compiler flags
- **LINK_FLAGS**: Additional linker flags

If you do not use CMake, you can still build against **HPX**, but you should refer to the section on *How to build **HPX** components with pkg-config*.

**Note:** Since **HPX** relies on dynamic libraries, the dynamic linker needs to know where to look for them. If **HPX** isn’t installed into a path that is configured as a linker search path, external projects need to either set `RPATH` or adapt `LD_LIBRARY_PATH` to point to where the **HPX** libraries reside. In order to set `RPATH`s, you can include `HPX_SetFullRPATH` in your project after all libraries you want to link against have been added. Please also consult the CMake documentation [here] (https://gitlab.kitware.com/cmake/community/wikis/doc/cmake/RPATH-handling).

Using HPX with Makefile

A basic project building with HPX is through creating makefiles. The process of creating one can get complex depending upon the use of cmake parameter HPX_WITH_HPX_MAIN (which defaults to ON).

How to build HPX applications with makefile

If HPX is installed correctly, you should be able to build and run a simple Hello World program. It prints Hello World! on the locality you run it on.

```cpp
#include <hpx/hpx_main.hpp>
#include <hpx/iostream.hpp>

int main()
{
    // Say hello to the world!
    hpx::cout << "Hello World!\n" << std::flush;
    return 0;
}
```

Copy the content of this program into a file called hello_world.cpp.

Now, in the directory where you put hello_world.cpp, create a Makefile. Add the following code:

```makefile
CXX=(CXX) # Add your favourite compiler here or let makefile choose default.
CXXFLAGS=-O3 -std=c++17
BOOST_ROOT=/path/to/boost
HWLOC_ROOT=/path/to/hwloc
TCMALLOC_ROOT=/path/to/tcmalloc
HPX_ROOT=/path/to/hpx

INCLUDE_DIRECTIVES=\$(HPX_ROOT)/include \$(BOOST_ROOT)/include \$(HWLOC_ROOT)/include

LIBRARY_DIRECTIVES=-L\$(HPX_ROOT)/lib \$(HPX_ROOT)/lib/hpx_init.a \$(HPX_ROOT)/lib/\...libhpx.so \$(BOOST_ROOT)/lib/libboost_atomic-mt.so \$(BOOST_ROOT)/lib/libboost_\...filesystem-mt.so \$(BOOST_ROOT)/lib/libboost_program_options-mt.so \$(BOOST_ROOT)/lib/\...libboost_regex-mt.so \$(BOOST_ROOT)/lib/libboost_system-mt.so -lpthread \$(TCMALLOC_\...ROOT)/libtcmalloc_minimal.so \$(HWLOC_ROOT)/libhwloc.so \-ldl -lrt

LINK_FLAGS=\$(HPX_ROOT)/lib/libhpx_wrap.a -Wl,-wrap=main # should be left empty for HPX_\...WITH_HPX_MAIN=OFF

hello_world: hello_world.o
    $\(CXX\)$\(CXXFLAGS\) -o hello_world hello_world.o $\(LIBRARY_DIRECTIVES\)$\(LINK_FLAGS\)

hello_world.o:
    $\(CXX\)$\(CXXFLAGS\) -c -o hello_world.o hello_world.cpp $\(INCLUDE_DIRECTIVES\)$

Important: LINK_FLAGS should be left empty if HPX_WITH_HPX_MAIN is set to OFF. Boost in the above example
is build with --layout=tagged. Actual Boost flags may vary on your build of Boost.

To build the program, type:

```
$ make
```

A successful build should result in hello_world binary. To test, type:

```
$ ./hello_world
```

**How to build HPX components with makefile**

Let’s try a more complex example involving an HPX component. An HPX component is a class that exposes HPX actions. HPX components are compiled into dynamically-loaded modules called component libraries. Here’s the source code:

**hello_world_component.cpp**

```cpp
#include <hpx/config.hpp>
#if !defined(HPX_COMPUTE_DEVICE_CODE)
#include <hpx/iostream.hpp>
#include "hello_world_component.hpp"
#endif

#include <iostream>

namespace examples { namespace server {
    void hello_world::invoke()
    {
        hpx::cout << "Hello HPX World!" << std::endl;
    }
}} // namespace examples::server

HPX_REGISTER_COMPONENT_MODULE()

typedef hpx::components::component<examples::server::hello_world>
    hello_world_type;

HPX_REGISTER_COMPONENT(hello_world_type, hello_world)

HPX_REGISTER_ACTION(
    examples::server::hello_world::invoke_action, hello_world_invoke_action)
#endif
```

**hello_world_component.hpp**

```cpp
#pragma once
#include <hpx/config.hpp>
#if !defined(HPX_COMPUTE_DEVICE_CODE)
#include <hpx/hpx.hpp>
#include <hpx/include/actions.hpp>
#include <hpx/include/components.hpp>
```

(continues on next page)
#include <hpx/include/lcos.hpp>
#include <hpx/serialization.hpp>
#include <utility>

namespace examples
{
    namespace server
    {
        struct HPX_COMPONENT_EXPORT hello_world : hpx::components::component_base<hello_world>
        {
            void invoke();
            HPX_DEFINE_COMPONENT_ACTION(hello_world, invoke)
        };
    }
}

HPX_REGISTER_ACTION_DECLARATION(
    examples::server::hello_world::invoke_action, hello_world_invoke_action)

namespace examples
{
    struct hello_world : hpx::components::client_base<hello_world, server::hello_world>
    {
        typedef hpx::components::client_base<hello_world, server::hello_world> base_type;

        hello_world(hpx::future<hpx::id_type>&& f) : base_type(std::move(f))
        {
        }

        hello_world(hpx::id_type&& f) : base_type(std::move(f))
        {
        }

        void invoke()
        {
            hpx::async<server::hello_world::invoke_action>(this->get_id()).get();
        }
    };
}

#endif

hello_world_client.cpp

#include <hpx/config.hpp>
#if defined(HPX_COMPUTE_HOST_CODE)
#include <hpx/wrap_main.hpp>
#include "hello_world_component.hpp"

(continues on next page)
```cpp
int main()
{
    // Create a single instance of the component on this locality.
    examples::hello_world client =
        hpx::new_<examples::hello_world>(hpx::find_here());

    // Invoke the component's action, which will print "Hello World!".
    client.invoke();

    return 0;
}
```

Now, in the directory, create a Makefile. Add the following code:

```makefile
CXX=(CXX)  # Add your favourite compiler here or let makefile choose default.
CXXFLAGS=-O3 -std=c++17
BOOST_ROOT=/path/to/boost
HWLOC_ROOT=/path/to/hwloc
TCMALLOC_ROOT=/path/to/tcmalloc
HPX_ROOT=/path/to/hpx

INCLUDE_DIRECTIVES= $(HPX_ROOT)/include $(BOOST_ROOT)/include $(HWLOC_ROOT)/include
LIBRARY_DIRECTIVES=-L$(HPX_ROOT)/lib $(HPX_ROOT)/lib/libhpx_init.a $(HPX_ROOT)/lib/
                      ...libhpx.so $(BOOST_ROOT)/lib/libboost_atomic-mt.so $(BOOST_ROOT)/lib/libboost_
                      ...filesystem-mt.so $(BOOST_ROOT)/lib/libboost_program_options-mt.so $(BOOST_ROOT)/lib/
                      ...libboost_regex-mt.so $(BOOST_ROOT)/lib/libboost_system-mt.so -lpthread $(TCMALLOC_ROOT/
                      ...ROOT)/libtcmalloc_minimal.so $(HWLOC_ROOT)/libhwloc.so -ldl -lrt
LINK_FLAGS= $(HPX_ROOT)/lib/libhpx_wrap.a -Wl,-wrap=main  # should be left empty for HPX_WITH_HPX_MAIN=OFF

hello_world_client: libhpx_hello_world hello_world_client.o
    $(CXX) $(CXXFLAGS) -o hello_world_client $(LIBRARY_DIRECTIVES) libhpx_hello_world
        $(LINK_FLAGS)

hello_world_client.o: hello_world_client.cpp
    $(CXX) $(CXXFLAGS) -o hello_world_client.o hello_world_client.cpp $(INCLUDEDIRECTIVES)

libhpx_hello_world: hello_world_component.o
    $(CXX) $(CXXFLAGS) -o libhpx_hello_world hello_world_component.o $(LIBRARY_DIRECTIVES)

hello_world_component.o: hello_world_component.cpp
    $(CXX) $(CXXFLAGS) -c -o hello_world_component.o hello_world_component.cpp $(INCLUDEDIRECTIVES)

To build the program, type:
A successful build should result in hello_world binary. To test, type:

```bash
$ ./hello_world
```

**Note:** Due to high variations in CMake flags and library dependencies, it is recommended to build HPX applications and components with pkg-config or CMakeLists.txt. Writing Makefile may result in broken builds if due care is not taken. pkg-config files and CMake systems are configured with CMake build of HPX. Hence, they are stable when used together and provide better support overall.

### 2.3.8 Starting the HPX runtime

In order to write an application that uses services from the HPX runtime system, you need to initialize the HPX library by inserting certain calls into the code of your application. Depending on your use case, this can be done in 3 different ways:

- **Minimally invasive:** Re-use the `main()` function as the main HPX entry point.
- **Balanced use case:** Supply your own main HPX entry point while blocking the main thread.
- **Most flexibility:** Supply your own main HPX entry point while avoiding blocking the main thread.
- **Suspend and resume:** As above but suspend and resume the HPX runtime to allow for other runtimes to be used.

#### Re-use the `main()` function as the main HPX entry point

This method is the least intrusive to your code. However, it provides you with the smallest flexibility in terms of initializing the HPX runtime system. The following code snippet shows what a minimal HPX application using this technique looks like:

```cpp
#include <hpx/hpx_main.hpp>

int main(int argc, char* argv[]) {
    return 0;
}
```

The only change to your code you have to make is to include the file hpx/hpx_main.hpp. In this case the function `main()` will be invoked as the first HPX thread of the application. The runtime system will be initialized behind the scenes before the function `main()` is executed and will automatically stop after `main()` has returned. For this method to work you must link your application to the CMake target `HPX::wrap_main`. This is done automatically if you are using the provided macros (Using macros to create new targets) to set up your application, but must be done explicitly if you are using targets directly (Using CMake targets). All HPX API functions can be used from within the `main()` function now.

**Note:** The function `main()` does not need to expect receiving `argc` and `argv` as shown above, but could expose the signature `int main()`. This is consistent with the usually allowed prototypes for the function `main()` in C++ applications.
All command line arguments specific to HPX will still be processed by the HPX runtime system as usual. However, those command line options will be removed from the list of values passed to \texttt{argc/argv} of the function \texttt{main()}. The list of values passed to \texttt{main()} will hold only the commandline options that are not recognized by the HPX runtime system (see the section \textit{HPX Command Line Options} for more details on what options are recognized by HPX).

**Note:** In this mode all one-letter shortcuts that are normally available on the HPX command line are disabled (such as \texttt{-t} or \texttt{-l} see HPX Command Line Options). This is done to minimize any possible interaction between the command line options recognized by the HPX runtime system and any command line options defined by the application.

The value returned from the function \texttt{main()} as shown above will be returned to the operating system as usual.

**Important:** To achieve this seamless integration, the header file \texttt{hpx/hpx_main.hpp} defines a macro:

```cpp
#define main hpx_startup::user_main
```

which could result in unexpected behavior.

**Important:** To achieve this seamless integration, we use different implementations for different operating systems. In case of Linux or macOS, the code present in \texttt{hpx_wrap.cpp} is put into action. We hook into the system function in case of Linux and provide alternate entry point in case of macOS. For other operating systems we rely on a macro:

```cpp
#define main hpx_startup::user_main
```

provided in the header file \texttt{hpx/hpx_main.hpp}. This implementation can result in unexpected behavior.

**Caution:** We make use of an \textit{override} variable \texttt{include_libhpx_wrap} in the header file \texttt{hpx/hpx_main.hpp} to swiftly choose the function call stack at runtime. Therefore, the header file should \textit{only} be included in the main executable. Including it in the components will result in multiple definition of the variable.

### Supply your own main HPX entry point while blocking the main thread

With this method you need to provide an explicit main-thread function named \texttt{hpx_main} at global scope. This function will be invoked as the main entry point of your HPX application on the console \textit{locality} only (this function will be invoked as the first HPX thread of your application). All HPX API functions can be used from within this function.

The thread executing the function \texttt{hpx::init} will block waiting for the runtime system to exit. The value returned from \texttt{hpx_main} will be returned from \texttt{hpx::init} after the runtime system has stopped.

The function \texttt{hpx::finalize} has to be called on one of the HPX localities in order to signal that all work has been scheduled and the runtime system should be stopped after the scheduled work has been executed.

This method of invoking HPX has the advantage of the user being able to decide which version of \texttt{hpx::init} to call. This allows to pass additional configuration parameters while initializing the HPX runtime system.

```cpp
#include <hpx/hpx_init.hpp>

int hpx_main(int argc, char* argv[]) {
   // Any HPX application logic goes here...
}
```

(continues on next page)
```cpp
return hpx::finalize();
}

int main(int argc, char* argv[])
{
    // Initialize HPX, run hpx_main as the first HPX thread, and
    // wait for hpx::finalize being called.
    return hpx::init(argc, argv);
}
```

**Note:** The function `hpx_main` does not need to expect receiving `argc/argv` as shown above, but could expose one of the following signatures:

```cpp
int hpx_main();
int hpx_main(int argc, char* argv[]);
int hpx_main(hpx::program_options::variables_map& vm);
```

This is consistent with (and extends) the usually allowed prototypes for the function `main()` in C++ applications.

The header file to include for this method of using HPX is `hpx/hpx_init.hpp`.

There are many additional overloads of `hpx::init` available, such as the ability to provide your own entry-point function instead of `hpx_main`. Please refer to the function documentation for more details (see: `hpx/hpx_init.hpp`).

### Supply your own main HPX entry point while avoiding blocking the main thread

With this method you need to provide an explicit main thread function named `hpx_main` at global scope. This function will be invoked as the main entry point of your HPX application on the console *locality* only (this function will be invoked as the first HPX thread of your application). All HPX API functions can be used from within this function.

The thread executing the function `hpx::start` will *not* block waiting for the runtime system to exit, but will return immediately. The function `hpx::finalize` has to be called on one of the HPX localities in order to signal that all work has been scheduled and the runtime system should be stopped after the scheduled work has been executed.

This method of invoking HPX is useful for applications where the main thread is used for special operations, such as a GUIs. The function `hpx::stop` can be used to wait for the HPX runtime system to exit and should at least be used as the last function called in `main()`. The value returned from `hpx_main` will be returned from `hpx::stop` after the runtime system has stopped.

```cpp
#include <hpx/hpx_start.hpp>

int hpx_main(int argc, char* argv[])
{
    // Any HPX application logic goes here...
    return hpx::finalize();
}

int main(int argc, char* argv[])
{
    // Initialize HPX, run hpx_main.
    hpx::start(argc, argv);
}
```
// ...Execute other code here...

// Wait for hpx::finalize being called.
return hpx::stop();
}

Note: The function \texttt{hpx\_main} does not need to expect receiving \texttt{argc/argv} as shown above, but could expose one of the following signatures:

\begin{verbatim}
int hpx\_main();
int hpx\_main(int argc, char* argv[]);
int hpx\_main(hpx::program\_options::variables\_map& vm);
\end{verbatim}

This is consistent with (and extends) the usually allowed prototypes for the function \texttt{main()} in C++ applications.

The header file to include for this method of using \textit{HPX} is \texttt{hpx/hpx\_start.hpp}.

There are many additional overloads of \texttt{hpx::start} available, such as the option for users to provide their own entry point function instead of \texttt{hpx\_main}. Please refer to the function documentation for more details (see: \texttt{hpx/hpx\_start.hpp}).

**Supply your own explicit startup function as the main \textit{HPX} entry point**

There is also a way to specify any function (besides \texttt{hpx\_main}) to be used as the main entry point for your \textit{HPX} application:

\begin{verbatim}
#include <hpx/hpx\_init.hpp>

int application\_entry\_point(int argc, char* argv[]) {
    // Any \textit{HPX} application logic goes here...
    return hpx::finalize();
}

int main(int argc, char* argv[]) {
    // Initialize \textit{HPX}, run application\_entry\_point as the first \textit{HPX} thread,
    // and wait for hpx::finalize being called.
    return hpx::init(&application\_entry\_point, argc, argv);
}
\end{verbatim}

Note: The function supplied to \texttt{hpx::init} must have one of the following prototypes:

\begin{verbatim}
int application\_entry\_point(int argc, char* argv[]); int application\_entry\_point(hpx::program\_options::variables\_map& vm);
\end{verbatim}

Note: If \texttt{nullptr} is used as the function argument, \textit{HPX} will not run any startup function on this locality.
Suspending and resuming the HPX runtime

In some applications it is required to combine HPX with other runtimes. To support this use case, HPX provides two functions: `hpx::suspend` and `hpx::resume`. `hpx::suspend` is a blocking call which will wait for all scheduled tasks to finish executing and then put the thread pool OS threads to sleep. `hpx::resume` simply wakes up the sleeping threads so that they are ready to accept new work. `hpx::suspend` and `hpx::resume` can be found in the header `hpx/hpx_suspend.hpp`.

```cpp
#include <hpx/hpx_start.hpp>
#include <hpx/hpx_suspend.hpp>

int main(int argc, char* argv[]) {
    // Initialize HPX, don't run hpx_main
    hpx::start(nullptr, argc, argv);

    // Schedule a function on the HPX runtime
    hpx::post(&my_function, ...);

    // Wait for all tasks to finish, and suspend the HPX runtime
    hpx::suspend();

    // Execute non-HPX code here

    // Resume the HPX runtime
    hpx::resume();

    // Schedule more work on the HPX runtime

    // hpx::finalize has to be called from the HPX runtime before hpx::stop
    hpx::post([]() { hpx::finalize(); });
    return hpx::stop();
}
```

Note: `hpx::suspend` does not wait for `hpx::finalize` to be called. Only call `hpx::finalize` when you wish to fully stop the HPX runtime.

Warning:

`hpx::suspend` only waits for local tasks, i.e. tasks on the current locality, to finish executing. When using `hpx::suspend` in a multi-locality scenario the user is responsible for ensuring that any work required from other localities has also finished.

HPX also supports suspending individual thread pools and threads. For details on how to do that, see the documentation for `hpx::threads::thread_pool_base`.  

Chapter 2. What’s so special about HPX?
Automatically suspending worker threads

The previous method guarantees that the worker threads are suspended when you ask for it and that they stay suspended. An alternative way to achieve the same effect is to tweak how quickly HPX suspends its worker threads when they run out of work. The following configuration values make sure that HPX idles very quickly:

```plaintext
hpx.max_idle_backoff_time = 1000
hpx.max_idle_loop_count = 0
```

They can be set on the command line using `--hpx:ini=hpx.max_idle_backoff_time=1000` and `--hpx:ini=hpx.max_idle_loop_count=0`. See *Launching and configuring HPX applications* for more details on how to set configuration parameters.

After setting idling parameters the previous example could now be written like this instead:

```c++
#include <hpx/hpx_start.hpp>

int main(int argc, char* argv[]) {
    // Initialize HPX, don't run hpx_main
    hpx::start(nullptr, argc, argv);

    // Schedule some functions on the HPX runtime
    // NOTE: run_as_hpx_thread blocks until completion.
    hpx::run_as_hpx_thread(&my_function, ...);
    hpx::run_as_hpx_thread(&my_other_function, ...);

    // hpx::finalize has to be called from the HPX runtime before hpx::stop
    hpx::post([]() { hpx::finalize(); });
    return hpx::stop();
}
```

In this example each call to `hpx::run_as_hpx_thread` acts as a “parallel region”.

Working of `hpx_main.hpp`

In order to initialize HPX from `main()`, we make use of linker tricks. It is implemented differently for different operating systems. The method of implementation is as follows:

- **Linux**: Using linker `--wrap` option.
- **Mac OSX**: Using the linker `-e` option.
- **Windows**: Using `#define main hpx_startup::user_main`
Linux implementation

We make use of the Linux linker ld’s --wrap option to wrap the main() function. This way any calls to main() are redirected to our own implementation of main. It is here that we check for the existence of hpx_main.hpp by making use of a shadow variable include_libhpx_wrap. The value of this variable determines the function stack at runtime. The implementation can be found in libhpx_wrap.a.

Important: It is necessary that hpx_main.hpp be not included more than once. Multiple inclusions can result in multiple definition of include_libhpx_wrap.

Mac OSX implementation

Here we make use of yet another linker option -e to change the entry point to our custom entry function initialize_main. We initialize the HPX runtime system from this function and call main from the initialized system. We determine the function stack at runtime by making use of the shadow variable include_libhpx_wrap. The implementation can be found in libhpx_wrap.a.

Important: It is necessary that hpx_main.hpp be not included more than once. Multiple inclusions can result in multiple definition of include_libhpx_wrap.

Windows implementation

We make use of a macro #define main hpx_startup::user_main to take care of the initializations.

This implementation could result in unexpected behaviors.

2.3.9 Launching and configuring HPX applications

Configuring HPX applications

All HPX applications can be configured using special command line options and/or using special configuration files. This section describes the available options, the configuration file format, and the algorithm used to locate possible predefined configuration files. Additionally, this section describes the defaults assumed if no external configuration information is supplied.

During startup any HPX application applies a predefined search pattern to locate one or more configuration files. All found files will be read and merged in the sequence they are found into one single internal database holding all configuration properties. This database is used during the execution of the application to configure different aspects of the runtime system.

In addition to the ini files, any application can supply its own configuration files, which will be merged with the configuration database as well. Moreover, the user can specify additional configuration parameters on the command line when executing an application. The HPX runtime system will merge all command line configuration options (see the description of the --hpx:ini, --hpx:config, and --hpx:app-config command line options).
The HPX ini file format

All HPX applications can be configured using a special file format that is similar to the well-known Windows INI file format\(^{41}\). This is a structured text format that allows users to group key/value pairs (properties) into sections. The basic element contained in an ini file is the property. Every property has a name and a value, delimited by an equal sign '='. The name appears to the left of the equal sign:

```
name=value
```

The value may contain equal signs as only the first '=' character is interpreted as the delimiter between name and value. Whitespace before the name, after the value and immediately before and after the delimiting equal sign is ignored. Whitespace inside the value is retained.

Properties may be grouped into arbitrarily named sections. The section name appears on a line by itself, in square brackets. All properties after the section declaration are associated with that section. There is no explicit "end of section" delimiter; sections end at the next section declaration or the end of the file:

```
[section]
```

In HPX sections can be nested. A nested section has a name composed of all section names it is embedded in. The section names are concatenated using a dot '.':

```
[outer_section.inner_section]
```

Here, inner_section is logically nested within outer_section.

It is possible to use the full section name concatenated with the property name to refer to a particular property. For example, in:

```
[a.b.c]
d = e
```

the property value of d can be referred to as a.b.c.d=e.

In HPX ini files can contain comments. Hash signs '#' at the beginning of a line indicate a comment. All characters starting with '#' until the end of the line are ignored.

If a property with the same name is reused inside a section, the second occurrence of this property name will override the first occurrence (discard the first value). Duplicate sections simply merge their properties together, as if they occurred contiguously.

In HPX ini files a property value \${FOO:default} will use the environmental variable FOO to extract the actual value if it is set and default otherwise. No default has to be specified. Therefore, \${FOO} refers to the environmental variable FOO. If FOO is not set or empty, the overall expression will evaluate to an empty string. A property value \${section.key:default} refers to the value held by the property section.key if it exists and default otherwise. No default has to be specified. Therefore \${section.key} refers to the property section.key. If the property section.key is not set or empty, the overall expression will evaluate to an empty string.

**Note:** Any property \${section.key:default} is evaluated whenever it is queried and not when the configuration data is initialized. This allows for lazy evaluation and relaxes initialization order of different sections. The only exception are recursive property values, e.g., values referring to the very key they are associated with. Those property values are evaluated at initialization time to avoid infinite recursion.

---

**Built-in default configuration settings**

During startup any *HPX* application applies a predefined search pattern to locate one or more configuration files. All found files will be read and merged in the sequence they are found into one single internal data structure holding all configuration properties.

As a first step the internal configuration database is filled with a set of default configuration properties. Those settings are described on a section by section basis below.

**Note:** You can print the default configuration settings used for an executable by specifying the command line option `--hpx:dump-config`.

---

**The `system` configuration section**

```
[system]
pid = <process-id>
prefix = <current prefix path of core HPX library>
executable = <current prefix path of executable>
```

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>system.pid</code></td>
<td>This is initialized to store the current OS-process id of the application instance.</td>
</tr>
<tr>
<td><code>system.prefix</code></td>
<td>This is initialized to the base directory <em>HPX</em> has been loaded from.</td>
</tr>
<tr>
<td><code>system.executable_prefix</code></td>
<td>This is initialized to the base directory the current executable has been loaded from.</td>
</tr>
</tbody>
</table>

---

**The `HPX` configuration section**

```
[hpx]
location = ${HPX_LOCATION:$[system.prefix]}
component_path = ${hpx.location}/lib/hpx:${system.executable_prefix}/lib/hpx:${system.executable_prefix}../lib/hpx
master_ini_path = ${hpx.location}/share/hpx-<version>:${system.executable_prefix}/share/hpx-<version>:

<tr>
<td>hpx. trace_depth</td>
<td>This setting defines the number of stack-levels printed in generated stack backtraces. This defaults to 20, but can be changed using the cmake HPX_WITH_THREAD_BACKTRACE_DEPTH configuration option.</td>
</tr>
</tbody>
</table>
The `hpx.threadpools` configuration section

```plaintext
[hpx.threadpools]
io_pool_size = ${HPX_NUM_IO_POOL_SIZE:2}
parcel_pool_size = ${HPX_NUM_PARCEL_POOL_SIZE:2}
timer_pool_size = ${HPX_NUM_TIMER_POOL_SIZE:2}
```

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hpx.threadpools.io_pool_size</td>
<td>The value of this property defines the number of OS threads created for the internal I/O thread pool.</td>
</tr>
<tr>
<td>hpx.threadpools.parcel_pool_size</td>
<td>The value of this property defines the number of OS threads created for the internal parcel thread pool.</td>
</tr>
<tr>
<td>hpx.threadpools.timer_pool_size</td>
<td>The value of this property defines the number of OS threads created for the internal timer thread pool.</td>
</tr>
</tbody>
</table>

The `hpx.thread_queue` configuration section

**Important:** These are the setting control internal values used by the thread scheduling queues in the HPX scheduler. You should not modify these settings unless you know exactly what you are doing.

```plaintext
[hpx.thread_queue]
min_tasks_to_steal_pending = ${HPX_THREAD_QUEUE_MIN_TASKS_TO_STEAL_PENDING:0}
min_tasks_to_steal_staged = ${HPX_THREAD_QUEUE_MIN_TASKS_TO_STEAL_STAGED:0}
min_add_new_count = ${HPX_THREAD_QUEUE_MIN_ADD_NEW_COUNT:10}
max_add_new_count = ${HPX_THREAD_QUEUE_MAX_ADD_NEW_COUNT:10}
max_delete_count = ${HPX_THREAD_QUEUE_MAX_DELETE_COUNT:1000}
```

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hpx.thread_queue.min_tasks_to_steal_pending</td>
<td>The value of this property defines the number of pending HPX threads that have to be available before neighboring cores are allowed to steal work. The default is to allow stealing always.</td>
</tr>
<tr>
<td>hpx.thread_queue.min_tasks_to_steal_staged</td>
<td>The value of this property defines the number of staged HPX tasks that need to be available before neighboring cores are allowed to steal work. The default is to allow stealing always.</td>
</tr>
<tr>
<td>hpx.thread_queue.min_add_new_count</td>
<td>The value of this property defines the minimal number of tasks to be converted into HPX threads whenever the thread queues for a core have run empty.</td>
</tr>
<tr>
<td>hpx.thread_queue.max_add_new_count</td>
<td>The value of this property defines the maximal number of tasks to be converted into HPX threads whenever the thread queues for a core have run empty.</td>
</tr>
<tr>
<td>hpx.thread_queue.max_delete_count</td>
<td>The value of this property defines the number of terminated HPX threads to discard during each invocation of the corresponding function.</td>
</tr>
</tbody>
</table>
The **hpx.components** configuration section

```
[hpx.components]
load_external = ${HPX_LOAD_EXTERNAL_COMPONENTS:1}
```

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hpx.components.load_external</td>
<td>This entry defines whether external components will be loaded on this <em>locality</em>. This entry is normally set to 1, and usually there is no need to directly change this value. It is automatically set to 0 for a dedicated AGAS server <em>locality</em>.</td>
</tr>
</tbody>
</table>

Additionally, the section **hpx.components** will be populated with the information gathered from all found components. The information loaded for each of the components will contain at least the following properties:

```
[hpx.components.<component_instance_name>]
name = <component_name>
path = <full_path_of_the_component_module>
enabled = ${[hpx.components.load_external]}
```

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hpx.components.&lt;component_instance_name&gt;.name</td>
<td>This is the name of a component, usually the same as the second argument to the macro used registering the component with <em>HPX_REGISTER_COMPONENT</em>. Set by the component factory.</td>
</tr>
<tr>
<td>hpx.components.&lt;component_instance_name&gt;.path</td>
<td>This is either the full path file name of the component module or the directory the component module is located in. In this case, the component module name will be derived from the property hpx.components.&lt;component_instance_name&gt;.name. Set by the component factory.</td>
</tr>
<tr>
<td>hpx.components.&lt;component_instance_name&gt;.enabled</td>
<td>This setting explicitly enables or disables the component. This is an optional property. <em>HPX</em> assumes that the component is enabled if it is not defined.</td>
</tr>
</tbody>
</table>

The value for `<component_instance_name>` is usually the same as for the corresponding name property. However, generally it can be defined to any arbitrary instance name. It is used to distinguish between different ini sections, one for each component.

The **hpx.parcel** configuration section

<td>hpx.agas.port</td>
<td>This property defines the default IP port to be used for the AGAS root server. This IP port will be used as long as no other values are specified (for instance, using the --hpx:agas command line option). The default depends on the compile time preprocessor constant HPX_INITIAL_IP_PORT (7009).</td>
</tr>
<tr>
<td>hpx.agas.service_mode</td>
<td>This property specifies what type of AGAS service is running on this locality. Currently, two modes exist. The locality that acts as the AGAS server runs in bootstrap mode. All other localities are in hosted mode.</td>
</tr>
<tr>
<td>hpx.agas.dedicated_server</td>
<td>This property specifies whether the AGAS server is exclusively running AGAS services and not hosting any application components. It is a boolean value. Set to 1 if --hpx:run-agas-server-only is present.</td>
</tr>
<tr>
<td>hpx.agas.max_pending_refcnt_requests</td>
<td>This property defines the number of reference counting requests (increments or decrements) to buffer. The default depends on the compile time preprocessor constant HPX_AGAS_MAX_PENDING_REFCNT_REQUESTS (4096).</td>
</tr>
<tr>
<td>hpx.agas.use_caching</td>
<td>This property specifies whether a software address translation cache is used. It is a boolean value. Defaults to 1.</td>
</tr>
<tr>
<td>hpx.agas.use_range_caching</td>
<td>This property specifies whether range-based caching is used by the software address translation cache. This property is ignored if hpx.agas.use_caching is false. It is a boolean value. Defaults to 1.</td>
</tr>
<tr>
<td>hpx.agas.local_cache_size</td>
<td>This property defines the size of the software address translation cache for AGAS services. This property is ignored if hpx.agas.use_caching is false. Note that if hpx.agas.use_range_caching is true, this size will refer to the maximum number of ranges stored in the cache, not the number of entries spanned by the cache. The default depends on the compile time preprocessor constant HPX_AGAS_LOCAL_CACHE_SIZE (4096).</td>
</tr>
</tbody>
</table>
The **hpx.commandline** configuration section

The following table lists the definition of all pre-defined command line option shortcuts. For more information about command line options, see the section *HPX Command Line Options*.

```yaml
[hpX.commandline]
aliasing = ${HPX_COMMANDLINE_ALIASING:1}
allow_unknown = ${HPX_COMMANDLINE_ALLOW_UNKNOWN:0}

[hpX.commandline.aliases]
-a = --hpx:agas
-c = --hpx:console
-h = --hpx:help
-I = --hpx:ini
-l = --hpx:localities
-p = --hpx:app-config
-q = --hpx:queueing
-r = --hpx:run-agas-server
-t = --hpx:threads
-v = --hpx:version
-w = --hpx:worker
-x = --hpx:hpx
-0 = --hpx:node=0
-1 = --hpx:node=1
-2 = --hpx:node=2
-3 = --hpx:node=3
-4 = --hpx:node=4
-5 = --hpx:node=5
-6 = --hpx:node=6
-7 = --hpx:node=7
-8 = --hpx:node=8
-9 = --hpx:node=9
```

**Note:** The short options listed above are disabled by default if the application is built using `#include <hpx/hpx_main.hpp>`. See *Re-use the main() function as the main HPX entry point* for more information. The rationale behind this is that in this case the user’s application may handle its own command line options, since *HPX* passes all unknown options to `main()`. Short options like `-t` are prone to create ambiguities regarding what the application will support. Hence, the user should instead rely on the corresponding long options like `--hpx:threads` in such a case.

</tbody>
</table>
Loading INI files

During startup and after the internal database has been initialized as described in the section *Built-in default configuration settings*, HPX will try to locate and load additional ini files to be used as a source for configuration properties. This allows for a wide spectrum of additional customization possibilities by the user and system administrators. The sequence of locations where HPX will try loading the ini files is well defined and documented in this section. All ini files found are merged into the internal configuration database. The merge operation itself conforms to the rules as described in the section *The HPX ini file format*.

1. Load all component shared libraries found in the directories specified by the property `hpx.component_path` and retrieve their default configuration information (see section *Loading components* for more details). This property can refer to a list of directories separated by `:` (Linux, Android, and MacOS) or by `;` (Windows).

2. Load all files named `hpx.ini` in the directories referenced by the property `hpx.master_ini_path` This property can refer to a list of directories separated by `:` (Linux, Android, and MacOS) or by `;` (Windows).

3. Load a file named `.hpx.ini` in the current working directory, e.g., the directory the application was invoked from.

4. Load a file referenced by the environment variable `HPX_INI`. This variable is expected to provide the full path name of the ini configuration file (if any).

5. Load a file named `/etc/hpx.ini`. This lookup is done on non-Windows systems only.

6. Load a file named `.hpx.ini` in the home directory of the current user, e.g., the directory referenced by the environment variable `HOME`.

7. Load a file named `.hpx.ini` in the directory referenced by the environment variable `PWD`.

8. Load the file specified on the command line using the option `--hpx:config`.

9. Load all properties specified on the command line using the option `--hpx:ini`. The properties will be added to the database in the same sequence as they are specified on the command line. The format for those options is, for instance, `--hpx:ini=hpx.default_stack_size=0x40000`. In addition to the explicit command line options, this will set the following properties as implied from other settings:
   - `hpx.parcel.address` and `hpx.parcel.port` as set by `--hpx:hpax`
   - `hpx.agas.address`, `hpx.agas.port` and `hpx.agas.service_mode` as set by `--hpx:agas`
   - `hpx.program_name` and `hpx.cmd_line` will be derived from the actual command line
   - `hpx.os_threads` and `hpx.localities` as set by `--hpx:threads` and `--hpx:localities`
   - `hpx.runtime_mode` will be derived from any explicit `--hpx:console`, `--hpx:worker`, or `--hpx:connect`, or it will be derived from other settings, such as `--hpx:node=0`, which implies `--hpx:console`.

10. Load files based on the pattern `*.ini` in all directories listed by the property `hpx.ini_path`. All files found during this search will be merged. The property `hpx.ini_path` can hold a list of directories separated by `:` (on Linux or Mac) or `;` (on Windows).

11. Load the file specified on the command line using the option `--hpx:app-config`. Note that this file will be merged as the content for a top level section `[application]`.

**Note:** Any changes made to the configuration database caused by one of the steps will influence the loading process for all subsequent steps. For instance, if one of the ini files loaded changes the property `hpx.ini_path`, this will influence the directories searched in step 9 as described above.
Important: The **HPX** core library will verify that all configuration settings specified on the command line (using the ```--hpx:ini``` option) will be checked for validity. That means that the library will accept only known configuration settings. This is to protect the user from unintentional typos while specifying those settings. This behavior can be overwritten by appending a `!' to the configuration key, thus forcing the setting to be entered into the configuration database. For instance: ```--hpx:ini=hp.x.foo! = 1``` 

If any of the environment variables or files listed above are not found, the corresponding loading step will be silently skipped.

**Loading components**

**HPX** relies on loading application specific components during the runtime of an application. Moreover, **HPX** comes with a set of preinstalled components supporting basic functionalities useful for almost every application. Any component in **HPX** is loaded from a shared library, where any of the shared libraries can contain more than one component type. During startup, **HPX** tries to locate all available components (e.g., their corresponding shared libraries) and creates an internal component registry for later use. This section describes the algorithm used by **HPX** to locate all relevant shared libraries on a system. As described, this algorithm is customizable by the configuration properties loaded from the ini files (see section **Loading INI files**).

Loading components is a two-stage process. First **HPX** tries to locate all component shared libraries, loads those, and generates a default configuration section in the internal configuration database for each component found. For each found component the following information is generated:

```
[hp.x.components.<component_instance_name>]
name = <name_of_shared_library>
path = $[component_path]
enabled = $[hp.x.components.load_external]
default = 1
```

The values in this section correspond to the expected configuration information for a component as described in the section **Built-in default configuration settings**.

In order to locate component shared libraries, **HPX** will try loading all shared libraries (files with the platform specific extension of a shared library, Linux: `*.so`, Windows: `*.dll`, MacOS: `*.dylib` found in the directory referenced by the ini property **hp.x.component_path**).

This first step corresponds to step 1) during the process of filling the internal configuration database with default information as described in section **Loading INI files**.

After all of the configuration information has been loaded, **HPX** performs the second step in terms of loading components. During this step, **HPX** scans all existing configuration sections ```[hp.x.component.<component_instance_name>]``` and instantiates a special factory object for each of the successfully located and loaded components. During the application’s life time, these factory objects are responsible for creating new and discarding old instances of the component they are associated with. This step is performed after step 11) of the process of filling the internal configuration database with default information as described in section **Loading INI files**.
Application specific component example

This section assumes there is a simple application component that exposes one member function as a component action. The header file `app_server.hpp` declares the C++ type to be exposed as a component. This type has a member function `print_greeting()`, which is exposed as an action `print_greeting_action`. We assume the source files for this example are located in a directory referenced by `$APP_ROOT`:

```cpp
// file: $APP_ROOT/app_server.hpp
#include <hpx/hpx.hpp>
#include <hpx/include/iostreams.hpp>

namespace app
{
  // Define a simple component exposing one action 'print_greeting'
  class HPX_COMPONENT_EXPORT server
  :
    public hpx::components::component_base<server>
  {
    void print_greeting ()
    {
      hpx::cout << "Hey, how are you?\n" << std::flush;
    }

    // Component actions need to be declared, this also defines the
    // type 'print_greeting_action' representing the action.
    HPX_DEFINE_COMPONENT_ACTION(server, print_greeting, print_greeting_action);
  }
}

// Declare boilerplate code required for each of the component actions.
HPX_REGISTER_ACTION_DECLARATION(app::server::print_greeting_action);
```

The corresponding source file contains mainly macro invocations that define the boilerplate code needed for HPX to function properly:

```cpp
// file: $APP_ROOT/app_server.cpp
#include "app_server.hpp"

// Define boilerplate required once per component module.
HPX_REGISTER_COMPONENT_MODULE();

// Define factory object associated with our component of type 'app::server'.
HPX_REGISTER_COMPONENT(app::server, app_server);

// Define boilerplate code required for each of the component actions. Use the
// same argument as used for HPX_REGISTER_ACTION_DECLARATION above.
HPX_REGISTER_ACTION(app::server::print_greeting_action);
```

The following gives an example of how the component can be used. Here, one instance of the `app::server` component is created on the current `locality` and the exposed action `print_greeting_action` is invoked using the global id of the newly created instance. Note that no special code is required to delete the component instance after it is not needed anymore. It will be deleted automatically when its last reference goes out of scope (shown in the example below at the closing brace of the block surrounding the code):
// file: $APP_ROOT/use_app_server_example.cpp
#include <hpx/hpx_init.hpp>
#include "app_server.hpp"

int hpx_main()
{
{
    // Create an instance of the app_server component on the current locality.
    hpx::naming:id_type app_server_instance =
        hpx::create_component<app::server>(hpx::find_here());

    // Create an instance of the action 'print_greeting_action'.
    app::server::print_greeting_action print_greeting;

    // Invoke the action 'print_greeting' on the newly created component.
    print_greeting(app_server_instance);
}
    return hpx::finalize();
}

int main(int argc, char* argv[])
{
    return hpx::init(argc, argv);
}

In order to make sure that the application will be able to use the component `app::server`, special configuration information must be passed to HPX. The simplest way to allow HPX to ‘find’ the component is to provide special ini configuration files that add the necessary information to the internal configuration database. The component should have a special ini file containing the information specific to the component `app_server`.

# file: $APP_ROOT/app_server.ini
[hpx.components.app_server]
name = app_server
path = $APP_LOCATION/

Here, $APP_LOCATION is the directory where the (binary) component shared library is located. HPX will attempt to load the shared library from there. The section name `hpx.components.app_server` reflects the instance name of the component (`app_server` is an arbitrary, but unique name). The property value for `hpx.components.app_server.name` should be the same as used for the second argument to the macro `HPX_REGISTER_COMPONENT` above.

Additionally, a file `.hpx.ini`, which could be located in the current working directory (see step 3 as described in the section Loading INI files), can be used to add to the ini search path for components:

# file: $PWD/.hpx.ini
[hpx]
ini_path = $[hpx.ini_path]:$APP_ROOT/

This assumes that the above ini file specific to the component is located in the directory $APP_ROOT.

Note: It is possible to reference the defined property from inside its value. HPX will gracefully use the previous value of `hpx.ini_path` for the reference on the right hand side and assign the overall (now expanded) value to the property.
Logging

HPX uses a sophisticated logging framework, allowing users to follow in detail what operations have been performed inside the HPX library in what sequence. This information proves to be very useful for diagnosing problems or just for improving the understanding of what is happening in HPX as a consequence of invoking HPX API functionality.

Default logging

Enabling default logging is a simple process. The detailed description in the remainder of this section explains different ways to customize the defaults. Default logging can be enabled by using one of the following:

- A command line switch `--hpx:debug-hpx-log`, which will enable logging to the console terminal.
- The command line switch `--hpx:debug-hpx-log=<filename>`, which enables logging to a given file `<filename>`.
- Setting an environment variable `HPX_LOGLEVEL=<loglevel>` while running the HPX application. In this case `<loglevel>` should be a number between (or equal to) 1 and 5 where 1 means minimal logging and 5 causes all available messages to be logged. When setting the environment variable, the logs will be written to a file named `hpx.<PID>.log` in the current working directory, where `<PID>` is the process id of the console instance of the application.

Customizing logging

Generally, logging can be customized either using environment variable settings or using by an ini configuration file. Logging is generated in several categories, each of which can be customized independently. All customizable configuration parameters have reasonable defaults, allowing for the use of logging without any additional configuration effort. The following table lists the available categories.

<table>
<thead>
<tr>
<th>Category</th>
<th>Category shortcut</th>
<th>Information to be generated</th>
<th>Environment variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>General</td>
<td>None</td>
<td>Logging information generated by different subsystems of HPX, such as thread-manager, parcel layer, LCOs, etc.</td>
<td>HPX_LOGLEVEL</td>
</tr>
<tr>
<td>AGAS</td>
<td>AGAS</td>
<td>Logging output generated by the AGAS subsystem</td>
<td>HPX_AGAS_LOGLEVEL</td>
</tr>
<tr>
<td>Application</td>
<td>APP</td>
<td>Logging generated by applications.</td>
<td>HPX_APP_LOGLEVEL</td>
</tr>
</tbody>
</table>

By default, all logging output is redirected to the console instance of an application, where it is collected and written to a file, one file for each logging category.

Each logging category can be customized at two levels. The parameters for each are stored in the ini configuration sections `hpx.logging.CATEGORY` and `hpx.logging.console.CATEGORY` (where CATEGORY is the category shortcut as listed in the table above). The former influences logging at the source locality and the latter modifies the logging behaviour for each of the categories at the console instance of an application.
Levels

All HPX logging output has seven different logging levels. These levels can be set explicitly or through environment variables in the main HPX ini file as shown below. The logging levels and their associated integral values are shown in the table below, ordered from most verbose to least verbose. By default, all HPX logs are set to 0, e.g., all logging output is disabled by default.

<table>
<thead>
<tr>
<th>Logging level</th>
<th>Integral value</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;debug&gt;</td>
<td>5</td>
</tr>
<tr>
<td>&lt;info&gt;</td>
<td>4</td>
</tr>
<tr>
<td>&lt;warning&gt;</td>
<td>3</td>
</tr>
<tr>
<td>&lt;error&gt;</td>
<td>2</td>
</tr>
<tr>
<td>&lt;fatal&gt;</td>
<td>1</td>
</tr>
<tr>
<td>No logging</td>
<td>0</td>
</tr>
</tbody>
</table>

Tip: The easiest way to enable logging output is to set the environment variable corresponding to the logging category to an integral value as described in the table above. For instance, setting HPX_LOGLEVEL=5 will enable full logging output for the general category. Please note that the syntax and means of setting environment variables varies between operating systems.

Configuration

Logs will be saved to destinations as configured by the user. By default, logging output is saved on the console instance of an application to hpx.<CATEGORY>.<PID>.log (where CATEGORY and PID are placeholders for the category shortcut and the OS process id). The output for the general logging category is saved to hpx.<PID>.log. The default settings for the general logging category are shown here (the syntax is described in the section The HPX ini file format):

```
[hpx.logging]
level = ${HPX_LOGLEVEL:0}
destination = ${HPX_LOGDESTINATION:console}
format = ${HPX_LOGFORMAT:(T%locality%/%hpxthread%.%hpxphase%/%hpxcomponent%) P%parentloc ...
˓
android_log
```

The logging level is taken from the environment variable HPX_LOGLEVEL and defaults to zero, e.g., no logging. The default logging destination is read from the environment variable HPX_LOGDESTINATION. On any of the localities it defaults to console, which redirects all generated logging output to the console instance of an application. The following table lists the possible destinations for any logging output. It is possible to specify more than one destination separated by whitespace.

<table>
<thead>
<tr>
<th>Logging destination</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file(&lt;filename&gt;)</td>
<td>Directs all output to a file with the given &lt;filename&gt;.</td>
</tr>
<tr>
<td>cout</td>
<td>Directs all output to the local standard output of the application instance on this locality.</td>
</tr>
<tr>
<td>cerr</td>
<td>Directs all output to the local standard error output of the application instance on this locality.</td>
</tr>
<tr>
<td>console</td>
<td>Directs all output to the console instance of the application. The console instance has its logging destinations configured separately.</td>
</tr>
<tr>
<td>android_log</td>
<td>Directs all output to the (Android) system log (available on Android systems only).</td>
</tr>
</tbody>
</table>
The logging format is read from the environment variable `HPX_LOGFORMAT`, and it defaults to a complex format description. This format consists of several placeholder fields (for instance `%locality%`), which will be replaced by concrete values when the logging output is generated. All other information is transferred verbatim to the output. The table below describes the available field placeholders. The separator character `|` separates the logging message prefix formatted as shown and the actual log message which will replace the separator.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>locality</code></td>
<td>The id of the <code>locality</code> on which the logging message was generated.</td>
</tr>
<tr>
<td><code>hpxthread</code></td>
<td>The id of the <code>HPX</code> thread generating this logging output.</td>
</tr>
<tr>
<td><code>hpxphase</code></td>
<td>The phase of the <code>HPX</code> thread generating this logging output.</td>
</tr>
<tr>
<td><code>hpxcomponent</code></td>
<td>The local virtual address of the component which the current <code>HPX</code> thread is accessing.</td>
</tr>
<tr>
<td><code>parentloc</code></td>
<td>The id of the <code>locality</code> where the <code>HPX</code> thread was running that initiated the current <code>HPX</code> thread. The current <code>HPX</code> thread is generating this logging output.</td>
</tr>
<tr>
<td><code>hpxparent</code></td>
<td>The id of the <code>HPX</code> thread that initiated the current <code>HPX</code> thread. The current <code>HPX</code> thread is generating this logging output.</td>
</tr>
<tr>
<td><code>hpxparentphase</code></td>
<td>The phase of the <code>HPX</code> thread when it initiated the current <code>HPX</code> thread. The current <code>HPX</code> thread is generating this logging output.</td>
</tr>
<tr>
<td><code>time</code></td>
<td>The time stamp for this logging output line as generated by the source <code>locality</code>.</td>
</tr>
<tr>
<td><code>idx</code></td>
<td>The sequence number of the logging output line as generated on the source <code>locality</code>.</td>
</tr>
<tr>
<td><code>osthread</code></td>
<td>The sequence number of the OS thread that executes the current <code>HPX</code> thread.</td>
</tr>
</tbody>
</table>

**Note:** Not all of the field placeholder may be expanded for all generated logging output. If no value is available for a particular field, it is replaced with a sequence of `-' characters.

Here is an example line from a logging output generated by one of the `HPX` examples (please note that this is generated on a single line, without a line break):

```
(T00000000/00000000002d46f90.01/00000000009ebc10) P--------/0000000002d46f80.02 17:49.37.
→ 320 [000000000000004d] <info> [RT] successfully created component {0000000100ff0001, 0000000000030002} of type: component_barrier[7(3)]
```

The default settings for the general logging category on the console is shown here:

```
[hpX.logging.console]
level = ${HPX_LOGLEVEL:=${hpX.logging.level}}
destination = ${HPX_CONSOLE_LOGDESTINATION:file(hpX.[system.pid].log)}
format = ${HPX_CONSOLE_LOGFORMAT:|}
```

These settings define how the logging is customized once the logging output is received by the console instance of an application. The logging level is read from the environment variable `HPX_LOGLEVEL` (as set for the console instance of the application). The level defaults to the same values as the corresponding settings in the general logging configuration shown before. The destination on the console instance is set to be a file that’s name is generated based on its OS process id. Setting the environment variable `HPX_CONSOLE_LOGDESTINATION` allows customization of the naming scheme for the output file. The logging format is set to leave the original logging output unchanged, as received from one of the localities the application runs on.

---

43 The phase of a `HPX`-thread counts how often this thread has been activated.
HPX Command Line Options

The predefined command line options for any application using `hpx::init` are described in the following subsections.

**HPX options (allowed on command line only)**

--hpx:help
Print out program usage (default: this message). Possible values: full (additionally prints options from components).

--hpx:version
Print out HPX version and copyright information.

--hpx:info
Print out HPX configuration information.

--hpx:options-file arg
Specify a file containing command line options (alternatively: @filepath).

**HPX options (additionally allowed in an options file)**

--hpx:worker
Run this instance in worker mode.

--hpx:console
Run this instance in console mode.

--hpx:connect
Run this instance in worker mode, but connecting late.

--hpx:run-agas-server
Run AGAS server as part of this runtime instance.

--hpx:run-hpx-main
Run the hpx_main function, regardless of locality mode.

--hpx:hpx arg
The IP address the HPX parcelport is listening on, expected format: address:port (default: 127.0.0.1:7910).

--hpx:agas arg
The IP address the AGAS root server is running on, expected format: address:port (default: 127.0.0.1:7910).

--hpx:run-agas-server-only
Run only the AGAS server.

--hpx:nodefile arg
The file name of a node file to use (list of nodes, one node name per line and core).

--hpx:nodes arg
The (space separated) list of the nodes to use (usually this is extracted from a node file).

--hpx:endnodes
This can be used to end the list of nodes specified using the option --hpx:nodes.
--hpx:ifsuffix arg
Suffix to append to host names in order to resolve them to the proper network interconnect.

--hpx:ifprefix arg
Prefix to prepend to host names in order to resolve them to the proper network interconnect.

--hpx:iftransform arg
Sed-style search and replace (s/search/replace/) used to transform host names to the proper network interconnect.

--hpx:force_ipv4
Network hostnames will be resolved to ipv4 addresses instead of using the first resolved endpoint. This is especially useful on Windows where the local hostname will resolve to an ipv6 address while remote network hostnames are commonly resolved to ipv4 addresses.

--hpx:localities arg
The number of localities to wait for at application startup (default: 1).

--hpx:node arg
Number of the node this locality is run on (must be unique).

--hpx:ignore-batch-env
Ignore batch environment variables.

--hpx:expect-connecting-localities
This locality expects other localities to dynamically connect (this is implied if the number of initial localities is larger than 1).

--hpx:pu-offset
The first processing unit this instance of HPX should be run on (default: 0).

--hpx:pu-step
The step between used processing unit numbers for this instance of HPX (default: 1).

--hpx:threads arg
The number of operating system threads to spawn for this HPX locality. Possible values are: numeric values 1, 2, 3 and so on, all (which spawns one thread per processing unit, includes hyperthreads), or cores (which spawns one thread per core) (default: cores).

--hpx:cores arg
The number of cores to utilize for this HPX locality (default: all, i.e., the number of cores is based on the number of threads --hpx:threads assuming --hpx:bind=compact.

--hpx:affinity arg
The affinity domain the OS threads will be confined to, possible values: pu, core, numa, machine (default: pu).

--hpx:bind arg
The detailed affinity description for the OS threads, see More details about HPX command line options for a detailed description of possible values. Do not use with --hpx:pu-step, --hpx:pu-offset or --hpx:affinity options. Implies --hpx:numa-sensitive (--hpx:bind=none) disables defining thread affinities.

--hpx:use-process-mask
Use the process mask to restrict available hardware resources (implies --hpx:ignore-batch-env).

--hpx:print-bind
Print to the console the bit masks calculated from the arguments specified to all --hpx:bind options.
--hpx:queuing arg

--hpx:high-priority-threads arg
   The number of operating system threads maintaining a high priority queue (default: number of OS threads), valid for --hpx:queuing=abp-priority, --hpx:queuing=static-priority and --hpx:queuing=local-priority only.

--hpx:numa-sensitive
   Makes the scheduler NUMA sensitive.

HPX configuration options

--hpx:app-config arg
   Load the specified application configuration (ini) file.

--hpx:config arg
   Load the specified HPX configuration (ini) file.

--hpx:ini arg
   Add a configuration definition to the default runtime configuration.

--hpx:exit
   Exit after configuring the runtime.

HPX debugging options

--hpx:list-symbolic-names
   List all registered symbolic names after startup.

--hpx:list-component-types
   List all dynamic component types after startup.

--hpx:dump-config-initial
   Print the initial runtime configuration.

--hpx:dump-config
   Print the final runtime configuration.

--hpx:debug-hpx-log [arg]
   Enable all messages on the HPX log channel and send all HPX logs to the target destination (default: cout).

--hpx:debug-agas-log [arg]
   Enable all messages on the AGAS log channel and send all AGAS logs to the target destination (default: cout).

--hpx:debug-parcel-log [arg]
   Enable all messages on the parcel transport log channel and send all parcel transport logs to the target destination (default: cout).

--hpx:debug-timing-log [arg]
   Enable all messages on the timing log channel and send all timing logs to the target destination (default: cout).
--hpx:debug-app-log [arg]
Enable all messages on the application log channel and send all application logs to the target destination (default: cout).

--hpx:debug-clp
Debug command line processing.

--hpx:attach-debugger arg
Wait for a debugger to be attached, possible arg values: startup or exception (default: startup)

**HPX options related to performance counters**

--hpx:print-counter
Print the specified performance counter either repeatedly and/or at the times specified by --hpx:print-counter-at (see also option --hpx:print-counter-interval).

--hpx:print-counter-reset
Print the specified performance counter either repeatedly and/or at the times specified by --hpx:print-counter-at. Reset the counter after the value is queried (see also option --hpx:print-counter-interval).

--hpx:print-counter-interval
Print the performance counter(s) specified with --hpx:print-counter repeatedly after the time interval (specified in milliseconds), (default: 0, which means print once at shutdown).

--hpx:print-counter-destination
Print the performance counter(s) specified with --hpx:print-counter to the given file (default: console).

--hpx:list-counters
List the names of all registered performance counters, possible values: minimal (prints counter name skeletons), full (prints all available counter names).

--hpx:list-counter-infos
List the description of all registered performance counters, possible values: minimal (prints info for counter name skeletons), full (prints all available counter infos).

--hpx:print-counter-format
Print the performance counter(s) specified with --hpx:print-counter. Possible formats in CSV include a format with a header or without any header (see option --hpx:no-csv-header). Possible values: csv (prints counter values in CSV format with full names as header), csv-short (prints counter values in CSV format with short names provided with --hpx:print-counter as --hpx:print-counter shortname), full-countername.

--hpx:no-csv-header
Print the performance counter(s) specified with --hpx:print-counter and csv or csv-short format specified with --hpx:print-counter-format without header.

--hpx:print-counter-at arg
Print the performance counter(s) specified with --hpx:print-counter (or --hpx:print-counter-reset) at the given point in time, possible argument values: startup, shutdown (default), noshutdown.

--hpx:reset-counters
Reset all performance counter(s) specified with --hpx:print-counter after they have been evaluated.
--hpx:print-counters-locally
Each locality prints only its own local counters. If this is used with --hpx:print-counter-destination=<file>, the code will append a ".<locality_id>" to the file name in order to avoid clashes between localities.

Command line argument shortcuts

Additionally, the following shortcuts are available from every HPX application.

<table>
<thead>
<tr>
<th>Shortcut option</th>
<th>Equivalent long option</th>
</tr>
</thead>
<tbody>
<tr>
<td>-a</td>
<td>--hpx:agas</td>
</tr>
<tr>
<td>-c</td>

</tr>
</tbody>
</table>

Note: The short options listed above are disabled by default if the application is built using #include <hpx/hpx_main.hpp>. See Re-use the main() function as the main HPX entry point for more information. The rationale behind this is that in this case the user’s application may handle its own command line options, since HPX passes all unknown options to main(). Short options like -t are prone to create ambiguities regarding what the application will support. Hence, the user should instead rely on the corresponding long options like --hpx:threads in such a case.

It is possible to define your own shortcut options. In fact, all of the shortcuts listed above are pre-defined using the technique described here. Also, it is possible to redefine any of the pre-defined shortcuts to expand differently as well.

Shortcut options are obtained from the internal configuration database. They are stored as key-value properties in a special properties section named hpx.commandline. You can define your own shortcuts by adding the corresponding definitions to one of the ini configuration files as described in the section Configuring HPX applications. For instance, in order to define a command line shortcut --p, which should expand to -hpx:print-counter, the following configuration information needs to be added to one of the ini configuration files:
---pc = --hpx:print-counter

Note: Any arguments for shortcut options passed on the command line are retained and passed as arguments to the corresponding expanded option. For instance, given the definition above, the command line option:

--pc=/threads{locality#0/total}/count/cumulative

would be expanded to:

--hpx:print-counter=/threads{locality#0/total}/count/cumulative

Important: Any shortcut option should either start with a single '-' or with two '--' characters. Shortcuts starting with a single '-' are interpreted as short options (i.e., everything after the first character following the '-' is treated as the argument). Shortcuts starting with '--' are interpreted as long options. No other shortcut formats are supported.

Specifying options for single localities only

For runs involving more than one locality, it is sometimes desirable to supply specific command line options to single localities only. When the HPX application is launched using a scheduler (like PBS; for more details see section How to use HPX applications with PBS), specifying dedicated command line options for single localities may be desirable.

For this reason all of the command line options that have the general format --hpx:<some_key> can be used in a more general form: --hpx:<N>:<some_key>, where <N> is the number of the locality this command line option will be applied to; all other localities will simply ignore the option. For instance, the following PBS script passes the option --hpx:pu-offset=4 to the locality '1' only.

```
#!/bin/bash
#
#PBS -l nodes=2:ppn=4

APP_PATH=~/packages/hpx/bin/hello_world_distributed
APP_OPTIONS=

pbsdsh -u $APP_PATH $APP_OPTIONS --hpx:1:pu-offset=4 --hpx:nodes=`cat $PBS_NODEFILE`
```

Caution: If the first application specific argument (inside $APP_OPTIONS) is a non-option (i.e., does not start with a - or a --), then it must be placed before the option --hpx:nodes, which, in this case, should be the last option on the command line.

Alternatively, use the option --hpx:endnodes to explicitly mark the end of the list of node names:

```
$ pbsdsh -u $APP_PATH --hpx:1:pu-offset=4 --hpx:nodes=`cat $PBS_NODEFILE` --
   --hpx:endnodes $APP_OPTIONS
```
More details about *HPX* command line options

This section documents the following list of the command line options in more detail:

- *The command line option* --hpx:bind

**The command line option --hpx:bind**

This command line option allows one to specify the required affinity of the *HPX* worker threads to the underlying processing units. As a result the worker threads will run only on the processing units identified by the corresponding bind specification. The affinity settings are to be specified using `--hpx:bind=<BINDINGS>`, where `<BINDINGS>` have to be formatted as described below.

In addition to the syntax described below, one can use `--hpx:bind=none` to disable all binding of any threads to a particular core. This is mostly supported for debugging purposes.

The specified affinities refer to specific regions within a machine hardware topology. In order to understand the hardware topology of a particular machine, it may be useful to run the lstopo tool, which is part of Portable Hardware Locality (HWLOC), to see the reported topology tree. Seeing and understanding a topology tree will definitely help in understanding the concepts that are discussed below.

Affinities can be specified using hwloc tuples. Tuples of hwloc objects and associated indexes can be specified in the form `object:index, object:index-index or object:index,...,index`. Hwloc objects represent types of mapped items in a topology tree. Possible values for objects are socket, numanode, core and pu (processing unit). Indexes are non-negative integers that specify a unique physical object in a topology tree using its logical sequence number.

Chaining multiple tuples together in the more general form `object1:index1[.object2:index2[...]]` is permissible. While the first tuple’s object may appear anywhere in the topology, the Nth tuple’s object must have a shallower topology depth than the (N+1)th tuple’s object. Put simply: as you move right in a tuple chain, objects must go deeper in the topology tree. Indexes specified in chained tuples are relative to the scope of the parent object. For example, `socket:0.core:1` refers to the second core in the first socket (all indices are zero based).

Multiple affinities can be specified using several `--hpx:bind` command line options or by appending several affinities separated by a ';' . By default, if multiple affinities are specified, they are added.

"all" is a special affinity consisting in the entire current topology.

**Note:** All “names” in an affinity specification, such as thread, socket, numanode, pu or all, can be abbreviated. Thus, the affinity specification `threads:0-3=socket:0.core:1.pu:1` is fully equivalent to its shortened form `t:0-3=s:0.c:1.p:1`.

Here is a full grammar describing the possible format of mappings:

```
mappings ::= distribution | mapping (";" mapping)*
distribution ::= "compact" | "scatter" | "balanced" | "numa-balanced"
mapping ::= thread_spec "=" pu_specs
thread_spec ::= "thread:" range_specs
pu_specs ::= pu_spec ("." pu_spec)*
pu_spec ::= type ":" range_specs | "~" pu_spec
range_specs ::= range_spec ("," range_spec)*
range_spec ::= int | int "-" int | "all"
type ::= "socket" | "numanode" | "core" | "pu"
```
The following example assumes a system with at least 4 cores, where each core has more than 1 processing unit (hardware threads). Running `hello_world_distributed` with 4 OS threads (on 4 processing units), where each of those threads is bound to the first processing unit of each of the cores, can be achieved by invoking:

```
$ hello_world_distributed -t4 --hpx:bind=thread:0-3=core:0-3.pu:0
```

Here, `thread:0-3` specifies the OS threads used to define affinity bindings, and `core:0-3.pu:` defines that for each of the cores (`core:0-3`) only their first processing unit `pu:0` should be used.

**Note:** The command line option `--hpx:print-bind` can be used to print the bitmasks generated from the affinity mappings as specified with `--hpx:bind`. For instance, on a system with hyperthreading enabled (i.e. 2 processing units per core), the command line:

```
$ hello_world_distributed -t4 --hpx:bind=thread:0-3=core:0-3.pu:0 --hpx:print-bind
```

will cause this output to be printed:

```
0: PU L#0(P#0), Core L#0, Socket L#0, Node L#0(P#0)
1: PU L#2(P#2), Core L#1, Socket L#0, Node L#0(P#0)
2: PU L#4(P#4), Core L#2, Socket L#0, Node L#0(P#0)
3: PU L#6(P#6), Core L#3, Socket L#0, Node L#0(P#0)
```

where each bit in the bitmasks corresponds to a processing unit the listed worker thread will be bound to run on.

The difference between the four possible predefined distribution schemes (`compact`, `scatter`, `balanced` and `numa-balanced`) is best explained with an example. Imagine that we have a system with 4 cores and 4 hardware threads per core on 2 sockets. If we place 8 threads the assignments produced by the `compact`, `scatter`, `balanced` and `numa-balanced` types are shown in the figure below. Notice that `compact` does not fully utilize all the cores in the system. For this reason it is recommended that applications are run using the `scatter` or `balanced/numa-balanced` options in most cases.

In addition to the predefined distributions it is possible to restrict the resources used by HPX to the process CPU mask. The CPU mask is typically set by e.g. MPI\(^{42}\) and batch environments. Using the command line option `--hpx:use-process-mask` makes HPX act as if only the processing units in the CPU mask are available for use by HPX. The number of threads is automatically determined from the CPU mask. The number of threads can still be changed manually using this option, but only to a number less than or equal to the number of processing units in the CPU mask. The option `--hpx:print-bind` is useful in conjunction with `--hpx:use-process-mask` to make sure threads are placed as expected.

### 2.3.10 Writing single-node applications

Being a C++ Standard Library for Concurrency and Parallelism, HPX implements all of the corresponding facilities as defined by the C++ Standard but also those which are proposed as part of the ongoing C++ standardization process. This section focuses on the features available in HPX for parallel and concurrent computation on a single node, although many of the features presented here are also implemented to work in the distributed case.

\(^{42}\) [https://en.wikipedia.org/wiki/Message_Passing_Interface](https://en.wikipedia.org/wiki/Message_Passing_Interface)
Fig. 2.7: Schematic of thread affinity type distributions.
Synchronization objects

The following objects are providing synchronization for HPX applications:

1. **Barrier**
2. **Condition variable**
3. **Latch**
4. **Mutex**
5. **Shared mutex**
6. **Semaphore**
7. **Composable guards**

**Barrier**

*Barriers* are used for synchronizing multiple threads. They provide a synchronization point, where all threads must wait until they have all reached the barrier, before they can continue execution. This allows multiple threads to work together to solve a common task, and ensures that no thread starts working on the next task until all threads have completed the current task. This ensures that all threads are in the same state before performing any further operations, leading to a more consistent and accurate computation.

Unlike latches, barriers are reusable: once the participating threads are released from a barrier’s synchronization point, they can re-use the same barrier. It is thus useful for managing repeated tasks, or phases of a larger task, that are handled by multiple threads. The code below shows how barriers can be used to synchronize two threads:

```cpp
#include <hpx/barrier.hpp>
#include <hpx/future.hpp>
#include <hpx/init.hpp>
#include <iostream>

int hpx_main()
{
    hpx::barrier b(2);

    hpx::future<void> f1 = hpx::async([&b]()
    { std::cout << "Thread 1 started." " std::endl;
        // Do some computation
        b.arrive_and_wait();
        // Continue with next task
        std::cout << "Thread 1 finished." " std::endl;
    });

    hpx::future<void> f2 = hpx::async([&b]()
    { std::cout << "Thread 2 started." " std::endl;
        // Do some computation
        b.arrive_and_wait();
        // Continue with next task
        std::cout << "Thread 2 finished." " std::endl;
    });
}
```

(continues on next page)
f1.get();
f2.get();

return hpx::local::finalize();
}

int main(int argc, char* argv[])
{
    return hpx::local::init(hpx_main, argc, argv);
}

In this example, two hpx::future objects are created, each representing a separate thread of execution. The wait function of the hpx::barrier object is called by each thread. The threads will wait at the barrier until both have reached it. Once both threads have reached the barrier, they can continue with their next task.

### Condition variable

A condition variable is a synchronization primitive in HPX that allows a thread to wait for a specific condition to be satisfied before continuing execution. It is typically used in conjunction with a mutex or a lock to protect shared data that is being modified by multiple threads. Hence, it blocks one or more threads until another thread both modifies a shared variable (the condition) and notifies the condition_variable. The code below shows how two threads modifying the shared variable data can be synchronized using the condition_variable:

```cpp
#include <hpx/condition_variable.hpp>
#include <hpx/init.hpp>
#include <hpx/mutex.hpp>
#include <hpx/thread.hpp>
#include <iostream>
#include <string>

hpx::condition_variable cv;
hpx::mutex m;
std::string data;
bool ready = false;
bool processed = false;

void worker_thread()
{
    // Wait until the main thread signals that data is ready
    std::unique_lock<hpx::mutex> lk(m);
    cv.wait(lk, [] { return ready; });

    // Access the shared resource
    std::cout << "Worker thread: Processing data...\n";
data = "Test data after";

    // Send data back to the main thread
    processed = true;
    std::cout << "Worker thread: data processing is complete\n";
}
```

(continues on next page)
// Manual unlocking is done before notifying, to avoid waking up
// the waiting thread only to block again
lk.unlock();
cv.notify_one();
}

int hpx_main()
{
  hpx::thread worker(worker_thread);

  // Do some work
  std::cout << "Main thread: Preparing data...\n"
            << "Test data before";
  data = "Test data before";
  hpx::this_thread::sleep_for(std::chrono::seconds(1));
  std::cout << "Main thread: Data before processing = " << data << '\n';

  // Signal that data is ready and send data to worker thread
  {
    std::lock_guard<hpx::mutex> lk(m);
    ready = true;
    std::cout << "Main thread: Data is ready...\n";
  }
  cv.notify_one();

  // Wait for the worker thread to finish
  {
    std::unique_lock<hpx::mutex> lk(m);
    cv.wait(lk, [] { return processed; });
  }
  std::cout << "Main thread: Data after processing = " << data << '\n';
  worker.join();

  return hpx::local::finalize();
}

int main(int argc, char* argv[])
{
  return hpx::local::init(hpx_main, argc, argv);
}

The main thread of the code above starts by creating a worker thread and preparing the shared variable data. Once the data is ready, the main thread acquires a lock on the mutex m using std::lock_guard<hpx::mutex> lk(m) and sets the ready flag to true, then signals the worker thread to start processing by calling cv.notify_one(). The cv.wait() call in the main thread then blocks until the worker thread signals that processing is complete by setting the processed flag.

The worker thread starts by acquiring a lock on the mutex m to ensure exclusive access to the shared data. The cv.wait() call blocks the thread until the ready flag is set by the main thread. Once this is true, the worker thread accesses the shared data resource, processes it, and sets the processed flag to indicate completion. The mutex is then unlocked using lk.unlock() and the cv.notify_one() call signals the main thread to resume execution. Finally, the new data is printed by the main thread to the console.
Latch

A *latch* is a downward counter which can be used to synchronize threads. The value of the counter is initialized on creation. Threads may block on the latch until the counter is decremented to zero. There is no possibility to increase or reset the counter, which makes the latch a single-use barrier.

In *HPX*, a latch is implemented as a counting semaphore, which can be initialized with a specific count value and decremented each time a thread reaches the latch. When the count value reaches zero, all waiting threads are unblocked and allowed to continue execution. The code below shows how latch can be used to synchronize 16 threads:

```cpp
std::ptrdiff_t num_threads = 16;

void wait_for_latch(hpx::latch& l) {
    l.arrive_and_wait();
}

int hpx_main(hpx::program_options::variables_map& vm) {
    num_threads = vm["num-threads"].as<std::ptrdiff_t>();
    hpx::latch l(num_threads + 1);
    std::vector<hpx::future<void>> results;
    for (std::ptrdiff_t i = 0; i != num_threads; ++i)
        results.push_back(hpx::async(&wait_for_latch, std::ref(l)));

    // Wait for all threads to reach this point.
    l.arrive_and_wait();
    hpx::wait_all(results);

    return hpx::local::finalize();
}
```

In the above code, the *hpx_main* function creates a latch object *l* with a count of `num_threads + 1` and `num_threads` number of threads using `hpx::async`. These threads call the *wait_for_latch* function and pass the reference to the latch object. In the *wait_for_latch* function, the thread calls the *arrive_and_wait* method on the latch, which decrements the count of the latch and causes the thread to wait until the count reaches zero. Finally, the main thread waits for all the threads to arrive at the latch by calling the *arrive_and_wait* method and then waits for all the threads to finish by calling the *hpx::wait_all* method.
Mutex

A mutex (short for "mutual exclusion") is a synchronization primitive in HPX used to control access to a shared resource, ensuring that only one thread can access it at a time. A mutex is used to protect data structures from race conditions and other synchronization-related issues. When a thread acquires a mutex, other threads that try to access the same resource will be blocked until the mutex is released. The code below shows the basic use of mutexes:

```cpp
#include <hpx/future.hpp>
#include <hpx/init.hpp>
#include <hpx/mutex.hpp>
#include <iostream>

int hpx_main()
{
    hpx::mutex m;

    hpx::future<void> f1 = hpx::async([&m]()
    {
        std::scoped_lock sl(m);
        std::cout << "Thread 1 acquired the mutex" << std::endl;
    });

    hpx::future<void> f2 = hpx::async([&m]()
    {
        std::scoped_lock sl(m);
        std::cout << "Thread 2 acquired the mutex" << std::endl;
    });

    hpx::wait_all(f1, f2);

    return hpx::local::finalize();
}

int main(int argc, char* argv[])
{
    return hpx::local::init(hpx_main, argc, argv);
}
```

In this example, two HPX threads created using hpx::async are acquiring a hpx::mutex m. std::scoped_lock sl(m) is used to take ownership of the given mutex m. When control leaves the scope in which the scoped_lock object was created, the scoped_lock is destructed and the mutex is released.

**Attention:** A common way to acquire and release mutexes is by using the function m.lock() before accessing the shared resource, and m.unlock() called after the access is complete. However, these functions may lead to deadlocks in case of exception(s). That is, if an exception happens when the mutex is locked then the code that unlocks the mutex will never be executed, the lock will remain held by the thread that acquired it, and other threads will be unable to access the shared resource. This can cause a deadlock if the other threads are also waiting to acquire the same lock. For this reason, we suggest you use std::scoped_lock, which prevents this issue by releasing the lock when control leaves the scope in which the scoped_lock object was created.
Shared mutex

A *shared mutex* is a synchronization primitive that can be used to protect shared data from being simultaneously accessed by multiple threads. In contrast to other mutex types which facilitate exclusive access, a *shared_mutex* has two levels of access:

- **Exclusive access** prevents any other thread from acquiring the mutex, just as with the normal mutex. It does not matter if the other thread tries to acquire shared or exclusive access.
- **Shared access** allows multiple threads to acquire the mutex, but all of them only in shared mode. Exclusive access is not granted until all of the previous shared holders have returned the mutex (typically, as long as an exclusive request is waiting, new shared ones are queued to be granted after the exclusive access).

Shared mutexes are especially useful when shared data can be safely read by any number of threads simultaneously, but a thread may only write the same data when no other thread is reading or writing at the same time. A typical scenario is a database: The data can be read simultaneously by different threads with no problem. However, modification of the database is critical: if some threads read data while another one is writing, the threads reading may receive inconsistent data. Hence, while a thread is writing, reading should not be allowed. After writing is complete, reads can occur simultaneously again. The code below shows how *shared_mutex* can be used to synchronize reads and writes:

```cpp
int const writers = 3;
int const readers = 3;
int const cycles = 10;

using std::chrono::milliseconds;

int hpx_main()
{
    std::vector<hpx::thread> threads;
    std::atomic<bool> ready(false);
    hpx::shared_mutex stm;

    for (int i = 0; i < writers; ++i)
    {
        threads.emplace_back([&ready, &stm, i] {
            std::mt19937 urng(static_cast<std::uint32_t>(std::time(nullptr)));
            std::uniform_int_distribution<int> dist(1, 1000);

            while (!ready)
            {
                /* wait... */
            }

            for (int j = 0; j < cycles; ++j)
            {
                // scope of unique_lock
                {
                    std::unique_lock<hpx::shared_mutex> ul(stm);

                    std::cout << "^^^ Writer " << i << " starting..." << std::endl;
                    hpx::this_thread::sleep_for(milliseconds(dist(urng)));
                    std::cout << "vvv Writer " << i << " finished." << std::endl;
                }
            }
        });
    }

    return 0;
}
```

(continues on next page)
/*
 * HPX Documentation, master
 */

(hpx::this_thread::sleep_for(milliseconds(dist(urng)))
 
for (int i = 0; i < readers; ++i)
{
    int k = writers + i;
    threads.emplace_back([&ready, &stm, k, i] {
        HPX_UNUSED(k);
        std::mt19937 urng(std::static_cast<std::uint32_t>(std::time(nullptr)));
        std::uniform_int_distribution<int> dist(1, 1000);
        while (!ready)
        { /* wait... */
        }

        for (int j = 0; j < cycles; ++j)
        {
            // scope of shared_lock
            {
                std::shared_lock<hpx::shared_mutex> sl(stm);
                std::cout << "Reader " << i << " starting..." << std::endl;
                hpx::this_thread::sleep_for(milliseconds(dist(urng)));
                std::cout << "Reader " << i << " finished." << std::endl;
            }
            hpx::this_thread::sleep_for(milliseconds(dist(urng)));
        }
    });
}

ready = true;
for (auto& t : threads)
t.join();

return hpx::local::finalize();
)

The above code creates writers and readers threads, each of which will perform cycles of operations. Both the writer and reader threads use the hpx::shared_mutex object stm to synchronize access to a shared resource.

- For the writer threads, a unique_lock on the shared mutex is acquired before each write operation and is released after control leaves the scope in which the unique_lock object was created.
- For the reader threads, a shared_lock on the shared mutex is acquired before each read operation and is released after control leaves the scope in which the shared_lock object was created.

Before each operation, both the reader and writer threads sleep for a random time period, which is generated using a random number generator. The random time period simulates the processing time of the operation.

2.3. Manual 135
Semaphore

Semaphores are a synchronization mechanism used to control concurrent access to a shared resource. The two types of semaphores are:

- counting semaphore: it has a counter that is bigger than zero. The counter is initialized in the constructor. Acquiring the semaphore decreases the counter and releasing the semaphore increases the counter. If a thread tries to acquire the semaphore when the counter is zero, the thread will block until another thread increments the counter by releasing the semaphore. Unlike `hpx::mutex`, an `hpx::counting_semaphore` is not bound to a thread, which means that the acquire and release call of a semaphore can happen on different threads.

- binary semaphore: it is an alias for a `hpx::counting_semaphore<1>`. In this case, the least maximal value is 1. `hpx::binary_semaphore` can be used to implement locks.

```cpp
#include <hpx/init.hpp>
#include <hpx/semaphore.hpp>
#include <hpx/thread.hpp>
#include <iostream>

// initialize the semaphore with a count of 3
hpx::counting_semaphore<> semaphore(3);

void worker()
{
    semaphore.acquire(); // decrement the semaphore's count
    std::cout << "Entering critical section" << std::endl;
    hpx::this_thread::sleep_for(std::chrono::seconds(1));
    semaphore.release(); // increment the semaphore's count
    std::cout << "Exiting critical section" << std::endl;
}

int hpx_main()
{
    hpx::thread t1(worker);
    hpx::thread t2(worker);
    hpx::thread t3(worker);
    hpx::thread t4(worker);
    hpx::thread t5(worker);

    t1.join();
    t2.join();
    t3.join();
    t4.join();
    t5.join();

    return hpx::local::finalize();
}

int main(int argc, char* argv[])
{
    return hpx::local::init(hpx_main, argc, argv);
}
```

In this example, the counting semaphore is initialized to the value of 3. This means that up to 3 threads can access the
critical section (the section of code inside the `worker()` function) at the same time. When a thread enters the critical section, it acquires the semaphore, which decrements the count, while when it exits the critical section, it releases the semaphore, incrementing thus the count. The `worker()` function simulates a critical section by acquiring the semaphore, sleeping for 1 second and then releasing the semaphore.

In the main function, 5 worker threads are created and started, each trying to enter the critical section. If the count of the semaphore is already 0, a worker will wait until another worker releases the semaphore (increasing its value).

**Composable guards**

Composable guards operate in a manner similar to locks, but are applied only to asynchronous functions. The guard (or guards) is automatically locked at the beginning of a specified task and automatically unlocked at the end. Because guards are never added to an existing task’s execution context, the calling of guards is freely composable and can never deadlock.

To call an application with a single guard, simply declare the guard and call `run_guarded()` with a function `(task)`:

```cpp
hpx::lcos::local::guard gu;
run_guarded(gu, task);
```

If a single method needs to run with multiple guards, use a guard set:

```cpp
std::shared_ptr<hpx::lcos::local::guard> gu1(new hpx::lcos::local::guard());
std::shared_ptr<hpx::lcos::local::guard> gu2(new hpx::lcos::local::guard());
gs.add(*gu1);
gs.add(*gu2);
run_guarded(gs, task);
```

Guards use two atomic operations (which are not called repeatedly) to manage what they do, so overhead should be extremely low.

**Execution control**

The following objects are providing control of the execution in *HPX* applications:

1. *Futures*
2. *Channels*
3. *Task blocks*
4. *Task groups*
5. *Threads*

**Futures**

*Futures* are a mechanism to represent the result of a potentially asynchronous operation. A future is a type that represents a value that will become available at some point in the future, and it can be used to write asynchronous and parallel code. Futures can be returned from functions that perform time-consuming operations, allowing the calling code to continue executing while the function performs its work. The value of the future is set when the operation completes and can be accessed later. Futures are used in *HPX* to write asynchronous and parallel code. Below is an example demonstrating different features of futures:
#include <hpx/assert.hpp>
#include <hpx/future.hpp>
#include <hpx/hpx_main.hpp>
#include <hpx/tuple.hpp>

#include <iostream>
#include <utility>

int main()
{
    // Asynchronous execution with futures
    hpx::future<void> f1 = hpx::async(hpx::launch::async, [](void) {});
    hpx::shared_future<int> f2 =
        hpx::async(hpx::launch::async, []() { return 42; });
    hpx::future<int> f3 =
        f2.then([](hpx::shared_future<int>&& f) { return f.get() * 3; });

    hpx::promise<double> p;
    auto f4 = p.get_future();
    HPX_ASSERT(!f4.is_ready());
    p.set_value(123.45);
    HPX_ASSERT(f4.is_ready());

    hpx::package_task<int> t([]() { return 43; });
    hpx::future<int> f5 = t.get_future();
    HPX_ASSERT(!f5.is_ready());
    t();
    HPX_ASSERT(f5.is_ready());

    // Fire-and-forget
    hpx::post([]() {
        std::cout << "This will be printed later\n" << std::flush;
    });

    // Synchronous execution
    hpx::sync([]() {
        std::cout << "This will be printed immediately\n" << std::flush;
    });

    // Combinators
    hpx::future<double> f6 = hpx::async([]() { return 3.14; });
    hpx::future<double> f7 = hpx::async([]() { return 42.0; });
    std::cout
        << hpx::when_all(f6, f7)
        .then([](hpx::future<hpx::tuple<hpx::future<double>, hpx::future<double>>> f) {
            hpx::tuple<hpx::future<double>, hpx::future<double>> t = f.get();
            double pi = hpx::get<0>(t).get();
            double r = hpx::get<1>(t).get();
            return pi * r * r;
        });
}

(continues on next page)
.get()
<< std::endl;

// Easier continuations with dataflow; it waits for all future or
// shared_future arguments before executing the continuation, and also
// accepts non-future arguments
hpx::future<double> f8 = hpx::async([]() { return 3.14; });
hpx::future<double> f9 = hpx::make_ready_future(42.0);

hpx::future<hpx::tuple<double, double>> f11 = hpx::dataflow(
    [](hpx::future<double> a, hpx::future<double> b, hpx::shared_future<double> c, double d) {
        return hpx::make_tuple<>(a.get() + b.get(), c.get() / d);
    },
    f8, f9, f10, -3.9);

// split_future gives a tuple of futures from a future of tuple
hpx::tuple<hpx::future<double>, hpx::future<double>> f12 =
    hpx::split_future(std::move(f11));
std::cout << hpx::get<1>(f12).get() << std::endl;

    return 0;

The first section of the main function demonstrates how to use futures for asynchronous execution. The first two lines create two futures, one for void and another for an integer, using the hpx::async() function. These futures are executed asynchronously in separate threads using the hpx::launch::async launch policy. The third future is created by chaining the second future using the then() member function. This future multiplies the result of the second future by 3.

The next part of the code demonstrates how to use promises and packaged tasks, which are constructs used for communicating data between threads. The promise class is used to store a value that can be retrieved later using a future. The packaged_task class represents a task that can be executed asynchronously, and its result can be obtained using a future. The last three lines create a packaged task that returns an integer, obtain its future, execute the task, and check whether the future is ready or not.

The code then demonstrates how to use the hpx::post() and hpx::sync() functions for fire-and-forget and synchronous execution, respectively. The hpx::post() function executes a given function asynchronously and returns immediately without waiting for the result. The hpx::sync() function executes a given function synchronously and waits for the result before returning.

Next the code demonstrates the use of combinators, which are higher-order functions that combine two or more futures into a single future. The hpx::when_all() function is used to combine two futures, which return double values, into a tuple of futures. The then() member function is then used to compute the area of a circle using the values of the two futures. The get() member function is used to retrieve the result of the computation.

The last section demonstrates the use of hpx::dataflow(), which is a higher-order function that waits for all the future or shared_future arguments to be ready before executing the continuation. The hpx::make_ready_future() function is used to create a future with a given value. The hpx::split_future() function is used to split a future of a tuple into a tuple of futures. The last line retrieves the value of the second future in the tuple using hpx::get() and prints it to the console.
Extended facilities for futures

Concurrency is about both decomposing and composing the program from the parts that work well individually and together. It is in the composition of connected and multicore components where today’s C++ libraries are still lacking.

The functionality of `std::future` offers a partial solution. It allows for the separation of the initiation of an operation and the act of waiting for its result; however, the act of waiting is synchronous. In communication-intensive code this act of waiting can be unpredictable, inefficient and simply frustrating. The example below illustrates a possible synchronous wait using futures:

```cpp
#include <future>
using namespace std;
int main()
{
    future<int> f = async([]() { return 123; });
    int result = f.get(); // might block
}
```

For this reason, HPX implements a set of extensions to `std::future` (as proposed by N4313). This proposal introduces the following key asynchronous operations to `hpx::future`, `hpx::shared_future` and `hpx::async`, which enhance and enrich these facilities.

<table>
<thead>
<tr>
<th>Facility</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>hpx::future::then</code></td>
<td>In asynchronous programming, it is very common for one asynchronous operation, on completion, to invoke a second operation and pass data to it. The current C++ standard does not allow one to register a continuation to a future. With <code>then</code>, instead of waiting for the result, a continuation is “attached” to the asynchronous operation, which is invoked when the result is ready. Continuations registered using <code>then</code> function will help to avoid blocking waits or wasting threads on polling, greatly improving the responsiveness and scalability of an application.</td>
</tr>
<tr>
<td>unwrapping constructor for <code>hpx::future</code></td>
<td>In some scenarios, you might want to create a future that returns another future, resulting in nested futures. Although it is possible to write code to unwrap the outer future and retrieve the nested future and its result, such code is not easy to write because users must handle exceptions and it may cause a blocking call. Unwrapping can allow users to mitigate this problem by doing an asynchronous call to unwrap the outermost future.</td>
</tr>
<tr>
<td><code>hpx::future::is_ready</code></td>
<td>There are often situations where a <code>get()</code> call on a future may not be a blocking call, or is only a blocking call under certain circumstances. This function gives the ability to test for early completion and allows us to avoid associating a continuation, which needs to be scheduled with some non-trivial overhead and near-certain loss of cache efficiency.</td>
</tr>
<tr>
<td><code>hpx::make_ready_future</code></td>
<td>Some functions may know the value at the point of construction. In these cases the value is immediately available, but needs to be returned as a future. By using <code>hpx::make_ready_future</code> a future can be created that holds a pre-computed result in its shared state. In the current standard it is non-trivial to create a future directly from a value. First a promise must be created, then the promise is set, and lastly the future is retrieved from the promise. This can now be done with one operation.</td>
</tr>
</tbody>
</table>

The standard also omits the ability to compose multiple futures. This is a common pattern that is ubiquitous in other asynchronous frameworks and is absolutely necessary in order to make C++ a powerful asynchronous programming language. Not including these functions is synonymous to Boolean algebra without AND/OR.

---

46 [http://wg21.link/n4313](http://wg21.link/n4313)
In addition to the extensions proposed by N4313\(^{47}\), HPX adds functions allowing users to compose several futures in a more flexible way.

</tr>
</tbody>
</table>

Channels

Channels combine communication (the exchange of a value) with synchronization (guaranteeing that two calculations (tasks) are in a known state). A channel can transport any number of values of a given type from a sender to a receiver:

```cpp
hpx::lcos::local::channel<int> c;
hpx::future<int> f = c.get();
HPX_ASSERT(!f.is_ready());
c.set(42);
HPX_ASSERT(f.is_ready());
std::cout << f.get() << std::endl;
```

Channels can be handed to another thread (or in case of channel components, to other localities), thus establishing a communication channel between two independent places in the program:

```cpp
void do_something(hpx::lcos::local::receive_channel<int> c,
                  hpx::lcos::local::send_channel<> done)
{
    // prints 43
    std::cout << c.get(hpx::launch::sync) << std::endl;
    // signal back
    done.set();
}

void send_receive_channel()
{
    hpx::lcos::local::channel<int> c;
    hpx::lcos::local::channel<> done;
}
```

\(^{47}\) http://wg21.link/n4313
hpx::post(&do_something, c, done);

// send some value
  c.set(43);
// wait for thread to be done
  done.get().wait();
}

Note how hpx::lcos::local::channel::get without any arguments returns a future which is ready when a value has been set on the channel. The launch policy hpx::launch::sync can be used to make hpx::lcos::local::channel::get block until a value is set and return the value directly.

A channel component is created on one locality and can be sent to another locality using an action. This example also demonstrates how a channel can be used as a range of values:

// channel components need to be registered for each used type (not needed for hpx::lcos::local::channel)
HPX_REGISTER_CHANNEL(double)

void channel_sender(hpx::lcos::channel<double> c)
{
  for (double d : c)
    hpx::cout << d << std::endl;
}

HPX_PLAIN_ACTION(channel_sender)

void channel()
{
  // create the channel on this locality
  hpx::lcos::channel<double> c(hpx::find_here());

  // pass the channel to a (possibly remote invoked) action
  hpx::post(channel_sender_action(), hpx::find_here(), c);

  // send some values to the receiver
  std::vector<double> v = {1.2, 3.4, 5.0};
  for (double d : v)
    c.set(d);

  // explicitly close the communication channel (implicit at destruction)
  c.close();
}
Task blocks

Task blocks in HPX provide a way to structure and organize the execution of tasks in a parallel program, making it easier to manage dependencies between tasks. A task block actually is a group of tasks that can be executed in parallel. Tasks in a task block can depend on other tasks in the same task block. The task block allows the runtime to optimize the execution of tasks, by scheduling them in an optimal order based on the dependencies between them.

The `define_task_block`, `run` and the `wait` functions implemented based on N4755\(^{48}\) are based on the task_block concept that is a part of the common subset of the Microsoft Parallel Patterns Library (PPL)\(^ {49}\) and the Intel Threading Building Blocks (TBB)\(^ {50}\) libraries.

These implementations adopt a simpler syntax than exposed by those libraries— one that is influenced by language-based concepts, such as spawn and sync from Cilk++\(^ {51}\) and async and finish from X10\(^ {52}\). They improve on existing practice in the following ways:

- The exception handling model is simplified and more consistent with normal C++ exceptions.
- Most violations of strict fork-join parallelism can be enforced at compile time (with compiler assistance, in some cases).
- The syntax allows scheduling approaches other than child stealing.

Consider an example of a parallel traversal of a tree, where a user-provided function `compute` is applied to each node of the tree, returning the sum of the results:

```cpp
template <typename Func>
int traverse(node& n, Func && compute)
{
    int left = 0, right = 0;
    define_task_block(
        [&](task_block<>& tr) {
            if (n.left)
                tr.run([&] { left = traverse(*n.left, compute); });
            if (n.right)
                tr.run([&] { right = traverse(*n.right, compute); });
        });

    return compute(n) + left + right;
}
```

The example above demonstrates the use of two of the functions, `hpx::experimental::define_task_block` and the `hpx::experimental::task_block::run` member function of a `hpx::experimental::task_block`.

The `task_block` function delineates a region in a program code potentially containing invocations of threads spawned by the `run` member function of the `task_block` class. The `run` function spawns an HPX thread, a unit of work that is allowed to execute in parallel with respect to the caller. Any parallel tasks spawned by `run` within the task block are joined back to a single thread of execution at the end of the `define_task_block`. `run` takes a user-provided function object `f` and starts it asynchronously—i.e., it may return before the execution of `f` completes. The HPX scheduler may choose to run `f` immediately or delay running `f` until compute resources become available.

A `task_block` can be constructed only by `define_task_block` because it has no public constructors. Thus, `run` can be invoked directly or indirectly only from a user-provided function passed to `define_task_block`.

Extensions for task blocks

Using execution policies with task blocks

HPX implements some extensions for task_block beyond the actual standards proposal N4755\(^{53}\). The main addition is that a task_block can be invoked with an execution policy as its first argument, very similar to the parallel algorithms.

An execution policy is an object that expresses the requirements on the ordering of functions invoked as a consequence of the invocation of a task block. Enabling passing an execution policy to define_task_block gives the user control over the amount of parallelism employed by the created task_block. In the following example the use of an explicit par execution policy makes the user’s intent explicit:

```cpp
template <typename Func>
int traverse(node *n, Func&& compute) {
    int left = 0, right = 0;

    define_task_block(
        execution::par,
        // execution::parallel_policy
        [&](task_block<> & tb) {
            if (n->left)
                tb.run([&] { left = traverse(n->left, compute); });
            if (n->right)
                tb.run([&] { right = traverse(n->right, compute); });
        });

    return compute(n) + left + right;
}
```

This also causes the hpx::experimental::task_block object to be a template in our implementation. The template argument is the type of the execution policy used to create the task block. The template argument defaults to hpx::execution::parallel_policy.

\(^{53}\) http://wg21.link/n4755
HPX still supports calling `hpx::experimental::define_task_block` without an explicit execution policy. In this case the task block will run using the `hpx::execution::parallel_policy`.

HPX also adds the ability to access the execution policy that was used to create a given `task_block`.

### Using executors to run tasks

Often, users want to be able to not only define an execution policy to use by default for all spawned tasks inside the task block, but also to customize the execution context for one of the tasks executed by `task_block::run`. Adding an optionally passed executor instance to that function enables this use case:

```cpp
// In traverse(node *n, Func&& compute)

int traverse(node *n, Func&& compute)
{
    int left = 0, right = 0;

    define_task_block(
        execution::par, // execution::parallel_policy
        [&](auto& tb) {
            if (n->left) {
                // use explicitly specified executor to run this task
                tb.run(my_executor(), [&] { left = traverse(n->left, compute); });
            }
            if (n->right) {
                // use the executor associated with the par execution policy
                tb.run([&] { right = traverse(n->right, compute); });
            }
        });

    return compute(n) + left + right;
}
```

HPX still supports calling `hpx::experimental::task_block::run` without an explicit executor object. In this case the task will be run using the executor associated with the execution policy that was used to call `hpx::experimental::define_task_block`.

### Task groups

A `task group` in HPX is a synchronization primitive that allows you to execute a group of tasks concurrently and wait for their completion before continuing. The tasks in an `hpx::experimental::task_group` can be added dynamically. This is the HPX implementation of `tbb::task_group` of the Intel Threading Building Blocks (TBB) library.

The example below shows that to use a task group, you simply create an `hpx::task_group` object and add tasks to it using the `run()` method. Once all the tasks have been added, you can call the `wait()` method to synchronize the tasks and wait for them to complete.

```cpp
#include <hpx/experimental/task_group.hpp>
#include <hpx/init.hpp>
```

(continues on next page)

{
    hpx::experimental::task_group tg;
    tg.run(task1);
    tg.run(task2);
    tg.wait();
    std::cout << "All tasks finished!" << std::endl;
    return hpx::local::finalize();
}

int main(int argc, char* argv[])
{
    return hpx::local::init(hpx_main, argc, argv);
}

Note: task groups and task blocks are both ways to group and synchronize parallel tasks, but task groups are used to group multiple tasks together as a single unit, while task blocks are used to execute a loop in parallel, with each iteration of the loop executing in a separate task. If the difference is not clear yet, continue reading.

A task group is a construct that allows multiple parallel tasks to be grouped together as a single unit. The task group provides a way to synchronize all the tasks in the group before continuing with the rest of the program.

A task block, on the other hand, is a parallel loop construct that allows you to execute a loop in parallel, with each iteration of the loop executing in a separate task. The loop iterations are executed in a block, meaning that the loop body is executed as a single task.
Threads

A thread in HPX refers to a sequence of instructions that can be executed concurrently with other such sequences in multithreading environments, while sharing a same address space. These threads can communicate with each other through various means, such as futures or shared data structures.

The example below demonstrates how to launch multiple threads and synchronize them using a `hpx::latch` object. It also shows how to query the state of threads and wait for futures to complete.

```cpp
#include <hpx/future.hpp>
#include <hpx/init.hpp>
#include <hpx/thread.hpp>
#include <functional>
#include <iostream>
#include <vector>

int const num_threads = 10;

void wait_for_latch(hpx::latch& l)
{
    l.arrive_and_wait();
}

int hpx_main()
{
    // Spawn a couple of threads
    hpx::latch l(num_threads + 1);
    std::vector<hpx::future<void>> results;
    results.reserve(num_threads);
    for (int i = 0; i != num_threads; ++i)
        results.push_back(hpx::async(&wait_for_latch, std::ref(l)));

    // Allow spawned threads to reach latch
    hpx::this_thread::yield();

    // Enumerate all suspended threads
    hpx::threads::enumerate_threads([](hpx::threads::thread_id_type id) -> bool {
        std::cout << "thread " << hpx::thread::id(id) << " is "
                  << hpx::threads::get_thread_state_name(hpx::threads::get_thread_state(id))
                  << std::endl;
        return true;  // always continue enumeration
    }, hpx::threads::thread_schedule_state::suspended);

    // Wait for all threads to reach this point.
    l.arrive_and_wait();
}
```

(continues on next page)
In more detail, the `wait_for_latch()` function is a simple helper function that waits for a `hpx::latch` object to be released. At this point we remind that `hpx::latch` is a synchronization primitive that allows multiple threads to wait for a common event to occur.

In the `hpx_main()` function, an `hpx::latch` object is created with a count of `num_threads + 1`, indicating that `num_threads` threads need to arrive at the latch before the latch is released. The loop that follows launches `num_threads` asynchronous operations, each of which calls the `wait_for_latch` function. The resulting futures are added to the vector.

After the threads have been launched, `hpx::this_thread::yield()` is called to give them a chance to reach the latch before the program proceeds. Then, the `hpx::threads::enumerate_threads` function prints the state of each suspended thread, while the next call of `l.arrive_and_wait()` waits for all the threads to reach the latch. Finally, `hpx::wait_all` is called to wait for all the futures to complete.

**Hint:** An advantage of using `hpx::thread` over other threading libraries is that it is optimized for high-performance parallelism, with support for lightweight threads and task scheduling to minimize thread overhead and maximize parallelism. Additionally, `hpx::thread` integrates seamlessly with other features of HPX such as futures, promises, and task groups, making it a powerful tool for parallel programming.

Checkout the examples of `Shared mutex`, `Condition variable`, `Semaphore` to see how HPX threads are used in combination with other features.

### High level parallel facilities

In preparation for the upcoming C++ Standards, there are currently several proposals targeting different facilities supporting parallel programming. HPX implements (and extends) some of those proposals. This is well aligned with our strategy to align the APIs exposed from HPX with current and future C++ Standards.

At this point, HPX implements several of the C++ Standardization working papers, most notably N4409\(^{55}\) (Working Draft, Technical Specification for C++ Extensions for Parallelism), N4755\(^{56}\) (Task Blocks), and N4406\(^{57}\) (Parallel Algorithms Need Executors).

\(^{56}\) [http://wg21.link/n4755](http://wg21.link/n4755)

\(^{57}\) [http://wg21.link/n4406](http://wg21.link/n4406)
Using parallel algorithms

A parallel algorithm is a function template declared in the namespace `hpx::parallel`. All parallel algorithms are very similar in semantics to their sequential counterparts (as defined in the namespace `std`) with an additional formal template parameter named `ExecutionPolicy`. The execution policy is generally passed as the first argument to any of the parallel algorithms and describes the manner in which the execution of these algorithms may be parallelized and the manner in which they apply user-provided function objects.

The applications of function objects in parallel algorithms invoked with an execution policy object of type `hpx::execution::sequenced_policy` or `hpx::execution::sequenced_task_policy` execute in sequential order. For `hpx::execution::sequenced_policy` the execution happens in the calling thread.

The applications of function objects in parallel algorithms invoked with an execution policy object of type `hpx::execution::parallel_policy` or `hpx::execution::parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and are indeterminately sequenced within each thread.

**Important:** It is the caller’s responsibility to ensure correctness, such as making sure that the invocation does not introduce data races or deadlocks.

The example below demonstrates how to perform a sequential and parallel `hpx::for_each` loop on a vector of integers.

```cpp
#include <hpx/algorithm.hpp>
#include <hpx/execution.hpp>
#include <hpx/init.hpp>

#include <iostream>
#include <vector>

int hpx_main()
{
    std::vector<int> v{1, 2, 3, 4, 5};
    auto print = [] (const int & n) { std::cout << n << ' '; };
    std::cout << "Print sequential: ";
    hpx::for_each(v.begin(), v.end(), print);
    std::cout << '\n';
    std::cout << "Print parallel: ";
    hpx::for_each(hpx::execution::par, v.begin(), v.end(), print);
    std::cout << '\n';

    return hpx::local::finalize();
}

int main(int argc, char* argv[])
{
    return hpx::local::init(hpx_main, argc, argv);
}
```

The above code uses `hpx::for_each` to print the elements of the vector `v{1, 2, 3, 4, 5}`. At first, `hpx::for_each()` is called without an execution policy, which means that it applies the lambda function `print` to each element in the vector sequentially. Hence, the elements are printed in order.
Next, `hpx::for_each()` is called with the `hpx::execution::par` execution policy, which applies the lambda function `print` to each element in the vector in parallel. Therefore, the output order of the elements in the vector is not deterministic and may vary from run to run.

Parallel exceptions

During the execution of a standard parallel algorithm, if temporary memory resources are required by any of the algorithms and no memory is available, the algorithm throws a `std::bad_alloc` exception.

During the execution of any of the parallel algorithms, if the application of a function object terminates with an uncaught exception, the behavior of the program is determined by the type of execution policy used to invoke the algorithm:

- If the execution policy object is of type `hpx::execution::parallel_unsequenced_policy`, `hpx::terminate` shall be called.
- If the execution policy object is of type `hpx::execution::sequenced_policy`, `hpx::execution::sequenced_task_policy`, `hpx::execution::parallel_policy`, or `hpx::execution::parallel_task_policy`, the execution of the algorithm terminates with an `hpx::exception_list` exception. All uncaught exceptions thrown during the application of user-provided function objects shall be contained in the `hpx::exception_list`.

For example, the number of invocations of the user-provided function object in `for_each` is unspecified. When `hpx::for_each` is executed sequentially, only one exception will be contained in the `hpx::exception_list` object.

These guarantees imply that, unless the algorithm has failed to allocate memory and terminated with `std::bad_alloc`, all exceptions thrown during the execution of the algorithm are communicated to the caller. It is unspecified whether an algorithm implementation will “forge ahead” after encountering and capturing a user exception.

The algorithm may terminate with the `std::bad_alloc` exception even if one or more user-provided function objects have terminated with an exception. For example, this can happen when an algorithm fails to allocate memory while creating or adding elements to the `hpx::exception_list` object.

Parallel algorithms

`HPX` provides implementations of the following parallel algorithms:
<table>
<thead>

Executor parameters and executor parameter traits

*HPX* introduces the notion of execution parameters and execution parameter traits. At this point, the only parameter that can be customized is the size of the chunks of work executed on a single *HPX* thread (such as the number of loop iterations combined to run as a single task).

An executor parameter object is responsible for exposing the calculation of the size of the chunks scheduled. It abstracts the (potentially platform-specific) algorithms of determining those chunk sizes.

The way executor parameters are implemented is aligned with the way executors are implemented. All functionalities of concrete executor parameter types are exposed and accessible through a corresponding customization point, e.g. `get_chunk_size()`.

With `executor_parameter_traits`, clients access all types of executor parameters uniformly, e.g.:

```cpp
std::size_t chunk_size =
    hpx::execution::get_chunk_size(my_parameter, my_executor,
    num_cores, num_tasks);
```

This call synchronously retrieves the size of a single chunk of loop iterations (or similar) to combine for execution on a single *HPX* thread if the overall number of cores `num_cores` and tasks to schedule is given by `num_tasks`. The lambda function exposes a means of test-probing the execution of a single iteration for performance measurement purposes. The execution parameter type might dynamically determine the execution time of one or more tasks in order to calculate the chunk size; see `hpx::execution::experimental::auto_chunk_size` for an example of this executor parameter type.

Other functions in the interface exist to discover whether an executor parameter type should be invoked once (i.e., it returns a static chunk size; see `hpx::execution::experimental::static_chunk_size`) or whether it should be invoked for each scheduled chunk of work (i.e., it returns a variable chunk size; for an example, see `hpx::execution::experimental::guided_chunk_size`).

Although this interface appears to require executor parameter type authors to implement all different basic operations, none are required. In practice, all operations have sensible defaults. However, some executor parameter types will naturally specialize all operations for maximum efficiency.

*HPX* implements the following executor parameter types:

- **`hpx::execution::experimental::auto_chunk_size`**: Loop iterations are divided into pieces and then assigned to threads. The number of loop iterations combined is determined based on measurements of how long the execution of 1% of the overall number of iterations takes. This executor parameter type makes sure that as many loop iterations are combined as necessary to run for the amount of time specified.

- **`hpx::execution::experimental::static_chunk_size`**: Loop iterations are divided into pieces of a given size and then assigned to threads. If the size is not specified, the iterations are, if possible, evenly divided contiguously among the threads. This executor parameters type is equivalent to OpenMP’s STATIC scheduling directive.

- **`hpx::execution::experimental::dynamic_chunk_size`**: Loop iterations are divided into pieces of a given size and then dynamically scheduled among the cores; when a core finishes one chunk, it is dynamically assigned another. If the size is not specified, the default chunk size is 1. This executor parameter type is equivalent to OpenMP’s DYNAMIC scheduling directive.

- **`hpx::execution::experimental::guided_chunk_size`**: Iterations are dynamically assigned to cores in blocks as cores request them until no blocks remain to be assigned. This is similar to `dynamic_chunk_size` except that the block size decreases each time a number of loop iterations is given to a thread. The size of the initial block is proportional to `number_of_iterations / number_of_cores`. Subsequent blocks are proportional to `number_of_iterations_remaining / number_of_cores`. The optional chunk size parameter defines the minimum block size. The default minimal chunk size is 1. This executor parameter type is equivalent to OpenMP’s GUIDED scheduling directive.
2.3.11 Writing distributed HPX applications

This section focuses on the features of HPX needed to write distributed applications, namely the Active Global Address Space (AGAS), remotely executable functions (i.e., actions), and distributed objects (i.e., components).

Global names

HPX implements an Active Global Address Space (AGAS) which exposes a single uniform address space spanning all localities an application runs on. AGAS is a fundamental component of the ParalleX execution model. Conceptually, there is no rigid demarcation of local or global memory in AGAS; all available memory is a part of the same address space. AGAS enables named objects to be moved (migrated) across localities without having to change the object’s name; i.e., no references to migrated objects have to be ever updated. This feature has significance for dynamic load balancing and in applications where the workflow is highly dynamic, allowing work to be migrated from heavily loaded nodes to less loaded nodes. In addition, immutability of names ensures that AGAS does not have to keep extra indirections (“bread crumbs”) when objects move, hence, minimizing complexity of code management for system developers as well as minimizing overheads in maintaining and managing aliases.

The AGAS implementation in HPX does not automatically expose every local address to the global address space. It is the responsibility of the programmer to explicitly define which of the objects have to be globally visible and which of the objects are purely local.

In HPX global addresses (global names) are represented using the hpx::id_type data type. This data type is conceptually very similar to void* pointers as it does not expose any type information of the object it is referring to.

The only predefined global addresses are assigned to all localities. The following HPX API functions allow one to retrieve the global addresses of localities:

- `hpx::find_here`: retrieves the global address of the locality this function is called on.
- `hpx::find_all_localities`: retrieves the global addresses of all localities available to this application (including the locality the function is being called on).
- `hpx::find_remote_localities`: retrieves the global addresses of all remote localities available to this application (not including the locality the function is being called on).
- `hpx::get_num_localities`: retrieves the number of localities available to this application.
- `hpx::find_locality`: retrieves the global address of any locality supporting the given component type.
- `hpx::get_colocation_id`: retrieves the global address of the locality currently hosting the object with the given global address.

Additionally, the global addresses of localities can be used to create new instances of components using the following HPX API function:

- `hpx::components::new_`: Creates a new instance of the given Component type on the specified locality.

Note: HPX does not expose any functionality to delete component instances. All global addresses (as represented using hpx::id_type) are automatically garbage collected. When the last (global) reference to a particular component instance goes out of scope, the corresponding component instance is automatically deleted.
Posting actions

Action type definition

Actions are special types used to describe possibly remote operations. For every global function and every member function which has to be invoked distantly, a special type must be defined. For any global function the special macro `HPXPLAIN_ACTION` can be used to define the action type. Here is an example demonstrating this:

```cpp
namespace app
{
  void some_global_function(double d)
  {
    cout << d;
  }
}
// This will define the action type 'some_global_action' which represents
// the function 'app::some_global_function'.
HPXPLAIN_ACTION(app::some_global_function, some_global_action);
```

**Important:** The macro `HPXPLAIN_ACTION` has to be placed in global namespace, even if the wrapped function is located in some other namespace. The newly defined action type is placed in the global namespace as well.

If the action type should be defined somewhere not in global namespace, the action type definition has to be split into two macro invocations (`HPX_DEFINE_PLAIN_ACTION` and `HPX_REGISTER_ACTION`) as shown in the next example:

```cpp
namespace app
{
  void some_global_function(double d)
  {
    cout << d;
  }
  // On conforming compilers the following macro expands to:
  // typedef hpx::actions::make_action<
  //   decltype(&some_global_function), &some_global_function
  // >::type some_global_action;
  // This will define the action type 'some_global_action' which represents
  // the function 'some_global_function'.
  HPX_DEFINE_PLAIN_ACTION(some_global_function, some_global_action);
}
// The following macro expands to a series of definitions of global objects
// which are needed for proper serialization and initialization support
// enabling the remote invocation of the function``some_global_function``
HPX_REGISTER_ACTION(app::some_global_action, app_some_global_action);
```

The shown code defines an action type `some_global_action` inside the namespace `app`.

**Important:** If the action type definition is split between two macros as shown above, the name of the action type to
create has to be the same for both macro invocations (here `some_global_action`).

**Important:** The second argument passed to `HPX_REGISTER_ACTION` (app::some_global_action) has to comprise a globally unique C++ identifier representing the action. This is used for serialization purposes.

For member functions of objects which have been registered with AGAS (e.g., ‘components’), a different registration macro `HPX_DEFINE_COMPONENT_ACTION` has to be utilized. Any component needs to be declared in a header file and have some special support macros defined in a source file. Here is an example demonstrating this. The first snippet has to go into the header file:

```cpp
namespace app
{
    struct some_component
    :
        hpx::components::component_base<some_component>
    {
        int some_member_function(std::string s)
        {
            return boost::lexical_cast<int>(s);
        }

        // This will define the action type 'some_member_action' which
        // represents the member function 'some_member_function' of the
        // object type 'some_component'.
        HPX_DEFINE_COMPONENT_ACTION(some_component, some_member_function,
                                     some_member_action);
    }

    // Note: The second argument to the macro below has to be systemwide-unique
    // C++ identifiers
    HPX_REGISTER_ACTION_DECLARATION(app::some_component::some_member_action, some_component_some_action);
}
```

The next snippet belongs in a source file (e.g., the main application source file) in the simplest case:

```cpp
typedef hpx::components::component<app::some_component> component_type;
typedef app::some_component some_component;

HPX_REGISTER_COMPONENT(component_type, some_component);

// The parameters for this macro have to be the same as used in the corresponding
// HPX_REGISTER_ACTION_DECLARATION() macro invocation above
typedef some_component::some_member_action some_component_some_action;
HPX_REGISTER_ACTION(some_component_some_action);
```

While these macro invocations are a bit more complex than those for simple global functions, they should still be manageable.

The most important macro invocation is the `HPX_DEFINE_COMPONENT_ACTION` in the header file as this defines the action type we need to invoke the member function. For a complete example of a simple component action see `component_in_executable.cpp`. 

160 Chapter 2. What’s so special about HPX?
Action invocation

The process of invoking a global function (or a member function of an object) with the help of the associated action is called ‘posting the action’. Actions can have arguments, which will be supplied while the action is applied. At the minimum, one parameter is required to post any action - the id of the locality the associated function should be invoked on (for global functions), or the id of the component instance (for member functions). Generally, HPX provides several ways to post an action, all of which are described in the following sections.

Generally, HPX actions are very similar to ‘normal’ C++ functions except that actions can be invoked remotely. Fig. 2.8 below shows an overview of the main API exposed by HPX. This shows the function invocation syntax as defined by the C++ language (dark gray), the additional invocation syntax as provided through C++ Standard Library features (medium gray), and the extensions added by HPX (light gray) where:

- \( f \): function to invoke,
- \( p.. \): (optional) arguments,
- \( R \): return type of \( f \),
- \( \text{action} \): action type defined by, \texttt{HPX\_DEFINE\_PLAIN\_ACTION} or \texttt{HPX\_DEFINE\_COMPONENT\_ACTION} encapsulating \( f \),
- \( a \): an instance of the type `action`,
- \( \text{id} \): the global address the action is applied to.

This figure shows that HPX allows the user to post ‘actions with a syntax similar to the C++ standard. In fact, all action types have an overloaded function operator allowing to synchronously `post the action. Further, \texttt{hpx}\_\texttt{async} which semantically works similar to the way \texttt{std}\_\texttt{async} works for plain C++ function.

Note: The similarity of posting an action to conventional function invocations extends even further. HPX implements \texttt{hpx}\_\texttt{bind} and \texttt{hpx}\_\texttt{function} two facilities which are semantically equivalent to the \texttt{std}\_\texttt{bind} and \texttt{std}\_\texttt{function} types as defined by the C++11 Standard. While \texttt{hpx}\_\texttt{async} extends beyond the conventional semantics by supporting actions and conventional C++ functions, the HPX facilities \texttt{hpx}\_\texttt{bind} and \texttt{hpx}\_\texttt{function}
extend beyond the conventional standard facilities too. The HPX facilities not only support conventional functions, but can be used for actions as well.

Additionally, HPX exposes `hpx::post` and `hpx::async_continue` both of which refine and extend the standard C++ facilities.

The different ways to invoke a function in HPX will be explained in more detail in the following sections.

**Posting an action asynchronously without any synchronization**

This method (‘fire and forget’) will make sure the function associated with the action is scheduled to run on the target locality. Posting the action does not wait for the function to start running, instead it is a fully asynchronous operation. The following example shows how to post the action as defined in the previous section on the local locality (the locality this code runs on):

```cpp
some_global_action act; // define an instance of some_global_action
hpx::post(act, hpx::find_here(), 2.0);
```

(the function `hpx::find_here()` returns the id of the local locality, i.e. the locality this code executes on).

Any component member function can be invoked using the same syntactic construct. Given that `id` is the global address for a component instance created earlier, this invocation looks like:

```cpp
some_component_action act; // define an instance of some_component_action
hpx::post(act, id, "42");
```

In this case any value returned from this action (e.g. in this case the integer 42 is ignored. Please look at Action type definition for the code defining the component action `some_component_action` used.

**Posting an action asynchronously with synchronization**

This method will make sure the action is scheduled to run on the target locality. Posting the action itself does not wait for the function to start running or to complete, instead this is a fully asynchronous operation similar to using `hpx::post` as described above. The difference is that this method will return an instance of a `hpx::future<>` encapsulating the result of the (possibly remote) execution. The future can be used to synchronize with the asynchronous operation. The following example shows how to post the action from above on the local locality:

```cpp
some_global_action act; // define an instance of some_global_action
hpx::future<void> f = hpx::async(act, hpx::find_here(), 2.0);
// // ... other code can be executed here
// f.get(); // this will possibly wait for the asynchronous operation to 'return'
```

(as before, the function `hpx::find_here()` returns the id of the local locality (the locality this code is executed on).

**Note**: The use of a `hpx::future<void>` allows the current thread to synchronize with any remote operation not returning any value.

**Note**: Any `std::future<>` returned from `std::async()` is required to block in its destructor if the value has not been set for this future yet. This is not true for `hpx::future<>` which will never block in its destructor, even if the...
value has not been returned to the future yet. We believe that consistency in the behavior of futures is more important than standards conformance in this case.

Any component member function can be invoked using the same syntactic construct. Given that \texttt{id} is the global address for a component instance created earlier, this invocation looks like:

```cpp
some_component_action act; // define an instance of some_component_action
hpx::future<int> f = hpx::async(act, id, "42");
// ...
// other code can be executed here
//
cout << f.get(); // this will possibly wait for the asynchronous operation to 'return'...
˓→42
```

\textbf{Note:} The invocation of \texttt{f.get()} will return the result immediately (without suspending the calling thread) if the result from the asynchronous operation has already been returned. Otherwise, the invocation of \texttt{f.get()} will suspend the execution of the calling thread until the asynchronous operation returns its result.

### Posting an action synchronously

This method will schedule the function wrapped in the specified action on the target \texttt{locality}. While the invocation appears to be synchronous (as we will see), the calling thread will be suspended while waiting for the function to return. Invoking a plain action (e.g. a global function) synchronously is straightforward:

```cpp
some_global_action act; // define an instance of some_global_action
act(hpx::find_here(), 2.0);
```

While this call looks just like a normal synchronous function invocation, the function wrapped by the action will be scheduled to run on a new thread and the calling thread will be suspended. After the new thread has executed the wrapped global function, the waiting thread will resume and return from the synchronous call.

Equivalently, any action wrapping a component member function can be invoked synchronously as follows:

```cpp
some_component_action act; // define an instance of some_component_action
int result = act(id, "42");
```

The action invocation will either schedule a new thread locally to execute the wrapped member function (as before, \texttt{id} is the global address of the component instance the member function should be invoked on), or it will send a parcel to the remote \texttt{locality} of the component causing a new thread to be scheduled there. The calling thread will be suspended until the function returns its result. This result will be returned from the synchronous action invocation.

It is very important to understand that this ‘synchronous’ invocation syntax in fact conceals an asynchronous function call. This is beneficial as the calling thread is suspended while waiting for the outcome of a potentially remote operation. The \texttt{HPX} thread scheduler will schedule other work in the meantime, allowing the application to make further progress while the remote result is computed. This helps overlapping computation with communication and hiding communication latencies.

\textbf{Note:} The syntax of posting an action is always the same, regardless whether the target \texttt{locality} is remote to the invocation \texttt{locality} or not. This is a very important feature of \texttt{HPX} as it frees the user from the task of keeping track what actions have to be applied locally and which actions are remote. If the target for posting an action is local, a new thread is automatically created and scheduled. Once this thread is scheduled and run, it will execute the function encapsulated by that action. If the target is remote, \texttt{HPX} will send a parcel to the remote \texttt{locality} which encapsulates
the action and its parameters. Once the parcel is received on the remote locality HPX will create and schedule a new thread there. Once this thread runs on the remote locality, it will execute the function encapsulated by the action.

**Posting an action with a continuation but without any synchronization**

This method is very similar to the method described in section *Posting an action asynchronously without any synchronization*. The difference is that it allows the user to chain a sequence of asynchronous operations, while handing the (intermediate) results from one step to the next step in the chain. Where `hpx::post` invokes a single function using ‘fire and forget’ semantics, `hpx::post_continue` asynchronously triggers a chain of functions without the need for the execution flow ‘to come back’ to the invocation site. Each of the asynchronous functions can be executed on a different locality.

**Posting an action with a continuation and with synchronization**

This method is very similar to the method described in section *Posting an action asynchronously with synchronization*. In addition to what `hpx::async` can do, the functions `hpx::async_continue` takes an additional function argument. This function will be called as the continuation of the executed action. It is expected to perform additional operations and to make sure that a result is returned to the original invocation site. This method chains operations asynchronously by providing a continuation operation which is automatically executed once the first action has finished executing.

As an example we chain two actions, where the result of the first action is forwarded to the second action and the result of the second action is sent back to the original invocation site:

```cpp
// first action
std::int32_t action1(std::int32_t i)
{
    return i + 1;
}
HPX_PLAIN_ACTION(action1); // defines action1_type

// second action
std::int32_t action2(std::int32_t i)
{
    return i * 2;
}
HPX_PLAIN_ACTION(action2); // defines action2_type

// this code invokes 'action1' above and passes along a continuation // function which will forward the result returned from 'action1' to // 'action2'.
action1_type act1; // define an instance of 'action1_type'
action2_type act2; // define an instance of 'action2_type'
hpx::future<int> f =
    hpx::async_continue(act1, hpx::make_continuation(act2),
                        hpx::find_here(), 42);
hpX::cout << f.get() << "\n"; // will print: 86 ((42 + 1) * 2)
```

By default, the continuation is executed on the same locality as `hpx::async_continue` is invoked from. If you want to specify the locality where the continuation should be executed, the code above has to be written as:
// this code invokes 'action1' above and passes along a continuation
// function which will forward the result returned from 'action1' to
// 'action2'.
action1_type act1; // define an instance of 'action1_type'
action2_type act2; // define an instance of 'action2_type'
hpx::future<int> f =
    hpx::async_continue(act1, hpx::make_continuation(act2, hpx::find_here()),
                        hpx::find_here(), 42);
hpx::cout << f.get() << "\n"; // will print: 86 ((42 + 1) * 2)

Similarly, it is possible to chain more than 2 operations:

action1_type act1; // define an instance of 'action1_type'
action2_type act2; // define an instance of 'action2_type'
hpx::future<int> f =
    hpx::async_continue(act1, hpx::make_continuation(act2, hpx::make_continuation(act1)),
                        hpx::find_here(), 42);
hpx::cout << f.get() << "\n"; // will print: 87 ((42 + 1) * 2 + 1)

The function hpx::make_continuation creates a special function object which exposes the following prototype:

```cpp
struct continuation
{
    template<typename Result>
    void operator() (hpx::id_type id, Result&& result) const
    {
        ...
    }
};
```

where the parameters passed to the overloaded function operator operator() are:

- the id is the global id where the final result of the asynchronous chain of operations should be sent to (in most cases this is the id of the hpx::future returned from the initial call to hpx::async_continue. Any custom continuation function should make sure this id is forwarded to the last operation in the chain.
- the result is the result value of the current operation in the asynchronous execution chain. This value needs to be forwarded to the next operation.

**Note:** All of those operations are implemented by the predefined continuation function object which is returned from hpx::make_continuation. Any (custom) function object used as a continuation should conform to the same interface.
Action error handling

Like in any other asynchronous invocation scheme it is important to be able to handle error conditions occurring while the asynchronous (and possibly remote) operation is executed. In HPX all error handling is based on standard C++ exception handling. Any exception thrown during the execution of an asynchronous operation will be transferred back to the original invocation locality, where it is rethrown during synchronization with the calling thread.

**Important:** Exceptions thrown during asynchronous execution can be transferred back to the invoking thread only for the synchronous and the asynchronous case with synchronization. Like with any other unhandled exception, any exception thrown during the execution of an asynchronous action without synchronization will result in calling `hpx::terminate` causing the running application to exit immediately.

**Note:** Even if error handling internally relies on exceptions, most of the API functions exposed by HPX can be used without throwing an exception. Please see Working with exceptions for more information.

As an example, we will assume that the following remote function will be executed:

```cpp
namespace app
{
    void some_function_with_error(int arg)
    {
        if (arg < 0) {
            HPX_THROW_EXCEPTION(hpx::error::bad_parameter,
                "some_function_with_error",
                "some really bad error happened");
        }
        // do something else...
    }
}
```

// This will define the action type 'some_error_action' which represents
// the function 'app::some_function_with_error'.
HPX_PLAIN_ACTION(app::some_function_with_error, some_error_action);

The use of `HPX_THROW_EXCEPTION` to report the error encapsulates the creation of a `hpx::exception` which is initialized with the error code `hpx::error::bad_parameter`. Additionally it carries the passed strings, the information about the file name, line number, and call stack of the point the exception was thrown from.

We invoke this action using the synchronous syntax as described before:

```cpp
// note: wrapped function will throw hpx::exception
some_error_action act; // define an instance of some_error_action
try {
    act(hpx::find_here(), -3); // exception will be rethrown from here
} catch (hpx::exception const& e) {
    // prints: 'some really bad error happened: HPX(bad parameter)'
    cout << e.what();
}
```

If this action is invoked asynchronously with synchronization, the exception is propagated to the waiting thread as well and is re-thrown from the future’s function `get()`:
// note: wrapped function will throw hpx::exception
some_error_action act;  // define an instance of some_error_action
hpx::future<void> f = hpx::async(act, hpx::find_here(), -3);
try {
    f.get();  // exception will be rethrown from here
}
catch (hpx::exception const& e) {
    // prints: 'some really bad error happened: HPX(bad parameter)'
    cout << e.what();
}

For more information about error handling please refer to the section Working with exceptions. There we also explain how to handle error conditions without having to rely on exception.

**Writing components**

A component in *HPX* is a C++ class which can be created remotely and for which its member functions can be invoked remotely as well. The following sections highlight how components can be defined, created, and used.

**Defining components**

In order for a C++ class type to be managed remotely in *HPX*, the type must be derived from the `hpx::components::component_base` template type. We call such C++ class types `components`.

Note that the component type itself is passed as a template argument to the base class:

```cpp
// header file some_component.hpp
#include <hpx/include/components.hpp>
namespace app {
    // Define a new component type 'some_component'
    struct some_component : hpx::components::component_base<some_component> {
        // This member function is has to be invoked remotely
        int some_member_function(std::string const& s) {
            return boost::lexical_cast<int>(s);
        }

        // This will define the action type 'some_member_action' which
        // represents the member function 'some_member_function' of the
        // object type 'some_component'.
        HPX_DEFINE_COMPONENT_ACTION(some_component, some_member_function, some_member_
action);
    }
}
```

// This will generate the necessary boiler-plate code for the action allowing
// it to be invoked remotely. This declaration macro has to be placed in the
// header file defining the component itself.
//
// Note: The second argument to the macro below has to be systemwide-unique
// C++ identifiers
//
HPX_REGISTER_ACTION_DECLARATION(app::some_component::some_member_action, some_component_
˓→some_action);

There is more boilerplate code which has to be placed into a source file in order for the component to be usable. Every component type is required to have macros placed into its source file, one for each component type and one macro for each of the actions defined by the component type.

For instance:

// source file some_component.cpp

#include "some_component.hpp"

// The following code generates all necessary boiler plate to enable the
// remote creation of 'app::some_component' instances with 'hpx::new_<>()'
//
using some_component = app::some_component;
using some_component_type = hpx::components::component<some_component>;

// Please note that the second argument to this macro must be a
// (system-wide) unique C++-style identifier (without any namespaces)
//
HPX_REGISTER_COMPONENT(some_component_type, some_component);

// The parameters for this macro have to be the same as used in the corresponding
// HPX_REGISTER_ACTION_DECLARATION() macro invocation in the corresponding
// header file.
//
// Please note that the second argument to this macro must be a
// (system-wide) unique C++-style identifier (without any namespaces)
//
HPX_REGISTER_ACTION(app::some_component::some_member_action, some_component_some_action);

Defining client side representation classes

Often it is very convenient to define a separate type for a component which can be used on the client side (from where the component is instantiated and used). This step might seem as unnecessary duplicating code, however it significantly increases the type safety of the code.

A possible implementation of such a client side representation for the component described in the previous section could look like:

#include <hpx/include/components.hpp>

namespace app
{
    // Define a client side representation type for the component type

// 'some_component' defined in the previous section.
//
struct some_component_client
    : hpx::components::client_base<some_component_client, some_component>
{
    using base_type = hpx::components::client_base<
        some_component_client, some_component>;

    some_component_client(hpx::future<hpx::id_type> && id)
        : base_type(std::move(id))
    {
    }

    hpx::future<int> some_member_function(std::string const & s)
    {
        some_component::some_member_action act;
        return hpx::async(act, get_id(), s);
    }
};

A client side object stores the global id of the component instance it represents. This global id is accessible by calling
the function client_base::get_id(). The special constructor which is provided in the example allows to create
this client side object directly using the API function hpx::new_.

Creating component instances

Instances of defined component types can be created in two different ways. If the component to create has a defined
client side representation type, then this can be used, otherwise use the server type.

The following examples assume that some_component_type is the type of the server side implementation of the
component to create. All additional arguments (see , ... notation below) are passed through to the corresponding
constructor calls of those objects:

// create one instance on the given locality
hpx::id_type here = hpx::find_here();
hpx::future<hpx::id_type> f =
    hpx::new_<some_component_type>(here, ...);

// create one instance using the given distribution
// policy (here: hpx::colocating_distribution_policy)
hpx::id_type here = hpx::find_here();
hpx::future<hpx::id_type> f =
    hpx::new_<some_component_type>(hpx::colocated(here), ...);

// create multiple instances on the given locality
hpx::id_type here = find_here();
hpx::future<std::vector<hpx::id_type>> f =
    hpx::new_<some_component_type[]>(here, num, ...);

// create multiple instances using the given distribution
// policy (here: hpx::binpacking_distribution_policy)
The examples below demonstrate the use of the same API functions for creating client side representation objects (instead of just plain ids). These examples assume that `client_type` is the type of the client side representation of the component type to create. As above, all additional arguments (see, ... notation below) are passed through to the corresponding constructor calls of the server side implementation objects corresponding to the `client_type`:

```cpp
hpx::id_type here = hpx::find_here();
client_type c = hpx::new_<client_type>(here, ...);
```

// create multiple instances on the given locality
```cpp
hpx::id_type here = hpx::find_here();
hpx::future<std::vector<client_type>> f =
    hpx::new_<client_type[]>(here, num, ...);
```

// create multiple instances using the given distribution
```cpp
// policy (here: hpx::colocating_distribution_policy)
hpx::id_type here = hpx::find_here();
client_type c = hpx::new_<client_type>(hpx::colocated(here), ...);
```

Using component instances

Segmented containers

In parallel programming, there is now a plethora of solutions aimed at implementing “partially contiguous” or segmented data structures, whether on shared memory systems or distributed memory systems. HPX implements such structures by drawing inspiration from Standard C++ containers.

Using segmented containers

A segmented container is a template class that is described in the namespace hpx. All segmented containers are very similar semantically to their sequential counterpart (defined in namespace std but with an additional template parameter named DistPolicy). The distribution policy is an optional parameter that is passed last to the segmented container constructor (after the container size when no default value is given, after the default value if not). The distribution policy describes the manner in which a container is segmented and the placement of each segment among the available runtime localities.

However, only a part of the std container member functions were reimplemented:

- (constructor), (destructor), operator=
- operator[]
- begin, cbegin, end, cend
- size
An example of how to use the `partitioned_vector` container would be:

```cpp
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments

HPX_REGISTER_PARTITIONED_VECTOR(double);

// By default, the number of segments is equal to the current number of
// localities

hpx::partitioned_vector<double> va(50);
hpx::partitioned_vector<double> vb(50, 0.0);
```

An example of how to use the `partitioned_vector` container with distribution policies would be:

```cpp
#include <hpx/include/partitioned_vector.hpp>
#include <hpx/runtime_distributed/find_localities.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments

HPX_REGISTER_PARTITIONED_VECTOR(double);

std::size_t num_segments = 10;
std::vector<hpx::id_type> locs = hpx::find_all_localities();

auto layout = hpx::container_layout(num_segments, locs);

// The number of segments is 10 and those segments are spread across the
// localities collected in the variable locs in a Round-Robin manner

hpx::partitioned_vector<double> va(50, layout);
hpx::partitioned_vector<double> vb(50, 0.0, layout);
```

By definition, a segmented container must be accessible from any thread although its construction is synchronous only for the thread who has called its constructor. To overcome this problem, it is possible to assign a symbolic name to the segmented container:

```cpp
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments

HPX_REGISTER_PARTITIONED_VECTOR(double);

hpx::future<void> fserver = hpx::async([](){
    hpx::partitioned_vector<double> v(50);
    // Register the 'partitioned_vector' with the name "some_name"
    //
    // (continues on next page)
    }
```
v.register_as("some_name");

    /* Do some code */
    
});

hpx::future<void> fclient =
    hpx::async(
        [](){
        // Naked 'partitioned_vector'
        // hpx::partitioned_vector<double> v;

        // Now the variable v points to the same 'partitioned_vector' that has
        // been registered with the name "some_name"
        //
        v.connect_to("some_name");

        /* Do some code */
    });

Segmented containers

HPX provides the following segmented containers:

Table 2.23: Sequence containers

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>In header</th>
<th>Class page at cppreference.com</th>
</tr>
</thead>
<tbody>
<tr>
<td>hpx::partitioned_vector</td>
<td>Dynamic segmented contiguous array.</td>
<td>&lt;hpx/include/partitioned_vector.hpp&gt;</td>
<td>vector¹⁴⁵</td>
</tr>
</tbody>
</table>

Table 2.24: Unordered associative containers

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>In header</th>
<th>Class page at cppreference.com</th>
</tr>
</thead>
<tbody>
<tr>
<td>hpx::unordered_map</td>
<td>Segmented collection of key-value pairs, hashed by keys, keys are unique.</td>
<td>&lt;hpx/include/unordered_map.hpp&gt;</td>
<td>unordered_map¹⁴⁶</td>
</tr>
</tbody>
</table>

Segmented iterators and segmented iterator traits

The basic iterator used in the STL library is only suitable for one-dimensional structures. The iterators we use in HPX must adapt to the segmented format of our containers. Our iterators are then able to know when incrementing themselves if the next element of type T is in the same data segment or in another segment. In this second case, the iterator will automatically point to the beginning of the next segment.

Note: Note that the dereference operation operator * does not directly return a reference of type T& but an intermediate object wrapping this reference. When this object is used as an l-value, a remote write operation is performed;

When this object is used as an r-value, implicit conversion to T type will take care of performing remote read operation.

It is sometimes useful not only to iterate element by element, but also segment by segment, or simply get a local iterator in order to avoid additional construction costs at each dereferencing operations. To mitigate this need, the `hpx::traits::segmented_iterator_traits` are used.

With `segmented_iterator_traits` users can uniformly get the iterators which specifically iterates over segments (by providing a segmented iterator as a parameter), or get the local begin/end iterators of the nearest local segment (by providing a per-segment iterator as a parameter):

```cpp
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments

HPX_REGISTER_PARTITIONED_VECTOR(double);

using iterator = hpx::partitioned_vector<T>::iterator;
using traits = hpx::traits::segmented_iterator_traits<iterator>;

hpx::partitioned_vector<T> v;
std::size_t count = 0;

auto seg_begin = traits::segment(v.begin());
auto seg_end = traits::segment(v.end());

// Iterate over segments
for (auto seg_it = seg_begin; seg_it != seg_end; ++seg_it)
{
    auto loc_begin = traits::begin(seg_it);
    auto loc_end = traits::end(seg_it);

    // Iterate over elements inside segments
    for (auto lit = loc_begin; lit != loc_end; ++lit, ++count)
    {
        *lit = count;
    }
}
```

Which is equivalent to:

```cpp
hpx::partitioned_vector<T> v;
std::size_t count = 0;

auto begin = v.begin();
auto end = v.end();

for (auto it = begin; it != end; ++it, ++count)
{
    *it = count;
}
```
Using views

The use of multidimensional arrays is quite common in the numerical field whether to perform dense matrix operations or to process images. It exist many libraries which implement such object classes overloading their basic operators (e.g. `+`, `-`, `*`, `()`, etc.). However, such operation becomes more delicate when the underlying data layout is segmented or when it is mandatory to use optimized linear algebra subroutines (i.e. BLAS subroutines).

Our solution is thus to relax the level of abstraction by allowing the user to work not directly on n-dimensionnal data, but on “n-dimensionnal collections of 1-D arrays”. The use of well-accepted techniques on contiguous data is thus preserved at the segment level, and the composability of the segments is made possible thanks to multidimensional array-inspired access mode.

Preface: Why SPMD?

Although HPX refutes by design this programming model, the locality plays a dominant role when it comes to implement vectorized code. To maximize local computations and avoid unneeded data transfers, a parallel section (or Single Programming Multiple Data section) is required. Because the use of global variables is prohibited, this parallel section is created via the RAII idiom.

To define a parallel section, simply write an action taking a spmd_block variable as a first parameter:

```cpp
#include <hpx/collectives/spmd_block.hpp>

void bulk_function(hpx::lcos::spmd_block block /* , arg0, arg1, ... */)
{
  // Parallel section
  /* Do some code */
}
HPX_PLAIN_ACTION(bulk_function, bulk_action);
```

Note: In the following paragraphs, we will use the term “image” several times. An image is defined as a lightweight process whose entry point is a function provided by the user. It’s an “image of the function”.

The spmd_block class contains the following methods:
- [def Team information] `get_num_images`, `this_image`, `images_per_locality`
- [def Control statements] `sync_all`, `sync_images`

Here is a sample code summarizing the features offered by the spmd_block class:

```cpp
#include <hpx/collectives/spmd_block.hpp>

void bulk_function(hpx::lcos::spmd_block block /* , arg0, arg1, ... */)
{
  std::size_t num_images = block.get_num_images();
  std::size_t this_image = block.this_image();
  std::size_t images_per_locality = block.images_per_locality();
  /* Do some code */
  // Synchronize all images in the team
}
```

(continues on next page)
block.sync_all();
/* Do some code */

// Synchronize image 0 and image 1
block.sync_images(0,1);
/* Do some code */

std::vector<std::size_t> vec_images = {2,3,4};

// Synchronize images 2, 3 and 4
block.sync_images(vec_images);

// Alternative call to synchronize images 2, 3 and 4
block.sync_images(vec_images.begin(), vec_images.end());
/* Do some code */

// Non-blocking version of sync_all()
hpx::future<void> event =
    block.sync_all(hpx::launch::async);

// Callback waiting for 'event' to be ready before being scheduled
hpx::future<void> cb =
    event.then(
        [](hpx::future<void>)
        {
/* Do some code */

    });

// Finally wait for the execution tree to be finished
    cb.get();
}
HPX_PLAIN_ACTION(bulk_test_function, bulk_test_action);

Then, in order to invoke the parallel section, call the function define_spmd_block specifying an arbitrary symbolic name and indicating the number of images per locality to create:

```cpp
void bulk_function(hpx::lcos::spmd_block block, /* , arg0, arg1, ... */)
{
}
}
HPX_PLAIN_ACTION(bulk_test_function, bulk_test_action);

int main()
{
/* std::size_t arg0, arg1, ... */
    bulk_action act;
```
std::size_t images_per_locality = 4;

// Instantiate the parallel section
hpx::lcos::define_spmd_block(
    "some_name", images_per_locality, std::move(act) /*, arg0, arg1, ... */);

return 0;

Note: In principle, the user should never call the spmd_block constructor. The define_spmd_block function is responsible of instantiating spmd_block objects and broadcasting them to each created image.

### SPMD multidimensional views

Some classes are defined as "container views" when the purpose is to observe and/or modify the values of a container using another perspective than the one that characterizes the container. For example, the values of an std::vector object can be accessed via the expression [i]. Container views can be used, for example, when it is desired for those values to be "viewed" as a 2D matrix that would have been flattened in a std::vector. The values would be possibly accessible via the expression vv(i,j) which would call internally the expression v[k].

By default, the partitioned_vector class integrates 1-D views of its segments:

```cpp
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the remote creation of 'partitioned_vector' segments
HPX_REGISTER_PARTITIONED_VECTOR(double);

using iterator = hpx::partitioned_vector<double>::iterator;
using traits = hpx::traits::segmented_iterator_traits<iterator>;

hpx::partitioned_vector<double> v;

// Create a 1-D view of the vector of segments
auto vv = traits::segment(v.begin());

// Access segment i
std::vector<double> v = vv[i];
```

Our views are called “multidimensional” in the sense that they generalize to N dimensions the purpose of segmented_iterator_traits::segment() in the 1-D case. Note that in a parallel section, the 2-D expression a(i,j) = b(i,j) is quite confusing because without convention, each of the images invoked will race to execute the statement. For this reason, our views are not only multidimensional but also “spmd-aware”.

Note: SPMD-awareness: The convention is simple. If an assignment statement contains a view subscript as an l-value, it is only and only the image holding the r-value who is evaluating the statement. (In MPI sense, it is called a Put operation).
Subscript-based operations

Here are some examples of using subscripts in the 2-D view case:

```cpp
#include <hpx/components/containers/partitioned_vector/partitioned_vector_view.hpp>
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
// HPX_REGISTER_PARTITIONED_VECTOR(double);

using Vec = hpx::partitioned_vector<double>;
using View_2D = hpx::partitioned_vector_view<double, 2>;

/* Do some code */
Vec v;

// Parallel section (suppose 'block' an spmd_block instance)
{
    std::size_t height, width;

    // Instantiate the view
    View_2D vv(block, v.begin(), v.end(), {height, width});

    // The l-value is a view subscript, the image that owns vv(1,0)
    // evaluates the assignment.
    vv(0,1) = vv(1,0);

    // The l-value is a view subscript, the image that owns the r-value
    // (result of expression 'std::vector<double>(4,1.0)') evaluates the
    // assignment : oops! race between all participating images.
    vv(2,3) = std::vector<double>(4,1.0);
}
```

Iterator-based operations

Here are some examples of using iterators in the 3-D view case:

```cpp
#include <hpx/components/containers/partitioned_vector/partitioned_vector_view.hpp>
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
// HPX_REGISTER_PARTITIONED_VECTOR(int);

using Vec = hpx::partitioned_vector<int>;
using View_3D = hpx::partitioned_vector_view<int, 3>;

/* Do some code */
```
Vec v1, v2;

// Parallel section (suppose 'block' an spmd_block instance)
{
    std::size_t size_x, size_y, size_z;

    // Instantiate the views
    View_3D vv1(block, v1.begin(), v1.end(), {size_x, size_y, size_z});
    View_3D vv2(block, v2.begin(), v2.end(), {size_x, size_y, size_z});

    // Save previous segments covered by vv1 into segments covered by vv2
    auto vv2_it = vv2.begin();
    auto vv1_it = vv1.cbegin();

    for(; vv2_it != vv2.end(); vv2_it++, vv1_it++)
    {
        // It's a Put operation
        *vv2_it = *vv1_it;
    }

    // Ensure that all images have performed their Put operations
    block.sync_all();

    // Ensure that only one image is putting updated data into the different
    // segments covered by vv1
    if(block.this_image() == 0)
    {
        int idx = 0;

        // Update all the segments covered by vv1
        for(auto i = vv1.begin(); i != vv1.end(); i++)
        {
            // It's a Put operation
            *i = std::vector<float>(elt_size, idx++);
        }
    }
}

Here is an example that shows how to iterate only over segments owned by the current image:

```
#include <hpx/components/containers/partitioned_vector/partitioned_vector_view.hpp>
#include <hpx/components/containers/partitioned_vector/partitioned_vector_local_view.hpp>
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(float);

using Vec = hpx::partitioned_vector<float>;
using View_1D = hpx::partitioned_vector_view<float, 1>;
```
/* Do some code */

Vec v;

// Parallel section (suppose 'block' an spmd_block instance)
{
    std::size_t num_segments;

    // Instantiate the view
    View_1D vv(block, v.begin(), v.end(), {num_segments});

    // Instantiate the local view from the view
    auto local_vv = hpx::local_view(vv);

    for ( auto i = local_vv.begin(); i != local_vv.end(); i++ )
    {
        std::vector<float> & segment = *i;

        /* Do some code */
    }
}

### Instantiating sub-views

It is possible to construct views from other views: we call it sub-views. The constraint nevertheless for the subviews is to retain the dimension and the value type of the input view. Here is an example showing how to create a sub-view:

```
#include <hpx/components/containers/partitioned_vector/partitioned_vector_view.hpp>
#include <hpx/include/partitioned_vector.hpp>

// The following code generates all necessary boiler plate to enable the
// remote creation of 'partitioned_vector' segments
//
HPX_REGISTER_PARTITIONED_VECTOR(float);

using Vec = hpx::partitioned_vector<float>;
using View_2D = hpx::partitioned_vector_view<float,2>;

/* Do some code */

Vec v;

// Parallel section (suppose 'block' an spmd_block instance)
{
    std::size_t N = 20;
    std::size_t tilesize = 5;

    // Instantiate the view
    View_2D vv(block, v.begin(), v.end(), {N,N});
```
// Instantiate the subview
View_2D svv(
    block,&vv(tilesize,0),&vv(2*tilesize-1,tilesize-1),{tilesize,tilesize},{N,N});

if(block.this_image() == 0)
{
    // Equivalent to 'vv(tilesize,0) = 2.0f'
    svv(0,0) = 2.0f;

    // Equivalent to 'vv(2*tilesize-1,tilesize-1) = 3.0f'
    svv(tilesize-1,tilesize-1) = 3.0f;
}

Note: The last parameter of the subview constructor is the size of the original view. If one would like to create a subview of the subview and so on, this parameter should stay unchanged. {N,N} for the above example).

C++ co-arrays

Fortran has extended its scalar element indexing approach to reference each segment of a distributed array. In this extension, a segment is attributed a ?co-index? and lives in a specific locality. A co-index provides the application with enough information to retrieve the corresponding data reference. In C++, containers present themselves as a ?smarter? alternative of Fortran arrays but there are still no corresponding standardized features similar to the Fortran co-indexing approach. We present here an implementation of such features in HPX.

Preface: co-array, a segmented container tied to a SPMD multidimensional views

As mentioned before, a co-array is a distributed array whose segments are accessible through an array-inspired access mode. We have previously seen that it is possible to reproduce such access mode using the concept of views. Nevertheless, the user must pre-create a segmented container to instantiate this view. We illustrate below how a single constructor call can perform those two operations:

```cpp
#include <hpx/components/containers/coarray/coarray.hpp>
#include <hpx/collectives/spmd_block.hpp>

// The following code generates all necessary boiler plate to enable the
// co-creation of 'coarray'

HPX_REGISTER_COARRAY(double);

// Parallel section (suppose 'block' an spmd_block instance)
{
    using hpx::container::placeholders::_;

    std::size_t height=32, width=4, segment_size=10;
```
Unlike segmented containers, a co-array object can only be instantiated within a parallel section. Here is the description of the parameters to provide to the coarray constructor:

Table 2.25: Parameters of coarray constructor

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>block</td>
<td>Reference to a spmd_block object</td>
</tr>
<tr>
<td>&quot;a&quot;</td>
<td>Symbolic name of type std::string</td>
</tr>
<tr>
<td>{height, width, _}</td>
<td>Dimensions of the coarray object</td>
</tr>
<tr>
<td>segment_size</td>
<td>Size of a co-indexed element (i.e. size of the object referenced by the expression a(i,j,k))</td>
</tr>
</tbody>
</table>

Note that the “last dimension size” cannot be set by the user. It only accepts the constexpr variable hpx::container::placeholders::_ This size, which is considered private, is equal to the number of current images (value returned by block.get_num_images()).

**Note:** An important constraint to remember about coarray objects is that all segments sharing the same “last dimension index” are located in the same image.

### Using co-arrays

The member functions owned by the coarray objects are exactly the same as those of spmd multidimensional views. These are:

* Subscript-based operations
* Iterator-based operations

However, one additional functionality is provided. Knowing that the element a(i,j,k) is in the memory of the kth image, the use of local subscripts is possible.

**Note:** For spmd multidimensional views, subscripts are only global as it still involves potential remote data transfers.

Here is an example of using local subscripts:

```cpp
#include <hpx/components/containers/coarray/coarray.hpp>
#include <hpx/collectives/spmd_block.hpp>

// The following code generates all necessary boiler plate to enable the
creation of 'coarray'
HPX_REGISTER_COARRAY(double);

// Parallel section (suppose 'block' an spmd_block instance)
{
```
using hpx::container::placeholders::_;

std::size_t height=32, width=4, segment_size=10;

hpx::coarray<double,3> a(block, "a", {height, width, _}, segment_size);

double idx = block.this_image()*height*width;

for (std::size_t j = 0; j<width; j++)
for (std::size_t i = 0; i<height; i++)
{
    // Local write operation performed via the use of local subscript
    a(i,j,_)= std::vector<double>(elt_size,idx);
    idx++;
}

block.sync_all();

Note: When the “last dimension index” of a subscript is equal to hpx::container::placeholders::_, local subscript (and not global subscript) is used. It is equivalent to a global subscript used with a “last dimension index” equal to the value returned by block.this_image().

2.3.12 Running on batch systems

This section walks you through launching HPX applications on various batch systems.

How to use HPX applications with PBS

Most HPX applications are executed on parallel computers. These platforms typically provide integrated job management services that facilitate the allocation of computing resources for each parallel program. HPX includes support for one of the most common job management systems, the Portable Batch System (PBS).

All PBS jobs require a script to specify the resource requirements and other parameters associated with a parallel job. The PBS script is basically a shell script with PBS directives placed within commented sections at the beginning of the file. The remaining (not commented-out) portions of the file executes just like any other regular shell script. While the description of all available PBS options is outside the scope of this tutorial (the interested reader may refer to in-depth documentation 147 for more information), below is a minimal example to illustrate the approach. The following test application will use the multithreaded hello_world_distributed program, explained in the section Remote execution with actions.

#!/bin/bash
#
#PBS -l nodes=2:ppn=4

APP_PATH=~/packages/hpx/bin/hello_world_distributed
APP_OPTIONS=

147 http://www.clusterresources.com/torquedocs21/
pbsdsh -u $APP_PATH $APP_OPTIONS --hpx: nodes=`cat $PBS_NODEFILE`

Caution: If the first application specific argument (inside $APP_OPTIONS) is a non-option (i.e., does not start with a - or a --), then the argument has to be placed before the option --hpx: nodes, which, in this case, should be the last option on the command line.

Alternatively, use the option --hpx: endnodes to explicitly mark the end of the list of node names:

$ pbsdsh -u $APP_PATH --hpx: nodes=`cat $PBS_NODEFILE` --hpx: endnodes $APP_OPTIONS

The #PBS -l nodes=2:ppn=4 directive will cause two compute nodes to be allocated for the application, as specified in the option nodes. Each of the nodes will dedicate four cores to the program, as per the option ppn, short for “processors per node” (PBS does not distinguish between processors and cores). Note that requesting more cores per node than physically available is pointless and may prevent PBS from accepting the script.

On newer PBS versions the PBS command syntax might be different. For instance, the PBS script above would look like:

```bash
#!/bin/bash
#
#PBS -l select=2:ncpus=4
APP_PATH=~/packages/hpx/bin/hello_world_distributed
APP_OPTIONS=

pbsdsh -u $APP_PATH $APP_OPTIONS --hpx: nodes=`cat $PBS_NODEFILE` --hpx: endnodes
```

APP_PATH and APP_OPTIONS are shell variables that respectively specify the correct path to the executable (hello_world_distributed in this case) and the command line options. Since the hello_world_distributed application doesn’t need any command line options, APP_OPTIONS has been left empty. Unlike in other execution environments, there is no need to use the --hpx: threads option to indicate the required number of OS threads per node; the HPX library will derive this parameter automatically from PBS.

Finally, pbsdsh is a PBS command that starts tasks to the resources allocated to the current job. It is recommended to leave this line as shown and modify only the PBS options and shell variables as needed for a specific application.

Important: A script invoked by pbsdsh starts in a very basic environment: the user’s $HOME directory is defined and is the current directory, the LANG variable is set to C and the PATH is set to the basic /usr/local/bin:/usr/bin:/bin as defined in a system-wide file pbs_environment. Nothing that would normally be set up by a system shell profile or user shell profile is defined, unlike the environment for the main job script.

Another choice is for the pbsdsh command in your main job script to invoke your program via a shell, like sh or bash, so that it gives an initialized environment for each instance. Users can create a small script `runme.sh`, which is used to invoke the program:

```bash
#!/bin/bash
# Small script which invokes the program based on what was passed on its
# command line.
#
# This script is executed by the bash shell which will initialize all
```

(continues on next page)
# environment variables as usual.

$@

Now, the script is invoked using the pbsdsh tool:

```bash
#!/bin/bash
#
#PBS -l nodes=2:ppn=4

APP_PATH=~/packages/hpx/bin/hello_world_distributed
APP_OPTIONS=$@

pbsdsh -u runme.sh $APP_PATH $APP_OPTIONS --hpx:nodes=`cat $PBS_NODEFILE`
```

All that remains now is submitting the job to the queuing system. Assuming that the contents of the PBS script were saved in the file `pbs_hello_world.sh` in the current directory, this is accomplished by typing:

```bash
$ qsub ./pbs_hello_world_pbs.sh
```

If the job is accepted, qsub will print out the assigned job ID, which may look like:

```bash
$ 42.supercomputer.some.university.edu
```

To check the status of your job, issue the following command:

```bash
$ qstat 42.supercomputer.some.university.edu
```

and look for a single-letter job status symbol. The common cases include:

- **Q** - signifies that the job is queued and awaiting its turn to be executed.
- **R** - indicates that the job is currently running.
- **C** - means that the job has completed.

The example qstat output below shows a job waiting for execution resources to become available:

<table>
<thead>
<tr>
<th>Job id</th>
<th>Name</th>
<th>User</th>
<th>Time</th>
<th>Use</th>
<th>S</th>
<th>Queue</th>
</tr>
</thead>
<tbody>
<tr>
<td>42.supercomputer...ello_world.sh joe_user</td>
<td>0</td>
<td>Q</td>
<td></td>
<td>Q</td>
<td></td>
<td>batch</td>
</tr>
</tbody>
</table>

After the job completes, PBS will place two files, `pbs_hello_world.sh.o42` and `pbs_hello_world.sh.e42`, in the directory where the job was submitted. The first contains the standard output and the second contains the standard error from all the nodes on which the application executed. In our example, the error output file should be empty and the standard output file should contain something similar to:

```
hello world from OS-thread 3 on locality 0
hello world from OS-thread 2 on locality 0
hello world from OS-thread 1 on locality 1
hello world from OS-thread 0 on locality 0
hello world from OS-thread 3 on locality 1
hello world from OS-thread 2 on locality 1
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 1
```

Congratulations! You have just run your first distributed *HPX* application!
How to use *HPX* applications with SLURM

Just like PBS (described in section *How to use HPX applications with PBS*), SLURM is a job management system which is widely used on large supercomputing systems. Any *HPX* application can easily be run using SLURM. This section describes how this can be done.

The easiest way to run an *HPX* application using SLURM is to utilize the command line tool *srun*, which interacts with the SLURM batch scheduling system:

```
$ srun -p <partition> -N <number-of-nodes> hpx-application <application-arguments>
```

Here, `<partition>` is one of the node partitions existing on the target machine (consult the machine’s documentation to get a list of existing partitions) and `<number-of-nodes>` is the number of compute nodes that should be used. By default, the *HPX* application is started with one *locality* per node and uses all available cores on a node. You can change the number of localities started per node (for example, to account for NUMA effects) by specifying the `-n` option of `srun`. The number of cores per *locality* can be set by `-c`. The `<application-arguments>` are any application specific arguments that need to be passed on to the application.

**Note:** There is no need to use any of the *HPX* command line options related to the number of localities, number of threads, or related to networking ports. All of this information is automatically extracted from the SLURM environment by the *HPX* startup code.

**Important:** The `srun` documentation explicitly states: “If `-c` is specified without `-n`, as many tasks will be allocated per node as possible while satisfying the `-c` restriction. For instance on a cluster with 8 CPUs per node, a job request for 4 nodes and 3 CPUs per task may be allocated 3 or 6 CPUs per node (1 or 2 tasks per node) depending upon resource consumption by other jobs.” For this reason, it’s recommended to always specify `-n <number-of-instances>`, even if `<number-of-instances>` is equal to one (1).

**Interactive shells**

To get an interactive development shell on one of the nodes, users can issue the following command:

```
$ srun -p <node-type> -N <number-of-nodes> --pty /bin/bash -l
```

After the shell has been opened, users can run their *HPX* application. By default, it uses all available cores. Note that if you requested one node, you don’t need to do *srun* again. However, if you requested more than one node, and want to run your distributed application, you can use *srun* again to start up the distributed *HPX* application. It will use the resources that have been requested for the interactive shell.

**Scheduling batch jobs**

The above mentioned method of running *HPX* applications is fine for development purposes. The disadvantage that comes with `srun` is that it only returns once the application is finished. This might not be appropriate for longer-running applications (for example, benchmarks or larger scale simulations). In order to cope with that limitation, users can use the `sbatch` command.

The `sbatch` command expects a script that it can run once the requested resources are available. In order to request resources, users need to add `#SBATCH` comments in their script or provide the necessary parameters to `sbatch` directly. The parameters are the same as with `run`. The commands you need to execute are the same you would need to start your application as if you were in an interactive shell.
2.3.13 Debugging HPX applications

Using a debugger with HPX applications

Using a debugger such as `gdb` with HPX applications is no problem. However, there are some things to keep in mind to make the experience somewhat more productive.

Call stacks in HPX can often be quite unwieldy as the library is heavily templated and the call stacks can be very deep. For this reason it is sometimes a good idea compile HPX in `RelWithDebInfo` mode, which applies some optimizations but keeps debugging symbols. This can often compress call stacks significantly. On the other hand, stepping through the code can also be more difficult because of statements being reordered and variables being optimized away. Also, note that because HPX implements user-space threads and context switching, call stacks may not always be complete in a debugger.

HPX launches not only worker threads but also a few helper threads. The first thread is the main thread, which typically does no work in an HPX application, except at startup and shutdown. If using the default settings, HPX will spawn six additional threads (used for service thread pools). The first worker thread is usually the eighth thread, and most user codes will be run on these worker threads. The last thread is a helper thread used for HPX shutdown.

Finally, since HPX is a multi-threaded runtime, the following `gdb` options can be helpful:

```
set pagination off
set non-stop on
```

Non-stop mode allows users to have a single thread stop on a breakpoint without stopping all other threads as well.

Using sanitizers with HPX applications

**Warning:** Not all parts of HPX are sanitizer clean. This means that users may end up with false positives from HPX itself when using sanitizers for their applications.

To use sanitizers with HPX, turn on `HPX_WITH_SANITIZERS` and turn off `HPX_WITH_STACKOVERFLOW_DETECTION` during CMake configuration. It’s recommended to also build Boost with the same sanitizers that will be used for HPX. The appropriate sanitizers can then be enabled using CMake by appending `-fsanitize=address -fno-omit-frame-pointer` to `CMAKE_CXX_FLAGS` and `-fsanitize=address` to `CMAKE_EXE_LINKER_FLAGS`. Replace `address` with the sanitizer that you want to use.

Debugging applications using core files

For HPX to generate useful core files, HPX has to be compiled without signal and exception handlers `HPX_WITH_DISABLED_SIGNAL_EXCEPTION_HANDLERS:BOOL`. If this option is not specified, the signal handlers change the application state. For example, after a segmentation fault the stack trace will show the signal handler. Similarly, unhandled exceptions are also caught by these handlers and the stack trace will not point to the location where the unhandled exception was thrown.

In general, core files are a helpful tool to inspect the state of the application at the moment of the crash (post-mortem debugging), without the need of attaching a debugger beforehand. This approach to debugging is especially useful if the error cannot be reliably reproduced, as only a single crashed application run is required to gain potentially helpful information like a stack trace.

To debug with core files, the operating system first has to be told to actually write them. On most Unix systems this can be done by calling:
$ ulimit -c unlimited

in the shell. Now the debugger can be started up with:

$ gdb <application> <core file name>

The debugger should now display the last state of the application. The default file name for core files is core.

### 2.3.14 Optimizing HPX applications

#### Performance counters

Performance counters in **HPX** are used to provide information as to how well the runtime system or an application is performing. The counter data can help determine system bottlenecks, and fine-tune system and application performance. The **HPX** runtime system, its networking, and other layers provide counter data that an application can consume to provide users with information about how well the application is performing.

Applications can also use counter data to determine how much system resources to consume. For example, an application that transfers data over the network could consume counter data from a network switch to determine how much data to transfer without competing for network bandwidth with other network traffic. The application could use the counter data to adjust its transfer rate as the bandwidth usage from other network traffic increases or decreases.

Performance counters are **HPX** parallel processes that expose a predefined interface. **HPX** exposes special API functions that allow one to create, manage, and read the counter data, and release instances of performance counters. Performance Counter instances are accessed by name, and these names have a predefined structure which is described in the section Performance counter names. The advantage of this is that any Performance Counter can be accessed remotely (from a different *locality*) or locally (from the same *locality*). Moreover, since all counters expose their data using the same API, any code consuming counter data can be utilized to access arbitrary system information with minimal effort.

Counter data may be accessed in real time. More information about how to consume counter data can be found in the section Consuming performance counter data.

All **HPX** applications provide command line options related to performance counters, such as the ability to list available counter types, or periodically query specific counters to be printed to the screen or save them in a file. For more information, please refer to the section HPX Command Line Options.

#### Performance counter names

All Performance Counter instances have a name uniquely identifying each instance. This name can be used to access the counter, retrieve all related meta data, and to query the counter data (as described in the section Consuming performance counter data). Counter names are strings with a predefined structure. The general form of a countername is:

```
/objectname{full_instancename}/countername@parameters
```

where *full_instancename* could be either another (full) counter name or a string formatted as:

```
parentinstancename#parentindex/instancename#instanceindex
```

Each separate part of a countername (e.g., *objectname*, *countername* *parentinstancename*, *instancename*, and *parameters*) should start with a letter ('a'...'z', 'A'...'Z') or an underscore character ('_'), optionally followed by letters, digits ('0'...'9'), hyphen ('-'), or underscore characters. Whitespace is not allowed inside a counter name. The characters '/' ', '{', '}', '#', and '@' have a special meaning and are used to delimit the different parts of the counter name.
The parts parentinstanceindex and instanceindex are integers. If an index is not specified, HPX will assume a default of -1.

Two counter name examples

This section gives examples of both simple counter names and aggregate counter names. For more information on simple and aggregate counter names, please see Performance counter instances.

An example of a well-formed (and meaningful) simple counter name would be:

```
/threads{locality#0/total}/count/cumulative
```

This counter returns the current cumulative number of executed (retired) HPX threads for the locality 0. The counter type of this counter is /threads/count/cumulative and the full instance name is locality#0/total. This counter type does not require an instanceindex or parameters to be specified.

In this case, the parentindex (the '0') designates the locality for which the counter instance is created. The counter will return the number of HPX threads retired on that particular locality.

Another example for a well formed (aggregate) counter name is:

```
/statistics{/threads{locality#0/total}/count/cumulative}/average@500
```

This counter takes the simple counter from the first example, samples its values every 500 milliseconds, and returns the average of the value samples whenever it is queried. The counter type of this counter is /statistics/average and the instance name is the full name of the counter for which the values have to be averaged. In this case, the parameters (the '500') specify the sampling interval for the averaging to take place (in milliseconds).

Performance counter types

Every performance counter belongs to a specific performance counter type which classifies the counters into groups of common semantics. The type of a counter is identified by the objectname and the countername parts of the name.

```
/objectname/countername
```

When an application starts HPX will register all available counter types on each of the localities. These counter types are held in a special performance counter registration database, which can be used to retrieve the meta data related to a counter type and to create counter instances based on a given counter instance name.

Performance counter instances

The full_instancename distinguishes different counter instances of the same counter type. The formatting of the full_instancename depends on the counter type. There are two types of counters: simple counters, which usually generate the counter values based on direct measurements, and aggregate counters, which take another counter and transform its values before generating their own counter values. An example for a simple counter is given above: counting retired HPX threads. An aggregate counter is shown as an example above as well: calculating the average of the underlying counter values sampled at constant time intervals.

While simple counters use instance names formatted as parentinstancename#parentindex/instancename#instanceindex, most aggregate counters have the full counter name of the embedded counter as their instance name.

Not all simple counter types require specifying all four elements of a full counter instance name; some of the parts (parentinstancename, parentindex, instancename, and instanceindex) are optional for specific counters.
Please refer to the documentation of a particular counter for more information about the formatting requirements for the name of this counter (see Existing HPX performance counters).

The parameters are used to pass additional information to a counter at creation time. They are optional, and they fully depend on the concrete counter. Even if a specific counter type allows additional parameters to be given, those usually are not required as sensible defaults will be chosen. Please refer to the documentation of a particular counter for more information about what parameters are supported, how to specify them, and what default values are assumed (see also Existing HPX performance counters).

Every locality of an application exposes its own set of performance counter types and performance counter instances. The set of exposed counters is determined dynamically at application start based on the execution environment of the application. For instance, this set is influenced by the current hardware environment for the locality (such as whether the locality has access to accelerators), and the software environment of the application (such as the number of OS threads used to execute HPX threads).

Using wildcards in performance counter names

It is possible to use wildcard characters when specifying performance counter names. Performance counter names can contain two types of wildcard characters:

- Wildcard characters in the performance counter type
- Wildcard characters in the performance counter instance name

A wildcard character has a meaning which is very close to usual file name wildcard matching rules implemented by common shells (like bash).

<table>
<thead>
<tr>
<th>Wildcard</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>This wildcard character matches any number (zero or more) of arbitrary characters.</td>
</tr>
<tr>
<td>?</td>
<td>This wildcard character matches any single arbitrary character.</td>
</tr>
<tr>
<td>[...]</td>
<td>This wildcard character matches any single character from the list of specified within the square brackets.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Wildcard</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>This wildcard character matches any locality or any thread, depending on whether it is used for locality#* or worker-thread#*. No other wildcards are allowed in counter instance names.</td>
</tr>
</tbody>
</table>

Consuming performance counter data

You can consume performance data using either the command line interface, the HPX application or the HPX API. The command line interface is easier to use, but it is less flexible and does not allow one to adjust the behaviour of your application at runtime. The command line interface provides a convenience abstraction but simplified abstraction for querying and logging performance counter data for a set of performance counters.
Consuming performance counter data from the command line

HPX provides a set of predefined command line options for every application that uses hpx::init for its initialization. While there are many more command line options available (see HPX Command Line Options), the set of options related to performance counters allows one to list existing counters, and query existing counters once at application termination or repeatedly after a constant time interval.

The following table summarizes the available command line options:

<table>
<thead>
<tr>
<th>Command line option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--hpx:print-counter</td>
<td>Prints the specified performance counter either repeatedly and/or at the times specified by --hpx:print-counter-at (see also option --hpx:print-counter-interval).</td>
</tr>
<tr>
<td>--hpx:print-counter-reset</td>
<td>Prints the specified performance counter either repeatedly and/or at the times specified by --hpx:print-counter-at. Reset the counter after the value is queried (see also option --hpx:print-counter-interval).</td>
</tr>
<tr>
<td>--hpx:print-counter-interval</td>
<td>Prints the performance counter(s) specified with --hpx:print-counter repeatedly after the time interval (specified in milliseconds) (default: 0 which means print once at shutdown).</td>
</tr>
<tr>
<td>--hpx:print-counter-destination</td>
<td>Prints the performance counter(s) specified with --hpx:print-counter to the given file (default: console).</td>
</tr>
<tr>
<td>--hpx:list-counters</td>
<td>Lists the names of all registered performance counters.</td>
</tr>
<tr>
<td>--hpx:list-counter-infos</td>
<td>Lists the description of all registered performance counters.</td>
</tr>
<tr>
<td>--hpx:print-counter-format</td>
<td>Prints the performance counter(s) specified with --hpx:print-counter. Possible formats in CSV format with header or without any header (see option --hpx:no-csv-header), possible values: csv (prints counter values in CSV format with full names as header) csv-short (prints counter values in CSV format with shortnames provided with --hpx:print-counter as --hpx:print-counter-shortname,full-countername).</td>
</tr>
<tr>
<td>--hpx:no-csv-header</td>
<td>Prints the performance counter(s) specified with --hpx:print-counter and csv or csv-short format specified with --hpx:print-counter-format without header.</td>
</tr>
<tr>
<td>--hpx:print-counter-at arg</td>
<td>Performance counter(s) specified with --hpx:print-counter (or --hpx:print-counter-reset) at the given point in time. Possible argument values: startup, shutdown (default), noshutdown.</td>
</tr>
<tr>
<td>--hpx:reset-counters</td>
<td>Resets all performance counter(s) specified with --hpx:print-counter after they have been evaluated.</td>
</tr>
<tr>
<td>--hpx:print-counter-types</td>
<td>Appends counter type description to generated output.</td>
</tr>
<tr>
<td>--hpx:print-counters-locally</td>
<td>Each locality prints only its own local counters.</td>
</tr>
</tbody>
</table>

While the options --hpx:list-counters and --hpx:list-counter-infos give a short list of all available counters, the full documentation for those can be found in the section Existing HPX performance counters.
A simple example

All of the commandline options mentioned above can be tested using the `hello_world_distributed` example.

Listing all available counters `hello_world_distributed --hpx:list-counters` yields:

```
List of available counter instances (replace * below with the appropriate sequence number)
-------------------------------------------------------------------------
/agas/count/allocate /agas/count/bind /agas/count/bind_gid
/agas/count/bind_name ... /threads{locality#/total}/count/objects
/threads{locality#/total}/count/stack-recycles
/threads{locality#/total}/idle-rate
/threads{locality#/worker-thread#/}/idle-rate
```

Providing more information about all available counters, `hello_world_distributed --hpx:list-counter-infos` yields:

```
Information about available counter instances (replace * below with the appropriate sequence number)
-------------------------------------------------------------------------
fullname: /agas/count/allocate helptext: returns the number of invocations of the AGAS service 'allocate' type: counter_type::raw version: 1.0.0
-------------------------------------------------------------------------
fullname: /agas/count/bind helptext: returns the number of invocations of the AGAS service 'bind' type: counter_type::raw version: 1.0.0
-------------------------------------------------------------------------
 fullname: /agas/count/bind_gid helptext: returns the number of invocations of the AGAS service 'bind_gid' type: counter_type::raw version: 1.0.0
-------------------------------------------------------------------------
...
```

This command will not only list the counter names but also a short description of the data exposed by this counter.

**Note:** The list of available counters may differ depending on the concrete execution environment (hardware or software) of your application.

Requesting the counter data for one or more performance counters can be achieved by invoking `hello_world_distributed` with a list of counter names:

```
$ hello_world_distributed
   --hpx:print-counter=/threads{locality#0/total}/count/cumulative
   --hpx:print-counter=/agas{locality#0/total}/count/bind
```

which yields for instance:

```
hello world from OS-thread 0 on locality 0
/threads{locality#0/total}/count/cumulative,1,0.212527,[s],33
/agas{locality#0/total}/count/bind,1,0.212790,[s],11
```
The first line is the normal output generated by `hello_world_distributed` and has no relation to the counter data listed. The last two lines contain the counter data as gathered at application shutdown. These lines have six fields, the counter name, the sequence number of the counter invocation, the time stamp at which this information has been sampled, the unit of measure for the time stamp, the actual counter value and an optional unit of measure for the counter value.

**Note:** The command line option `--hpx:print-counter-types` will append a seventh field to the generated output. This field will hold an abbreviated counter type.

The actual counter value can be represented by a single number (for counters returning singular values) or a list of numbers separated by `:` (for counters returning an array of values, like for instance a histogram).

**Note:** The name of the performance counter will be enclosed in double quotes """ if it contains one or more commas ",".

Requesting to query the counter data once after a constant time interval with this command line:

```bash
$ hello_world_distributed
   --hpx:print-counter=/threads{locality#0/total}/count/cumulative
   --hpx:print-counter=/agas{locality#0/total}/count/bind
   --hpx:print-counter-interval=20
```

yields for instance (leaving off the actual console output of the `hello_world_distributed` example for brevity):

```
threads{locality#0/total}/count/cumulative,1,0.002409,[s],22
agas{locality#0/total}/count/bind,1,0.002542,[s],9
threads{locality#0/total}/count/cumulative,2,0.023002,[s],41
agas{locality#0/total}/count/bind,2,0.023557,[s],10
threads{locality#0/total}/count/cumulative,3,0.037514,[s],46
agas{locality#0/total}/count/bind,3,0.038679,[s],10
```

The command `--hpx:print-counter-destination=<file>` will redirect all counter data gathered to the specified file name, which avoids cluttering the console output of your application.

The command line option `--hpx:print-counter` supports using a limited set of wildcards for a (very limited) set of use cases. In particular, all occurrences of `*` as in `locality#*` and in `worker-thread#*` will be automatically expanded to the proper set of performance counter names representing the actual environment for the executed program. For instance, if your program is utilizing four worker threads for the execution of `HPX` threads (see command line option `--hpx:threads`) the following command line

```bash
$ hello_world_distributed
   --hpx:threads=4
   --hpx:print-counter=/threads{locality#0/worker-thread#*}/count/cumulative
```

will print the value of the performance counters monitoring each of the worker threads:

```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 0
hello world from OS-thread 3 on locality 0
hello world from OS-thread 2 on locality 0
/threads{locality#0/worker-thread#0}/count/cumulative,1,0.0025214,[s],27
/threads{locality#0/worker-thread#1}/count/cumulative,1,0.0025433,[s],33
```
The command `--hpx:print-counter-format` takes values `csv` and `csv-short` to generate CSV formatted counter values with a header.

With format as `csv`:
```
$ hello_world_distributed \
  --hpx:threads=2 \
  --hpx:print-counter-format csv \
  --hpx:print-counter /threads{locality#*/total}/count/cumulative \
  --hpx:print-counter /threads{locality#*/total}/count/cumulative-phases
```

will print the values of performance counters in CSV format with the full countername as a header:
```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 0
/threads{locality#*/total}/count/cumulative,/threads{locality#*/total}/count/cumulative-phases
39,93
```

With format `csv-short`:
```
$ hello_world_distributed \
  --hpx:threads 2 \
  --hpx:print-counter-format csv-short \
  --hpx:print-counter cumulative,/threads{locality#*/total}/count/cumulative \
  --hpx:print-counter phases,/threads{locality#*/total}/count/cumulative-phases
```

will print the values of performance counters in CSV format with the short countername as a header:
```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 0
cumulative,phases
39,93
```

With format `csv` and `csv-short` when used with `--hpx:print-counter-interval`:
```
$ hello_world_distributed \
  --hpx:threads 2 \
  --hpx:print-counter-format csv-short \
  --hpx:print-counter cumulative,/threads{locality#*/total}/count/cumulative \
  --hpx:print-counter phases,/threads{locality#*/total}/count/cumulative-phases \
  --hpx:print-counter-interval 5
```

will print the header only once repeating the performance counter value(s) repeatedly:
```
cum,phases
25,42
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 0
44,95
```
The command `--hpx:no-csv-header` can be used with `--hpx:print-counter-format` to print performance counter values in CSV format without any header:

```
$ hello_world_distributed \
   --hpx:threads 2 \
   --hpx:print-counter-format csv-short \
   --hpx:print-counter cumulative,/threads{locality#*/total}/count/cumulative \
   --hpx:print-counter phases,/threads{locality#*/total}/count/cumulative-phases \
   --hpx:no-csv-header
```

will print:

```
hello world from OS-thread 1 on locality 0
hello world from OS-thread 0 on locality 0
37,91
```

### Consuming performance counter data using the HPX API

HPX provides an API that allows users to discover performance counters and to retrieve the current value of any existing performance counter from any application.

**Discover existing performance counters**

**Retrieve the current value of any performance counter**

Performance counters are specialized HPX components. In order to retrieve a counter value, the performance counter needs to be instantiated. HPX exposes a client component object for this purpose:

```
// instantiating a client component object
hpx::performance_counters::performance_counter counter(std::string const& name);
```

Instantiating an instance of this type will create the performance counter identified by the given name. Only the first invocation for any given counter name will create a new instance of that counter. All following invocations for a given counter name will reference the initially created instance. This ensures that at any point in time there is never more than one active instance of any of the existing performance counters.

In order to access the counter value (or to invoke any of the other functionality related to a performance counter, like `start`, `stop` or `reset`) member functions of the created client component instance should be called:

```
// print the current number of threads created on locality 0
hpx::performance_counters::performance_counter count("/threads{locality#0/total}/count/cumulative");
HPX::cout << count.get_value<int>().get() << std::endl;
```

For more information about the client component type, see `hpx::performance_counters::performance_counter`

**Note:** In the above example `count.get_value()` returns a future. In order to print the result we must append `.get()` to retrieve the value. You could write the above example like this for more clarity:

```
// print the current number of threads created on locality 0
hpx::performance_counters::performance_counter count("/threads{locality#0/total}/count/cumulative");
```
Providing performance counter data

HPX offers several ways by which you may provide your own data as a performance counter. This has the benefit of exposing additional, possibly application-specific information using the existing Performance Counter framework, unifying the process of gathering data about your application.

An application that wants to provide counter data can implement a performance counter to provide the data. When a consumer queries performance data, the HPX runtime system calls the provider to collect the data. The runtime system uses an internal registry to determine which provider to call.

Generally, there are two ways of exposing your own performance counter data: a simple, function-based way and a more complex, but more powerful way of implementing a full performance counter. Both alternatives are described in the following sections.

Exposing performance counter data using a simple function

The simplest way to expose arbitrary numeric data is to write a function which will then be called whenever a consumer queries this counter. Currently, this type of performance counter can only be used to expose integer values. The expected signature of this function is:

```
std::int64_t some_performance_data(bool reset);
```

The argument `bool reset` (which is supplied by the runtime system when the function is invoked) specifies whether the counter value should be reset after evaluating the current value (if applicable).

For instance, here is such a function returning how often it was invoked:

```
// The atomic variable 'counter' ensures the thread safety of the counter.
boost::atomic<std::int64_t> counter(0);

std::int64_t some_performance_data(bool reset)
{
    std::int64_t result = ++counter;
    if (reset)
        counter = 0;
    return result;
}
```

This example function exposes a linearly-increasing value as our performance data. The value is incremented on each invocation, i.e., each time a consumer requests the counter data of this performance counter.

The next step in exposing this counter to the runtime system is to register the function as a new raw counter type using the HPX API function `hpx::performance_counters::install_counter_type`. A counter type represents certain common characteristics of counters, like their counter type name and any associated description information. The following snippet shows an example of how to register the function `some_performance_data`, which is shown above, for a counter type named "/test/data". This registration has to be executed before any consumer instantiates, and queries an instance of this counter type:
```cpp
#include <hpx/include/performance_counters.hpp>

void register_counter_type()
{
    // Call the HPX API function to register the counter type.
    hpx::performance_counters::install_counter_type(
        "/test/data", // counter type name
        &some_performance_data, // function providing counter
        "returns a linearly increasing counter value" // description text (optional)
        "", // unit of measure (optional)
        data);
}
```

Now it is possible to instantiate a new counter instance based on the naming scheme "/test{locality*/total}/data" where * is a zero-based integer index identifying the locality for which the counter instance should be accessed. The function `hpx::performance_counters::install_counter_type` enables users to instantiate exactly one counter instance for each locality. Repeated requests to instantiate such a counter will return the same instance, i.e., the instance created for the first request.

If this counter needs to be accessed using the standard HPX command line options, the registration has to be performed during application startup, before `hpx_main` is executed. The best way to achieve this is to register an HPX startup function using the API function `hpx::register_startup_function` before calling `hpx::init` to initialize the runtime system:

```cpp
int main(int argc, char* argv[])
{
    // By registering the counter type we make it available to any consumer
    // who creates and queries an instance of the type "/test/data".
    //
    // This registration should be performed during startup. The
    // function 'register_counter_type' should be executed as an HPX thread right
    // before hpx_main is executed.
    hpx::register_startup_function(&register_counter_type);

    // Initialize and run HPX.
    return hpx::init(argc, argv);
}
```

Please see the code in `simplest_performance_counter.cpp` for a full example demonstrating this functionality.

### Implementing a full performance counter

Sometimes, the simple way of exposing a single value as a performance counter is not sufficient. For that reason, HPX provides a means of implementing full performance counters which support:

- Retrieving the descriptive information about the performance counter
- Retrieving the current counter value
- Resetting the performance counter (value)
- Starting the performance counter
- Stopping the performance counter
Setting the (initial) value of the performance counter

Every full performance counter will implement a predefined interface:

```cpp
#include <hpx/config.hpp>
#include <hpx/async_base/launch_policy.hpp>
#include <hpx/components/client_base.hpp>
#include <hpx/functional/bind_front.hpp>
#include <hpx/futures/future.hpp>
#include <hpx/modules/execution.hpp>
#include <hpx/performance_counters/counters_fwd.hpp>
#include <hpx/performance_counters/server/base_performance_counter.hpp>
#include <string>
#include <utility>
#include <vector>
#include <hpx/config/warnings_prefix.hpp>

namespace hpx::performance_counters {

    struct HPX_EXPORT performance_counter
        : components::client_base<performance_counter,
                                   server::base_performance_counter>
    {
        using base_type = components::client_base<performance_counter,
                                                   server::base_performance_counter>;

        performance_counter() = default;

        explicit performance_counter(std::string const& name);

        performance_counter(
            std::string const& name, hpx::id_type const& locality);

        performance_counter(id_type const& id)
            : base_type(id)
        {
        }

        performance_counter(future<id_type>&& id)
            : base_type(HPX_MOVE(id))
        {
```
performance_counter(hpx::future<performance_counter>&& c)
  : base_type(HPX_MOVE(c))
{
}

///////////////////////////////////////////////////////////////////////
future<counter_info> get_info() const;
counter_info get_info(
  launch::sync_policy, error_code& ec = throws) const;

future<counter_value> get_counter_value(bool reset) const;

private:
  template <typename T>
  static T extract_value(future<counter_value>&& value)
  {
    return value.get().get_value<T>();
  }

(continues on next page)
In order to implement a full performance counter, you have to create an HPX component exposing this interface. To simplify this task, HPX provides a ready-made base class which handles all the boiler plate of creating a component for you. The remainder of this section will explain the process of creating a full performance counter based on the Sine example, which you can find in the directory examples/performance_counters/sine/.

The base class is defined in the header file base_performance_counter.cpp as:

```cpp
#pragma once
#include <hpx/config.hpp>
#include <hpx/actions_base/component_action.hpp>

public:
    template <typename T>
    future<T> get_value(bool reset = false)
    {
        return get_counter_value(reset).then(hpx::launch::sync,
            hpx::bind_front(&performance_counter::extract_value<T>));
    }

    template <typename T>
    T get_value(
        launch::sync_policy, bool reset = false, error_code& ec = throws)
    {
        return get_counter_value(launch::sync, reset).get_value<T>(ec);
    }

    template <typename T>
    future<T> get_value() const
    {
        return get_counter_value(false).then(hpx::launch::sync,
            hpx::bind_front(&performance_counter::extract_value<T>));
    }

    template <typename T>
    T get_value(launch::sync_policy, error_code& ec = throws) const
    {
        return get_counter_value(launch::sync, false).get_value<T>(ec);
    }

    // Return all counters matching the given name (with optional wild cards).
    HPX_EXPORT std::vector<performance_counter> discover_counters(
        std::string const& name, error_code& ec = throws);
} // namespace hpx::performance_counters
```

```cpp
#include <hpx/config/warnings_suffix.hpp>

2.3. Manual
```
```cpp
#include <hpx/components_base/component_type.hpp>
#include <hpx/components_base/server/component_base.hpp>
#include <hpx/performance_counters/counters.hpp>
#include <hpx/performance_counters/server/base_performance_counter.hpp>

namespace hpx { namespace performance_counters {
    template <typename Derived>
    class base_performance_counter {
    public:
        using type_holder = Derived;
        using base_type_holder = hpx::performance_counters::server::base_performance_counter;
        base_performance_counter() = default;
        base_performance_counter(hpx::performance_counters::counter_info const& info)
            : base_type_holder(info) {}
    
    // Disambiguate finalize() which is implemented in both base classes
    void finalize()
    {
        base_type_holder::finalize();
        base_type::finalize();
    }

    hpx::naming::address get_current_address() const
    {
        return hpx::naming::address(
            hpx::naming::get_gid_from_locality_id(hpx::get_locality_id()),
            hpx::components::get_component_type<Derived>(),
            const_cast<Derived*>(static_cast<Derived const*>(this)));
    }
    }} // namespace hpx::performance_counters
```
The single template parameter is expected to receive the type of the derived class implementing the performance counter. In the Sine example this looks like:

```cpp
#include <cstdint>
namespace performance_counters { namespace sine { namespace server {
    class sine_counter : public hpx::performance_counters::base_performance_counter<sine_counter>
    {
    public:
        sine_counter();
        explicit sine_counter(hpx::performance_counters::counter_info const& info);

        /// This function will be called in order to query the current value of
        /// this performance counter
        hpx::performance_counters::counter_value get_counter_value(bool reset);

        /// The functions below will be called to start and stop collecting
        /// counter values from this counter.
        bool start();
        bool stop();

        /// finalize() will be called just before the instance gets destructed
        void finalize();

    protected:
        bool evaluate();

    private:
        typedef hpx::spinlock mutex_type;
    }
}
}}
```

(continues on next page)
mutable mutex_type mtx_;  
double current_value_;  
std::uint64_t evaluated_at_;  

hpx::util::interval_timer timer_;  
};  
}}}  // namespace performance_counters::sine::server

i.e., the type sine_counter is derived from the base class passing the type as a template argument (please see simplest_performance_counter.cpp for the full source code of the counter definition). For more information about this technique (called Curiously Recurring Template Pattern - CRTP), please see for instance the corresponding Wikipedia article\textsuperscript{148}. This base class itself is derived from the performance_counter interface described above.

Additionally, a full performance counter implementation not only exposes the actual value but also provides information about:

- The point in time a particular value was retrieved.
- A (sequential) invocation count.
- The actual counter value.
- An optional scaling coefficient.
- Information about the counter status.

**Existing HPX performance counters**

The HPX runtime system exposes a wide variety of predefined performance counters. These counters expose critical information about different modules of the runtime system. They can help determine system bottlenecks and fine-tune system and application performance.

\textsuperscript{148} \url{http://en.wikipedia.org/wiki/Curiously_recurring_template_pattern}
Table 2.29: AGAS performance counter /agas/count/

| Counter type | /agas/count/<agas_service>
|---------------|----------------------------------|
|               | where <agas_service> is one of the following:
|               |  * primary namespace services:*  
|               |      route, bind_gid, resolve_gid, unbind_gid,
|               |      increment_credit, decrement_credit, allocate, begin_migration,
|               |      end_migration
|               |  * component namespace services:*  
|               |      bind_prefix, bind_name, resolve_id, unbind_name,
|               |      iterate_types, get_component_typename, num_localities_type
|               |  * locality namespace services:*  
|               |      free, localities, num_localities, num_threads,
|               |      resolve_locality, resolved_localities
|               |  * symbol namespace services:*  
|               |      bind, resolve, unbind, iterate_names,
|               |      on_symbol_namespace_event

| Counter instance formatting | <agas_instance>/total
|----------------------------|----------------------------------|
|                            | where <agas_instance> is the name of the AGAS service to query. Currently, this value will be locality#0 where 0 is the root locality (the id of the locality hosting the AGAS service). The value for * can be any locality id for the following <agas_service>: route, bind_gid, resolve_gid, unbind_gid, increment_credit, decrement_credit, bin, resolve, unbind, and iterate_names (only the primary and symbol AGAS service components live on all localities, whereas all other AGAS services are available on locality#0 only).

| Description | Returns the total number of invocations of the specified AGAS service since its creation. |

Table 2.30: AGAS performance counter /agas/

| Counter type | /agas/<agas_service_category>/count
|---------------|----------------------------------|
|               | where <agas_service_category> is one of the following: primary, locality, component or symbol

| Counter instance formatting | <agas_instance>/total
|----------------------------|----------------------------------|
|                            | where <agas_instance> is the name of the AGAS service to query. Currently, this value will be locality#0 where 0 is the root locality (the id of the locality hosting the AGAS service). Except for <agas_service_category>, primary or symbol for which the value for * can be any locality id (only the primary and symbol AGAS service components live on all localities, whereas all other AGAS services are available on locality#0 only).

| Description | Returns the overall total number of invocations of all AGAS services provided by the given AGAS service category since its creation. |

Table 2.31: AGAS performance counter /agas/

| Counter type | /agas/<agas_service_category>/count
|---------------|----------------------------------|
|               | where <agas_service_category> is one of the following: primary, locality, component or symbol

| Counter instance formatting | <agas_instance>/total
|----------------------------|----------------------------------|
|                            | where <agas_instance> is the name of the AGAS service to query. Currently, this value will be locality#0 where 0 is the root locality (the id of the locality hosting the AGAS service). Except for <agas_service_category>, primary or symbol for which the value for * can be any locality id (only the primary and symbol AGAS service components live on all localities, whereas all other AGAS services are available on locality#0 only).

| Description | Returns the overall total number of invocations of all AGAS services provided by the given AGAS service category since its creation. |

</tr>
</tbody>
</table>

Counter instance formatting: locality#*/total

where * is the locality id of the locality the overall number of transmitted bytes should be queried for. The locality id is a (zero based) number identifying the locality.

Description: Returns the overall number of raw (uncompressed) bytes sent or received (see <operation>, e.g. sent or received) for the specified <connection_type>.

The performance counters are available only if the compile time constant HPX_HAVE_PARCELPORT_COUNTERS was defined while compiling the HPX core library (which is not defined by default). The corresponding cmake configuration constant is HPX_WITH_PARCELPORT_COUNTERS.

The performance counters for the connection type mpi are available only if the compile time constant HPX_HAVE_PARCELPORT_MPI was defined while compiling the HPX core library (which is not defined by default). The corresponding cmake configuration constant is HPX_WITH_PARCELPORT_MPI.

Please see CMake options for more details.

Table 2.39: Parcel layer performance counter /data/time/<connection_type>/<operation>

<table>

</table>

**Description**

Returns the overall number of bytes transferred (see <operation>, e.g. sent or received possibly compressed) for the specified <connection_type> by the given locality. The performance counters are available only if the compile time constant `HPX_HAVE_PARCELPORT_COUNTERS` was defined while compiling the HPX core library (which is not defined by default). The corresponding cmake configuration constant is `HPX_WITH_PARCELPORT_COUNTERS`.

The performance counters for the connection type mpi are available only if the compile time constant `HPX_HAVE_PARCELPORT_MPI` was defined while compiling the HPX core library (which is not defined by default). The corresponding cmake configuration constant is `HPX_WITH_PARCELPORT_MPI`.

Please see CMakelists for more details.

<th>locality#*/total</th>
</tr>
</thead>
<tbody>
<tr>
<td>where * is the locality id of the locality the serialization time should be queried for. The locality id is a (zero based) number identifying the locality.</td>
</tr>
</tbody>
</table>

**Description**

Returns the overall time spent performing outgoing data serialization for the specified <connection_type> on the given locality (see <operation>, e.g. sent or received). The performance counters are available only if the compile time constant `HPX_HAVE_PARCELPORT_COUNTERS` was defined while compiling the HPX core library (which is not defined by default). The corresponding cmake configuration constant is `HPX_WITH_PARCELPORT_COUNTERS`.

The performance counters for the connection type mpi are available only if the compile time constant `HPX_HAVE_PARCELPORT_MPI` was defined while compiling the HPX core library (which is not defined by default). The corresponding cmake configuration constant is `HPX_WITH_PARCELPORT_MPI`.

Please see CMakelists for more details.

**Parameters**

If the configure-time option `-DHPX_WITH_PARCELPORT_ACTION_COUNTERS=On` was specified, this counter allows one to specify an optional action name as its parameter. In this case the counter will report the number of bytes transmitted for the given action only.
Table 2.42: Parcel layer performance counter /parcels/count/routed

<td></td>
</tr>
</tbody>
</table>

Description

Returns the background overhead on the given locality since application start. If the instance name is total the counter returns the background overhead for all worker threads (cores) on that locality. If the instance name is worker-thread#* the counter will return background overhead for all worker threads separately. This counter is available only if the configuration time constants HPX_WITH_BACKGROUND_THREAD_COUNTERS (default: OFF) and HPX_WITH_THREAD_IDLE_RATES are set to ON (default: OFF). The unit of measure displayed for this counter is 0.1%.

</tbody>
</table>
Table 2.115: Performance counter /arithmetics/min

<table>
<thead>
<tr>
<th>Counter type</th>
<th>/arithmetics/min</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>Returns the minimum value of all values queried from the underlying counters (the ones specified as the parameters).</td>
</tr>
<tr>
<td>Parameters</td>
<td>The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.</td>
</tr>
</tbody>
</table>

Table 2.116: Performance counter /arithmetics/max

<table>
<thead>
<tr>
<th>Counter type</th>
<th>/arithmetics/max</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>Returns the maximum value of all values queried from the underlying counters (the ones specified as the parameters).</td>
</tr>
<tr>
<td>Parameters</td>
<td>The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.</td>
</tr>
</tbody>
</table>

Table 2.117: Performance counter /arithmetics/count

<table>
<thead>
<tr>
<th>Counter type</th>
<th>/arithmetics/count</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>Returns the count value of all values queried from the underlying counters (the ones specified as the parameters).</td>
</tr>
<tr>
<td>Parameters</td>
<td>The parameter will be interpreted as a comma separated list of full performance counter names which are queried whenever this counter is accessed. Any wildcards in the counter names will be expanded.</td>
</tr>
</tbody>
</table>

Note: The /arithmetics counters can consume an arbitrary number of other counters. For this reason those have to be specified as parameters (a comma separated list of counters appended after a '@'). For instance:

```
$ ./bin/hello_world_distributed -t2 \
  --hpx:print-counter=/threads{locality#0/worker-thread#*}/count/cumulative  \
  --hpx:print-counter=/arithmetics/add@/threads{locality#0/worker-thread#*}/count/  
  --cumulative  
Hello world from OS-thread 0 on locality 0  
Hello world from OS-thread 1 on locality 0  
/threads{locality#0/worker-thread#0}/count/cumulative,1,0.515640,[s],25  
/threads{locality#0/worker-thread#1}/count/cumulative,1,0.515520,[s],36  
/arithmetics/add@/threads{locality#0/worker-thread#*}/count/cumulative,1,0.516445,[s],64
```

Since all wildcards in the parameters are expanded, this example is fully equivalent to specifying both counters separately to /arithmetics/add:

```
$ ./bin/hello_world_distributed -t2 \
  --hpx:print-counter=/threads{locality#0/worker-thread#*}/count/cumulative  \
  --hpx:print-counter=/arithmetics/add@/threads{locality#0/worker-thread#0}/count/cumulative,\  
  /threads{locality#0/worker-thread#1}/count/cumulative
```

</table>

Table 2.121: Performance counter /coalescing/time/average-parcel-arrival

<table>
<thead>
<tr>
<th>Counter type</th>
<th>/coalescing/time/average-parcel-arrival</th>
</tr>
</thead>
<tbody>
<tr>
<td>Counter instance formatting</td>
<td>locality*/total</td>
</tr>
<tr>
<td>where:</td>
<td>* is the locality id of the locality the average time between parcels for the given action should be queried for. The locality id is a (zero based) number identifying the locality.</td>
</tr>
<tr>
<td>Description</td>
<td>Returns the average time between arriving parcels for the action which is given by the counter parameter.</td>
</tr>
<tr>
<td>Parameters</td>
<td>The action type. This is the string which has been used while registering the action with HPX, e.g. which has been passed as the second parameter to the macro \texttt{HPX_REGISTER_ACTION} or \texttt{HPX_REGISTER_ACTION_ID}.</td>
</tr>
</tbody>
</table>
### Table 2.122: Performance counter /coalescing/time/parcel-arrival-histogram

<table>
<thead>
<tr>
<th>Counter type</th>
<th>/coalescing/time/parcel-arrival-histogram</th>
</tr>
</thead>
<tbody>
<tr>
<td>Counter instance formatting</td>
<td>locality#*/total</td>
</tr>
<tr>
<td>where:</td>
<td>* is the locality id of the locality the average time between parcels for the given action should be queried for. The locality id is a (zero based) number identifying the locality.</td>
</tr>
<tr>
<td>Description</td>
<td>Returns a histogram representing the times between arriving parcels for the action which is given by the counter parameter. This counter returns an array of values, where the first three values represent the three parameters used for the histogram followed by one value for each of the histogram buckets. The first unit of measure displayed for this counter [ns] refers to the lower and upper boundary values in the returned histogram data only. The second unit of measure displayed [0..1%] refers to the actual histogram data. For each bucket the counter shows a value between 0 and 1000 which corresponds to a percentage value between 0% and 100%.</td>
</tr>
<tr>
<td>Parameters</td>
<td>The action type and optional histogram parameters. The action type is the string which has been used while registering the action with HPX, e.g. which has been passed as the second parameter to the macro HPX_REGISTER_ACTION or HPX_REGISTER_ACTION_ID. The action type may be followed by a comma separated list of up-to three numbers: the lower and upper boundaries for the collected histogram, and the number of buckets for the histogram to generate. By default these three numbers will be assumed to be 0 ([ns], lower bound), 1000000 ([ns], upper bound), and 20 (number of buckets to generate).</td>
</tr>
</tbody>
</table>

**Note:** The performance counters related to parcel coalescing are available only if the configuration time constant HPX_WITH_PARCEL_COALESCING is set to ON (default: ON). However, even in this case it will be available only for actions that are enabled for parcel coalescing (see the macros HPX_ACTION_USES_MESSAGE_COALESCING and HPX_ACTION_USES_MESSAGE_COALESCING_NOTHROW).

### APEX integration

HPX provides integration with APEX\(^{150}\), which is a framework for application profiling using task timers and various performance counters Huck et al.\(^{153}\). It can be added as a git submodule by turning on the option HPX_WITH_APEX:BOOL during CMake configuration. TAU\(^{151}\) is an optional dependency when using APEX.

To build HPX with APEX, add HPX_WITH_APEX=ON, and, optionally, TAU_ROOT=$PATH_TO_TAU to your CMake configuration. In addition, you can override the tag used for APEX with the HPX_WITH_APEX_TAG option. Please see the APEX HPX documentation\(^{152}\) for detailed instructions on using APEX with HPX.

\(^{151}\) https://www.cs.uoregon.edu/research/tau/home.php

Basic information

The Lightweight Communication Interface\textsuperscript{154} (LCI) is an ongoing research project aiming to provide efficient support for applications with irregular and asynchronous communication patterns such as graph analysis, sparse linear algebra, and task-based runtime on modern parallel architectures. Its features include (a) support for more communication primitives such as two-sided send/recv and one-sided (dynamic or direct) remote put/get (b) better multi-threaded performance (c) explicit user control of communication resource (d) flexible signaling mechanisms such as synchronizer, completion queue, and active message handler. It is designed to be a low-level communication library used by high-level libraries and frameworks.

The LCI parcelport is an experimental parcelport. It aims to provide the best possible communication performance on high-performance computation platforms. Compared to the MPI parcelport, it uses much fewer messages and memory copies to transfer an \textit{HPX} parcel over the network. Its message transmission path involves minimum synchronization points and is almost lock-free. It is expected to be much faster than the MPI parcelport.

Build \textit{HPX} with the LCI parcelport

While building \textit{HPX}, you can specify a set of CMake variables to enable and configure the LCI parcelport. Below, there is a set of the most important and frequently used CMake variables.

\texttt{HPX\_WITH\_PARCELPORT\_LCI}

Enable the LCI parcelport. This enables the use of LCI for networking operations in the \textit{HPX} runtime. The default value is \texttt{OFF} because it’s not available on all systems and/or requires another dependency. However, this experimental parcelport may provide better performance than the MPI parcelport. You must set this variable to \texttt{ON} in order to use the LCI parcelport. All the following variables only make sense when this variable is set to \texttt{ON}.

\texttt{HPX\_WITH\_FETCH\_LCI}

Use FetchContent to fetch LCI. The default value is \texttt{OFF}. If this option is set to \texttt{OFF}, you need to install your own LCI library and \textit{HPX} will try to find it using CMake \texttt{find\_package}. You can specify the location of the LCI installation by the environmental variable \texttt{LCI\_ROOT}. Refer to the LCI README\textsuperscript{155} for how to install LCI. If this option is set to \texttt{ON}, \textit{HPX} will fetch and build LCI for you. You can use the following CMake variables to configure this behavior for your platform.

\texttt{HPX\_WITH\_LCI\_TAG}

This variable only takes effect when \texttt{HPX\_WITH\_FETCH\_LCI} is set to \texttt{ON} and \texttt{FETCHCONTENT\_SOURCE\_DIR\_LCI} is not set. \textit{HPX} will fetch LCI from its github repository. This variable controls the branch/tag LCI will be fetched.

\texttt{FETCHCONTENT\_SOURCE\_DIR\_LCI}

This variable only takes effect when \texttt{HPX\_WITH\_FETCH\_LCI} is set to \texttt{ON}. When it is defined, \texttt{HPX\_WITH\_LCI\_TAG} will be ignored. It accepts a path to a local version of LCI source code and \textit{HPX} will fetch and build LCI from there. The default value is set conservatively for the stability of \textit{HPX}, but users are welcome to set this variable to \texttt{master} for potentially better performance.

\textsuperscript{154} https://github.com/uci-hpc/LC
\textsuperscript{155} https://github.com/uci-hpc/LC#readme
Run HPX with the LCI parcelport

We use the same mechanisms as MPI to launch LCI, so you can use the same way you run MPI parcelport to run LCI parcelport. Typically, it would be hpxrun, mpirun, or srun.

If you are using hpxrun.py, just pass --parcelport lci to the scripts.

If you are using mpirun or srun, you can just pass --hpx:ini=hpx.parcel.lci.priority=1000, --hpx:ini=hpx.parcel.lci.enable=1, and --hpx:ini=hpx.parcel.bootstrap=lci to the HPX applications.

If you are running on a Cray machine, you need to pass --mpi=pmix or --mpi=pmi2 to srun to enable the PMIx or PMI2 support of SLURM since LCI does not support the default Cray PMI. For example,

```bash
$ srun --mpi=pmix [hpx application]
```

Performance tuning of the LCI parcelport

We encourage users to set the following environmental variables when using the LCI parcelport to get better performance.

```bash
$ export LCI_SERVER_MAX_SENDS=1024
$ export LCI_SERVER_MAX_RECVS=4096
$ export LCI_SERVER_NUM_PKTS=65536
$ export LCI_SERVER_MAX_CQES=65536
$ export LCI_PACKET_SIZE=12288
```

This setting needs roughly 800MB memory per process. The memory consumption mainly comes from the packets, which can be calculated using $LCI_SERVER_NUM_PKTS \times LCI_PACKET_SIZE$.

2.3.16 HPX runtime and resources

HPX thread scheduling policies

The HPX runtime has five thread scheduling policies: local-priority, static-priority, local, static and abp-priority. These policies can be specified from the command line using the command line option --hpx:queuing. In order to use a particular scheduling policy, the runtime system must be built with the appropriate scheduler flag turned on (e.g. cmake -DHPX_THREAD_SCHEDULERS=local, see CMake options for more information).

Priority local scheduling policy (default policy)

The priority local scheduling policy maintains one queue per operating system (OS) thread. The OS thread pulls its work from this queue. By default the number of high priority queues is equal to the number of OS threads; the number of high priority queues can be specified on the command line using --hpx:high-priority-threads. High priority threads are executed by any of the OS threads before any other work is executed. When a queue is empty, work will be taken from high priority queues first. There is one low priority queue from which threads will be scheduled only when there is no other work.

For this scheduling policy there is an option to turn on NUMA sensitivity using the command line option --hpx:numa-sensitive. When NUMA sensitivity is turned on, work stealing is done from queues associated with the same NUMA domain first, only after that work is stolen from other NUMA domains.

This scheduler is enabled at build time by default using the FIFO (first-in-first-out) queuing policy. This policy can be invoked using --hpx:queuing=local-priority-fifo. The scheduler can also be enabled using the
LIFO (last-in-first-out) policy. This is not the default policy and must be invoked using the command line option `--hpx:queuing=local-priority-lifo`.

**Static priority scheduling policy**

- invoke using: `--hpx:queuing=static-priority` (or `-qs`)
- flag to turn on for build: `HPX_THREAD_SCHEDULERS=all` or `HPX_THREAD_SCHEDULERS=static-priority`

The static scheduling policy maintains one queue per OS thread from which each OS thread pulls its tasks (user threads). Threads are distributed in a round robin fashion. There is no thread stealing in this policy.

**Local scheduling policy**

- invoke using: `--hpx:queuing=local` (or `-ql`)
- flag to turn on for build: `HPX_THREAD_SCHEDULERS=all` or `HPX_THREAD_SCHEDULERS=local`

The local scheduling policy maintains one queue per OS thread from which each OS thread pulls its tasks (user threads).

**Static scheduling policy**

- invoke using: `--hpx:queuing=static`
- flag to turn on for build: `HPX_THREAD_SCHEDULERS=all` or `HPX_THREAD_SCHEDULERS=static`

The static scheduling policy maintains one queue per OS thread from which each OS thread pulls its tasks (user threads). Threads are distributed in a round robin fashion. There is no thread stealing in this policy.

**Priority ABP scheduling policy**

- invoke using: `--hpx:queuing=abp-priority-fifo`
- flag to turn on for build: `HPX_THREAD_SCHEDULERS=all` or `HPX_THREAD_SCHEDULERS=abp-priority`

Priority ABP policy maintains a double ended lock free queue for each OS thread. By default the number of high priority queues is equal to the number of OS threads; the number of high priority queues can be specified on the command line using `--hpx:high-priority-threads`. High priority threads are executed by the first OS threads before any other work is executed. When a queue is empty work will be taken from high priority queues first. There is one low priority queue from which threads will be scheduled only when there is no other work. For this scheduling policy there is an option to turn on NUMA sensitivity using the command line option `--hpx:numa-sensitive`. When NUMA sensitivity is turned on work stealing is done from queues associated with the same NUMA domain first, only after that work is stolen from other NUMA domains.

This scheduler can be used with two underlying queuing policies (FIFO: first-in-first-out, and LIFO: last-in-first-out). In order to use the LIFO policy use the command line option `--hpx:queuing=abp-priority-lifo`.

---

242  Chapter 2. What’s so special about HPX?
The **HPX resource partitioner**

The **HPX resource partitioner** lets you take the execution resources available on a system—processing units, cores, and numa domains—and assign them to thread pools. By default **HPX** creates a single thread pool name **default**. While this is good for most use cases, the resource partitioner lets you create multiple thread pools with custom resources and options.

Creating custom thread pools is useful for cases where you have tasks which absolutely need to run without interference from other tasks. An example of this is when using **MPI** for distribution instead of the built-in mechanisms in **HPX** (useful in legacy applications). In this case one can create a thread pool containing a single thread for MPI communication. MPI tasks will then always run on the same thread, instead of potentially being stuck in a queue behind other threads.

Note that **HPX** thread pools are completely independent from each other in the sense that task stealing will never happen between different thread pools. However, tasks running on a particular thread pool can schedule tasks on another thread pool.

**Note:** It is simpler in some situations to schedule important tasks with high priority instead of using a separate thread pool.

**Using the resource partitioner**

The **hpx::resource::partitioner** is now created during **HPX** runtime initialization without explicit action needed from the user. To specify some of the initialization parameters you can use the **hpx::init_params**.

The resource partitioner callback is the interface to add thread pools to the **HPX** runtime and to assign resources to the thread pools. In order to create custom thread pools you can specify the resource partitioner callback **hpx::init_params::rp_callback** which will be called once the resource partitioner will be created, see the example below. You can also specify other parameters, see **hpx::init_params**.

To add a thread pool use the **hpx::resource::partitioner::create_thread_pool** method. If you simply want to use the default scheduler and scheduler options, it is enough to call **rp.create_thread_pool(“my-thread-pool”)**.

Then, to add resources to the thread pool you can use the **hpx::resource::partitioner::add_resource** method. The resource partitioner exposes the hardware topology retrieved using Portable Hardware Locality (HWLOC) and lets you iterate through the topology to add the wanted processing units to the thread pool. Below is an example of adding all processing units from the first NUMA domain to a custom thread pool, unless there is only one NUMA domain in which case we leave the first processing unit for the default thread pool:

**Note:** Whatever processing units are not assigned to a thread pool by the time **hpx::init** is called will be added to the default thread pool. It is also possible to explicitly add processing units to the default thread pool, and to create the default thread pool manually (in order to e.g. set the scheduler type).

**Tip:** The command line option **--hpx:print-bind** is useful for checking that the thread pools have been set up the way you expect.

---

157 [https://www.open-mpi.org/projects/hwloc/](https://www.open-mpi.org/projects/hwloc/)
Difference between the old and new version

In the old version, you had to create an instance of the `resource_partitioner` with `argc` and `argv`.

```cpp
int main(int argc, char** argv)
{
    hpx::resource::partitioner rp(argc, argv);
    hpx::init();
}
```

From HPX 1.5.0 onwards, you just pass `argc` and `argv` to `hpx::init()` or `hpx::start()` for the binding options to be parsed by the resource partitioner.

```cpp
int main(int argc, char** argv)
{
    hpx::init_params init_args;
    hpx::init(argc, argv, init_args);
}
```

In the old version, when creating a custom thread pool, you just called the utilities on the resource partitioner instantiated previously.

```cpp
int main(int argc, char** argv)
{
    hpx::resource::partitioner rp(argc, argv);

    rp.create_thread_pool("my-thread-pool");

    bool one_numa_domain = rp.numa_domains().size() == 1;
    bool skipped_first_pu = false;
    hpx::resource::numa_domain const& d = rp.numa_domains()[0];

    for (const hpx::resource::core& c : d.cores())
    {
        for (const hpx::resource::pu& p : c.pus())
        {
            if (one_numa_domain && !skipped_first_pu)
            {
                skipped_first_pu = true;
                continue;
            }

            rp.add_resource(p, "my-thread-pool");
        }
    }

    hpx::init();
}
```

You now specify the resource partitioner callback which will tie the resources to the resource partitioner created during runtime initialization.

You now specify the resource partitioner callback which will tie the resources to the resource partitioner created during runtime initialization.
void init_resource_partitioner_handler(hpx::resource::partitioner& rp)
{
    rp.create_thread_pool("my-thread-pool");

    bool one_numa_domain = rp.numa_domains().size() == 1;
    bool skipped_first_pu = false;

    hpx::resource::numa_domain const& d = rp.numa_domains()[0];

    for (const hpx::resource::core& c : d.cores())
    {
        for (const hpx::resource::pu& p : c.pus())
        {
            if (one_numa_domain && !skipped_first_pu)
            {
                skipped_first_pu = true;
                continue;
            }

            rp.add_resource(p, "my-thread-pool");
        }
    }
}

int main(int argc, char* argv[])
{
    hpx::init_params init_args;
    init_args_rp_callback = &init_resource_partitioner_handler;

    hpx::init(argc, argv, init_args);
}

Advanced usage

It is possible to customize the built in schedulers by passing scheduler options to hpx::resource::partitioner::create_thread_pool. It is also possible to create and use custom schedulers.

Note: It is not recommended to create your own scheduler. The HPX developers use this to experiment with new scheduler designs before making them available to users via the standard mechanisms of choosing a scheduler (command line options). If you would like to experiment with a custom scheduler the resource partitioner example shared_priority_queue_scheduler.cpp contains a fully implemented scheduler with logging, etc. to make exploration easier.

To choose a scheduler and custom mode for a thread pool, pass additional options when creating the thread pool like this:

```cpp
rp.create_thread_pool("my-thread-pool",
    hpx::resource::policies::local_priority_lifo,
    hpx::policies::scheduler_mode(
```

(continues on next page)
The available schedulers are documented here: `hpx::resource::scheduling_policy`, and the available scheduler modes here: `hpx::threads::policies::scheduler_mode`. Also see the examples folder for examples of advanced resource partitioner usage: `simple_resource_partitioner.cpp` and `oversubscribing_resource_partitioner.cpp`.

### 2.3.17 Miscellaneous

#### Error handling

Like in any other asynchronous invocation scheme, it is important to be able to handle error conditions occurring while the asynchronous (and possibly remote) operation is executed. In HPX all error handling is based on standard C++ exception handling. Any exception thrown during the execution of an asynchronous operation will be transferred back to the original invocation `locality`, where it will be rethrown during synchronization with the calling thread.

The source code for this example can be found here: `error_handling.cpp`.

#### Working with exceptions

For the following description assume that the function `raise_exception()` is executed by invoking the plain action `raise_exception_type`.

```cpp
#include <hpx/iostream.hpp>
#include <hpx/modules/runtime_local.hpp>

// [error_handling_raise_exception]
void raise_exception()
```

The exception is thrown using the macro `HPX_THROW_EXCEPTION`. The type of the thrown exception is `hpx::exception`. This associates additional diagnostic information with the exception, such as file name and line number, `locality` id and thread id, and stack backtrace from the point where the exception was thrown.

Any exception thrown during the execution of an action is transferred back to the (asynchronous) invocation site. It will be rethrown in this context when the calling thread tries to wait for the result of the action by invoking either `future<>::get()` or the synchronous action invocation wrapper as shown here:

```cpp
{
  // Error reporting using exceptions
  // [exception_diagnostic_information]
  hpx::cout << "Error reporting using exceptions\n";
  try
  {
    // invoke raise_exception() which throws an exception
    raise_exception_action do_it;
    do_it(hpx::find_here());
  }
  catch (hpx::exception const& e)
  {
  }
}
```

(continues on next page)
Note: The exception is transferred back to the invocation site even if it is executed on a different *locality*.

Additionally, this example demonstrates how an exception thrown by an (possibly remote) action can be handled. It shows the use of `hpx::diagnostic_information`, which retrieves all available diagnostic information from the exception as a formatted string. This includes, for instance, the name of the source file and line number, the sequence number of the OS thread and the *HPX* thread id, the *locality* id and the stack backtrace of the point where the original exception was thrown.

Under certain circumstances it is desirable to output only some of the diagnostics, or to output those using different formatting. For this case, *HPX* exposes a set of lower-level functions as demonstrated in the following code snippet:

```cpp
{
    // Print just the essential error information.
    hpx::cout << "caught exception: " << e.what() << "\n";
}

// Detailed error reporting using exceptions
// [exception_diagnostic_elements
hpx::cout << "Detailed error reporting using exceptions\n";
try
{
    // Invoke raise_exception() which throws an exception.
    raise_exception_action do_it;
    do_it(hpx::find_here());
}
catch (hpx::exception const& e)
{
    // Print the elements of the diagnostic information separately.
    hpx::cout << "{what}: " << hpx::get_error_what(e) << "\n";
    hpx::cout << "{locality-id}: " << hpx::get_error_locality_id(e) << "\n";
    hpx::cout << "{hostname}: " << hpx::get_error_host_name(e) << "\n";
    hpx::cout << "{pid}: " << hpx::get_error_process_id(e) << "\n";
    hpx::cout << "{function}: " << hpx::get_error_function_name(e) << "\n";
    hpx::cout << "{file}: " << hpx::get_error_file_name(e) << "\n";
    hpx::cout << "{line}: " << hpx::get_error_line_number(e) << "\n";
}

hpx::cout << std::flush;
```

2.3. Manual 247
Working with error codes

Most of the API functions exposed by HPX can be invoked in two different modes. By default those will throw an exception on error as described above. However, sometimes it is desirable not to throw an exception in case of an error condition. In this case an object instance of the hpx::error_code type can be passed as the last argument to the API function. In case of an error, the error condition will be returned in that hpx::error_code instance. The following example demonstrates extracting the full diagnostic information without exception handling:

```cpp
<< "\n"

hpx::cout << "{stack-trace}: " << hpx::get_error_backtrace(e)
 << "\n"

hpx::cout << "{env}: " << hpx::get_error_env(e) << "\n"

}

hpx::cout << std::flush;

//

///////////////////////////////////////////////////////////////////////
// Error reporting using error code
{

    // error_handling_diagnostic_information
    hpx::cout << "Error reporting using error code\n"

    // Create a new error_code instance.
    hpx::error_code ec;

    // If an instance of an error_code is passed as the last argument while
    // invoking the action, the function will not throw in case of an error
    // but store the error information in this error_code instance instead.
    raise_exception_action do_it;
    do_it(hpx::find_here(), ec);

Note: The error information is transferred back to the invocation site even if it is executed on a different locality.

This example show how an error can be handled without having to resolve to exceptions and that the returned hpx::error_code instance can be used in a very similar way as the hpx::exception type above. Simply pass it to the hpx::diagnostic_information, which retrieves all available diagnostic information from the error code instance as a formatted string.

As for handling exceptions, when working with error codes, under certain circumstances it is desirable to output only some of the diagnostics, or to output those using different formatting. For this case, HPX exposes a set of lower-level functions usable with error codes as demonstrated in the following code snippet:

```cpp
    // Print all of the available diagnostic information as stored with
    // the exception.
    hpx::cout << "diagnostic information:"
    << hpx::diagnostic_information(ec) << "\n"

}

hpx::cout << std::flush;
//]
```

(continues on next page)
```cpp
// Detailed error reporting using error code
{
    // [error_handling_diagnostic_elements
    hpx::cout << "Detailed error reporting using error code\n";

    // Create a new error_code instance.
    hpx::error_code ec;

    // If an instance of an error_code is passed as the last argument while
    // invoking the action, the function will not throw in case of an error
    // but store the error information in this error_code instance instead.
    raise_exception_action do_it;
    do_it(hpx::find_here(), ec);

    if (ec)
    {
        // Print the elements of the diagnostic information separately.
        hpx::cout << "{what}: " << hpx::get_error_what(ec) << "\n";
        hpx::cout << "{locality-id}: " << hpx::get_error_locality_id(ec)
                     << "\n";
        hpx::cout << "{hostname}: " << hpx::get_error_host_name(ec)
                     << "\n";
        hpx::cout << "{pid}: " << hpx::get_error_process_id(ec) << "\n";

        for (auto& entry : ec)
        {
            if (entry.first == "\n")
            {
                continue;
            }

            hpx::cout << std::hex;
            hpx::cout << entry.first << "\n";
            hpx::cout << std::hex;
        }

        hpx::cout << std::flush;
    }
}
```

For more information please refer to the documentation of `hpx::get_error_what`, `hpx::get_error_locality_id`, `hpx::get_error_host_name`, `hpx::get_error_process_id`, `hpx::get_error_function_name`, `hpx::get_error_file_name`, `hpx::get_error_line_number`, `hpx::get_error_os_thread`, `hpx::get_error_thread_id`, `hpx::get_error_thread_description`, `hpx::get_error_backtrace`, `hpx::get_error_env`, and `hpx::get_error_state`.

### Lightweight error codes

Sometimes it is not desirable to collect all the ambient information about the error at the point where it happened as this might impose too much overhead for simple scenarios. In this case, HPX provides a lightweight error code facility that will hold the error code only. The following snippet demonstrates its use:

```cpp
<< "\n";
    hpx::cout << "{thread-id}: " << std::hex
    << hpx::get_error_thread_id(ec) << "\n";
    hpx::cout << "{thread-description}: "
    << hpx::get_error_thread_description(ec) << "\n\n";
    hpx::cout << "{state}: " << std::hex << hpx::get_error_state(ec)
    << "\n";
    hpx::cout << "{stack-trace}: " << hpx::get_error_backtrace(ec)
    << "\n";
    hpx::cout << "{env}: " << hpx::get_error_env(ec) << "\n";
}
    hpx::cout << std::flush;
    //]
```

// Error reporting using lightweight error code
{
    // [lightweight_error_handling_diagnostic_information
    hpx::cout << "Error reporting using a lightweight error code\n";
}

All functions that retrieve other diagnostic elements from the hpx::error_code will fail if called with a lightweight error_code instance.

Utilities in HPX

In order to ease the burden of programming, HPX provides several utilities to users. The following section documents those facilities.

Checkpoint

See checkpoint.

The HPX I/O-streams component

The HPX I/O-streams subsystem extends the standard C++ output streams std::cout and std::cerr to work in the distributed setting of an HPX application. All of the output streamed to hpx::cout will be dispatched to std::cout on the console locality. Likewise, all output generated from hpx::cerr will be dispatched to std::cerr on the console locality.

Note: All existing standard manipulators can be used in conjunction with hpx::cout and hpx::cerr.

In order to use either hpx::cout or hpx::cerr, application codes need to #include <hpx/include/iostreams.hpp>. For an example, please see the following ‘Hello world’ program:

```cpp
#include <hpx/hpx_main.hpp>
#include <hpx/iostream.hpp>

int main()
{
    // Say hello to the world!
}```
hpx::cout << "Hello World!\n" << std::flush;
return 0;
}
//]

Additionally, those applications need to link with the iostreams component. When using CMake this can be achieved by using the COMPONENT_DEPENDENCIES parameter; for instance:

```cpp
#include(HPX_AddExecutable)

add_hpx_executable(
  hello_world
  SOURCES hello_world.cpp
  COMPONENT_DEPENDENCIES iostreams
)
```

**Note:** The hpx::cout and hpx::cerr streams buffer all output locally until a std::endl or std::flush is encountered. That means that no output will appear on the console as long as either of these is explicitly used.

### 2.3.18 Troubleshooting

#### Common issues

This section contains commonly encountered problems when compiling or using HPX.

See also the closed issues on GitHub[^1] to find out how other people resolved a similar problem. If nothing of that works, you can also open a new issue on GitHub[^2] or contact us using one the options found in [Support for deploying and using HPX](https://github.com/STEllAR-GROUP/hpx/blob/master/.github/SUPPORT.md).

**Undefined reference to hpx::cout**

You may see a linker error message that looks a bit like this:

```
hello_world.cpp:(.text+0x5aa): undefined reference to `hpx::cout'
```

This usually happens if you are trying to use HPX iostreams functionality such as hpx::cout but are not linking against it. The iostreams functionality is not part of the core HPX library, and must be linked to explicitly. Typically this can be solved by adding COMPONENT_DEPENDENCIES iostreams to a call to `add_hpx_library/add_hpx_executable/hpx_setup_target` if using CMake. See [Creating HPX projects](https://github.com/STEllAR-GROUP/hpx/blob/master/.github/SUPPORT.md) for more details.

[^1]: https://github.com/STEllAR-GROUP/hpx/issues?q=is%3Aissue+is%3Aclosed
[^2]: https://github.com/STEllAR-GROUP/hpx/issues
Fail compiling for examples with hpx::future and co_await

You may see an error message that looks a bit like this:

```
error: coroutines require a traits template; cannot find 'std::coroutine_traits'
```

This can be resolved by using `-DHPX_WITH_CXX_STANDARD=20` to the cmake command line. Note that a compiler that supports C++20 is needed.

See also the corresponding closed Issue #5784.\(^{161}\)

Build fails with ASIO error

You may see an error message that looks a bit like this:

```
Cannot open include file asio/io_context.hpp
```

This can be resolved by using `-DHPX_WITH_FETCH_ASIO=ON` to the cmake command line.

See also the corresponding closed Issue #5404\(^{162}\) for more information.

Build fails with TCMalloc error

You may see an error message that looks a bit like this:

```
Could NOT find TCMalloc (missing: TCMALLOC_LIBRARY TCMALLOC_INCLUDE_DIR)
ERROR: HPX_WITH_MALLOC was set to tcmalloc, but tcmalloc could not be found. Valid options for HPX_WITH_MALLOC are: system, tcmalloc, jemalloc, mimalloc, tbbmalloc, and custom
```

This can be resolved either by defining `HPX_WITH_MALLOC=system` or by installing TCMalloc. This error occurs when users don’t specify an option for `HPX_WITH_MALLOC`; in that case, HPX will be looking tcmalloc, which is the default value.

Useful suggestions

Reducing compilation time

If you want to significantly reduce compilation time, you can just use the local part of HPX for parallelism by disabling the distributed functionality. Moreover, you can avoid compiling examples. These can be done with the following flags:

```
-DHPX_WITH_NETWORKING=OFF
-DHPX_WITH_DISTRIBUTED_RUNTIME=OFF
-DHPX_WITH_EXAMPLES=OFF
-DHPX_WITH_TESTS=OFF
```

\(^{161}\) [https://github.com/STEllAR-GROUP/hpx/issues/5784](https://github.com/STEllAR-GROUP/hpx/issues/5784)

\(^{162}\) [https://github.com/STEllAR-GROUP/hpx/issues/5404](https://github.com/STEllAR-GROUP/hpx/issues/5404)
Linking HPX to your application

If you want to avoid installing and linking HPX, you can just build HPX and then use the following flag on your HPX application CMake configuration:

```
-DHPX_DIR=<build_dir>/lib/cmake/HPX
```

**Note:** For this to work you need not to specify `-DCMAKE_INSTALL_PREFIX` when building HPX.

**HPX-application build type conformance**

Your application’s build type should align with the HPX build type. For example, if you specified `-DCMAKE_BUILD_TYPE=Debug` during the HPX compilation, then your application needs to be compiled with the same flag. We recommend keeping a separate build folder for different build types and just point accordingly to the type you want by using `-DHPX_DIR=<build_dir>/lib/cmake/HPX`.

### 2.4 Terminology

This section gives definitions for some of the terms used throughout the HPX documentation and source code.

**Locality** A locality in HPX describes a synchronous domain of execution, or the domain of bounded upper response time. This normally is just a single node in a cluster or a NUMA domain in a SMP machine.

**Active Global Address Space**

AGAS HPX incorporates a global address space. Any executing thread can access any object within the domain of the parallel application with the caveat that it must have appropriate access privileges. The model does not assume that global addresses are cache coherent; all loads and stores will deal directly with the site of the target object. All global addresses within a Synchronous Domain are assumed to be cache coherent for those processor cores that incorporate transparent caches. The Active Global Address Space used by HPX differs from research PGAS models. Partitioned Global Address Space is passive in their means of address translation. Copy semantics, distributed compound operations, and affinity relationships are some of the global functionality supported by AGAS.

**Process** The concept of the “process” in HPX is extended beyond that of either sequential execution or communicating sequential processes. While the notion of process suggests action (as do “function” or “subroutine”) it has a further responsibility of context, that is, the logical container of program state. It is this aspect of operation that process is employed in HPX. Furthermore, referring to “parallel processes” in HPX designates the presence of parallelism within the context of a given process, as well as the coarse grained parallelism achieved through concurrency of multiple processes of an executing user job. HPX processes provide a hierarchical name space within the framework of the active global address space and support multiple means of internal state access from external sources.

**Parcel** The Parcel is a component in HPX that communicates data, invokes an action at a distance, and distributes flow-control through the migration of continuations. Parcels bridge the gap of asynchrony between synchronous domains while maintaining symmetry of semantics between local and global execution. Parcels enable message-driven computation and may be seen as a form of “active messages”. Other important forms of message-driven computation predating active messages include dataflow tokens, the J-machine’s support for remote method

---

163 https://www.pgas.org/
164 http://en.wikipedia.org/wiki/Dataflow_architecture
instantiation, and at the coarse grained variations of Unix remote procedure calls, among others. This enables work to be moved to the data as well as performing the more common action of bringing data to the work. A parcel can cause actions to occur remotely and asynchronously, among which are the creation of threads at different system nodes or synchronous domains.

**Local Control Object**

**Lightweight Control Object**

LCO A local control object (sometimes called a lightweight control object) is a general term for the synchronization mechanisms used in *HPX*. Any object implementing a certain concept can be seen as an LCO. This concept encapsulates the ability to be triggered by one or more events which when taking the object into a predefined state will cause a thread to be executed. This could either create a new thread or resume an existing thread.

The LCO is a family of synchronization functions potentially representing many classes of synchronization constructs, each with many possible variations and multiple instances. The LCO is sufficiently general that it can subsume the functionality of conventional synchronization primitives such as spinlocks, mutexes, semaphores, and global barriers. However due to the rich concept an LCO can represent powerful synchronization and control functionality not widely employed, such as dataflow and futures (among others), which open up enormous opportunities for rich diversity of distributed control and operation.

See lcos for more details on how to use LCOs in *HPX*.

**Action** An action is a function that can be invoked remotely. In *HPX* a plain function can be made into an action using a macro. See applying actions for details on how to use actions in *HPX*.

**Component** A component is a C++ object which can be accessed remotely. A component can also contain member functions which can be invoked remotely. These are referred to as component actions. See Writing components for details on how to use components in *HPX*.

### 2.5 Why *HPX*?

Current advances in high performance computing (HPC) continue to suffer from the issues plaguing parallel computation. These issues include, but are not limited to, ease of programming, inability to handle dynamically changing workloads, scalability, and efficient utilization of system resources. Emerging technological trends such as multi-core processors further highlight limitations of existing parallel computation models. To mitigate the aforementioned problems, it is necessary to rethink the approach to parallelization models. ParalleX contains mechanisms such as multi-threading, parcels, global name space support, percolation and local control objects (LCO). By design, ParalleX overcomes limitations of current models of parallelism by alleviating contention, latency, overhead and starvation. With ParalleX, it is further possible to increase performance by at least an order of magnitude on challenging parallel algorithms, e.g., dynamic directed graph algorithms and adaptive mesh refinement methods for astrophysics. An additional benefit of ParalleX is fine-grained control of power usage, enabling reductions in power consumption.

#### 2.5.1 ParalleX—a new execution model for future architectures

ParalleX is a new parallel execution model that offers an alternative to the conventional computation models, such as message passing. ParalleX distinguishes itself by:

- Split-phase transaction model
- Message-driven
- Distributed shared memory (not cache coherent)
- Multi-threaded
- Futures synchronization
• Local Control Objects (LCOs)
• Synchronization for anonymous producer-consumer scenarios
• Percolation (pre-staging of task data)

The ParalleX model is intrinsically latency hiding, delivering an abundance of variable-grained parallelism within a hierarchical namespace environment. The goal of this innovative strategy is to enable future systems delivering very high efficiency, increased scalability and ease of programming. ParalleX can contribute to significant improvements in the design of all levels of computing systems and their usage from application algorithms and their programming languages to system architecture and hardware design together with their supporting compilers and operating system software.

2.5.2 What is HPX?

High Performance ParalleX (HPX) is the first runtime system implementation of the ParalleX execution model. The HPX runtime software package is a modular, feature-complete, and performance-oriented representation of the ParalleX execution model targeted at conventional parallel computing architectures, such as SMP nodes and commodity clusters. It is academically developed and freely available under an open source license. We provide HPX to the community for experimentation and application to achieve high efficiency and scalability for dynamic adaptive and irregular computational problems. HPX is a C++ library that supports a set of critical mechanisms for dynamic adaptive resource management and lightweight task scheduling within the context of a global address space. It is solidly based on many years of experience in writing highly parallel applications for HPC systems.

The two-decade success of the communicating sequential processes (CSP) execution model and its message passing interface (MPI) programming model have been seriously eroded by challenges of power, processor core complexity, multi-core sockets, and heterogeneous structures of GPUs. Both efficiency and scalability for some current (strong scaled) applications and future Exascale applications demand new techniques to expose new sources of algorithm parallelism and exploit unused resources through adaptive use of runtime information.

The ParalleX execution model replaces CSP to provide a new computing paradigm embodying the governing principles for organizing and conducting highly efficient scalable computations greatly exceeding the capabilities of today’s problems. HPX is the first practical, reliable, and performance-oriented runtime system incorporating the principal concepts of the ParalleX model publicly provided in open source release form.

HPX is designed by the STE||AR\textsuperscript{166} Group (Systems Technology, Emergent Parallelism, and Algorithm Research) at Louisiana State University (LSU)\textsuperscript{167}’s Center for Computation and Technology (CCT)\textsuperscript{168} to enable developers to exploit the full processing power of many-core systems with an unprecedented degree of parallelism. STE||AR\textsuperscript{169} is a research group focusing on system software solutions and scientific application development for hybrid and many-core hardware architectures.

For more information about the STE||AR\textsuperscript{170} Group, see People.

\textsuperscript{166}https://stellar-group.org
\textsuperscript{167}https://www.lsu.edu
\textsuperscript{168}https://www.cct.lsu.edu
\textsuperscript{169}https://stellar-group.org
\textsuperscript{170}https://stellar-group.org
2.5.3 What makes our systems slow?

 Estimates say that we currently run our computers at well below 100% efficiency. The theoretical peak performance (usually measured in FLOPS\textsuperscript{171}—floating point operations per second) is much higher than any practical peak performance reached by any application. This is particularly true for highly parallel hardware. The more hardware parallelism we provide to an application, the better the application must scale in order to efficiently use all the resources of the machine. Roughly speaking, we distinguish two forms of scalability: strong scaling (see Amdahl’s Law\textsuperscript{172}) and weak scaling (see Gustafson's Law\textsuperscript{173}). Strong scaling is defined as how the solution time varies with the number of processors for a fixed total problem size. It gives an estimate of how much faster we can solve a particular problem by throwing more resources at it. Weak scaling is defined as how the solution time varies with the number of processors for a fixed problem size per processor. In other words, it defines how much more data can we process by using more hardware resources.

In order to utilize as much hardware parallelism as possible an application must exhibit excellent strong and weak scaling characteristics, which requires a high percentage of work executed in parallel, i.e., using multiple threads of execution. Optimally, if you execute an application on a hardware resource with N processors it either runs N times faster or it can handle N times more data. Both cases imply 100% of the work is executed on all available processors in parallel. However, this is just a theoretical limit. Unfortunately, there are more things that limit scalability, mostly inherent to the hardware architectures and the programming models we use. We break these limitations into four fundamental factors that make our systems SLOW:

- Starvation occurs when there is insufficient concurrent work available to maintain high utilization of all resources.
- Latencies are imposed by the time-distance delay intrinsic to accessing remote resources and services.
- Overhead is work required for the management of parallel actions and resources on the critical execution path, which is not necessary in a sequential variant.
- Waiting for contention resolution is the delay due to the lack of availability of oversubscribed shared resources.

Each of those four factors manifests itself in multiple and different ways; each of the hardware architectures and programming models expose specific forms. However, the interesting part is that all of them are limiting the scalability of applications no matter what part of the hardware jungle we look at. Hand-holds, PCs, supercomputers, or the cloud, all suffer from the reign of the 4 horsemen: Starvation, Latency, Overhead, and Contention. This realization is very important as it allows us to derive the criteria for solutions to the scalability problem from first principles, and it allows us to focus our analysis on very concrete patterns and measurable metrics. Moreover, any derived results will be applicable to a wide variety of targets.

2.5.4 Technology demands new response

Today’s computer systems are designed based on the initial ideas of John von Neumann\textsuperscript{174}, as published back in 1945, and later extended by the Harvard architecture\textsuperscript{175}. These ideas form the foundation, the execution model, of computer systems we use currently. However, a new response is required in the light of the demands created by today’s technology.

So, what are the overarching objectives for designing systems allowing for applications to scale as they should? In our opinion, the main objectives are:

- Performance: as previously mentioned, scalability and efficiency are the main criteria people are interested in.
- Fault tolerance: the low expected mean time between failures (MTBF\textsuperscript{176}) of future systems requires embracing faults, not trying to avoid them.

\textsuperscript{171} http://en.wikipedia.org/wiki/FLOPS
\textsuperscript{172} http://en.wikipedia.org/wiki/Amdahl%27s_law
\textsuperscript{173} http://en.wikipedia.org/wiki/Gustafson%27s_law
\textsuperscript{174} http://qss.stanford.edu/~godfrey/vonNeumann/vnedvac.pdf
\textsuperscript{175} http://en.wikipedia.org/wiki/Harvard_architecture
\textsuperscript{176} http://en.wikipedia.org/wiki/Mean_time_between_failures
• Power: minimizing energy consumption is a must as it is one of the major cost factors today, and will continue to rise in the future.
• Generality: any system should be usable for a broad set of use cases.
• Programmability: for programmer this is a very important objective, ensuring long term platform stability and portability.

What needs to be done to meet those objectives, to make applications scale better on tomorrow’s architectures? Well, the answer is almost obvious: we need to devise a new execution model—a set of governing principles for the holistic design of future systems—targeted at minimizing the effect of the outlined SLOW factors. Everything we create for future systems, every design decision we make, every criteria we apply, have to be validated against this single, uniform metric. This includes changes in the hardware architecture we prevalently use today, and it certainly involves new ways of writing software, starting from the operating system, runtime system, compilers, and at the application level. However, the key point is that all those layers have to be co-designed; they are interdependent and cannot be seen as separate facets. The systems we have today have been evolving for over 50 years now. All layers function in a certain way, relying on the other layers to do so. But we do not have the time to wait another 50 years for a new coherent system to evolve. The new paradigms are needed now—therefore, co-design is the key.

2.5.5 Governing principles applied while developing HPX

As it turn out, we do not have to start from scratch. Not everything has to be invented and designed anew. Many of the ideas needed to combat the 4 horsemen already exist, many for more than 30 years. All it takes is to gather them into a coherent approach. We’ll highlight some of the derived principles we think to be crucial for defeating SLOW. Some of those are focused on high-performance computing, others are more general.

Focus on latency hiding instead of latency avoidance

It is impossible to design a system exposing zero latencies. In an effort to come as close as possible to this goal many optimizations are mainly targeted towards minimizing latencies. Examples for this can be seen everywhere, such as low latency network technologies like InfiniBand\(^\text{177}\), caching memory hierarchies in all modern processors, the constant optimization of existing MPI\(^\text{178}\) implementations to reduce related latencies, or the data transfer latencies intrinsic to the way we use GPGPUs\(^\text{179}\) today. It is important to note that existing latencies are often tightly related to some resource having to wait for the operation to be completed. At the same time it would be perfectly fine to do some other, unrelated work in the meantime, allowing the system to hide the latencies by filling the idle-time with useful work. Modern systems already employ similar techniques (pipelined instruction execution in the processor cores, asynchronous input/output operations, and many more). What we propose is to go beyond anything we know today and to make latency hiding an intrinsic concept of the operation of the whole system stack.

Embrace fine-grained parallelism instead of heavyweight threads

If we plan to hide latencies even for very short operations, such as fetching the contents of a memory cell from main memory (if it is not already cached), we need to have very lightweight threads with extremely short context switching times, optimally executable within one cycle. Granted, for mainstream architectures, this is not possible today (even if we already have special machines supporting this mode of operation, such as the Cray XMT\(^\text{180}\)). For conventional systems, however, the smaller the overhead of a context switch and the finer the granularity of the threading system, the better will be the overall system utilization and its efficiency. For today’s architectures we already see a flurry of libraries providing exactly this type of functionality: non-pre-emptive, task-queue based parallelization solutions,

\(^{177}\) http://en.wikipedia.org/wiki/InfiniBand

\(^{178}\) https://en.wikipedia.org/wiki/Message_Passing_Interface

such as Intel Threading Building Blocks (TBB)\textsuperscript{181}, Microsoft Parallel Patterns Library (PPL)\textsuperscript{182}, Cilk++\textsuperscript{183}, and many others. The possibility to suspend a current task if some preconditions for its execution are not met (such as waiting for I/O or the result of a different task), seamlessly switching to any other task which can continue, and to reschedule the initial task after the required result has been calculated, which makes the implementation of latency hiding almost trivial.

**Rediscover constraint-based synchronization to replace global barriers**

The code we write today is riddled with implicit (and explicit) global barriers. By “global barriers,” we mean the synchronization of the control flow between several (very often all) threads (when using OpenMP\textsuperscript{184}) or processes (MPI\textsuperscript{185}). For instance, an implicit global barrier is inserted after each loop parallelized using OpenMP\textsuperscript{186} as the system synchronizes the threads used to execute the different iterations in parallel. In MPI\textsuperscript{187} each of the communication steps imposes an explicit barrier onto the execution flow as (often all) nodes have to be synchronized. Each of those barriers is like the eye of a needle the overall execution is forced to be squeezed through. Even minimal fluctuations in the execution times of the parallel threads (jobs) causes them to wait. Additionally, it is often only one of the executing threads that performs the actual reduce operation, which further impedes parallelism. A closer analysis of a couple of key algorithms used in science applications reveals that these global barriers are not always necessary. In many cases it is sufficient to synchronize a small subset of the threads. Any operation should proceed whenever the preconditions for its execution are met, and only those. Usually there is no need to wait for iterations of a loop to finish before you can continue calculating other things; all you need is to complete the iterations that produce the required results for the next operation. Goodbye global barriers, hello constraint based synchronization! People have been trying to build this type of computing (and even computers) since the 1970s. The theory behind what they did is based on ideas around static and dynamic dataflow. There are certain attempts today to get back to those ideas and to incorporate them with modern architectures. For instance, a lot of work is being done in the area of constructing dataflow-oriented execution trees. Our results show that employing dataflow techniques in combination with the other ideas, as outlined herein, considerably improves scalability for many problems.

**Adaptive locality control instead of static data distribution**

While this principle seems to be a given for single desktop or laptop computers (the operating system is your friend), it is everything but ubiquitous on modern supercomputers, which are usually built from a large number of separate nodes (i.e., Beowulf clusters), tightly interconnected by a high-bandwidth, low-latency network. Today’s prevalent programming model for those is MPI, which does not directly help with proper data distribution, leaving it to the programmer to decompose the data to all of the nodes the application is running on. There are a couple of specialized languages and programming environments based on PGAS\textsuperscript{188} (Partitioned Global Address Space) designed to overcome this limitation, such as Chapel\textsuperscript{189}, X10\textsuperscript{190}, UPC\textsuperscript{191}, or Fortress\textsuperscript{192}. However, all systems based on PGAS rely on static data distribution. This works fine as long as this static data distribution does not result in heterogeneous workload distributions or other resource utilization imbalances. In a distributed system these imbalances can be mitigated by migrating part of the application data to different localities (nodes). The only framework supporting (limited) migration today is Charm++\textsuperscript{193}. The first attempts towards solving related problem go back decades as well, a good example is the Linda coordination language\textsuperscript{194}. Nevertheless, none of the other mentioned systems support data migration today, which

\textsuperscript{191} http://upc.lbl.gov/
\textsuperscript{192} https://en.wikipedia.org/wiki/Linda_(coordination_language)
forces the users to either rely on static data distribution and live with the related performance hits or to implement
everything themselves, which is very tedious and difficult. We believe that the only viable way to flexibly support dy-
namic and adaptive \textit{locality} control is to provide a global, uniform address space to the applications, even on distributed
systems.

\textbf{Prefer moving work to the data over moving data to the work}

For the best performance it seems obvious to minimize the amount of bytes transferred from one part of the system
to another. This is true on all levels. At the lowest level we try to take advantage of processor memory caches, thus,
minimizing memory latencies. Similarly, we try to amortize the data transfer time to and from GPGPUs\textsuperscript{195} as much
as possible. At high levels we try to minimize data transfer between different nodes of a cluster or between different
virtual machines on the cloud. Our experience (well, it’s almost common wisdom) shows that the amount of bytes
necessary to encode a certain operation is very often much smaller than the amount of bytes encoding the data the
operation is performed upon. Nevertheless, we still often transfer the data to a particular place where we execute the
operation just to bring the data back to where it came from afterwards. As an example let’s look at the way we usually
write our applications for clusters using MPI. This programming model is all about data transfer between nodes. MPI
is the prevalent programming model for clusters, and it is fairly straightforward to understand and to use. Therefore,
we often write applications in a way that accommodates this model, centered around data transfer. These applications
usually work well for smaller problem sizes and for regular data structures. The larger the amount of data we have to
churn and the more irregular the problem domain becomes, the worse the overall machine utilization and the (strong)
scaling characteristics become. While it is not impossible to implement more dynamic, data driven, and asynchronous
applications using MPI, it is somewhat difficult to do so. At the same time, if we look at applications that prefer to
execute the code close to the \textit{locality} where the data was placed, i.e., utilizing active messages (for instance based on
Charm++\textsuperscript{196}), we see better asynchrony, simpler application codes, and improved scaling.

\textbf{Favor message driven computation over message passing}

Today’s prevalently used programming model on parallel (multi-node) systems is MPI. It is based on message passing,
as the name implies, which means that the receiver has to be aware of a message about to come in. Both codes, the
sender and the receiver, have to synchronize in order to perform the communication step. Even the newer, asynchronous
interfaces require explicitly coding the algorithms around the required communication scheme. As a result, everything
but the most trivial MPI applications spends a considerable amount of time waiting for incoming messages, thus,
causing starvation and latencies to impede full resource utilization. The more complex and more dynamic the data
structures and algorithms become, the larger the adverse effects. The community discovered message-driven and data-
driven methods of implementing algorithms a long time ago, and systems such as Charm++\textsuperscript{197} have already integrated
active messages demonstrating the validity of the concept. Message-driven computation allows for sending messages
without requiring the receiver to actively wait for them. Any incoming message is handled asynchronously and triggers
the encoded action by passing along arguments and—possibly— continuations. \textit{HPX} combines this scheme with work-
queue based scheduling as described above, which allows the system to almost completely overlap any communication
with useful work, thereby minimizing latencies.

2.7 Overview

HPX is organized into different sub-libraries and those in turn into modules. The libraries and modules are independent, with clear dependencies and no cycles. As an end-user, the use of these libraries is completely transparent. If you use e.g. `add_hpx_executable` to create a target in your project you will automatically get all modules as dependencies. See below for a list of the available libraries and modules. Currently these are nothing more than an internal grouping and do not affect usage. They cannot be consumed individually at the moment.

Note: There is a dependency report that displays useful information about the structure of the code. It is available for each commit at HPX Dependency report.

2.7.1 Core modules

affinity

The affinity module contains helper functionality for mapping worker threads to hardware resources.

See the API reference of the module for more details.

\(^{203}\) https://gitlab.com/-/snippets/1822983
\(^{204}\) https://gitlab.com/-/snippets/1828131
algorithms

The algorithms module exposes the full set of algorithms defined by the C++ standard. There is also partial support for C++ ranges.

See the API reference of the module for more details.

allocator_support

This module provides utilities for allocators. It contains hpx::util::internal_allocator which directly forwards allocation calls to jemalloc. This utility is mainly useful on Windows.

See the API reference of the module for more details.

asio

The asio module is a thin wrapper around the Boost.Asio\textsuperscript{205} library, providing a few additional helper functions.

See the API reference of the module for more details.

assertion

The assertion library implements the macros HPX_ASSERT and HPX_ASSERT_MSG. Those two macros can be used to implement assertions which are turned off during a release build.

By default, the location and function where the assert has been called from are displayed when the assertion fires. This behavior can be modified by using hpx::assertion::set_assertion_handler. When HPX initializes, it uses this function to specify a more elaborate assertion handler. If your application needs to customize this, it needs to do so before calling hpx::init, hpx_main or using the C-main wrappers.

See the API reference of the module for more details.

async_base

The async_base module defines the basic functionality for spawning tasks on thread pools. This module does not implement any functionality on its own, but is extended by async_local and async_distributed with implementations for the local and distributed cases.

See the API reference of this module for more details.

async_combinators

This module contains combinators for futures. The when_* functions allow you to turn multiple futures into a single future which is ready when all, any, some, or each of the given futures are ready. The wait_* combinators are equivalent to the when_* functions except that they do not return a future. Those wait for all futures to become ready before returning to the user. Note that the wait_* functions will rethrow one of the exceptions from exceptional futures. The wait_*nothrow combinators are equivalent to the wait_* functions except that they do not throw if one of the futures has become exceptional.

The split_future combinator takes a single future of a container (e.g. tuple) and turns it into a container of futures.

See lcos_local, synchronization, and async_distributed for other synchronization facilities.

See the API reference of this module for more details.

\textsuperscript{205} https://www.boost.org/doc/libs/release/doc/html/boost_asio.html
async_cuda

This library adds a simple API that enables the user to retrieve a future from a CUDA stream. Typically, a user may launch one or more kernels and then get a future from the stream that will become ready when those kernels have completed. It is important to note that multiple kernels may be launched without fetching a future, and multiple futures may be obtained from the helper. Please refer to the unit tests and examples for further examples.

See the API reference of this module for more details.

async_local

This module extends async_base to provide local implementations of hpx::async, hpx::post, hpx::sync, and hpx::dataflow. The async_distributed module extends the functionality in this module to work with actions.

See the API reference of this module for more details.

async_mpi

The MPI library is intended to simplify the process of integrating MPI based codes with the HPX runtime. Any MPI function that is asynchronous and uses an MPI_Request may be converted into an hpx::future. The syntax is designed to allow a simple replacement of the MPI call with a futurized async version that accepts an executor instead of a communicator, and returns a future instead of assigning a request. Typically, an MPI call of the form

\[
\text{int MPI_Isend}(\text{buf}, \text{count}, \text{datatype}, \text{rank}, \text{tag}, \text{comm}, \text{request});
\]

becomes

\[
hpx::\text{future<int> } f = \text{hpx::async(executor, MPI_Isend, buf, count, datatype, rank, tag);}
\]

When the MPI operation is complete, the future will become ready. This allows communication to integrated cleanly with the rest of HPX, in particular the continuation style of programming may be used to build up more complex code. Consider the following example, that chains user processing, sends and receives using continuations...

```cpp
// create an executor for MPI dispatch
hpx::mpi::experimental::executor exec(MPI_COMM_WORLD);

// post an asynchronous receive using MPI_Irecv
hpx::future<int> f_recv = hpx::async(
    exec, MPI_Irecv, &data, rank, MPI_INT, rank_from, i);

// attach a continuation to run when the recv completes,
f_recv.then([&tokens, &counter](auto&&)
{
    // call an application specific function
    msg_recv(rank, size, rank_to, rank_from, tokens[i], i);

    // send a new message
    hpx::future<int> f_send = hpx::async(
        exec, MPI_Isend, &tokens[i], 1, MPI_INT, rank_to, i);

    // when that send completes

(continues on next page)
```

---

207 https://en.wikipedia.org/wiki/Message_Passing_Interface
The example above makes use of `MPI_Isend` and `MPI_Irecv`, but any MPI function that uses requests may be futurized in this manner. The following is a (non-exhaustive) list of MPI functions that should be supported, though not all have been tested at the time of writing (please report any problems to the issue tracker).

```cpp
int MPI_Isend(...);
int MPI_Ibsend(...);
int MPI_Issend(...);
int MPI_Irsend(...);
int MPI_Irecv(...);
int MPI_Imrecv(...);
int MPI_Ibarrier(...);
int MPI_Ibcast(...);
int MPI_Igather(...);
int MPI_Igatherv(...);
int MPI_Iscatter(...);
int MPI_Iscatterv(...);
int MPI_Iallgather(...);
int MPI_Iallgatherv(...);
int MPI_Ialltoall(...);
int MPI_Ialltoallv(...);
int MPI_Ialltoallw(...);
int MPI_Ireduce(...);
int MPI_Iallreduce(...);
int MPI_Ireduce_scatter(...);
int MPI_Ireduce_scatter_block(...);
int MPI_Iscan(...);
int MPI_Iexscan(...);
int MPI_Ineighbor_allgather(...);
int MPI_Ineighbor_allgatherv(...);
int MPI_Ineighbor_alltoall(...);
int MPI_Ineighbor_alltoallv(...);
int MPI_Ineighbor_alltoallw(...);
```

Note that the `HPX` mpi futurization wrapper should work with any asynchronous MPI call, as long as the function signature has the last two arguments `MPI_xxx(..., MPI_Comm comm, MPI_Request *request)` - internally these two parameters will be substituted by the executor and future data parameters that are supplied by template instantiations inside the `hpx::mpi` code.

See the API reference of this module for more details.
async_sycl

This module allows creating HPX futures using SYCL events, effectively integrating asynchronous SYCL kernels and memory transfers with HPX. Building on this integration, this module also contains a SYCL executor. This executor encapsulates a SYCL queue. When SYCL queue member functions are launched with this executor, the user can automatically obtain the HPX futures associated with them.

The creation of the HPX futures using SYCL events is based on the same event polling mechanism that the CUDA HPX integration uses. Each registered event gets an associated callback and gets inserted into a callback vector to be polled by the scheduler in between tasks. Once the polling reveals the event is complete, the callback will be called, which in turn sets the future to ready (see sycl_event_callback.cpp). There are multiple adaptions for HipSYCL for this: To keep the runtime alive (avoiding the repeated on-the-fly creation of the runtime during the polling), we keep a default queue. Furthermore, we flush the internal SYCL DAG to ensure that the launched SYCL function is actually being executed.

The SYCL executor offers the usual post and async_execute functions. Additionally, it contains two get_future functions. One expects a pre-existing SYCL event to return a future, the other one does not but will launch an empty SYCL kernel instead, to obtain an event (causing higher overhead for the sake of being more convenient). The post and async_execute implementations here are actually different for HipSYCL and OneAPI, since the sycl::queue in OneAPI uses a different interface (using a code_location parameter) which requires some adaptations here.

To make this module compile, we use the -fno-sycl and -fsycl compiler parameters for the OneAPI use-case (requiring HPX to be compiled with dpcpp). For HipSYCL we use its cmake integration instead (requiring HPX to be compiled with clang++ and including HipSYCL as a library).

To build with OneAPI, use the CMake Variable HPX_WITH_SYCL=ON. To build with HipSYCL, use HPX_WITH_SYCL=ON and HPX_WITH_HIPSYCL=ON (and make sure find_package will find HipSYCL).

Lastly, the module contains three tests/examples. All three implement a simple vector add example. The first one obtains a future using the free method get_future, the second one uses a single SYCL executor and the last one is using multiple executors called from multiple host threads.

To build the tests, use "make tests.unit.modules.async_sycl" To run the tests, use "ctest -R sycl".

NOTE: Theoretically, this module could work with other SYCL implementations, but was only tested using OneAPI and HipSYCL so far.

See the API reference of this module for more details.

batch_environments

This module allows for the detection of execution as batch jobs, a series of programs executed without user intervention. All data is preselected and will be executed according to preset parameters, such as date or completion of another task. Batch environments are especially useful for executing repetitive tasks.

HPX supports the creation of batch jobs through the Portable Batch System (PBS) and SLURM.

For more information on batch environments, see Running on batch systems and the API reference for the module.
cache

This module provides two cache data structures:

- `hpx::util::cache::local_cache`
- `hpx::util::cache::lru_cache`

See the API reference of the module for more details.

concepts

This module provides helpers for emulating concepts. It provides the following macros:

- `HPX_CONCEPT_REQUIRES`
- `HPX_HAS_MEMBER_XXX_TRAIT_DEF`
- `HPX_HAS_XXX_TRAIT_DEF`

See the API reference of the module for more details.

concurrency

This module provides concurrency primitives useful for multi-threaded programming such as:

- `hpx::barrier`
- `hpx::util::cache_line_data` and `hpx::util::cache_aligned_data`: wrappers for aligning and padding data to cache lines.
- various lockfree queue data structures

See the API reference of the module for more details.

config

The config module contains various configuration options, typically hidden behind macros that choose the correct implementation based on the compiler and other available options. It also contains platform independent macros to control inlining, export sets and more.

See the API reference of the module for more details.

config_registry

The config_registry module is a low level module providing helper functionality for registering configuration entries to a global registry from other modules. The `hpx::config_registry::add_module_config` function is used to add configuration options, and `hpx::config_registry::get_module_configs` can be used to retrieve configuration entries registered so far. `add_module_config_helper` can be used to register configuration entries through static global options.

See the API reference of this module for more details.
coroutines

The coroutines module provides coroutine (user-space thread) implementations for different platforms.
See the API reference of the module for more details.

datastructures

The datastructures module provides basic data structures (typically provided for compatibility with older C++ standards):

- hpx::detail::small_vector
- hpx::util::basic_any
- hpx::util::member_pack
- hpx::optional
- hpx::tuple
- hpx::variant

See the API reference of the module for more details.

debugging

This module provides helpers for demangling symbol names.
See the API reference of the module for more details.

errors

This module provides support for exceptions and error codes:

- hpx::exception
- hpx::error_code
- hpx::error

See the API reference of the module for more details.

execution

This library implements executors and execution policies for use with parallel algorithms and other facilities related to managing the execution of tasks.
See the API reference of the module for more details.
The basic execution module is the main entry point to implement parallel and concurrent operations. It is modeled after P0443 with some additions and implementations for the described concepts. Most notably, it provides an abstraction for execution resources, execution contexts and execution agents in such a way, that it provides customization points that those aforementioned concepts can be replaced and combined with ease.

For that purpose, three virtual base classes are provided to be able to provide implementations with different properties:

- **resource_base**: This is the abstraction for execution resources, that is for example CPU cores or an accelerator.
- **context_base**: An execution context uses execution resources and is able to spawn new execution agents, as new threads of executions on the available resources.
- **agent_base**: The execution agent represents the thread of execution, and can be used to yield, suspend, resume or abort a thread of execution.

### Executors

The executors module exposes executors and execution policies. Most importantly, it exposes the following classes and constants:

- `hpx::execution::sequenced_executor`
- `hpx::execution::parallel_executor`
- `hpx::execution::sequenced_policy`
- `hpx::execution::parallel_policy`
- `hpx::execution::parallel_unsequenced_policy`
- `hpx::execution::sequenced_task_policy`
- `hpx::execution::parallel_task_policy`
- `hpx::execution::seq`
- `hpx::execution::par`
- `hpx::execution::par_unseq`
- `hpx::execution::task`

See the API reference of this module for more details.

### Filesystem

This module provides a compatibility layer for the C++17 filesystem library. If the filesystem library is available this module will simply forward its contents into the `hpx::filesystem` namespace. If the library is not available it will fall back to Boost.Filesystem instead.

See the API reference of the module for more details.

---

209 http://wg21.link/p0443
format

The format module exposes the `format` and `format_to` functions for formatting strings.
See the API reference of the module for more details.

functional

This module provides function wrappers and helpers for managing functions and their arguments.

- `hpx::function`
- `hpx::function_ref`
- `hpx::move_only_function`
- `hpx::bind`
- `hpx::bind_back`
- `hpx::bind_front`
- `hpx::util::deferred_call`
- `hpx::invoke`
- `hpx::invoke_r`
- `hpx::invoke_fused`
- `hpx::invoke_fused_r`
- `hpx::mem_fn`
- `hpx::util::one_shot`
- `hpx::util::protect`
- `hpx::util::result_of`
- `hpx::placeholders::_1`
- `hpx::placeholders::_2`
- ...  
- `hpx::placeholders::_9`

See the API reference of the module for more details.

futures

This module defines the `hpx::future` and `hpx::shared_future` classes corresponding to the C++ standard library classes `std::future`\(^{210}\) and `std::shared_future`\(^{211}\). Note that the specializations of `hpx::future::then` for executors and execution policies are defined in the `execution` module.

See the API reference of this module for more details.

hardware

The hardware module abstracts away hardware specific details of timestamps and CPU features.
See the API reference of the module for more details.

hashing

The hashing module provides two hashing implementations:

- `hpx::util::fibhash`
- `hpx::util::jenkins_hash`

See the API reference of the module for more details.

include_local

This module provides no functionality in itself. Instead it provides headers that group together other headers that often appear together. This module provides local-only headers.
See the API reference of this module for more details.

io_service

This module provides an abstraction over Boost.ASIO, combining multiple `asio::io_context`s into a single pool. `hpx::util::io_service_pool` provides a simple pool of `asio::io_context`s with an API similar to `asio::io_context`. `hpx::threads::detail::io_service_thread_pool` wraps `hpx::util::io_service_pool` into an interface derived from `hpx::threads::detail::thread_pool_base`.
See the API reference of this module for more details.

iterator_support

This module provides helpers for iterators. It provides `hpx::util::iterator_facade` and `hpx::util::iterator_adaptor` for creating new iterators, and the trait `hpx::util::is_iterator` along with more specific iterator traits.
See the API reference of the module for more details.

itt_notify

This module provides support for profiling with Intel VTune\textsuperscript{212}.
See the API reference of this module for more details.

\textsuperscript{212} https://software.intel.com/content/www/us/en/develop/tools/vtune-profiler.html
lci_base

This module provides helper functionality for detecting LCI environments.
See the API reference of this module for more details.

lcos_local

This module provides the following local LCOs:
- hpx::lcos::local::and_gate
- hpx::lcos::local::channel
- hpx::lcos::local::one_element_channel
- hpx::lcos::local::receive_channel
- hpx::lcos::local::send_channel
- hpx::lcos::local::guard
- hpx::lcos::local::guard_set
- hpx::lcos::local::run_guarded
- hpx::lcos::local::conditional_trigger
- hpx::packaged_task
- hpx::promise
- hpx::lcos::local::receive_buffer
- hpx::lcos::local::trigger

See lcos_distributed for distributed LCOs. Basic synchronization primitives for use in HPX threads can be found in synchronization. async_combinators contains useful utility functions for combining futures.
See the API reference of this module for more details.

lock_registration

This module contains functionality for registering locks to detect when they are locked and unlocked on different threads.
See the API reference of this module for more details.

logging

This module provides useful macros for logging information.
See the API reference of the module for more details.
**memory**

Part of this module is a forked version of `boost::intrusive_ptr` from Boost.SmartPtr\(^{213}\). See the API reference of the module for more details.

**mpi_base**

This module provides helper functionality for detecting MPI\(^{214}\) environments. See the API reference of this module for more details.

**pack_traversal**

This module exposes the basic functionality for traversing various packs, both synchronously and asynchronously: `hpx::util::traverse_pack` and `hpx::util::traverse_pack_async`. It also exposes the higher level functionality of unwrapping nested futures: `hpx::util::unwrap` and its function object form `hpx::util::functional::unwrap`. See the API reference of this module for more details.

**plugin**

This module provides base utilities for creating plugins. See the API reference of the module for more details.

**prefix**

This module provides utilities for handling the prefix of an HPX application, i.e. the paths used for searching components and plugins. See the API reference of this module for more details.

**preprocessor**

This library contains useful preprocessor macros:

- `HPX_PP_CAT`: Concatenate two tokens
- `HPX_PP_EXPAND`: Expands a preprocessor token
- `HPX_PP_NARGS`: Determines the number of arguments passed to a variadic macro
- `HPX_PP_STRINGIZE`: Turns a token into a string
- `HPX_PP_STRIP_PARENS`: Strips parenthesis from a token

See the API reference of the module for more details.

program_options

The module program_options is a direct fork of the Boost.Program_options\textsuperscript{215} library (Boost V1.70.0\textsuperscript{216}). In order to be included as an HPX module, the Boost.Program_options library has been moved to the namespace hpx::program_options. We have also replaced all Boost facilities the library depends on with either the equivalent facilities from the standard library or from HPX. As a result, the HPX program_options module is fully interface compatible with Boost.Program_options (sans the hpx namespace and the \#include <hpx/modules/program_options.hpp> changes that need to be applied to all code relying on this library).

All credit goes to Vladimir Prus, the author of the excellent Boost.Program_options library. All bugs have been introduced by us.

See the API reference of the module for more details.

properties

This module implements the prefer customization point for properties in terms of P2220\textsuperscript{217}. This differs from P1393\textsuperscript{218} in that it relies fully on tag_invoke overloads and fewer base customization points. Actual properties are defined in modules. All functionality is experimental and can be accessed through the hpx::experimental namespace.

See the API reference of this module for more details.

resiliency

In HPX, a program failure is a manifestation of a failing task. This module exposes several APIs that allow users to manage failing tasks in a convenient way by either replaying a failed task or by replicating a specific task.

Task replay is analogous to the Checkpoint/Restart mechanism found in conventional execution models. The key difference being localized fault detection. When the runtime detects an error, it replays the failing task as opposed to completely rolling back the entire program to the previous checkpoint.

Task replication is designed to provide reliability enhancements by replicating a set of tasks and evaluating their results to determine a consensus among them. This technique is most effective in situations where there are few tasks in the critical path of the DAG which leaves the system underutilized or where hardware or software failures may result in an incorrect result instead of an error. However, the drawback of this method is the additional computational cost incurred by repeating a task multiple times.

The following API functions are exposed:

- hpx::resiliency::experimental::async_replay: This version of task replay will catch user-defined exceptions and automatically reschedule the task N times before throwing an hpx::resiliency::experimental::abort_replay_exception if no task is able to complete execution without an exception.
- hpx::resiliency::experimental::async_replay_validate: This version of replay adds an argument to async replay which receives a user-provided validation function to test the result of the task against. If the task’s output is validated, the result is returned. If the output fails the check or an exception is thrown, the task is replayed until no errors are encountered or the number of specified retries has been exceeded.
- hpx::resiliency::experimental::async_replicate: This is the most basic implementation of the task replication. The API returns the first result that runs without detecting any errors.

\textsuperscript{215} https://www.boost.org/doc/html/program_options.html
\textsuperscript{216} https://www.boost.org/doc/libs/1_70_0/doc/html/program_options.html
\textsuperscript{217} https://wg21.link/p2220
\textsuperscript{218} http://wg21.link/p1393
• hpx::resiliency::experimental::async_replicate_validate: This API additionally takes a validation function which evaluates the return values produced by the threads. The first task to compute a valid result is returned.

• hpx::resiliency::experimental::async_replicate_vote: This API adds a vote function to the basic replicate function. Many hardware or software failures are silent errors which do not interrupt program flow. In order to detect errors of this kind, it is necessary to run the task several times and compare the values returned by every version of the task. In order to determine which return value is “correct”, the API allows the user to provide a custom consensus function to properly form a consensus. This voting function then returns the “correct” answer.

• hpx::resiliency::experimental::async_replicate_vote_validate: This combines the features of the previously discussed replicate set. Replicate vote validate allows a user to provide a validation function to filter results. Additionally, as described in replicate vote, the user can provide a “voting function” which returns the consensus formed by the voting logic.

• hpx::resiliency::experimental::dataflow_replay: This version of dataflow replay will catch user-defined exceptions and automatically reschedules the task N times before throwing an hpx::resiliency::experimental::abort_replay_exception if no task is able to complete execution without an exception. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.

• hpx::resiliency::experimental::dataflow_replay_validate: This version of replay adds an argument to dataflow replay which receives a user-provided validation function to test the result of the task against. If the task’s output is validated, the result is returned. If the output fails the check or an exception is thrown, the task is replayed until no errors are encountered or the number of specified retries have been exceeded. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.

• hpx::resiliency::experimental::dataflow_replicate: This is the most basic implementation of the task replication. The API returns the first result that runs without detecting any errors. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.

• hpx::resiliency::experimental::dataflow_replicate_validate: This API additionally takes a validation function which evaluates the return values produced by the threads. The first task to compute a valid result is returned. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.

• hpx::resiliency::experimental::dataflow_replicate_vote: This API adds a vote function to the basic replicate function. Many hardware or software failures are silent errors which do not interrupt program flow. In order to detect errors of this kind, it is necessary to run the task several times and compare the values returned by every version of the task. In order to determine which return value is “correct”, the API allows the user to provide a custom consensus function to properly form a consensus. This voting function then returns the “correct” answer. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.

• hpx::resiliency::experimental::dataflow_replicate_vote_validate: This combines the features of the previously discussed replicate set. Replicate vote validate allows a user to provide a validation function to filter results. Additionally, as described in replicate vote, the user can provide a “voting function” which returns the consensus formed by the voting logic. Any arguments for the executed task that are futures will cause the task invocation to be delayed until all of those futures have become ready.

See the API reference of the module for more details.
resource_partitioner

The resource_partitioner module defines `hpx::resource::partitioner`, the class used by the runtime and users to partition available hardware resources into thread pools. See *Using the resource partitioner* for more details on using the resource partitioner in applications.

See the API reference of this module for more details.

runtime_configuration

This module handles the configuration options required by the runtime.

See the API reference of this module for more details.

schedulers

This module provides schedulers used by thread pools in the `thread_pools` module. There are currently three main schedulers:

- `hpx::threads::policies::local_priority_queue_scheduler`
- `hpx::threads::policies::static_priority_queue_scheduler`
- `hpx::threads::policies::shared_priority_queue_scheduler`

Other schedulers are specializations or variations of the above schedulers. See the examples of the `resource_partitioner` module for examples of specifying a custom scheduler for a thread pool.

See the API reference of this module for more details.

serialization

This module provides serialization primitives and support for all built-in types as well as all C++ Standard Library collection and utility types. This list is extended by *HPX* vocabulary types with proper support for global reference counting. *HPX*’s mode of serialization is derived from *Boost’s serialization model*\(^{219}\) and, as such, is mostly interface compatible with its Boost counterpart.

The purest form of serializing data is to copy the content of the payload bit by bit; however, this method is impractical for generic C++ types, which might be composed of more than just regular built-in types. Instead, *HPX*’s approach to serialization is derived from the Boost Serialization library, and is geared towards allowing the programmer of a given class explicit control and syntax of what to serialize. It is based on operator overloading of two special archive types that hold a buffer or stream to store the serialized data and is responsible for dispatching the serialization mechanism to the intrusive or non-intrusive version. The serialization process is recursive. Each member that needs to be serialized must be specified explicitly. The advantage of this approach is that the serialization code is written in C++ and leverages all necessary programming techniques. The generic, user-facing interface allows for effective application of the serialization process without obstructing the algorithms that need special code for packing and unpacking. It also allows for optimizations in the implementation of the archives.

See the API reference of the module for more details.

---

\(^{219}\) [https://www.boost.org/doc/libs/1_72_0/libs/serialization/doc/index.html](https://www.boost.org/doc/libs/1_72_0/libs/serialization/doc/index.html)
static_reinit

This module provides a simple wrapper around static variables that can be reinitialized.
See the API reference of this module for more details.

string_util

This module contains string utilities inspired by the Boost String Algorithms Library.
See the API reference of this module for more details.

synchronization

This module provides synchronization primitives that should be used rather than the C++ standard ones in HPX threads:

- `hpx::barrier`
- `hpx::binary_semaphore`
- `hpx::call_once`
- `hpx::condition_variable`
- `hpx::condition_variable_any`
- `hpx::counting_semaphore`
- `hpx::lcos::local::event`
- `hpx::latch`
- `hpx::mutex`
- `hpx::no_mutex`
- `hpx::once_flag`
- `hpx::recursive_mutex`
- `hpx::shared_mutex`
- `hpx::sliding_semaphore`
- `hpx::spinlock` (*std::mutex* compatible spinlock)
- `hpx::spinlock_no_backoff` (*boost::mutex* compatible spinlock)
- `hpx::spinlock_pool`
- `hpx::stop_callback`
- `hpx::stop_source`
- `hpx::stop_token`
- `hpx::in_place_stop_token`
- `hpx::timed_mutex`
- `hpx::upgrade_to_unique_lock`
- `hpx::upgrade_lock`

See `lcos_local`, `async_combinators`, and `async_distributed` for higher level synchronization facilities.
See the API reference of this module for more details.
testing

The testing module contains useful macros for testing. The results of tests can be printed with `hpx::util::report_errors`. The following macros are provided:

- `HPX_TEST`
- `HPX_TEST_MSG`
- `HPX_TEST_EQ`
- `HPX_TEST_NEQ`
- `HPX_TEST_LT`
- `HPX_TEST_LTE`
- `HPX_TEST_RANGE`
- `HPX_TEST_EQ_MSG`
- `HPX_TEST_NEQ_MSG`
- `HPX_SANITY`
- `HPX_SANITY_MSG`
- `HPX_SANITY_EQ`
- `HPX_SANITY_NEQ`
- `HPX_SANITY_LT`
- `HPX_SANITY_LTE`
- `HPX_SANITY_RANGE`
- `HPX_SANITY_EQ_MSG`

See the API reference of the module for more details.

thread_pool_util

This module contains helper functions for asynchronously suspending and resuming thread pools and their worker threads.

See the API reference of this module for more details.

thread_pools

This module defines the thread pools and utilities used by the HPX runtime. The only thread pool implementation provided by this module is `hpx::threads::detail::scheduled_thread_pool`, which is derived from `hpx::threads::detail::thread_pool_base` defined in the threading_base module.

See the API reference of this module for more details.
thread_support

This module provides miscellaneous utilities for threading and concurrency.
See the *API reference* of the module for more details.

threading

This module provides the equivalents of `std::thread` and `std::jthread` for lightweight *HPX* threads:

- `hpx::thread`
- `hpx::jthread`

See the *API reference* of this module for more details.

threading_base

This module contains the base class definition required for threads. The base class `hpx::threads::thread_data` is inherited by two specializations for stackful and stackless threads: `hpx::threads::thread_data_stackful` and `hpx::threads::thread_data_stackless`. In addition, the module defines the base classes for schedulers and thread pools: `hpx::threads::policies::scheduler_base` and `hpx::threads::thread_pool_base`.

See the API reference of this module for more details.

thread_manager

This module defines the `hpx::threads::threadmanager` class. This is used by the runtime to manage the creation and destruction of thread pools. The *resource_partitioner* module handles the partitioning of resources into thread pools, but not the creation of thread pools.

See the API reference of this module for more details.

timed_execution

This module provides extensions to the executor interfaces defined in the *execution* module that allow timed submission of tasks on thread pools (at or after a specified time).

See the *API reference* of this module for more details.

timing

This module provides the timing utilities (clocks and timers).

See the *API reference* of the module for more details.
topology

This module provides the class `hpx::threads::topology` which represents the hardware resources available on a node. The class is a light wrapper around the Portable Hardware Locality (HWLOC)\(^{220}\) library. The `hpx::threads::cpu_mask` is a small companion class that represents a set of resources on a node.

See the API reference of the module for more details.

type_support

This module provides helper facilities related to types.

See the API reference of the module for more details.

util

The util module provides miscellaneous standalone utilities.

See the API reference of the module for more details.

version

This module macros and functions for accessing version information about HPX and its dependencies.

See the API reference of this module for more details.

2.7.2 Main HPX modules

agas_base

This module holds the implementation of the four AGAS services: primary namespace, locality namespace, component namespace, and symbol namespace.

See the API reference of this module for more details.

async_distributed

This module contains functionality for asynchronously launching work on remote localities: `hpx::async`, `hpx::post`.

This module extends the local-only functions in libs_async_local.

See the API reference of this module for more details.

\(^{220}\) https://www.open-mpi.org/projects/hwloc/
checkpoint

A common need of users is to periodically backup an application. This practice provides resiliency and potential restart points in code. HPX utilizes the concept of a checkpoint to support this use case.

Found in hpx/util/checkpoint.hpp, checkpoints are defined as objects that hold a serialized version of an object or set of objects at a particular moment in time. This representation can be stored in memory for later use or it can be written to disk for storage and/or recovery at a later point. In order to create and fill this object with data, users must use a function called save_checkpoint. In code the function looks like this:

```cpp
hpx::future<hpx::util::checkpoint> hpx::util::save_checkpoint(a, b, c, ...);
```

save_checkpoint takes arbitrary data containers, such as `int`, `double`, `float`, `vector`, and `future`, and serializes them into a newly created checkpoint object. This function returns a `future` to a checkpoint containing the data. Here's an example of a simple use case:

```cpp
using hpx::util::checkpoint;
using hpx::util::save_checkpoint;

std::vector<int> vec{1,2,3,4,5};
auto save_checkpoint = save_checkpoint(vec);
```

Once the future is ready, the checkpoint object will contain the vector `vec` and its five elements.

prepare_checkpoint takes arbitrary data containers (same as for save_checkpoint), such as `int`, `double`, `float`, `vector`, and `future`, and calculates the necessary buffer space for the checkpoint that would be created if save_checkpoint was called with the same arguments. This function returns a `future` to a checkpoint that is appropriately initialized. Here's an example of a simple use case:

```cpp
using hpx::util::checkpoint;
using hpx::util::prepare_checkpoint;

std::vector<int> vec{1,2,3,4,5};
auto prepare_checkpoint = prepare_checkpoint(vec);
```

Once the future is ready, the checkpoint object will be initialized with an appropriately sized internal buffer.

It is also possible to modify the launch policy used by save_checkpoint. This is accomplished by passing a launch policy as the first argument. It is important to note that passing `hpx::launch::sync` will cause save_checkpoint to return a checkpoint instead of a future to a checkpoint. All other policies passed to save_checkpoint will return a future to a checkpoint.

Sometimes checkpoints must be declared before they are used. save_checkpoint allows users to move pre-created checkpoint s into the function as long as they are the first container passing into the function (In the case where a launch policy is used, the checkpoint will immediately follow the launch policy). An example of these features can be found below:

```cpp
char character = 'd';
int integer = 10;
float flt = 10.01f;
bool boolean = true;
std::string str = "I am a string of characters";
std::vector<char> vec(str.begin(), str.end());
checkpoint archive;

// Test 1
```
Once users can create checkpoints they must now be able to restore the objects they contain into memory. This is accomplished by the function `restore_checkpoint`. This function takes a `checkpoint` and fills its data into the containers it is provided. It is important to remember that the containers must be ordered in the same way they were placed into the checkpoint. For clarity see the example below:

```cpp
char character2;
int integer2;
float flt2;
bool boolean2;
std::string str2;
std::vector<char> vec2;

restore_checkpoint(data, character2, integer2, flt2, boolean2, str2, vec2);
```

The core utility of `checkpoint` is in its ability to make certain data persistent. Often, this means that the data needs to be stored in an object, such as a file, for later use. HPX has two solutions for these issues: stream operator overloads and access iterators.

HPX contains two stream overloads, `operator<<` and `operator>>`, to stream data out of and into `checkpoint`. Here is an example of the overloads in use below:

```cpp
double a9 = 1.0, b9 = 1.1, c9 = 1.2;
std::ofstream test_file_9("test_file_9.txt");
hpx::future<checkpoint> f_9 = save_checkpoint(a9, b9, c9);
test_file_9 << f_9.get();
test_file_9.close();

double a9_1, b9_1, c9_1;
std::ifstream test_file_9_1("test_file_9.txt");
checkpoint archive9;
test_file_9_1 >> archive9;
restore_checkpoint(archive9, a9_1, b9_1, c9_1);
```

This is the primary way to move data into and out of a `checkpoint`. It is important to note, however, that users should be cautious when using a stream operator to load data and another function to remove it (or vice versa). Both `operator<<` and `operator>>` rely on a `.write()` and a `.read()` function respectively. In order to know how much data to read from the `std::istream`, the `operator<<` will write the size of the `checkpoint` before writing the `checkpoint` data. Correspondingly, the `operator>>` will read the size of the stored data before reading the data into a new instance of `checkpoint`. As long as the user employs the `operator<<` and `operator>>` to stream the data, this detail can be ignored.

**Important:** Be careful when mixing `operator<<` and `operator>>` with other facilities to read and write to a `checkpoint`. `operator<<` writes an extra variable, and `operator>>` reads this variable back separately. Used together the user will not encounter any issues and can safely ignore this detail.

Users may also move the data into and out of a `checkpoint` using the exposed `.begin()` and `.end()` iterators. An example of this use case is illustrated below.
Checkpointing components

save_checkpoint and restore_checkpoint are also able to store components inside checkpoints. This can be done in one of two ways. First a client of the component can be passed to save_checkpoint. When the user wishes to resurrect the component she can pass a client instance to restore_checkpoint.

This technique is demonstrated below:

```cpp
// Try to checkpoint and restore a component with a client
std::vector<int> vec3{10, 10, 10, 10, 10};

// Create a component instance through client constructor
data_client D(hpx::find_here(), std::move(vec3));
hpx::future<checkpoint> f3 = save_checkpoint(D);

// Create a new client
data_client E;

// Restore server inside client instance
restore_checkpoint(f3.get(), E);
```

The second way a user can save a component is by passing a shared_ptr to the component to save_checkpoint. This component can be resurrected by creating a new instance of the component type and passing a shared_ptr to the new instance to restore_checkpoint.

This technique is demonstrated below:

```cpp
// test checkpoint a component using a shared_ptr
std::vector<int> vec{1, 2, 3, 4, 5};
```
data_client A(hpx::find_here(), std::move(vec));

// Checkpoint Server
hpx::id_type old_id = A.get_id();

hpx::future<std::shared_ptr<data_server>> f_a_ptr = hpx::get_ptr<data_server>(A.get_id());
std::shared_ptr<data_server> a_ptr = f_a_ptr.get();
hpx::future<checkpoint> f = save_checkpoint(a_ptr);
auto&& data = f.get();

// test prepare_checkpoint API
checkpoint c = prepare_checkpoint(hpx::launch::sync, a_ptr);
HPX_TEST(c.size() == data.size());

// Restore Server
// Create a new server instance
std::shared_ptr<data_server> b_server;
restore_checkpoint(data, b_server);

checkpoint_base

The checkpoint_base module contains lower level facilities that wrap simple check-pointing capabilities. This module
does not implement special handling for futures or components, but simply serializes all arguments to or from a given
container.

This module exposes the hpx::util::save_checkpoint_data, hpx::util::restore_checkpoint_data, and
hpx::util::prepare_checkpoint_data APIs. These functions encapsulate the basic serialization functionalities
necessary to save/restore a variadic list of arguments to/from a given data container.

See the API reference of this module for more details.

collectives

The collectives module exposes a set of distributed collective operations. Those can be used to exchange data between
participating sites in a coordinated way. At this point the module exposes the following collective primitives:

- hpx::collectives::all_gather: receives a set of values from all participating sites.
- hpx::collectives::all_reduce: performs a reduction on data from each participating site to each partici-
- hpx::collectives::all_to_all: each participating site provides its element of the data to collect while all
- hpx::collectives::broadcast_to and hpx::collectives::broadcast_from: performs a broadcast
- cpp:func:hpx::collectives::exclusive_scan performs an exclusive scan operation
- hpx::collectives::gather_here and hpx::collectives::gather_there: gathers values from all par-

282 Chapter 2. What’s so special about HPX?
HPX Documentation, master

- **cpp:func:hpx::collectives::inclusive_scan** performs an inclusive scan operation on a set of values received from all call sites operating on the given base name.
- **hpx::collectives::reduce_here** and **hpx::collectives::reduce_there**: performs a reduction on data from each participating site to a root site.
- **hpx::collectives::scatter_to** and **hpx::collectives::scatter_from**: receives an element of a set of values operating on the given base name.
- **hpx::lcos::broadcast**: performs a given action on all given global identifiers.
- **hpx::distributed::barrier**: distributed barrier.
- **hpx::lcos::fold**: performs a fold with a given action on all given global identifiers.
- **hpx::distributed::latch**: distributed latch.
- **hpx::lcos::reduce**: performs a reduction on data from each given global identifiers.
- **hpx::lcos::spmd_block**: performs the same operation on a local image while providing handles to the other images.

See the API reference of the module for more details.

### command_line_handling

The command_line_handling module defines and handles the command-line options required by the **HPX** runtime, combining them with configuration options defined by the **runtime_configuration** module. The actual parsing of command line options is handled by the **program_options** module.

See the API reference of the module for more details.

### compute

The compute module provides utilities for handling task and memory affinity on host systems.

See the API reference of the module for more details.

### executors_distributed

This module provides the executor **hpx::parallel::execution::distribution_policy_executor**. It allows one to create work that is implicitly distributed over multiple localities.

See the API reference of this module for more details.

### include

This module provides no functionality in itself. Instead it provides headers that group together other headers that often appear together.

See the API reference of this module for more details.
**lcos_distributed**

This module contains distributed LCOs. Currently the only LCO provided is `cpp:class::hpx::lcos::channel`, a construct for sending values from one locality to another. See `libs_lcos_local` for local LCOs.

See the API reference of this module for more details.

**naming_base**

This module provides a forward declaration of `address_type`, `component_type` and `invalid_locality_id`.

See the API reference of this module for more details.

**performance_counters**

This module provides the basic functionality required for defining performance counters. See Performance counters for more information about performance counters.

See the API reference of this module for more details.

**resiliency_distributed**

Software resiliency features of HPX were introduced in the resiliency module. This module extends the APIs to run on distributed-memory systems allowing the user to invoke the failing task on other localities at runtime. This is useful in cases where a node is identified to fail more often (e.g., for certain ALU computes) as the task can now be replayed or replicated among different localities. The API exposed allows for an easy integration with the local only resiliency APIs as well.

Distributed software resilience APIs have a similar function signature and lives under the same namespace of `hpx::resiliency::experimental`. The difference arises in the formal parameters where distributed APIs takes the localities as the first argument, and an action as opposed to a function or a function object. The localities signify the order in which the API will either schedule (in case of Task Replay) tasks in a round robin fashion or replicate the tasks onto the list of localities.

The list of APIs exposed by distributed resiliency modules is the same as those defined in local resiliency module.

See the API reference of this module for more details.

**segmented_algorithms**

Segmented algorithms extend the usual parallel algorithms by providing overloads that work with distributed containers, such as partitioned vectors.

See the API reference of the module for more details.
statistics

This module provides some statistics utilities like rolling min/max and histogram.

See the API reference of the module for more details.

2.8 API reference

HPX follows a versioning scheme with three numbers: \texttt{major.minor.patch}. We guarantee no breaking changes in the API for patch releases. Minor releases may remove or break existing APIs, but only after a deprecation period of at least two minor releases. In rare cases do we outright remove old and unused functionality without a deprecation period.

We do not provide any ABI compatibility guarantees between any versions, debug and release builds, and builds with different C++ standards.

The public API of HPX is presented below. Clicking on a name brings you to the full documentation for the class or function. Including the header specified in a heading brings in the features listed under that heading.

\textbf{Note:} Names listed here are guaranteed stable with respect to semantic versioning. However, at the moment the list is incomplete and certain unlisted features are intended to be in the public API. While we work on completing the list, if you’re unsure about whether a particular unlisted name is part of the public API you can get into contact with us or open an issue and we’ll clarify the situation.

2.8.1 Public API

Our API is semantically conforming; hence, the reader is highly encouraged to refer to the corresponding facility in the \texttt{C++ Standard} if needed. All names below are also available in the top-level \texttt{hpx} namespace unless otherwise noted. The names in \texttt{hpx} should be preferred. The names in sub-namespaces will eventually be removed.

\texttt{hpx/algorithm.hpp}

[^345]: [https://wg21.link/p2440](https://wg21.link/p2440)
hpx/any.hpp

The header `hpx/any.hpp`\(^{356}\) corresponds to the C++ standard library header `any`\(^{357}\). `hpx::any` is compatible with `std::any`.

### Classes

<table>
<thead>
<tr>
<th>Class</th>

</tr>
<tr>
<td><code>hpx::make_unique_any_nonser</code></td>
<td></td>
</tr>
</tbody>
</table>

### hpx/assert.hpp

The header `hpx/assert.hpp`\(^{362}\) corresponds to the C++ standard library header `cassert`\(^{363}\).

`HPX_ASSERT` is the HPX equivalent to `assert` in `cassert`. `HPX_ASSERT` can also be used in CUDA device code.

### Macros

<table>

hp/x/barrier.hpp

The header `hp/x/barrier.hpp`\(^{364}\) corresponds to the C++ standard library header `std::barrier`\(^{365}\) and contains a distributed barrier implementation. This functionality is also exposed through the `hp/x::distributed` namespace. The name in `hp/x::distributed` should be preferred.

**Classes**

<table>

</tbody>
</table>

hpx/future.hpp

The header hpx/future.hpp[^393] corresponds to the C++ standard library header future[^394]. See Extended facilities for futures for more information about extensions to futures compared to the C++ standard library.

This header file also contains overloads of hpx::async, hpx::post, hpx::sync, and hpx::dataflow that can be used with actions. See Action invocation for more information about invoking actions.

Classes

Table 2.141: Classes of header hpx/future.hpp

<table>

hpx/init.hpp

The header hpx/init.hpp\(^\text{\ref{hpx/init.hpp}}\) contains functionality for starting, stopping, suspending, and resuming the HPX runtime. This is the main way to explicitly start the HPX runtime. See Starting the HPX runtime for more details on starting the HPX runtime.

\(^\text{\ref{hpx/init.hpp}}\) http://github.com/STEllAR-GROUP/hpx/blob/dd17010adf02cdab681d96f10f96626d476459c0/libs/full/init_runtime/include/hpx/init.hpp

**hpx/latch.hpp**

The header `hpx/latch.hpp`\(^\text{416}\) corresponds to the C++ standard library header `latch`\(^\text{417}\). It contains a local and a distributed latch implementation. This functionality is also exposed through the `hpx::distributed` namespace. The name in `hpx::distributed` should be preferred.

**Classes**

300 Chapter 2. What’s so special about HPX?
hpx/numeric.hpp

The header `hpx/numeric.hpp`\(^{449}\) corresponds to the C++ standard library header `numeric`\(^{450}\). See *Using parallel algorithms* for more information about the parallel algorithms.

**Functions**

Table 2.152: `hpx` functions of header `hpx/numeric.hpp`

<table>
<thead>
<tr>
<th><code>hpx</code> function</th>
<th>C++ standard</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>hpx::adjacent_difference</code></td>
<td><code>std::adjacent_difference</code>(^{451})</td>
</tr>
<tr>
<td><code>hpx::exclusive_scan</code></td>
<td><code>std::exclusive_scan</code>(^{452})</td>

hpx/wrap_main.hpp

The header hpx/wrap_main.hpp\(^{513}\) does not provide any direct functionality but is used for implicitly using `main` as the runtime entry point. See *Re-use the main() function as the main HPX entry point* for more details on implicitly starting the HPX runtime.

2.8.2 Full API

The full API of HPX is presented below. The listings for the public API above refer to the full documentation below.

**Note:** Most names listed in the full API reference are implementation details or considered unstable. They are listed mostly for completeness. If there is a particular feature you think deserves being in the public API we may consider promoting it. In general we prioritize making sure features corresponding to C++ standard library features are stable and complete.

algorithms

See *Public API* for a list of names and headers that are part of the public HPX API.

hpx/parallel/task_block.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace hpx

namespace experimental

Top-level namespace.

\(^{513}\) [http://github.com/STEllAR-GROUP/hpx/blob/dd17010adf02cdab681d96f1096626d476459c0/include/hpx/wrap_main.hpp](http://github.com/STEllAR-GROUP/hpx/blob/dd17010adf02cdab681d96f1096626d476459c0/include/hpx/wrap_main.hpp)
Functions

template<typename ExPolicy, typename F>
decay(auto) define_task_block(ExPolicy &&policy, F &&f)
    Constructs a task_block, tr, using the given execution policy policy, and invokes the expression f(tr) on the user-provided object, f.

Postcondition: All tasks spawned from f have finished execution. A call to define_task_block may return on a different thread than that on which it was called.

Note: It is expected (but not mandated) that f will (directly or indirectly) call tr.run(callable_object).

Template Parameters
  • ExPolicy – The type of the execution policy to use (deduced). It describes the manner in which the execution of the task block may be parallelized.
  • F – The type of the user defined function to invoke inside the define_task_block (deduced). F shall be MoveConstructible.

Parameters
  • policy – The execution policy to use for the scheduling of the iterations.
  • f – The user defined function to invoke inside the task block. Given an lvalue tr of type task_block, the expression, (void)f(tr), shall be well-formed.

Throws exception_list – specified in Exception Handling.

template<typename F>
void define_task_block(F &&f)
    Constructs a task_block, tr, and invokes the expression f(tr) on the user-provided object, f. This version uses parallel_policy for task scheduling.

Postcondition: All tasks spawned from f have finished execution. A call to define_task_block may return on a different thread than that on which it was called.

Note: It is expected (but not mandated) that f will (directly or indirectly) call tr.run(callable_object).

Template Parameters F – The type of the user defined function to invoke inside the define_task_block (deduced). F shall be MoveConstructible.

Parameters f – The user defined function to invoke inside the task block. Given an lvalue tr of type task_block, the expression, (void)f(tr), shall be well-formed.

Throws exception_list – specified in Exception Handling.

template<typename ExPolicy, typename F>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy> define_task_block_restore_thread(ExPolicy &&policy, F &&f)

Constructs a task_block, tr, and invokes the expression f(tr) on the user-provided object, f.

Postcondition: All tasks spawned from f have finished execution. A call to define_task_block_restore_thread always returns on the same thread as that on which it was called.
Note: It is expected (but not mandated) that f will (directly or indirectly) call tr.run(callable_object).

Template Parameters
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the task block may be parallelized.
- **F** – The type of the user defined function to invoke inside the define_task_block (deduced). F shall be MoveConstructible.

Parameters
- **policy** – The execution policy to use for the scheduling of the iterations.
- **f** – The user defined function to invoke inside the define_task_block. Given an lvalue tr of type task_block, the expression, (void)f(tr), shall be well-formed.

Throws exception_list – specified in Exception Handling.

```cpp
template<typename F>
void define_task_block_restore_thread(F &&f)

Constructs a task_block, tr, and invokes the expression f(tr) on the user-provided object, f. This version uses parallel_policy for task scheduling.
```

Postcondition: All tasks spawned from f have finished execution. A call to define_task_block_restore_thread always returns on the same thread as that on which it was called.

Note: It is expected (but not mandated) that f will (directly or indirectly) call tr.run(callable_object).

Template Parameters **F** – The type of the user defined function to invoke inside the define_task_block (deduced). F shall be MoveConstructible.

Parameters **f** – The user defined function to invoke inside the define_task_block. Given an lvalue tr of type task_block, the expression, (void)f(tr), shall be well-formed.

Throws exception_list – specified in Exception Handling.

```cpp
template<typename ExPolicy = hpx::execution::parallel_policy>
class task_block
```

#include <task_block.hpp> The class task_block defines an interface for forking and joining parallel tasks. The define_task_block and define_task_block_restore_thread function templates create an object of type task_block and pass a reference to that object to a user-provided callable object.

An object of class task_block cannot be constructed, destroyed, copied, or moved except by the implementation of the task region library. Taking the address of a task_block object via operator& or addressof is ill formed. The result of obtaining its address by any other means is unspecified.

A task_block is active if it was created by the nearest enclosing task block, where “task block” refers to an invocation of define_task_block or define_task_block_restore_thread and “nearest enclosing” means the most recent invocation that has not yet completed. Code designated for execution in another thread by means other than the facilities in this section (e.g., using thread or async) are not enclosed in the task region and a task_block passed to (or captured by) such code is not active within that code. Performing any operation on a task_block that is not active results in undefined behavior.

The task_block that is active before a specific call to the run member function is not active within the asynchronous function that invoked run. (The invoked function should not, therefore, capture the task_block from the surrounding block.)
Example:
```cpp
define_task_block([&] (auto & tr) {
    tr.run([&] { f(); }); // Error: tr is not active
    define_task_block([&] (auto & tr) { // Nested task block
        tr.run(f); // OK: inner tr is active
        /// ...
    });
    }); // ...
});
```

**Template Parameters**  
**ExPolicy** – The execution policy an instance of a task_block was created with. This defaults to parallel_policy.

**Public Types**

```
using execution_policy = ExPolicy
```

Refers to the type of the execution policy used to create the task_block.

**Public Functions**

```
inline constexpr execution_policy const & get_execution_policy() const noexcept
```

Return the execution policy instance used to create this task_block.

```
template<typename F, typename ...Ts>
inline void run(F &&f, Ts&&... ts)
```

Causes the expression f() to be invoked asynchronously. The invocation of f is permitted to run on an unspecified thread in an unordered fashion relative to the sequence of operations following the call to run(f) (the continuation), or indeterminately sequenced within the same thread as the continuation.

The call to run synchronizes with the invocation of f. The completion of f() synchronizes with the next invocation of wait on the same task_block or completion of the nearest enclosing task block (i.e., the define_task_block or define_task_block_restore_thread that created this task block).

Requires: F shall be MoveConstructible. The expression, (void)f(), shall be well-formed.

Precondition: this shall be the active task_block.

Postconditions: A call to run may return on a different thread than that on which it was called.

**Note:** The call to run is sequenced before the continuation as if run returns on the same thread. The invocation of the user-supplied callable object f may be immediate or may be delayed until compute resources are available. run might or might not return before invocation of f completes.

**Throws** task_canceled_exception – described in Exception Handling.

```
template-typename Executor, typename F, typename ...Ts>
inline void run(Executor &&exec, F &&&f, Ts&&&... ts)
```

Causes the expression f() to be invoked asynchronously using the given executor. The invocation of f is permitted to run on an unspecified thread associated with the given executor and in an
unordered fashion relative to the sequence of operations following the call to run(exec, f) (the continuation), or indeterminately sequenced within the same thread as the continuation.

The call to run synchronizes with the invocation of f. The completion of f() synchronizes with the next invocation of wait on the same task_block or completion of the nearest enclosing task block (i.e., the define_task_block or define_task_block_restore_thread that created this task block).

Requires: Executor shall be a type modeling the Executor concept. F shall be MoveConstructible. The expression, (void)f(), shall be well-formed.

Precondition: this shall be the active task_block.

Postconditions: A call to run may return on a different thread than that on which it was called.

Note: The call to run is sequenced before the continuation as if run returns on the same thread. The invocation of the user-supplied callable object f may be immediate or may be delayed until compute resources are available. run might or might not return before invocation of f completes.

Throws task_canceled_exception – described in Exception Handling. The function will also throw an exception_list holding all exceptions that were caught while executing the tasks.

inline void wait()
Blocks until the tasks spawned using this task_block have finished.

Precondition: this shall be the active task_block.

Postcondition: All tasks spawned by the nearest enclosing task region have finished. A call to wait may return on a different thread than that on which it was called.

Example:

```cpp
define_task_block([&](auto& tr) {
    tr.run([&]{ process(a, w, x); }); // Process a[w] through a[x]
    if (y < x) tr.wait(); // Wait if overlap between (w, x] and [y, z)
    process(a, y, z); // Process a[y] through a[z]
});
```

Note: The call to wait is sequenced before the continuation as if wait returns on the same thread.

Throws This – function may throw task_canceled_exception, as described in Exception Handling. The function will also throw a exception_list holding all exceptions that were caught while executing the tasks.

inline ExPolicy &policy() noexcept
Returns a reference to the execution policy used to construct this object.

Precondition: this shall be the active task_block.

inline constexpr ExPolicy const &policy() const noexcept
Returns a reference to the execution policy used to construct this object.

Precondition: this shall be the active task_block.

`template<typename Executor, typename F, typename ...Ts>`

`inline void run(Executor&& exec, F &&f, Ts&&... ts)`

Adds a task to compute \( f() \) and returns immediately.

**Template Parameters**

- `Executor` – The type of the executor to associate with this execution policy.
- `F` – The type of the user defined function to invoke.
- `Ts` – The type of additional arguments used to invoke \( f() \).

**Parameters**

2.8. API reference 315
• **exec** – The executor to use for the execution of the parallel algorithm the returned execution policy is used with.
• **f** – The user defined function to invoke inside the task group.
• **ts** – Additional arguments to use to invoke \( f() \).

```cpp
template<typename F, typename ... Ts>
inline void run(F &&f, Ts&&... ts)
    Adds a task to compute \( f() \) and returns immediately.

Template Parameters
• **F** – The type of the user defined function to invoke.
• **Ts** – The type of additional arguments used to invoke \( f() \).

Parameters
• **f** – The user defined function to invoke inside the task group.
• **ts** – Additional arguments to use to invoke \( f() \).
```

```cpp
void wait()
    Waits for all tasks in the group to complete or be cancelled.

void add_exception(std::exception_ptr p)
    Adds an exception to this task_group.

namespace hpx

Functions

template<typename FwdIter1, typename FwdIter2>
FwdIter2 adjacent_difference(FwdIter1 first, FwdIter1 last, FwdIter2 dest)
Assigns each value in the range given by result its corresponding element in the range [first, last] and the one preceding it except *result, which is assigned *first.

Note: Complexity: Exactly (last - first) - 1 application of the binary operator and (last - first) assignments.

Template Parameters

• FwdIter1 – The type of the source iterators used for the input range (deduced). This iterator type must meet the requirements of a forward iterator.
• **FwdIter2** – The type of the source iterators used for the output range (deduced). This iterator type must meet the requirements of a forward iterator.

**Parameters**

• **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.

• **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.

• **dest** – Refers to the beginning of the sequence of elements the results will be assigned to.

**Returns** The `adjacent_difference` algorithm returns a `FwdIter2`. The `adjacent_difference` algorithm returns an iterator to the element past the last element written.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> adjacent_difference(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest)
```

Assigns each value in the range given by `result` its corresponding element in the range `[first, last]` and the one preceding it except `*result`, which is assigned `*first`. Executed according to the policy.

The difference operations in the parallel `adjacent_difference` invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The difference operations in the parallel `adjacent_difference` invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Exactly `(last - first) - 1` application of the binary operator and `(last - first)` assignments.

**Template Parameters**

• **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **FwdIter1** – The type of the source iterators used for the input range (deduced). This iterator type must meet the requirements of a forward iterator.

• **FwdIter2** – The type of the source iterators used for the output range (deduced). This iterator type must meet the requirements of a forward iterator.

**Parameters**

• **policy** – The execution policy to use for the scheduling of the iterations.

• **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.

• **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.

• **dest** – Refers to the beginning of the sequence of elements the results will be assigned to.
Returns The \texttt{adjacent\_difference} algorithm returns a \texttt{hpx::future\textless\texttt{FwdIter2}\textgreater} if the execution policy is of type \texttt{sequenced\_task\_policy} or \texttt{parallel\_task\_policy} and returns \texttt{FwdIter2} otherwise. The \texttt{adjacent\_difference} algorithm returns an iterator to the element past the last element written.

```cpp
template<typename FwdIter1, typename FwdIter2, typename Op>
FwdIter2 adjacent_difference(FwdIter1 first, FwdIter1 last, FwdIter2 dest, Op &&op)
```

Assigns each value in the range given by result its corresponding element in the range \([\text{first}, \text{last}]\) and the one preceding it except \(*\text{result}\), which is assigned \(*\text{first}\)

\textbf{Note:} Complexity: \(\text{Exactly (last - first) - 1 application of the binary operator and (last - first) assignments.}\)

\textbf{Template Parameters}

- \texttt{FwdIter1} – The type of the source iterators used for the input range (deduced). This iterator type must meet the requirements of a forward iterator.
- \texttt{FwdIter2} – The type of the source iterators used for the output range (deduced). This iterator type must meet the requirements of a forward iterator.
- \texttt{Op} – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \texttt{adjacent\_difference} requires \texttt{Op} to meet the requirements of \texttt{Copy\textunderscore Constructible}.

\textbf{Parameters}

- \texttt{first} – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- \texttt{last} – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- \texttt{dest} – Refers to the beginning of the sequence of elements the results will be assigned to.
- \texttt{op} – The binary operator which returns the difference of elements. The signature should be equivalent to the following:

```cpp
bool op(const Type1 &a, const Type1 &b);
```

The signature does not need to have \texttt{const \&}, but the function must not modify the objects passed to it. The types \texttt{Type1} must be such that objects of type \texttt{FwdIter1} can be dereferenced and then implicitly converted to the dereferenced type of \texttt{dest}.

\textbf{Returns} The \texttt{adjacent\_difference} algorithm returns \texttt{FwdIter2}. The \texttt{adjacent\_difference} algorithm returns an iterator to the element past the last element written.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Op>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> adjacent_difference(ExPolicy &&policy,
FwdIter1 first,
FwdIter1 last,
FwdIter2 dest,
Op &&op)
```

Assigns each value in the range given by result its corresponding element in the range \([\text{first}, \text{last}]\) and the one preceding it except \(*\text{result}\), which is assigned \(*\text{first}\)
The difference operations in the parallel `adjacent_difference` invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The difference operations in the parallel `adjacent_difference` invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Exactly (last - first) - 1 application of the binary operator and (last - first) assignments.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the input range (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used for the output range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Op** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `adjacent_difference` requires `Op` to meet the requirements of `CopyConstructible`.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **dest** – Refers to the beginning of the sequence of elements the results will be assigned to.
- **op** – The binary operator which returns the difference of elements. The signature should be equivalent to the following:

```
bool op(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types `Type1` must be such that objects of type `FwdIter1` can be dereferenced and then implicitly converted to the dereferenced type of `dest`.

**Returns** The `adjacent_difference` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `adjacent_difference` algorithm returns an iterator to the element past the last element written.
namespace hpx

Functions

template<typename InIter, typename Pred = hpx::parallel::detail::equal_to>
InIter adjacent_find(InIter first, InIter last, Pred &&pred = Pred())

Searches the range [first, last) for two consecutive identical elements.

Note: Complexity: Exactly the smaller of \((result - first) + 1\) and \((last - first) - 1\) application of the predicate where \(result\) is the value returned

Template Parameters

- **InIter** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an input iterator.
- **Pred** – The type of an optional function/function object to use.

Parameters

- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **pred** – The binary predicate which returns \(true\) if the elements should be treated as equal. The signature should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types \(Type1\) must be such that objects of type \(InIter\) can be dereferenced and then implicitly converted to \(Type1\).

Returns The adjacent_find algorithm returns an iterator to the first of the identical elements. If no such elements are found, \(last\) is returned.

template<typename ExPolicy, typename FwdIter, typename Pred = hpx::parallel::detail::equal_to>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> adjacent_find(ExPolicy &&policy,
  FwdIter first, FwdIter last, Pred &&pred = Pred())

Searches the range [first, last) for two consecutive identical elements. This version uses the given binary predicate pred

The comparison operations in the parallel adjacent_find invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.
The comparison operations in the parallel `adjacent_find` invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of `adjacent_find` is available if the user decides to provide their algorithm their own binary predicate `pred`.

**Note:** Complexity: Exactly the smaller of \((result - first) + 1\) and \((last - first) - 1\) application of the predicate where `result` is the value returned

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **pred** – The binary predicate which returns `true` if the elements should be treated as equal. The signature should be equivalent to the following:

  ```cpp
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

**Returns** The `adjacent_find` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `adjacent_find` algorithm returns an iterator to the first of the identical elements. If no such elements are found, `last` is returned.
namespace hpx

Functions

template<typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result_t<ExPolicy, bool> none_of(ExPolicy &&policy, FwdIter first, FwdIter last, F &&f)

Checks if unary predicate \( f \) returns true for no elements in the range \([\text{first}, \text{last})\).

The application of function objects in parallel algorithm invoked with an execution policy object of type \textit{sequenced\_policy} execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type \textit{parallel\_policy} or \textit{parallel\_task\_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

| Note: Complexity: At most \( \text{last} - \text{first} \) applications of the predicate \( f \) |

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \textit{none\_of} requires \( F \) to meet the requirements of \textit{CopyConstructible}.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have \textit{const }\&, but the function must not modify the objects passed to it. The type \textit{Type} must be such that an object of type \textit{FwdIter} can be dereferenced and then implicitly converted to Type.
**Returns** The `none_of` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `none_of` algorithm returns true if the unary predicate `f` returns true for no elements in the range, false otherwise. It returns true if the range is empty.

```cpp
template<typename InIter, typename F>
bool none_of(InIter first, InIter last, F &&f)
```

Checks if unary predicate `f` returns true for no elements in the range `[first, last)

**Note:** Complexity: At most `last - first` applications of the predicate `f`

**Template Parameters**
- `InIter` – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- `F` – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `none_of` requires `F` to meet the requirements of `CopyConstructible`.

**Parameters**
- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements the algorithm will be applied to.
- `f` – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. The signature of this predicate should be equivalent to:

```
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `InIter` can be dereferenced and then implicitly converted to `Type`.

**Returns** The `none_of` algorithm returns a `bool`. The `none_of` algorithm returns true if the unary predicate `f` returns true for no elements in the range, false otherwise. It returns true if the range is empty.

```cpp
template<typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result_t<ExPolicy, bool> any_of(ExPolicy &&policy, FwdIter first, FwdIter last, F &&f)
```

Checks if unary predicate `f` returns true for at least one element in the range `[first, last)

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most `last - first` applications of the predicate `f`
Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `any_of` requires `F` to meet the requirements of `CopyConstructible`.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

  ```cpp
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

Returns The `any_of` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `any_of` algorithm returns true if the unary predicate `f` returns true for at least one element in the range, false otherwise. It returns false if the range is empty.

template<typename InIter, typename F>
bool any_of(InIter first, InIter last, F &&f)
Checks if unary predicate `f` returns true for at least one element in the range [first, last).

Note: Complexity: At most `last - first` applications of the predicate `f`
```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `InIter` can be dereferenced and then implicitly converted to Type.

**Returns** The `any_of` algorithm returns a `bool`. The `any_of` algorithm returns true if the unary predicate `f` returns true for at least one element in the range, false otherwise. It returns false if the range is empty.

```cpp
template<typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result_t<ExPolicy, bool> all_of(ExPolicy &&policy, FwdIter first, FwdIter last, F &&f)
```

Checks if unary predicate `f` returns true for all elements in the range `[first, last)`.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most `last - first` applications of the predicate `f`

**Template Parameters**

- `ExPolicy` – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- `FwdIter` – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- `F` – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `all_of` requires `F` to meet the requirements of `CopyConstructible`.

**Parameters**

- `policy` – The execution policy to use for the scheduling of the iterations.
- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements the algorithm will be applied to.
- `f` – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to Type.
Returns The \texttt{all\_of} algorithm returns a \texttt{hpx::future<bool>} if the execution policy is of type \texttt{sequenced\_task\_policy} or \texttt{parallel\_task\_policy} and returns \texttt{bool} otherwise. The \texttt{all\_of} algorithm returns true if the unary predicate \texttt{f} returns true for all elements in the range, false otherwise. It returns true if the range is empty.

\begin{verbatim}
template<typename ExPolicy, typename InIter, typename F>
bool all_of(InIter first, InIter last, F &&f)
    Checks if unary predicate \texttt{f} returns true for all elements in the range \texttt{[first, last)}. 
\end{verbatim}

\underline{Note:} Complexity: At most \texttt{last - first} applications of the predicate \texttt{f}

\underline{Template Parameters}
\begin{itemize}
  \item \texttt{InIter} – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
  \item \texttt{F} – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \texttt{all\_of} requires \texttt{F} to meet the requirements of \texttt{CopyConstructible}.
\end{itemize}

\underline{Parameters}
\begin{itemize}
  \item \texttt{first} – Refers to the beginning of the sequence of elements the algorithm will be applied to.
  \item \texttt{last} – Refers to the end of the sequence of elements the algorithm will be applied to.
  \item \texttt{f} – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \texttt{[first, last)}. The signature of this predicate should be equivalent to:
    \begin{verbatim}
    bool pred(const Type &a);
    \end{verbatim}
    The signature does not need to have const&, but the function must not modify the objects passed to it. The type \texttt{Type} must be such that an object of type \texttt{InIter} can be dereferenced and then implicitly converted to \texttt{Type}.
\end{itemize}

\underline{Returns} The \texttt{all\_of} algorithm returns a \texttt{bool}. The \texttt{all\_of} algorithm returns true if the unary predicate \texttt{f} returns true for all elements in the range, false otherwise. It returns true if the range is empty.

\texttt{hpx/parallel/algorithms/copy.hpp}

See \textit{Public API} for a list of names and headers that are part of the public \textit{HPX} API.

\begin{verbatim}
namespace hpx
\end{verbatim}
Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2>

hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> copy(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest)

Copies the elements in the range, defined by [first, last), to another range beginning at dest. Executed according to the policy.

The assignments in the parallel copy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The assignments in the parallel copy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: Performs exactly last - first assignments.

Template Parameters

• ExPolicy – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• FwdIter1 – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

• FwdIter2 – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

• policy – The execution policy to use for the scheduling of the iterations.

• first – Refers to the beginning of the sequence of elements the algorithm will be applied to.

• last – Refers to the end of the sequence of elements the algorithm will be applied to.

• dest – Refers to the beginning of the destination range.

Returns The copy algorithm returns a hpx::future<FwdIter2> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter2> otherwise. The copy algorithm returns the pair of the input iterator last and the output iterator to the element in the destination range, one past the last element copied.

template<typename FwdIter1, typename FwdIter2>

FwdIter2 copy(FwdIter1 first, FwdIter1 last, FwdIter2 dest)

Copies the elements in the range, defined by [first, last), to another range beginning at dest.

Note: Complexity: Performs exactly last - first assignments.

Template Parameters

• FwdIter1 – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
• **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

• **dest** – Refers to the beginning of the destination range.

**Returns** The `copy` algorithm returns a `FwdIter2`. The `copy` algorithm returns the pair of the input iterator `last` and the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename Size, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> copy_n(ExPolicy &&policy, FwdIter1 first, Size count, FwdIter2 dest)
```

Copies the elements in the range `[first, first + count)`, starting from `first` and proceeding to `first + count - 1`, to another range beginning at `dest`. Executed according to the policy.

The assignments in the parallel `copy_n` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `copy_n` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs exactly `count` assignments, if `count > 0`, no assignments otherwise.

**Template Parameters**

• **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

• **Size** – The type of the argument specifying the number of elements to apply `f` to.

• **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

• **policy** – The execution policy to use for the scheduling of the iterations.

• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **count** – Refers to the number of elements starting at `first` the algorithm will be applied to.

• **dest** – Refers to the beginning of the destination range.

**Returns** The `copy_n` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `copy_n`
algorithm returns Iterator in the destination range, pointing past the last element copied if count>0 or result otherwise.

template<typename FwdIter1, typename Size, typename FwdIter2>
FwdIter2 copy_n(FwdIter1 first, Size count, FwdIter2 dest)

Copies the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest.

**Note:** Complexity: Performs exactly count assignments, if count > 0, no assignments otherwise.

**Template Parameters**
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply f to.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at first the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The copy_n algorithm returns a FwdIter2. The copy_n algorithm returns Iterator in the destination range, pointing past the last element copied if count>0 or result otherwise.

template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred>

hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> copy_if(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest, Pred &&pred)

Copies the elements in the range, defined by [first, last), to another range beginning at dest. Copies only the elements for which the predicate f returns true. The order of the elements that are not removed is preserved. Executed according to the policy.

The assignments in the parallel copy_if algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The assignments in the parallel copy_if algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs not more than last - first assignments, exactly last - first applications of the predicate f.

**Template Parameters**
• **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

• **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

• **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *copy_if* requires *F* to meet the requirements of *CopyConstructible*.

**Parameters**

• **policy** – The execution policy to use for the scheduling of the iterations.

• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

• **dest** – Refers to the beginning of the destination range.

• **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns *true* for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*.

**Returns** The *copy_if* algorithm returns a *hpx::future<FwdIter2>* > if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *copy_if* algorithm returns output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename FwdIter1, typename FwdIter2, typename Pred>
FwdIter2 copy_if(FwdIter1 first, FwdIter1 last, FwdIter2 dest, Pred &&pred)
```

Copies the elements in the range, defined by [first, last), to another range beginning at dest. Copies only the elements for which the predicate *f* returns true. The order of the elements that are not removed is preserved.

**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the predicate *f*.

**Template Parameters**

• **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

• **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

• **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *copy_if* requires *F* to meet the requirements of *CopyConstructible*. 

---

2.8. API reference 331
Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`.

**Returns** The `copy_if` algorithm returns a `FwdIter2`. The `copy_if` algorithm returns output iterator to the element in the destination range, one past the last element copied.

`hpx/parallel/algorithms/count.hpp`

See [Public API](#) for a list of names and headers that are part of the public HPX API.

```cpp
namespace hpx {

Functions

```cpp
template<typename ExPolicy, typename FwdIter, typename T>
util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<FwdIter>::difference_type>::type count(ExPolicy &&policy,
    FwdIter first, FwdIter last, T const &value)
```

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts the elements that are equal to the given `value`. Executed according to the policy.

The comparisons in the parallel `count` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note:** Complexity: Performs exactly \( last - first \) comparisons.

**Note:** The comparisons in the parallel `count` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified...
threads, and indeterminately sequenced within each thread.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the comparisons.
- **FwdIter** – The type of the source iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to search for (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to search for.

Returns

The `count` algorithm returns a `hpx::future<difference_type>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `difference_type` otherwise (where `difference_type` is defined by `std::iterator_traits<FwdIter>::difference_type`). The `count` algorithm returns the number of elements satisfying the given criteria.

```cpp
template<typename InIter, typename T>
std::iterator_traits<InIter>::difference_type count(InIter first, InIter last, T const &value)
```

Returns the number of elements in the range `[first, last)` satisfying a specific criteria. This version counts the elements that are equal to the given `value`.

**Note:** Complexity: Performs exactly `last - first` comparisons.

Template Parameters

- **InIter** – The type of the source iterator used (deduced). This iterator type must meet the requirements of an input iterator.
- **T** – The type of the value to search for (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to search for.

Returns

The `count` algorithm returns a `difference_type` (where `difference_type` is defined by `std::iterator_traits<InIter>::difference_type`). The `count` algorithm returns the number of elements satisfying the given criteria.

```cpp
template<typename ExPolicy, typename FwdIter, typename F>
```
util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<FwdIter>::difference_type>::type count_if(ExPolicy &&policy, FwdIter first, FwdIter last, F &&f)

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts elements for which predicate f returns true. Executed according to the policy.

**Note:** Complexity: Performs exactly last - first applications of the predicate.

**Note:** The assignments in the parallel count if algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note:** The assignments in the parallel count if algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Template Parameters**

- ExPolicy – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the comparisons.

- FwdIter – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.

- F – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of count_if requires F to meet the requirements of CopyConstructible.

**Parameters**

- policy – The execution policy to use for the scheduling of the iterations.

- first – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- last – Refers to the end of the sequence of elements the algorithm will be applied to.

- f – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns true for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type FwdIter can be dereferenced and then implicitly converted to Type.
Returns The `count_if` algorithm returns `hpx::future<difference_type>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `difference_type` otherwise (where `difference_type` is defined by `std::iterator_traits<FwdIter>::difference_type`).

The `count` algorithm returns the number of elements satisfying the given criteria.

```
template<typename InIter, typename F>
std::iterator_traits<InIter>::difference_type count_if(InIter first, InIter last, F &&f)
```

Returns the number of elements in the range `[first, last)` satisfying a specific criteria. This version counts elements for which predicate `f` returns true.

**Note:** Complexity: Performs exactly `last - first` applications of the predicate.

**Template Parameters**

- `InIter` – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an input iterator.
- `F` – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `count_if` requires `F` to meet the requirements of `CopyConstructible`.

**Parameters**

- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements the algorithm will be applied to.
- `f` – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `InIter` can be dereferenced and then implicitly converted to `Type`.

**Returns** The `count_if` algorithm returns `difference_type` (where a `difference_type` is defined by `std::iterator_traits<InIter>::difference_type`). The `count` algorithm returns the number of elements satisfying the given criteria.
**Functions**

template<typename ExPolicy, typename FwdIter>
util::detail::algorithm_result_t<ExPolicy> destroy(ExPolicy &policy, FwdIter first, FwdIter last)

Destroys objects of type typename iterator_traits<ForwardIt>::value_type in the range [first, last). Executed according to the policy.

The operations in the parallel `destroy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The operations in the parallel `destroy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs exactly last - first operations.

**Template Parameters**

- `ExPolicy` – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- `FwdIter` – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

- `policy` – The execution policy to use for the scheduling of the iterations.

- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- `last` – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The `destroy` algorithm returns a `hpx::future<void>`, if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `void` otherwise.

template<typename FwdIter>
void destroy(FwdIter first, FwdIter last)

Destroys objects of type typename iterator_traits<ForwardIt>::value_type in the range [first, last).

**Note:** Complexity: Performs exactly last - first operations.

**Template Parameters** `FwdIter` – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- `last` – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The `destroy` algorithm returns a `void`
template<typename ExPolicy, typename FwdIter, typename Size>
util::detail::algorithm_result_t<ExPolicy, FwdIter> destroy_n(ExPolicy &policy, FwdIter first, Size count)

Destroys objects of type typename iterator_traits<ForwardIt>::value_type in the range [first, first + count). Executed according to the policy.

The operations in the parallel destroy_n algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The operations in the parallel destroy_n algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs exactly `count` operations, if `count > 0`, no assignments otherwise.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply this algorithm to.

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at `first` the algorithm will be applied to.

**Returns** The destroy_n algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns `FwdIter` otherwise. The destroy_n algorithm returns the iterator to the element in the source range, one past the last element constructed.

template<typename FwdIter, typename Size>
FwdIter destroy_n(FwdIter first, Size count)

Destroys objects of type typename iterator_traits<ForwardIt>::value_type in the range [first, first + count).

**Note:** Complexity: Performs exactly `count` operations, if `count > 0`, no assignments otherwise.

**Template Parameters**
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply this algorithm to.

**Parameters**
• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **count** – Refers to the number of elements starting at `first` the algorithm will be applied to.

**Returns** The `destroy_n` algorithm returns a `FwdIter`. The `destroy_n` algorithm returns the iterator to the element in the source range, one past the last element constructed.

```cpp
namespace hpx {
    template<typename InIter1, typename InIter2, typename Pred>
    bool ends_with(InIter1 first1, InIter1 last1, InIter2 first2, InIter2 last2, Pred &&pred) {
        Checks whether the second range defined by `[first1, last1)` matches the suffix of the first range defined by `[first2, last2)`
    }
}
```

The assignments in the parallel `ends_with` algorithm invoked without an execution policy object execute in sequential order in the calling thread.

**Note:** Complexity: Linear: at most min(N1, N2) applications of the predicate and both projections.

**Template Parameters**

- **InIter1** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an input iterator.

- **InIter2** – The type of the begin destination iterators used (deduced). This iterator type must meet the requirements of a input iterator.

- **Pred** – The binary predicate that compares the projected elements.

**Parameters**

- **first1** – Refers to the beginning of the source range.

- **last1** – Refers to the end of the source range.

- **first2** – Refers to the beginning of the destination range.

- **last2** – Refers to the end of the destination range.

- **pred** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the in two ranges projected by `proj1` and `proj2` respectively.

**Returns** The `ends_with` algorithm returns `bool`. The `ends_with` algorithm returns a boolean with the value true if the second range matches the suffix of the first range, false otherwise.
hpx::parallel::util::detail::algorithm_result<ExPolicy, bool>::type ends_with(ExPolicy &policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, Pred &&pred)

Checks whether the second range defined by [first1, last1) matches the suffix of the first range defined by [first2, last2). Executed according to the policy.

The assignments in the parallel ends_with algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The assignments in the parallel ends_with algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Linear: at most min(N1, N2) applications of the predicate and both projections.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter1** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

- **FwdIter2** – The type of the begin destination iterators used deduced). This iterator type must meet the requirements of a forward iterator.

- **Pred** – The binary predicate that compares the projected elements.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first1** – Refers to the beginning of the source range.

- **last1** – Refers to the end of the source range.

- **first2** – Refers to the beginning of the destination range.

- **last2** – Refers to the end of the destination range.

- **pred** – Specifies the binary predicate function (or function object) which will be invoked for

**Returns** The ends_with algorithm returns a hpx::future<bool> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns bool otherwise. The ends_with algorithm returns a boolean with the value true if the second range matches the suffix of the first range, false otherwise.
namespace hpx

Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result_t<ExPolicy, bool> equal(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1,
            FwdIter2 first2, FwdIter2 last2, Pred &&op = Pred())

Returns true if the range [first1, last1) is equal to the range [first2, last2), and false otherwise. Executed
according to the policy.

The comparison operations in the parallel equal algorithm invoked with an execution policy object of type
sequenced_policy execute in sequential order in the calling thread.

The comparison operations in the parallel equal algorithm invoked with an execution policy object of type
parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified
threads, and indeterminately sequenced within each thread.

Note: Complexity: O(min(last1 - first1, last2 - first2)) applications of the predicate op.

Note: The two ranges are considered equal if, for every iterator i in the range [first1, last1), *i equals *(first2
+ (i - first1)). This overload of equal uses operator== to determine if two elements are equal.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner
  in which the execution of the algorithm may be parallelized and the manner in which it
  executes the assignments.

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator
  type must meet the requirements of an forward iterator.

- **FwdIter2** – The type of the source iterators used for the second range (deduced). This
  iterator type must meet the requirements of an forward iterator.

- **Pred** – The type of an optional function/function object to use. Unlike its sequential form,
  the parallel overload of equal requires Pred to meet the requirements of CopyConstructible.
  This defaults to std::equal_to<>.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first1** – Refers to the beginning of the sequence of elements of the first range the algo-
  rithm will be applied to.

- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will
  be applied to.
• **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

• **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

• **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

**Returns** The `equal` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `equal` algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range `[first1, last1)` does not equal the length of the range `[first2, last2)`, it returns false.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
util::detail::algorithm_result_t<ExPolicy, bool> equal(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2)
```

Returns true if the range `[first1, last1)` is equal to the range `[first2, last2)`, and false otherwise. Executed according to policy.

The comparison operations in the parallel `equal` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `equal` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: $O(\min(last1 - first1, last2 - first2))$ applications of the predicate `std::equal_to`.

**Note:** The two ranges are considered equal if, for every iterator `i` in the range `[first1,last1), *i equals *(first2 + (i - first1)). This overload of `equal` uses `operator==` to determine if two elements are equal.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**
• **policy** – The execution policy to use for the scheduling of the iterations.

• **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

• **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

• **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

• **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

**Returns**
The equal algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The equal algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range `[first1, last1)` does not equal the length of the range `[first2, last2)`, it returns false.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result_t<ExPolicy, bool> equal(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, Pred &&op = Pred())
```

Returns true if the range [first1, last1) is equal to the range starting at first2, and false otherwise. Executed according to policy.

The comparison operations in the parallel equal algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel equal algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: O(min(last1 - first1, last2 - first2)) applications of the predicate op.

**Note:** The two ranges are considered equal if, for every iterator i in the range [first1, last1), *i equals *(first2 + (i - first1)). This overload of equal uses operator== to determine if two elements are equal.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of equal requires Pred to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`

**Parameters**
• **policy**  – The execution policy to use for the scheduling of the iterations.

• **first1**  – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

• **last1**  – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

• **first2**  – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

• **op**  – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively.

**Returns**  The equal algorithm returns a hpx: :future<hpx: :bool> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns bool otherwise. The equal algorithm returns true if the elements in the two ranges are equal, otherwise it returns false.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
util::detail::algorithm_result_t<ExPolicy, bool> equal(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2)
```

Returns true if the range [first1, last1) is equal to the range [first2, last2), and false otherwise. Executed according to policy.

The comparison operations in the parallel equal algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The comparison operations in the parallel equal algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most last1 - first1 applications of the predicate op.

**Note:** The two ranges are considered equal if, for every iterator i in the range [first1,last1), *i equals *(first2 + (i - first1)). This overload of equal uses operator== to determine if two elements are equal.

**Template Parameters**

• **ExPolicy**  – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **FwdIter1**  – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

• **FwdIter2**  – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

Returns

The equal algorithm returns a `hpx: future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The equal algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range `[first1, last1)` does not equal the length of the range `[first2, last2)`, it returns false.

```cpp
template<typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
bool equal(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, Pred &&op = Pred())
```

Returns true if the range `[first1, last1)` is equal to the range `[first2, last2)`, and false otherwise.

**Note:** Complexity: At most min(last1 - first1, last2 - first2) applications of the predicate `op`.

**Note:** The two ranges are considered equal if, for every iterator `i` in the range `[first1, last1)`, `*i` equals `*(first2 + (i - first1))`. This overload of equal uses operator== to determine if two elements are equal.

Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of equal requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`

Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:
```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively.

**Returns** The `equal` algorithm returns a `bool`. The `equal` algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range `[first1, last1)` does not equal the length of the range `[first2, last2)`, it returns false.

```cpp
template<
    typename FwdIter1,
    typename FwdIter2
>
bool equal(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2)
```

Returns true if the range `[first1, last1)` is equal to the range `[first2, last2)`, and false otherwise.

**Note:** Complexity: At most `min(last1 - first1, last2 - first2)` applications of the predicate `std::equal_to`.

**Note:** The two ranges are considered equal if, for every iterator `i` in the range `[first1, last1)`, `*i` equals `*(first2 + (i - first1))`. This overload of `equal` uses `operator==` to determine if two elements are equal.

**Template Parameters**

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of a forward iterator.

**Parameters**

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

**Returns** The `equal` algorithm returns a `bool`. The `equal` algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range `[first1, last1)` does not equal the length of the range `[first2, last2)`, it returns false.

```cpp
template<
    typename FwdIter1,
    typename FwdIter2,
    typename Pred = detail::equal_to
>
bool equal(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, Pred &&op = Pred())
```

Returns true if the range `[first1, last1)` is equal to the range `[first2, first2 + (last1 - first1))`, and false otherwise.

**Note:** Complexity: At most `last1 - first1` applications of the predicate `op`.  

2.8. API reference 345
**Note:** The two ranges are considered equal if, for every iterator i in the range \([\text{first}_1, \text{last}_1)\), \(*i\) equals \(*(\text{first}_2 + (i - \text{first}_1))\). This overload of equal uses operator== to determine if two elements are equal.

**Template Parameters**

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`.

**Parameters**

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

  ```cpp
def pred(const Type1 &a, const Type2 &b);```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

**Returns** The `equal` algorithm returns a `bool`. The `equal` algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range \([\text{first}_1, \text{last}_1)\) does not equal the length of the range \([\text{first}_2, \text{last}_2)\), it returns false.

`hpx/parallel/algorithms/exclusive_scan.hpp`

See Public API for a list of names and headers that are part of the public HPX API.

namespace `hpx`
Functions

template<typename InIter, typename OutIter, typename T>
OutIter exclusive_scan(InIter first, InIter last, OutIter dest, T init)

Assigns through each iterator \(i\) in \([\text{result}, \text{result} + (\text{last} - \text{first}))\) the value of GENERALIZED_NONCOMMUTATIVE_SUM(+, init, *first, ..., *(first + (i - result) - 1))

The reduce operations in the parallel exclusive_scan algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between exclusive_scan and inclusive_scan is that inclusive_scan includes the \(i\)th input element in the \(i\)th sum.

Note: Complexity: \(O(last - first)\) applications of the predicate \(std::plus<T>\).

Note: GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ..., aN) is defined as:
- \(a1\) when \(N\) is 1
- GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ..., aK) - GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, ..., aN) where \(1 < K+{1} = M <= N\).

Template Parameters
- \textbf{InIter} – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- \textbf{OutIter} – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- \textbf{T} – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters
- \textbf{first} – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- \textbf{last} – Refers to the end of the sequence of elements the algorithm will be applied to.
- \textbf{dest} – Refers to the beginning of the destination range.
- \textbf{init} – The initial value for the generalized sum.

Returns The exclusive_scan algorithm returns OutIter. The exclusive_scan algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename T>
util::detail::algorithm_result_t<ExPolicy, FwdIter2> exclusive_scan(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest, T init)

Assigns through each iterator \(i\) in \([\text{result}, \text{result} + (\text{last} - \text{first}))\) the value of GENERALIZED_NONCOMMUTATIVE_SUM(+, init, *first, ..., *(first + (i - result) - 1))
The reduce operations in the parallel `exclusive_scan` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The reduce operations in the parallel `exclusive_scan` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `exclusive_scan` and `inclusive_scan` is that `inclusive_scan` includes the ith input element in the ith sum.

**Note:** Complexity: O(last - first) applications of the predicate `std::plus<T>`.

**Note:** GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ..., aN) is defined as:

- a1 when N is 1
- GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ..., aK) - GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, ..., aN) where 1 < K+1 = M <= N.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.

**Returns** The `exclusive_scan` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `exclusive_scan` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename InIter, typename OutIter, typename T, typename Op>
OutIter exclusive_scan(InIter first, InIter last, OutIter dest, T init, Op &&op)
```

Assigns through each iterator i in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(binary_op, init, *first, ..., *(first + (i - result) - 1)).
The reduce operations in the parallel `exclusive_scan` algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between `exclusive_scan` and `inclusive_scan` is that `inclusive_scan` includes the ith input element in the ith sum. If `op` is not mathematically associative, the behavior of `inclusive_scan` may be non-deterministic.

**Note:** Complexity: O(last - first) applications of the predicate `op`.

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN)` is defined as:

- `a1` when `N` is 1
- `op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN))` where `1 < K+1 = M <= N`.

**Template Parameters**

- `InIter` – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- `OutIter` – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- `T` – The type of the value to be used as initial (and intermediate) values (deduced).
- `Op` – The type of the binary function object used for the reduction operation.

**Parameters**

- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements the algorithm will be applied to.
- `dest` – Refers to the beginning of the destination range.
- `init` – The initial value for the generalized sum.
- `op` – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types `Type1` and `Ret` must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

**Returns** The `exclusive_scan` algorithm returns `OutIter`. The `exclusive_scan` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
#include <hpx/algorithm.hpp>

template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Op, typename T>
util::detail::algorithm_result_t<ExPolicy, FwdIter2> exclusive_scan(ExPolicy &&policy, FwdIter1 first,
  FwdIter1 last, FwdIter2 dest, T init, Op &&op)
```
Assigns through each iterator \( i \) in \([\text{result}, \text{result} + (\text{last} - \text{first}))\) the value of \text{GENERALIZED_NONCOMMUTATIVE\_SUM}(\text{binary\_op, init, *first, ..., *(first + (i - \text{result}) - 1)}).

The reduce operations in the parallel \text{exclusive\_scan} algorithm invoked with an execution policy object of type \text{sequenced\_policy} execute in sequential order in the calling thread.

The reduce operations in the parallel \text{exclusive\_scan} algorithm invoked with an execution policy object of type \text{parallel\_policy} or \text{parallel\_task\_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between \text{exclusive\_scan} and \text{inclusive\_scan} is that \text{inclusive\_scan} includes the \( i \)th input element in the \( i \)th sum. If \text{op} is not mathematically associative, the behavior of \text{inclusive\_scan} may be non-deterministic.

\textbf{Note:} Complexity: \( O(\text{last} - \text{first}) \) applications of the predicate \text{op}.

\textbf{Note:} \text{GENERALIZED_NONCOMMUTATIVE\_SUM}(\text{op, a1, ..., aN}) is defined as:

- \( a1 \) when \( N \) is 1
- \( \text{op}(\text{GENERALIZED_NONCOMMUTATIVE\_SUM}(\text{op, a1, ..., aK}), \text{GENERALIZED_NONCOMMUTATIVE\_SUM}(\text{op, aM, ..., aN})) \) where \( 1 < K+1 = M <= N \).

\textbf{Template Parameters}

- \textbf{ExPolicy} – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- \textbf{FwdIter1} – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- \textbf{FwdIter2} – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- \textbf{Op} – The type of the binary function object used for the reduction operation.
- \textbf{T} – The type of the value to be used as initial (and intermediate) values (deduced).

\textbf{Parameters}

- \textbf{policy} – The execution policy to use for the scheduling of the iterations.
- \textbf{first} – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- \textbf{last} – Refers to the end of the sequence of elements the algorithm will be applied to.
- \textbf{dest} – Refers to the beginning of the destination range.
- \textbf{init} – The initial value for the generalized sum.
- \textbf{op} – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:
Ret fun(const Type1 &a, const Type1 &b);

The signature does not need to have const&, but the function must not modify the objects passed to it. The types Type1 and Ret must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

**Returns** The exclusive_scan algorithm returns a hpx::future<OutIter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns OutIter otherwise. The exclusive_scan algorithm returns the output iterator to the element in the destination range, one past the last element copied.

**hpx/parallel/algorithms/fill.hpp**

See Public API for a list of names and headers that are part of the public HPX API.

namespace hpx

**Functions**

template<typename ExPolicy, typename FwdIter, typename T>
util::detail::algorithm_result_t<ExPolicy> fill(ExPolicy &&policy, FwdIter first, FwdIter last, T value)

Assigns the given value to the elements in the range [first, last). Executed according to the policy.

The comparisons in the parallel fill algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The comparisons in the parallel fill algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs exactly last - first assignments.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

- **T** – The type of the value to be assigned (deduced).

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **value** – The value to be assigned.
Returns The `fill` algorithm returns a `hpx::future<void>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `difference_type` otherwise (where `difference_type` is defined by `void`.

```cpp
template<typename FwdIter, typename T>
void fill(FwdIter first, FwdIter last, T value)
Assigns the given value to the elements in the range [first, last).
```

**Note:** Complexity: Performs exactly `last - first` assignments.

**Template Parameters**

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be assigned (deduced).

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to be assigned.

**Returns** The `fill` algorithm returns a `void`.

```cpp
template<typename ExPolicy, typename FwdIter, typename Size, typename T>
util::detail::algorithm_result_t<ExPolicy, FwdIter> fill_n(ExPolicy &&policy, FwdIter first, Size count, T value)
Assigns the given value value to the first count elements in the range beginning at first if count > 0. Does nothing otherwise. Executed according to the policy.
```

The comparisons in the parallel `fill_n` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparisons in the parallel `fill_n` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs exactly `count` assignments, for `count > 0`.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply `f` to.
- **T** – The type of the value to be assigned (deduced).
Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at first the algorithm will be applied to.
- **value** – The value to be assigned.

Returns The `fill_n` algorithm returns a `hpx::future<void>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `difference_type` otherwise (where `difference_type` is defined by `void`).

```cpp
template<typename FwdIter, typename Size, typename T>
FwdIter fill_n(FwdIter first, Size count, T value)
```
Assigns the given value value to the first count elements in the range beginning at first if count > 0. Does nothing otherwise.

Note: Complexity: Performs exactly count assignments, for count > 0.

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply f to.
- **T** – The type of the value to be assigned (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at first the algorithm will be applied to.
- **value** – The value to be assigned.

Returns The `fill_n` algorithm returns a `FwdIter`.

See Public API for a list of names and headers that are part of the public HPX API.
Functions

template<typename ExPolicy, typename FwdIter, typename T>
util::detail::algorithm_result_t<ExPolicy, FwdIter> find(ExPolicy &&policy, FwdIter first, FwdIter last, T const &val)

Returns the first element in the range [first, last) that is equal to value. Executed according to the policy.

The comparison operations in the parallel find algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The comparison operations in the parallel find algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: At most last - first applications of the operator==().

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

- **T** – The type of the value to find (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

- **val** – the value to compare the elements to

Returns The find algorithm returns a hpx::future<FwdIter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter otherwise. The find algorithm returns the first element in the range [first,last) that is equal to val. If no such element in the range of [first,last) is equal to val, then the algorithm returns last.

template<typename InIter, typename T>
InIter find(InIter first, InIter last, T const &val)

Returns the first element in the range [first, last) that is equal to value. Executed according to the policy.

Note: Complexity: At most last - first applications of the operator==().

Template Parameters

- **InIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an input iterator.
• \( T \) – The type of the value to find (deduced).

**Parameters**

• \( \text{first} \) – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

• \( \text{last} \) – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

• \( \text{val} \) – the value to compare the elements to

**Returns** The find algorithm returns a InIter. The find algorithm returns the first element in the range \([\text{first}, \text{last})\) that is equal to \( \text{val} \). If no such element in the range of \([\text{first}, \text{last})\) is equal to \( \text{val} \), then the algorithm returns \( \text{last} \).

\[
\text{template<typename } \text{ExPolicy}, \text{ typename FwdIter, typename F > }
\text{util::detail::algorithm_result_t<ExPolicy, FwdIter> } \text{find_if}(\text{ExPolicy &&policy}, \text{ FwdIter } \text{first}, \text{ FwdIter } \text{last}, \text{ F &&f})
\]

Returns the first element in the range \([\text{first, last})\) for which predicate \( f \) returns true. Executed according to the policy.

The comparison operations in the parallel find_if algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The comparison operations in the parallel find_if algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most last - first applications of the predicate.

**Template Parameters**

• \( \text{ExPolicy} \) – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• \( \text{FwdIter} \) – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.

• \( \text{F} \) – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of equal requires \( \text{F} \) to meet the requirements of CopyConstructible.

**Parameters**

• \( \text{policy} \) – The execution policy to use for the scheduling of the iterations.

• \( \text{first} \) – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

• \( \text{last} \) – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

• \( \text{f} \) – The unary predicate which returns true for the required element. The signature of the predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```
The signature does not need to have const &, but the function must not modify the objects passed to it. The type Type must be such that objects of type FwdIter can be dereferenced and then implicitly converted to Type.

**Returns** The find_if algorithm returns a hpx::future<FwdIter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter otherwise. The find_if algorithm returns the first element in the range [first,last) that satisfies the predicate f. If no such element exists that satisfies the predicate f, the algorithm returns last.

```cpp
template<typename InIter, typename F>
InIter find_if(InIter first, InIter last, F &&f)
```

Returns the first element in the range [first, last) for which predicate f returns true.

**Note:** Complexity: At most last - first applications of the predicate.

**Template Parameters**

- **InIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of equal requires F to meet the requirements of CopyConstructible.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **f** – The unary predicate which returns true for the required element. The signature of the predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type Type must be such that objects of type InIter can be dereferenced and then implicitly converted to Type.

**Returns** The find_if algorithm returns a InIter. The find_if algorithm returns the first element in the range [first,last) that satisfies the predicate f. If no such element exists that satisfies the predicate f, the algorithm returns last.

```cpp
template<typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result_t<ExPolicy, FwdIter> find_if_not(ExPolicy &&policy, FwdIter first, FwdIter last, F &&f)
```

Returns the first element in the range [first, last) for which predicate f returns false. Executed according to the policy.

The comparison operations in the parallel find_if_not algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The comparison operations in the parallel find_if_not algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
Note: Complexity: At most last - first applications of the predicate.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.

- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `F` to meet the requirements of `CopyConstructible`.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

- **f** – The unary predicate which returns false for the required element. The signature of the predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

Returns The `find_if_not` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `find_if_not` algorithm returns the first element in the range `[first, last)` that does not satisfy the predicate `f`. If no such element exists that does not satisfy the predicate `f`, the algorithm returns `last`.

```cpp
template<typename FwdIter, typename F>
FwdIter find_if_not(FwdIter first, FwdIter last, F &&f)
```

Returns the first element in the range `[first, last)` for which predicate `f` returns false.

Note: Complexity: At most last - first applications of the predicate.

Template Parameters

- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.

- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `F` to meet the requirements of `CopyConstructible`.

Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
• **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

• **f** – The unary predicate which returns false for the required element. The signature of the predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

**Returns** The `find_if_not` algorithm returns a `FwdIter`. The `find_if_not` algorithm returns the first element in the range `[first, last)` that does not satisfy the predicate `f`. If no such element exists that does not satisfy the predicate `f`, the algorithm returns `last`.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result_t<ExPolicy, FwdIter1> find_end(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, Pred &&op = Pred())
```

Returns the last subsequence of elements `[first2, last2)` found in the range `[first, last)` using the given predicate `op` to compare elements. Executed according to the policy.

The comparison operations in the parallel `find_end` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `find_end` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of `find_end` is available if the user decides to provide the algorithm their own predicate `op`.

**Note:** Complexity: at most \( S*(N-S+1) \) comparisons where \( S = \text{distance(first2, last2)} \) and \( N = \text{distance(first1, last1)} \).

**Template Parameters**

• **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

• **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

• **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `replace` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`

**Parameters**

• **policy** – The execution policy to use for the scheduling of the iterations.
• **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

• **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

• **first2** – Refers to the beginning of the sequence of elements the algorithm will be searching for.

• **last2** – Refers to the end of the sequence of elements of the algorithm will be searching for.

• **op** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

**Returns** The `find_end` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `find_end` algorithm returns an iterator to the beginning of the last subsequence `[first2, last2)` in range `[first, last)`. If the length of the subsequence `[first2, last2)` is greater than the length of the range `[first1, last1)`, `last1` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `last1` is also returned.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
util::detail::algorithm_result_t<ExPolicy, FwdIter1> find_end(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2)
```

Returns the last subsequence of elements `[first2, last2)` found in the range `[first, last)`. Elements are compared using `operator==`. Executed according to the policy.

The comparison operations in the parallel `find_end` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `find_end` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: at most \( S^*(N-S+1) \) comparisons where \( S = \text{distance(first2, last2)} \) and \( N = \text{distance(first1, last1)} \).

**Template Parameters**

• **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

• **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **last2** – Refers to the end of the sequence of elements of the algorithm will be searching for.

Returns

The `find_end` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `find_end` algorithm returns an iterator to the beginning of the last subsequence `[first2, last2)` in range `[first, last)`. If the length of the subsequence `[first2, last2)` is greater than the length of the range `[first1, last1)`, `last1` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `last1` is also returned.

```cpp
template<typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
FwdIter1 find_end(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, Pred &&op = Pred())
```

Returns the last subsequence of elements `[first2, last2)` found in the range `[first, last)` using the given predicate `op` to compare elements.

This overload of `find_end` is available if the user decides to provide the algorithm their own predicate `op`.

**Note:** Complexity: at most $S*(N-S+1)$ comparisons where $S = \text{distance(first2, last2)}$ and $N = \text{distance(first1, last1)}$.

Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `replace` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`

Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **last2** – Refers to the end of the sequence of elements of the algorithm will be searching for.
• **op** – The binary predicate which returns *true* if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

**Returns** The `find_end` algorithm returns a `FwdIter1`. The `find_end` algorithm returns an iterator to the beginning of the last subsequence `[first2, last2)` in range `[first, last)`. If the length of the subsequence `[first2, last2)` is greater than the length of the range `[first1, last1)`, `last1` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `last1` is also returned.

```cpp
template<typename FwdIter1, typename FwdIter2>
FwdIter1 find_end(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2)
```

Returns the last subsequence of elements `[first2, last2)` found in the range `[first, last)`. Elements are compared using `operator==`.

**Note:** Complexity: at most $S*(N-S+1)$ comparisons where $S = \text{distance}(first2, last2)$ and $N = \text{distance}(first1, last1)$.

**Template Parameters**

- `FwdIter1` – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

- `FwdIter2` – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

- `first1` – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

- `last1` – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

- `first2` – Refers to the beginning of the sequence of elements the algorithm will be searching for.

- `last2` – Refers to the end of the sequence of elements of the algorithm will be searching for.

**Returns** The `find_end` algorithm returns a `FwdIter1`. The `find_end` algorithm returns an iterator to the beginning of the last subsequence `[first2, last2)` in range `[first, last)`. If the length of the subsequence `[first2, last2)` is greater than the length of the range `[first1, last1)`, `last1` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `last1` is also returned.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
util::detail::algorithm_result_t<ExPolicy, FwdIter1> find_first_of(ExPolicy &&policy, FwdIter1 first,
                    FwdIter1 last, FwdIter2 s_first, FwdIter2 s_last, Pred &&op = Pred())
```
Searches the range [first, last) for any elements in the range [s_first, s_last). Uses binary predicate \( op \) to compare elements. Executed according to the policy.

The comparison operations in the parallel \( \text{find\_first\_of} \) algorithm invoked with an execution policy object of type \( \text{sequenced\_policy} \) execute in sequential order in the calling thread.

The comparison operations in the parallel \( \text{find\_first\_of} \) algorithm invoked with an execution policy object of type \( \text{parallel\_policy} \) or \( \text{parallel\_task\_policy} \) are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of \( \text{find\_first\_of} \) is available if the user decides to provide the algorithm their own predicate \( op \).

**Note:** Complexity: at most \( (S*N) \) comparisons where \( S = \text{distance}(s\_first, s\_last) \) and \( N = \text{distance}(\text{first, last}) \).

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of \( \text{equal} \) requires \( \text{Pred} \) to meet the requirements of \( \text{CopyConstructible} \). This defaults to \( \text{std::equal\_to<}> \)

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – The binary predicate which returns \( \text{true} \) if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have \( \text{const} \) &\, but the function must not modify the objects passed to it. The types \( \text{Type1} \) and \( \text{Type2} \) must be such that objects of types \( \text{FwdIter1} \) and \( \text{FwdIter2} \) are convertible to them.
FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively.

**Returns** The `find_first_of` algorithm returns a `hpx::future<FwdIter1>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter1` otherwise. The `find_first_of` algorithm returns an iterator to the first element in the range `[first, last)` that is equal to an element from the range `[s_first, s_last)`. If the length of the subsequence `[s_first, s_last) is greater than the length of the range `[first, last)`, last is returned. Additionally if the size of the subsequence is empty or no subsequence is found, last is also returned.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
util::detail::algorithm_result_t<ExPolicy, FwdIter1> find_first_of(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 s_first, FwdIter2 s_last)
```

Searches the range `[first, last)` for any elements in the range `[s_first, s_last)`. Elements are compared using `operator==`. Executed according to the policy.

The comparison operations in the parallel `find_first_of` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `find_first_of` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: at most $(S*N)$ comparisons where $S = \text{distance}(s\_first, s\_last)$ and $N = \text{distance}(\text{first}, \text{last})$.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.

**Returns** The `find_first_of` algorithm returns a `hpx::future<FwdIter1>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter1` otherwise. The
find_first_of algorithm returns an iterator to the first element in the range [first, last) that is equal to an element from the range [s_first, s_last). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, last), last is returned. Additionally if the size of the subsequence is empty or no subsequence is found, last is also returned.

template<typename FwdIter1, typename FwdIter2, typename Pred = detail::equal_to>
FwdIter1 find_first_of(FwdIter1 first, FwdIter1 last, FwdIter2 s_first, FwdIter2 s_last, Pred &&op = Pred())

Searches the range [first, last) for any elements in the range [s_first, s_last). Uses binary predicate op to compare elements.

This overload of find_first_of is available if the user decides to provide the algorithm their own predicate op.

Note: Complexity: at most ($S^*N$) comparisons where $S = \text{distance}(s_{\text{first}}, s_{\text{last}})$ and $N = \text{distance}(\text{first}, \text{last})$.

Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of equal requires Pred to meet the requirements of CopyConstructible. This defaults to std::equal_to<>.

Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – The binary predicate which returns true if the elements should be treated as equal.

The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively.

Returns The find_first_of algorithm returns a FwdIter1. The find_first_of algorithm returns an iterator to the first element in the range [first, last) that is equal to an element from the range [s_first, s_last). If the length of the subsequence [s_first, s_last) is greater than the length of
the range [first, last), last is returned. Additionally if the size of the subsequence is empty or no subsequence is found, last is also returned.

```cpp
template<
typename FwdIter1,
typename FwdIter2>
FwdIter1 find_first_of(FwdIter1 first, FwdIter1 last, FwdIter2 s_first, FwdIter2 s_last)
    Searches the range [first, last) for any elements in the range [s_first, s_last). Elements are compared using operator==.

Note: Complexity: at most (S*N) comparisons where S = distance(s_first, s_last) and N = distance(first, last).
```

Template Parameters
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.

Returns The `find_first_of` algorithm returns a `FwdIter1`. The `find_first_of` algorithm returns an iterator to the first element in the range [first, last) that is equal to an element from the range [s_first, s_last). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, last), last is returned. Additionally if the size of the subsequence is empty or no subsequence is found, last is also returned.

`hpx/parallel/algorithms/for_each.hpp`

See Public API for a list of names and headers that are part of the public HPX API.

namespace `hpx`
Functions

template<typename InIter, typename F>
F for_each(InIter first, InIter last, F &&f)

Applies \( f \) to the result of dereferencing every iterator in the range \([\text{first}, \text{last})\).

If \( f \) returns a result, the result is ignored.

If the type of \( \text{first} \) satisfies the requirements of a mutable iterator, \( f \) may apply non-constant functions through the dereferenced iterator.

\begin{center}
\textbf{Note:} Complexity: Applies \( f \) exactly \( \text{last - first} \) times.
\end{center}

Template Parameters

- \textbf{InIter} – The type of the source begin and end iterator used (deduced). This iterator type must meet the requirements of an input iterator.

- \textbf{F} – The type of the function/function object to use (deduced). \( F \) must meet requirements of \textit{MoveConstructible}.

Parameters

- \textbf{first} – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- \textbf{last} – Refers to the end of the sequence of elements the algorithm will be applied to.

- \textbf{f} – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last}). \) The signature of this predicate should be equivalent to:

\begin{verbatim}
<ignored> pred(const Type &a);
\end{verbatim}

The signature does not need to have const&. The type \textit{Type} must be such that an object of type \textit{InIter} can be dereferenced and then implicitly converted to Type.

\textbf{Returns} \( f \).

template<typename ExPolicy, typename FwdIter, typename F>
util::detail::algorithm_result_t<ExPolicy, void> for_each(ExPolicy &&policy, FwdIter first, FwdIter last, F &&f)

Applies \( f \) to the result of dereferencing every iterator in the range \([\text{first}, \text{last}). \) Executed according to the policy.

If \( f \) returns a result, the result is ignored.

If the type of \( \text{first} \) satisfies the requirements of a mutable iterator, \( f \) may apply non-constant functions through the dereferenced iterator.

Unlike its sequential form, the parallel overload of \textit{for_each} does not return a copy of its \textit{Function} parameter, since parallelization may not permit efficient state accumulation.
The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Applies $f$ exactly $last - first$ times.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter** – The type of the source begin and end iterator used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `for_each` requires $F$ to meet the requirements of `CopyConstructible`.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. The signature of this predicate should be equivalent to:

```cpp
<ignored> pred(const Type &a);
```

The signature does not need to have const&. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

**Returns** The `for_each` algorithm returns a `hpx::future<void>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `void` otherwise.

```cpp
template<typename InIter, typename Size, typename F> InIter for_each_n(InIter first, Size count, F &&f)
```

Applies $f$ to the result of dereferencing every iterator in the range `[first, first + count)`, starting from first and proceeding to first + count - 1.

If $f$ returns a result, the result is ignored.

If the type of `first` satisfies the requirements of a mutable iterator, $f$ may apply non-constant functions through the dereferenced iterator.

**Note:** Complexity: Applies $f$ exactly `count` times.
• InIter – The type of the source begin and end iterator used (deduced). This iterator type must meet the requirements of an input iterator.

• Size – The type of the argument specifying the number of elements to apply $f$ to.

• F – The type of the function/function object to use (deduced). F must meet requirements of MoveConstructible.

Parameters

• first – Refers to the beginning of the sequence of elements the algorithm will be applied to.

• count – Refers to the number of elements starting at first the algorithm will be applied to.

• $f$ – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

  ```cpp
  <ignored> pred(const Type &a);
  ```

  The signature does not need to have const&. The type Type must be such that an object of type InIter can be dereferenced and then implicitly converted to Type.

Returns first + count for non-negative values of count and first for negative values.

```
template<typename ExPolicy, typename FwdIter, typename Size, typename F>
util::detail::algorithm_result_t<ExPolicy, FwdIter> for_each_n(ExPolicy &&policy, FwdIter first, Size count, F &&f)
```

Applies $f$ to the result of dereferencing every iterator in the range [first, first + count), starting from first and proceeding to first + count - 1. Executed according to the policy.

If $f$ returns a result, the result is ignored.

If the type of first satisfies the requirements of a mutable iterator, $f$ may apply non-constant functions through the dereferenced iterator.

Unlike its sequential form, the parallel overload of for_each_n does not return a copy of its Function parameter, since parallelization may not permit efficient state accumulation.

The application of function objects in parallel algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: Applies $f$ exactly count times.

Template Parameters

• ExPolicy – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

- **Size** – The type of the argument specifying the number of elements to apply $f$ to.

- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `for_each_n` requires $F$ to meet the requirements of `CopyConstructible`.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **count** – Refers to the number of elements starting at `first` the algorithm will be applied to.

- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. The signature of this predicate should be equivalent to:

  ```cpp
  <ignored> pred(const Type &a);
  ```

  The signature does not need to have const&. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

### Returns

The `for_each_n` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. It returns `first + count` for non-negative values of `count` and `first` for negative values.

### hpx/parallel/algorithms/for_loop.hpp

See **Public API** for a list of names and headers that are part of the public **HPX** API.

```cpp
namespace hpx
{
    namespace experimental
    {
        Top-level namespace.
    }

    template<typename I, typename ...Args>
    void for_loop(std::decay_t<I> first, I last, Args&... args)
    {
        The `for_loop` implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

        The execution of `for_loop` without specifying an execution policy is equivalent to specifying `hpx::execution::seq` as the execution policy.

        Requires: $I$ shall be an integral type or meet the requirements of an input iterator type. The `args` parameter pack shall have at least one element, comprising objects returned by invocations of `reduction` and/or `induction` function templates followed by exactly one element invocable element-access function, $f$. $f$ shall meet the requirements of `MoveConstructible`.
    }
}
```
Effects: Applies \( f \) to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the \( \text{args} \) parameter pack. The length of the input sequence is \( \text{last} - \text{first} \).

The first element in the input sequence is specified by \( \text{first} \). Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the \( \text{args} \) parameter pack excluding \( f \), an additional argument is passed to each application of \( f \) as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of \( f \) in the input sequence.

Complexity: Applies \( f \) exactly once for each element of the input sequence.

Remarks: If \( f \) returns a result, the result is ignored.

Note: As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

Note: The order of the elements of the input sequence is important for determining ordinal position of an application of \( f \), even though the applications themselves may be unordered.

**Template Parameters**

- \( I \) – The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- \( \text{Args} \) – A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**

- \( \text{first} \) – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- \( \text{last} \) – Refers to the end of the sequence of elements the algorithm will be applied to.
- \( \text{args} \) – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by \( [\text{first}, \text{last}) \) should expose a signature equivalent to:

\[
\text{<ignored>} \ pred(I \ \text{const}\& \ a, \ ...);
\]

The signature does not need to have \text{const}\&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

```cpp
template<typename \text{ExPolicy}, typename I, typename ...\text{Args}>
\text{hpx::parallel::util::detail::algorithm_result_t<ExPolicy> for_loop(ExPolicy &&policy, std::decay_t<I> first, I last, Args &&... args)}
```

The for_loop implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator. Executed according to the policy.
Requires: \( I \) shall be an integral type or meet the requirements of an input iterator type. The \( \text{args} \) parameter pack shall have at least one element, comprising objects returned by invocations of \textit{reduction} and/or \textit{induction} function templates followed by exactly one element invocable element-access function, \( f \). \( f \) shall meet the requirements of \textit{MoveConstructible}.

Effects: Applies \( f \) to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the \( \text{args} \) parameter pack. The length of the input sequence is \( \text{last} - \text{first} \).

The first element in the input sequence is specified by \( \text{first} \). Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the \( \text{args} \) parameter pack excluding \( f \), an additional argument is passed to each application of \( f \) as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of \( f \) in the input sequence.

Complexity: Applies \( f \) exactly once for each element of the input sequence.

Remarks: If \( f \) returns a result, the result is ignored.

\begin{itemize}
  \item \textbf{Note:} As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.
  \item \textbf{Note:} The order of the elements of the input sequence is important for determining ordinal position of an application of \( f \), even though the applications themselves may be unordered.
\end{itemize}

\begin{itemize}
  \item \textbf{Template Parameters}
  \begin{itemize}
    \item \textit{ExPolicy} – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
    \item \textit{I} – The type of the iteration variable. This could be an (forward) iterator type or an integral type.
    \item \textit{Args} – A parameter pack, its last element is a function (object) to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.
  \end{itemize}
  \item \textbf{Parameters}
  \begin{itemize}
    \item \textit{policy} – The execution policy to use for the scheduling of the iterations.
    \item \textit{first} – Refers to the beginning of the sequence of elements the algorithm will be applied to.
    \item \textit{last} – Refers to the end of the sequence of elements the algorithm will be applied to.
    \item \textit{args} – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\) should expose a signature equivalent to:
      \begin{verbatim}
<ignored> pred(I const& a, ...);
      \end{verbatim}
  \end{itemize}
\end{itemize}

The signature does not need to have \texttt{const\&}. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.
Returns The for_loop algorithm returns a hpx::future<void> if the execution policy is of type hpx::execution::sequenced_task_policy or hpx::execution::parallel_task_policy and returns void otherwise.

template<typename I, typename S, typename ...Args>
void for_loop_strided(std::decay_t<I> first, I last, S stride, Args&&... args)

The for_loop_strided implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of for_loop without specifying an execution policy is equivalent to specifying hpx::execution::seq as the execution policy.

Requires: I shall be an integral type or meet the requirements of an input iterator type. The args parameter pack shall have at least one element, comprising objects returned by invocations of reduction and/or induction function templates followed by exactly one element invocable element-access function, f, shall meet the requirements of MoveConstructible.

Effects: Applies f to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the args parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by first. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the args parameter pack excluding f, an additional argument is passed to each application of f as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of f in the input sequence.

Complexity: Applies f exactly once for each element of the input sequence.

Remarks: If f returns a result, the result is ignored.

Note: As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

Note: The order of the elements of the input sequence is important for determining ordinal position of an application of f, even though the applications themselves may be unordered.

Template Parameters
- I – The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- S – The type of the stride variable. This should be an integral type.
- Args – A parameter pack, it’s last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

Parameters
- first – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last – Refers to the end of the sequence of elements the algorithm will be applied to.
• **stride** – Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if \( I \) has integral type or meets the requirements of a bidirectional iterator.

• **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\) should expose a signature equivalent to:

\[
\text{<ignored> pred}(I \text{ const& a, } \ldots);
\]

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

```cpp
template<typename ExPolicy, typename I, typename S, typename ... Args>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy> for_loop_strided(ExPolicy &&policy,
std::decay_t<I> first, I last, S stride, Args&&... args)
```

The `for_loop_strided` implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator. Executed according to the policy.

Requires: `I` shall be an integral type or meet the requirements of an input iterator type. The `args` parameter pack shall have at least one element, comprising objects returned by invocations of `reduction` and/or `induction` function templates followed by exactly one element invocable element-access function, \( f \) shall meet the requirements of `MoveConstructible`.

Effects: Applies \( f \) to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the `args` parameter pack. The length of the input sequence is `last - first`.

The first element in the input sequence is specified by `first`. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the `args` parameter pack excluding \( f \), an additional argument is passed to each application of \( f \) as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of \( f \) in the input sequence.

Complexity: Applies \( f \) exactly once for each element of the input sequence.

Remarks: If \( f \) returns a result, the result is ignored.

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using `advance` and `distance`.

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of \( f \), even though the applications themselves may be unordered.
Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **I** – The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- **S** – The type of the stride variable. This should be an integral type.
- **Args** – A parameter pack, it’s last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **stride** – Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if I has integral type or meets the requirements of a bidirectional iterator.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

```cpp
<ignored> pred(I const & a, ...);
```

The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Returns** The for_loop_strided algorithm returns a hpx::future<void> if the execution policy is of type hpx::execution::sequenced_task_policy or hpx::execution::parallel_task_policy and returns void otherwise.

```cpp
template<typename I, typename Size, typename ...Args>
void for_loop_n(I first, Size size, Args&&... args)
```

The for_loop_n implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of for_loop_n without specifying an execution policy is equivalent to specifying hpx::execution::seq as the execution policy.

Requires: I shall be an integral type or meet the requirements of an input iterator type. The args parameter pack shall have at least one element, comprising objects returned by invocations of reduction and/or induction function templates followed by exactly one element invocable element-access function, f, shall meet the requirements of MoveConstructible.

Effects: Applies f to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the args parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by first. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the args parameter pack excluding f, an additional argument is passed to each application of f as follows:
If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of \( f \) in the input sequence.

Complexity: Applies \( f \) exactly once for each element of the input sequence.

Remarks: If \( f \) returns a result, the result is ignored.

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of \( f \), even though the applications themselves may be unordered.

**Template Parameters**
- \( I \) – The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- \( \text{Size} \) – The type of a non-negative integral value specifying the number of items to iterate over.
- \( \text{Args} \) – A parameter pack, it’s last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**
- \( \text{first} \) – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- \( \text{size} \) – Refers to the number of items the algorithm will be applied to.
- \( \text{args} \) – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by \( \text{first}, \text{last} \) should expose a signature equivalent to:

\[
\text{<ignored- pred(I const& a, ...);}
\]

The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

```cpp
template<typename ExPolicy, typename I, typename Size, typename ...Args>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy> for_loop_n(ExPolicy &&policy, I first, Size size, Args&&... args)
```

The for_loop_n implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator. Executed according to the policy.

**Requires:** \( I \) shall be an integral type or meet the requirements of an input iterator type. The \( \text{args} \) parameter pack shall have at least one element, comprising objects returned by invocations of reduction and/or induction function templates followed by exactly one element invocable element-access function, \( f \). \( f \) shall meet the requirements of MoveConstructible.

**Effects:** Applies \( f \) to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the \( \text{args} \) parameter pack. The length of the input sequence is \( \text{last} - \text{first} \).
The first element in the input sequence is specified by \texttt{first}. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the \texttt{args} parameter pack excluding \texttt{f}, an additional argument is passed to each application of \texttt{f} as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of \texttt{f} in the input sequence.

Complexity: Applies \texttt{f} exactly once for each element of the input sequence.

Remarks: If \texttt{f} returns a result, the result is ignored.

\textbf{Note:} As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

\textbf{Note:} The order of the elements of the input sequence is important for determining ordinal position of an application of \texttt{f}, even though the applications themselves may be unordered.

\textbf{Template Parameters}

- \texttt{ExPolicy} – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- \texttt{I} – The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- \texttt{Size} – The type of a non-negative integral value specifying the number of items to iterate over.
- \texttt{Args} – A parameter pack, it’s last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

\textbf{Parameters}

- \texttt{policy} – The execution policy to use for the scheduling of the iterations.
- \texttt{first} – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- \texttt{size} – Refers to the number of items the algorithm will be applied to.
- \texttt{args} – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by \{first, last\} should expose a signature equivalent to:

\begin{verbatim}
<ignored> pred(I const& a, ...);
\end{verbatim}

The signature does not need to have \texttt{const}&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

\textbf{Returns} The \texttt{for\_loop\_n} algorithm returns a \texttt{hpx::future<void>} if the execution policy is of type \texttt{hpx::execution::sequenced\_task\_policy} or \texttt{hpx::execution::parallel\_task\_policy} and returns \texttt{void} otherwise.

\begin{verbatim}
template<
    typename I, typename Size, typename S, typename ...Args>
\end{verbatim}
**void for_loop_n_strided(I first, Size size, S stride, Args&&... args)**

The for_loop_n_strided implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of for_loop without specifying an execution policy is equivalent to specifying `hpx::execution::seq` as the execution policy.

**Requires:** I shall be an integral type or meet the requirements of an input iterator type. The args parameter pack shall have at least one element, comprising objects returned by invocations of `reduction` and/or `induction` function templates followed by exactly one element invocable element-access function, f, f shall meet the requirements of `MoveConstructible`.

**Effects:** Applies f to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the args parameter pack. The length of the input sequence is `last - first`.

The first element in the input sequence is specified by `first`. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the args parameter pack excluding f, an additional argument is passed to each application of f as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of f in the input sequence.

**Complexity:** Applies f exactly once for each element of the input sequence.

**Remarks:** If f returns a result, the result is ignored.

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of f, even though the applications themselves may be unordered.

**Template Parameters**
- I – The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- Size – The type of a non-negative integral value specifying the number of items to iterate over.
- S – The type of the stride variable. This should be an integral type.
- Args – A parameter pack, it’s last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**
- first – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- size – Refers to the number of items the algorithm will be applied to.
• **stride** – Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if I has integral type or meets the requirements of a bidirectional iterator.

• **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

```cpp
<ignored> pred(I const& a, ...);
```

The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

```cpp
template<typename ExPolicy, typename I, typename Size, typename S, typename ...Args>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy> for_loop_n_strided(ExPolicy &&policy, I first, Size size, S stride, Args&&... args)
```

The for_loop_n_strided implements loop functionality over a range specified by integral or iterator bounds. For the iterator case, these algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator. Executed according to the policy.

Requires: I shall be an integral type or meet the requirements of an input iterator type. The args parameter pack shall have at least one element, comprising objects returned by invocations of reduction and/or induction function templates followed by exactly one element invocable element-access function, f. f shall meet the requirements of MoveConstructible.

Effects: Applies f to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the args parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by first. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the args parameter pack excluding f, an additional argument is passed to each application of f as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of f in the input sequence.

Complexity: Applies f exactly once for each element of the input sequence.

Remarks: If f returns a result, the result is ignored.

---

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

---

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of f, even though the applications themselves may be unordered.
Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **I** – The type of the iteration variable. This could be an (forward) iterator type or an integral type.
- **Size** – The type of a non-negative integral value specifying the number of items to iterate over.
- **S** – The type of the stride variable. This should be an integral type.
- **Args** – A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **size** – Refers to the number of items the algorithm will be applied to.
- **stride** – Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if I has integral type or meets the requirements of a bidirectional iterator.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

  ```cpp
  <ignored> pred(I const& a, ...);
  ```

  The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

Returns

The `for_loop_n_strided` algorithm returns a `hpx::future<void>` if the execution policy is of type `hpx::execution::sequenced_task_policy` or `hpx::execution::parallel_task_policy` and returns `void` otherwise.

See Public API for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **experimental**

Top-level namespace.
Functions

template<typename T>
constexpr hpx::parallel::detail::induction_stride_helper<T> induction(T &&value, std::size_t stride)

The function template returns an induction object of unspecified type having a value type and encapsulating an initial value value of that type and, optionally, a stride.

For each element in the input range, a looping algorithm over input sequence S computes an induction value from an induction variable and ordinal position p within S by the formula i + p * stride if a stride was specified or i + p otherwise. This induction value is passed to the element access function.

If the value argument to induction is a non-const lvalue, then that lvalue becomes the live-out object for the returned induction object. For each induction object that has a live-out object, the looping algorithm assigns the value of i + n * stride to the live-out object upon return, where n is the number of elements in the input range.

Template Parameters  T – The value type to be used by the induction object.

Parameters

  • value – [in] The initial value to use for the induction object
  • stride – [in] The (optional) stride to use for the induction object (default: 1)

Returns  This returns an induction object with value type T, initial value value, and (if specified) stride stride. If T is an lvalue of non-const type, value is used as the live-out object for the induction object; otherwise there is no live-out object.

namespace parallel

hpx/parallel/algorithms/for_loop_reduction.hpp

See Public API for a list of names and headers that are part of the public HPX API.

namespace hpx

namespace experimental

Top-level namespace.

Functions

template<typename T, typename Op>
constexpr hpx::parallel::detail::reduction_helper<T, std::decay_t<Op>> reduction(T &var, T const &identity, Op &&combiner)

The function template returns a reduction object of unspecified type having a value type and encapsulating an identity value for the reduction, a combiner function object, and a live-out object from which the initial value is obtained and into which the final value is stored.

A parallel algorithm uses reduction objects by allocating an unspecified number of instances, called views, of the reduction’s value type. Each view is initialized with the reduction object’s identity value, except that the live-out object (which was initialized by the caller) comprises one of the views. The algorithm passes a reference to a view to each application of an element-access function, ensuring that no two concurrently-executing invocations share the same view. A view can be shared between two applications that do not execute concurrently, but initialization is performed only once per view.
Modifications to the view by the application of element access functions accumulate as partial results. At some point before the algorithm returns, the partial results are combined, two at a time, using the reduction object’s combiner operation until a single value remains, which is then assigned back to the live-out object.

T shall meet the requirements of CopyConstructible and MoveAssignable. The expression

\[
\text{var} = \text{combiner}(\text{var}, \text{var})
\]

shall be well formed.

**Note:** In order to produce useful results, modifications to the view should be limited to commutative operations closely related to the combiner operation. For example if the combiner is \text{plus}<\mathcal{T}>, incrementing the view would be consistent with the combiner but doubling it or assigning to it would not.

**Template Parameters**
- \( \mathcal{T} \) – The value type to be used by the induction object.
- \( \mathcal{Op} \) – The type of the binary function (object) used to perform the reduction operation.

**Parameters**
- \( \text{var} \) – [in,out] The life-out value to use for the reduction object. This will hold the reduced value after the algorithm is finished executing.
- \( \text{identity} \) – [in] The identity value to use for the reduction operation.
- \( \text{combiner} \) – [in] The binary function (object) used to perform a pairwise reduction on the elements.

**Returns** This returns a reduction object of unspecified type having a value type of \( \mathcal{T} \). When the return value is used by an algorithm, the reference to \( \text{var} \) is used as the live-out object, new views are initialized to a copy of identity, and views are combined by invoking the copy of combiner, passing it the two views to be combined.

namespace **parallel**

**hpx/parallel/algorithms/generate.hpp**

See Public API for a list of names and headers that are part of the public HPX API.

namespace **hpx**

**Functions**

\[
\text{hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> } \text{generate}( \text{ExPolicy} &&\text{policy}, \text{FwdIter} \text{first, FwdIter last, F} &&\text{f})
\]

Assign each element in range \([\text{first, last})\) a value generated by the given function object \(\text{f} \). Executed according to the policy.

The assignments in the parallel `generate` algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.
The assignments in the parallel `generate` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Exactly \( distance(first, last) \) invocations of \( f \) and assignments.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires \( F \) to meet the requirements of `CopyConstructible`.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **f** – generator function that will be called. signature of function should be equivalent to the following:

  ```
  Ret fun();
  ```

  The type `Ret` must be such that an object of type `FwdIter` can be dereferenced and assigned a value of type `Ret`.

**Returns** The `generate` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise.

```cpp
template<typename FwdIter, typename F>
FwdIter generate(FwdIter first, FwdIter last, F &&f)
```

Assign each element in range \([first, last)\) a value generated by the given function object \( f \).

**Note:** Complexity: Exactly \( distance(first, last) \) invocations of \( f \) and assignments.

**Template Parameters**

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires \( F \) to meet the requirements of `CopyConstructible`.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
• **f** – generator function that will be called. signature of function should be equivalent to the following:

```cpp
Ret fun();
```

The type `Ret` must be such that an object of type `FwdIter` can be dereferenced and assigned a value of type `Ret`.

**Returns** The `generate` algorithm returns a `FwdIter`.

```cpp
template<typename ExPolicy, typename FwdIter, typename Size, typename F>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> generate_n(ExPolicy &&policy, FwdIter first, Size count, F &&f)
```

Assigns each element in range `[first, first+)` a value generated by the given function object `f`. Executed according to the policy.

The assignments in the parallel `generate_n` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `generate_n` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Exactly `count` invocations of `f` and assignments, for `count > 0`.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Size** – The type of a non-negative integral value specifying the number of items to iterate over.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `F` to meet the requirements of `CopyConstructible`.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements in the sequence the algorithm will be applied to.
- **f** – Refers to the generator function object that will be called. The signature of the function should be equivalent to

```cpp
Ret fun();
```

The type `Ret` must be such that an object of type `OutputIt` can be dereferenced and assigned a value of type `Ret`. 
Returns  The generate_n algorithm returns a \texttt{hpx\_future\textless FwdIter\textgreater} if the execution policy is of type \texttt{sequenced\_task\_policy} or \texttt{parallel\_task\_policy} and returns \texttt{FwdIter} otherwise. generate_n algorithm returns iterator one past the last element assigned if count>0, first otherwise.

template\texttt{<typename FwdIter, typename Size, typename F>}
\texttt{FwdIter generate\_n(FwdIter first, Size count, F \&\&f)}

Assigns each element in range \texttt{[first, first+)} a value generated by the given function object \texttt{f}.

**Note:** Complexity: Exactly count invocations of \texttt{f} and assignments, for count > 0.

**Template Parameters**
- Size – The type of a non-negative integral value specifying the number of items to iterate over.
- FwdIter – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- F – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \texttt{equal} requires \texttt{F} to meet the requirements of \texttt{CopyConstructible}.

**Parameters**
- first – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- count – Refers to the number of elements in the sequence the algorithm will be applied to.
- \texttt{f} – Refers to the generator function object that will be called. The signature of the function should be equivalent to

\begin{verbatim}
  Ret fun();
\end{verbatim}

The type \texttt{Ret} must be such that an object of type \texttt{OutputIt} can be dereferenced and assigned a value of type \texttt{Ret}.

**Returns** The generate_n algorithm returns a \texttt{FwdIter}. generate_n algorithm returns iterator one past the last element assigned if count>0, first otherwise.

**hpx/parallel/algorithms/includes.hpp**

See **Public API** for a list of names and headers that are part of the public HPX API.
Functions

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = hpx::parallel::detail::less>
    hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool>::type
        includes(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1,
        FwdIter2 first2, FwdIter2 last2, Pred &&op = Pred())
```

Returns true if every element from the sorted range \([\text{first2}, \text{last2})\) is found within the sorted range \([\text{first1}, \text{last1})\). Also returns true if \([\text{first2}, \text{last2})\) is empty. The version expects both ranges to be sorted with the user supplied binary predicate \(f\). Executed according to the policy.

The comparison operations in the parallel includes algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel includes algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** At most \(2 \times (N1+N2-1)\) comparisons, where \(N1 = \text{std::distance(first1, last1)}\) and \(N2 = \text{std::distance(first2, last2)}\).

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `includes` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as includes. The signature of the predicate function should be equivalent to the following:
The `includes` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `includes` algorithm returns true every element from the sorted range `[first2, last2)` is found within the sorted range `[first1, last1)`. Also returns true if `[first2, last2)` is empty.

**Returns**
The `includes` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `includes` algorithm returns true every element from the sorted range `[first2, last2)` is found within the sorted range `[first1, last1)`. Also returns true if `[first2, last2)` is empty. The version expects both ranges to be sorted with the user supplied binary predicate `f`.

**Note:** At most 2*(N1+N2-1) comparisons, where N1 = std::distance(first1, last1) and N2 = std::distance(first2, last2).

### Template Parameters
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `includes` requires `Pred` to meet the requirements of Copy-Constructible. This defaults to `std::less<>`.

### Parameters
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as includes. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.
**Returns** The `includes` algorithm returns a `bool`. The `includes` algorithm returns true every element from the sorted range `[first2, last2)` is found within the sorted range `[first1, last1)`. Also returns true if `[first2, last2)` is empty.

**hpx/parallel/algorithms/inclusive_scan.hpp**

See `Public API` for a list of names and headers that are part of the public `HPX` API.

namespace `hpx`

**Functions**

```cpp
template<typename InIter, typename OutIter>
OutIter inclusive_scan(InIter first, InIter last, OutIter dest)
```

Assigns through each iterator `i` in `result`, `result + (last - first)` the value of `GENERALIZED_NONCOMMUTATIVE_SUM(\(+, \ast first, \ldots, \ast(first + (i - result)))`. The reduce operations in the parallel `inclusive_scan` algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between `exclusive_scan` and `inclusive_scan` is that `inclusive_scan` includes the `i`th input element in the `i`th sum.

**Note:** Complexity: O(`last - first`) applications of the predicate `op`, here `std::plus<>()`.

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(\(+, a1, \ldots, aN)` is defined as:

- `a1` when `N` is `1`
- `GENERALIZED_NONCOMMUTATIVE_SUM(\(+, a1, \ldots, aK)`
  - `GENERALIZED_NONCOMMUTATIVE_SUM(\(+, aM, \ldots, aN)` where `1 < K+1 = M <= N`.

**Template Parameters**

- `InIter` – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- `OutIter` – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

**Parameters**

- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements the algorithm will be applied to.
- `dest` – Refers to the beginning of the destination range.

**Returns** The `inclusive_scan` algorithm returns `OutIter`. The `inclusive_scan` algorithm returns the output iterator to the element in the destination range, one past the last element copied.
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> inclusive_scan(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest)

Assigns through each iterator \( i \) in \([\text{result}, \text{result} + (\text{last} - \text{first}))\) the value of GENERALIZED_NONCOMMUTATIVE_SUM(+, *first, ... , *(first + (i - result))). Executed according to the policy.

The reduce operations in the parallel inclusive_scan algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The reduce operations in the parallel inclusive_scan algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between exclusive_scan and inclusive_scan is that inclusive_scan includes the \( i \)th input element in the \( i \)th sum.

**Note:** Complexity: \( O(\text{last} - \text{first}) \) applications of the predicate \( op \), here std::plus<>().

**Note:** GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ..., aN) is defined as:

- \( a1 \) when \( N \) is 1
- GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ..., aK)
  - GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, ..., aN) where \( 1 < K+1 = M <= N \).

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **dest** – Refers to the beginning of the destination range.

**Returns** The inclusive_scan algorithm returns a hpx::future<FwdIter2> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter2 otherwise. The inclusive_scan algorithm returns the output iterator to the element in the destination range, one past the last element copied.
In the parallel inclusive_scan algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between exclusive_scan and inclusive_scan is that inclusive_scan includes the ith input element in the ith sum.

Note: Complexity: $O(last - first)$ applications of the predicate $op$.

Note: GENERALIZED_NONCOMMUTATIVE_SUM(+, $a_1$, ..., $a_N$) is defined as:

- $a_1$ when $N$ is 1
- GENERALIZED_NONCOMMUTATIVE_SUM(+, $a_1$, ..., $a_K$) - GENERALIZED_NONCOMMUTATIVE_SUM(+, $a_M$, ..., $a_N$) where $1 < K+1 = M <= N$.

Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Op** – The type of the binary function object used for the reduction operation.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

  ```cpp
  Ret fun(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types `Type1` and `Ret` must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

Returns The inclusive_scan algorithm returns `OutIter`. The inclusive_scan algorithm returns the output iterator to the element in the destination range, one past the last element copied.
Assigns through each iterator $i$ in $[\text{result, result + (last - first))$ the value of \text{GENERALIZED_NONCOMMUTATIVE_SUM}(\text{op, *first, \ldots, *(first + (i - result))).}$ Executed according to the policy.

The reduce operations in the parallel \textit{inclusive_scan} algorithm invoked with an execution policy object of type \textit{sequenced_policy} execute in sequential order in the calling thread.

The reduce operations in the parallel \textit{inclusive_scan} algorithm invoked with an execution policy object of type \textit{parallel_policy} or \textit{parallel_task_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between \textit{exclusive_scan} and \textit{inclusive_scan} is that \textit{inclusive_scan} includes the $i$th input element in the $i$th sum.

\textbf{Note:} Complexity: $O(last - first)$ applications of the predicate $\text{op}$.

\textbf{Note:} \text{GENERALIZED_NONCOMMUTATIVE_SUM}(+, a1, \ldots, aN) is defined as:

- $a1$ when $N$ is 1
- \text{GENERALIZED_NONCOMMUTATIVE_SUM}(\text{op, a1, \ldots, aK})
  \hspace{1em} – \text{GENERALIZED_NONCOMMUTATIVE_SUM}(+, aM, \ldots, aN)$ where $1 < K+1 = M <= N$.

\textbf{Template Parameters}

- \textbf{ExPolicy} – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- \textbf{FwdIter1} – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

- \textbf{FwdIter2} – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

- \textbf{Op} – The type of the binary function object used for the reduction operation.

\textbf{Parameters}

- \textbf{policy} – The execution policy to use for the scheduling of the iterations.

- \textbf{first} – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- \textbf{last} – Refers to the end of the sequence of elements the algorithm will be applied to.

- \textbf{dest} – Refers to the beginning of the destination range.

- \textbf{op} – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:
Ret fun(const Type1 &a, const Type1 &b);

The signature does not need to have const&, but the function must not modify the objects passed to it. The types Type1 and Ret must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

Returns The inclusive_scan algorithm returns a hpx::future<FwdIter2> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter2 otherwise. The inclusive_scan algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename InIter, typename OutIter, typename Op, typename T>
OutIter inclusive_scan(InIter first, InIter last, OutIter dest, Op &&op, T init)
Assigns through each iterator \( i \) in \([\text{result}, \text{result} + (\text{last} - \text{first}))\) the value of GENERALIZED_NONCOMMUTATIVE_SUM(op, init, *first, ..., *(first + (i - result))).

The reduce operations in the parallel inclusive_scan algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between exclusive_scan and inclusive_scan is that inclusive_scan includes the \( i \)th input element in the \( i \)th sum. If \( op \) is not mathematically associative, the behavior of inclusive_scan may be non-deterministic.

Note: Complexity: \( O(\text{last} - \text{first}) \) applications of the predicate \( op \).

Note: GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN) is defined as:
- a1 when \( N \) is 1
- \( op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN)) \) where \( 1 < K+1 = M \leq N \).

Template Parameters
- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Op** – The type of the binary function object used for the reduction operation.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types `Type1` and `Ret` must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

- **init** – The initial value for the generalized sum.

**Returns** The `inclusive_scan` algorithm returns `OutIter`. The `inclusive_scan` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Op, typename T>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> inclusive_scan(
    ExPolicy &&policy,
    FwdIter1 first,
    FwdIter1 last,
    FwdIter2 dest,
    Op &&op,
    T init)
```

Assigns through each iterator `i` in `[result, result + (last - first))` the value of `GENERALIZED_NONCOMMUTATIVE_SUM(op, init, *first, ..., *(first + (i - result)))`. Executed according to the policy.

The reduce operations in the parallel `inclusive_scan` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The reduce operations in the parallel `inclusive_scan` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `exclusive_scan` and `inclusive_scan` is that `inclusive_scan` includes the `i`th input element in the `i`th sum. If `op` is not mathematically associative, the behavior of `inclusive_scan` may be non-deterministic.

**Note:** Complexity: `O(last - first)` applications of the predicate `op`.

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN)` is defined as:

- `a1` when `N` is 1
- `op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN))` where `1 < K+1 = M <= N`.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
• **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

• **Op** – The type of the binary function object used for the reduction operation.

• **T** – The type of the value to be used as initial (and intermediate) values (deduced).

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **dest** – Refers to the beginning of the destination range.

- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types `Type1` and `Ret` must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

- **init** – The initial value for the generalized sum.

### Returns

The `inclusive_scan` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `inclusive_scan` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

`hpx/parallel/algorithms/is_heap.hpp`

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename RandIter, typename Comp = hpx::parallel::detail::less>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> is_heap(ExPolicy &&policy, RandIter first, RandIter last, Comp &&comp = Comp())
```

Returns whether the range is max heap. That is, true if the range is max heap, false otherwise. The function uses the given comparison function object `comp` (defaults to using `operator<()`). Executed according to the policy.

`comp` has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.
The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Linear in the distance between `first` and `last`.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RandIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced).

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – `comp` is a callable object. The return value of the INVOKE operation applied to an object of type `Comp`, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator.

**Returns** The `is_heap` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `is_heap` algorithm returns whether the range is max heap. That is, true if the range is max heap, false otherwise. The function uses the given comparison function object `comp` (defaults to using `operator<()`).

```
template<typename RandIter, typename Comp = hpx::parallel::detail::less>
bool is_heap(RandIter first, RandIter last, Comp &&comp = Comp())
```

Returns whether the range is max heap. That is, true if the range is max heap, false otherwise. The function uses the given comparison function object `comp` (defaults to using `operator<()`).

**Note:** Complexity: Linear in the distance between `first` and `last`.

**Template Parameters**
- **RandIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced).

**Parameters**
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
• **comp** – *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that *comp* will not apply any non-constant function through the dereferenced iterator.

**Returns** The is_heap a bool. The is_heap algorithm returns whether the range is max heap. That is, true if the range is max heap, false otherwise.

```cpp
template<typename ExPolicy, typename RandIter, typename Comp = hpx::parallel::detail::less>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, RandIter> is_heap_until(ExPolicy &&policy, RandIter first, RandIter last, Comp &&comp = Comp())
```

Returns the upper bound of the largest range beginning at *first* which is a max heap. That is, the last iterator *it* for which range [first, it) is a max heap. The function uses the given comparison function object *comp* (defaults to using operator<()). Executed according to the policy.

*comp* has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Linear in the distance between *first* and *last*.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RandIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced).

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that *comp* will not apply any non-constant function through the dereferenced iterator.

**Returns** The is_heap_until algorithm returns a hpx::future<RandIter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns *RandIter* otherwise. The is_heap_until algorithm returns the upper bound of the largest range beginning at *first* which is a max heap. That is, the last iterator *it* for which range [first, it) is a max heap.

```cpp
template<typename RandIter, typename Comp = hpx::parallel::detail::less>
**RandIter** *is_heap_until*(**RandIter** first, **RandIter** last, **Comp** &comp = **Comp**())

Returns the upper bound of the largest range beginning at `first` which is a max heap. That is, the last iterator `it` for which range `[first, it)` is a max heap. The function uses the given comparison function object `comp` (defaults to using operator<()).

`comp` has to induce a strict weak ordering on the values.

**Note:** Complexity: Linear in the distance between `first` and `last`.

**Template Parameters**

- **RandIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced).

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – `comp` is a callable object. The return value of the INVOKE operation applied to an object of type `Comp`, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator.

**Returns** The `is_heap_until` algorithm returns a **RandIter**. The `is_heap_until` algorithm returns the upper bound of the largest range beginning at `first` which is a max heap. That is, the last iterator `it` for which range `[first, it)` is a max heap.

**hpx/parallel/algorithms/is_partitioned.hpp**

See Public API for a list of names and headers that are part of the public HPX API.

namespace hpx

**Functions**

template<**typename** FwdIter,**typename** Pred>
bool *is_partitioned*(**FwdIter** first,**FwdIter** last,**Pred**&pred)

Determines if the range `[first, last)` is partitioned.

**Note:** Complexity: at most (N) predicate evaluations where N = distance(first, last).

**Template Parameters**

- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced).

**Parameters**
• **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.

• **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.

• **pred** – Refers to the unary predicate which returns true for elements expected to be found in the beginning of the range. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.

**Returns** The `is_partitioned` algorithm returns `bool`. The `is_partitioned` algorithm returns true if each element in the sequence for which `pred` returns true precedes those for which `pred` returns false. Otherwise `is_partitioned` returns false. If the range `[first, last)` contains less than two elements, the function is always true.

```cpp
template<typename ExPolicy, typename FwdIter, typename Pred>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> is_partitioned(ExPolicy &&policy, FwdIter first, FwdIter last, Pred &&pred)
```

Determines if the range `[first, last)` is partitioned. Executed according to the policy.

The predicate operations in the parallel `is_partitioned` algorithm invoked with an execution policy object of type `sequenced_policy` executes in sequential order in the calling thread.

The comparison operations in the parallel `is_partitioned` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: at most (N) predicate evaluations where N = distance(first, last).

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.

- **Pred** – The type of the function/function object to use (deduced). `Pred` must be `CopyConstructible` when using a parallel policy.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
• **pred** – Refers to the unary predicate which returns true for elements expected to be found in the beginning of the range. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type Type must be such that objects of types FwdIter can be dereferenced and then implicitly converted to Type.

**Returns** The is_partitioned algorithm returns a hpx::future<bool> if the execution policy is of type task_execution_policy and returns bool otherwise. The is_partitioned algorithm returns true if each element in the sequence for which pred returns true precedes those for which pred returns false. Otherwise is_partitioned returns false. If the range [first, last) contains less than two elements, the function is always true.

**hpx/parallel/algorithms/is_sorted.hpp**

See Public API for a list of names and headers that are part of the public HPX API.

namespace hpx

**Functions**

template<typename FwdIter, typename Pred = hpx::parallel::detail::less>
bool is_sorted(FwdIter first, FwdIter last, Pred &&pred = Pred())

Determines if the range [first, last) is sorted. Uses pred to compare elements.

The comparison operations in the parallel is_sorted algorithm executes in sequential order in the calling thread.

**Note:** Complexity: at most (N+S-1) comparisons where N = distance(first, last). S = number of partitions

**Template Parameters**

- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a, const Type &b);
```
The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.

**Returns** The `is_sorted` algorithm returns a `bool`. The `is_sorted` algorithm returns true if each element in the sequence `[first, last)` satisfies the predicate passed. If the range `[first, last)` contains less than two elements, the function always returns true.

```cpp
template<typename ExPolicy, typename FwdIter, typename Pred = hpx::parallel::detail::less>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> is_sorted(ExPolicy &&policy, FwdIter first, FwdIter last, Pred &&pred = Pred())
```

Determines if the range `[first, last)` is sorted. Uses `pred` to compare elements. Executed according to the policy.

The comparison operations in the parallel `is_sorted` algorithm invoked with an execution policy object of type `sequenced_policy` executes in sequential order in the calling thread.

The comparison operations in the parallel `is_sorted` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: at most \((N+S-1)\) comparisons where \(N = \text{distance(}first, last)\). \(S = \text{number of partitions}\)

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `is_sorted` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a, const Type &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`. 
Returns

The is_sorted algorithm returns a `hpx::future<bool>` if the execution policy is of type `task_execution_policy` and returns `bool` otherwise. The is_sorted algorithm returns a bool if each element in the sequence [first, last) satisfies the predicate passed. If the range [first, last) contains less than two elements, the function always returns true.

```cpp
template<typename FwdIter, typename Pred = hpx::parallel::detail::less>
FwdIter is_sorted_until(FwdIter first, FwdIter last, Pred &&pred = Pred())
```

Returns the first element in the range [first, last) that is not sorted. Uses a predicate to compare elements or the less than operator.

The comparison operations in the parallel is_sorted_until algorithm execute in sequential order in the calling thread.

**Note:** Complexity: at most \((N+S-1)\) comparisons where \(N = \text{distance(first, last)}\). \(S = \text{number of partitions}\)

**Template Parameters**

- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

  ```cpp
  bool pred(const Type &a, const Type &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.

**Returns**

The is_sorted_until algorithm returns a `FwdIter`. The is_sorted_until algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, last is returned.

```cpp
template<typename ExPolicy, typename FwdIter, typename Pred = hpx::parallel::detail::less>
hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type
is_sorted_until(ExPolicy &&policy, FwdIter first, FwdIter last, Pred &&pred = Pred())
```

Returns the first element in the range [first, last) that is not sorted. Uses a predicate to compare elements or the less than operator. Executed according to the policy.

The comparison operations in the parallel is_sorted_until algorithm invoked with an execution policy object of type `sequenced_policy` executes in sequential order in the calling thread.
The comparison operations in the parallel `is_sorted_until` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: at most (N+S-1) comparisons where N = distance(first, last). S = number of partitions

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `is_sorted_until` requires Pred to meet the requirements of Copy-Constructible. This defaults to `std::less<>`

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a, const Type &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to Type.

**Returns** The `is_sorted_until` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `is_sorted_until` algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, `last` is returned.

`hpx/parallel/algorithms/lexicographical_compare.hpp`

See **Public API** for a list of names and headers that are part of the public **HPX** API.
# Functions

```cpp
template<typename InIter1, typename InIter2, typename Pred = hpx::parallel::detail::less>
bool lexicographical_compare(InIter1 first1, InIter1 last1, InIter2 first2, InIter2 last2, Pred &&pred)
```

Checks if the first range \([\text{first1}, \text{last1})\) is lexicographically less than the second range \([\text{first2}, \text{last2})\). uses a provided predicate to compare elements.

The comparison operations in the parallel `lexicographical_compare` algorithm invoked without an execution policy object execute in sequential order in the calling thread.

---

**Note:** Complexity: At most \(2 \times \min(N1, N2)\) applications of the comparison operation, where \(N1 = \text{std::distance(first1, last)}\) and \(N2 = \text{std::distance(first2, last2)}\).

---

**Note:** Lexicographical comparison is an operation with the following properties

- Two ranges are compared element by element
- The first mismatching element defines which range is lexicographically less or greater than the other
- If one range is a prefix of another, the shorter range is lexicographically less than the other
- If two ranges have equivalent elements and are of the same length, then the ranges are lexicographically equal
- An empty range is lexicographically less than any non-empty range
- Two empty ranges are lexicographically equal

---

**Template Parameters**

- `InIter1` – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an input iterator.

- `InIter2` – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an input iterator.

- `Pred` – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `lexicographical_compare` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`

**Parameters**

- `first1` – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

- `last1` – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

- `first2` – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

- `last2` – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

- `pred` – Refers to the comparison function that the first and second ranges will be applied to.
**Returns** The `lexicographically_compare` algorithm returns a `return bool` if the execution policy object is not passed in. The `lexicographically_compare` algorithm returns true if the first range is lexicographically less, otherwise it returns false. range [first2, last2), it returns false.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = hpx::parallel::detail::less>
  hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> lexicographical_compare(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, Pred &&pred)
```

Checks if the first range [first1, last1) is lexicographically less than the second range [first2, last2). uses a provided predicate to compare elements.

The comparison operations in the parallel `lexicographical_compare` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `lexicographical_compare` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most $2 \times \min(N1, N2)$ applications of the comparison operation, where $N1 = \text{std::distance(first1, last)}$ and $N2 = \text{std::distance(first2, last2)}$.

**Note:** Lexicographical comparison is an operation with the following properties

- Two ranges are compared element by element
- The first mismatching element defines which range is lexicographically *less* or *greater* than the other
- If one range is a prefix of another, the shorter range is lexicographically *less* than the other
- If two ranges have equivalent elements and are of the same length, then the ranges are lexicographically *equal
- An empty range is lexicographically *less* than any non-empty range
- Two empty ranges are lexicographically *equal

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
• **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `lexicographical_compare` requires `Pred` to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`

**Parameters**

• **policy** – The execution policy to use for the scheduling of the iterations.

• **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

• **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

• **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

• **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

• **pred** – Refers to the comparison function that the first and second ranges will be applied to.

**Returns** The `lexicographically_compare` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `lexicographically_compare` algorithm returns true if the first range is lexicographically less, otherwise it returns false. range `[first2, last2)`, it returns false.

**Public API**

See *Public API* for a list of names and headers that are part of the public *HPX* API.

**namespace** `hpx`

**Functions**

```cpp
template<typename ExPolicy, typename RndIter, typename Comp>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy> make_heap(ExPolicy &&policy, RndIter first, RndIter last, Comp &&comp)
```

Constructs a max heap in the range `[first, last)`. Executed according to the policy.

The predicate operations in the parallel `make_heap` algorithm invoked with an execution policy object of type `sequential_execution_policy` executes in sequential order in the calling thread.

The comparison operations in the parallel `make_heap` algorithm invoked with an execution policy object of type `parallel_execution_policy` or `parallel_task_execution_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: at most `(3*N)` comparisons where `N = distance(first, last)`.

**Template Parameters**
• **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **RndIter** – The type of the source iterators used for algorithm. This iterator must meet the requirements for a random access iterator.

• **Comp** – Comparison function object (i.e. an object that satisfies the requirements of Compare) which returns true if the first argument is less than the second. The signature of the comparison function should be equivalent to the following:

```cpp
bool cmp(const Type1 &a, const Type2 &b);
```

While the signature does not need to have const &, the function must not modify the objects passed to it and must be able to accept all values of type (possibly const) `Type1` and `Type2` regardless of value category (thus, `Type1` & is not allowed, nor is `Type1` unless for `Type1` a move is equivalent to a copy. The types `Type1` and `Type2` must be such that an object of type `RandomIt` can be dereferenced and then implicitly converted to both of them.

**Parameters**

• **policy** – The execution policy to use for the scheduling of the iterations.

• **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.

• **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.

• **comp** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second. The signature of the function should be equivalent to

```cpp
bool comp(const Type &a, const Type &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `RndIter` can be dereferenced and then implicitly converted to `Type`.

**Returns** The `make_heap` algorithm returns a `hpx::future<void>` if the execution policy is of type `task_execution_policy` and returns `void` otherwise.

```cpp
template<typename ExPolicy, typename RndIter>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy> make_heap(ExPolicy &&policy, RndIter first, RndIter last)
```

Constructs a max heap in the range [first, last). Uses the operator `<` for comparisons. Executed according to the policy.

The predicate operations in the parallel `make_heap` algorithm invoked with an execution policy object of type `sequential_execution_policy` executes in sequential order in the calling thread.

The comparison operations in the parallel `make_heap` algorithm invoked with an execution policy object of type `parallel_execution_policy` or `parallel_task_execution_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: at most (3*N) comparisons where N = distance(first, last).
Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **RndIter** – The type of the source iterators used for algorithm. This iterator must meet the requirements for a random access iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.

Returns: The make_heap algorithm returns a `hpx::future<void>` if the execution policy is of type `task_execution_policy` and returns `void` otherwise.

```cpp
template<typename RndIter, typename Comp>
void make_heap(RndIter first, RndIter last, Comp &&comp)

Constructs a max heap in the range [first, last).
```

**Note:** Complexity: at most \(3*N\) comparisons where \(N = \text{distance}(\text{first}, \text{last})\).

Template Parameters

- **RndIter** – The type of the source iterators used for algorithm. This iterator must meet the requirements for a random access iterator.

- **Comp** – Comparison function object (i.e. an object that satisfies the requirements of `Compare`) which returns true if the first argument is less than the second. The signature of the comparison function should be equivalent to the following:

```cpp
bool cmp(const Type1 &a, const Type2 &b);
```

While the signature does not need to have `const &`, the function must not modify the objects passed to it and must be able to accept all values of type (possibly `const`) `Type1` and `Type2` regardless of value category (thus, `Type1` & is not allowed, nor is `Type1` unless for `Type1` a move is equivalent to a copy. The types `Type1` and `Type2` must be such that an object of type `RandomIt` can be dereferenced and then implicitly converted to both of them.

Parameters

- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.

- **comp** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second. The signature of the function should be equivalent to

```cpp
bool comp(const Type &a, const Type &b);
```
The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `RndIter` can be dereferenced and then implicitly converted to `Type`.

**Returns** The `make_heap` algorithm returns a `void`.

```cpp
template<typename RndIter>
void make_heap(RndIter first, RndIter last)
```

Constructs a `max heap` in the range `[first, last)`.

**Note:** Complexity: at most (3*N) comparisons where N = `distance(first, last)`.

**Template Parameters** `RndIter` – The type of the source iterators used for algorithm. This iterator must meet the requirements for a random access iterator.

**Parameters**
- `first` – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements of that the algorithm will be applied to.

**Returns** The `make_heap` algorithm returns a `void`.

See `Public API` for a list of names and headers that are part of the public `HPX API`.

namespace `hpx`

**Functions**

```cpp
template<typename ExPolicy, typename RandIter1, typename RandIter2, typename RandIter3,
         typename Comp = hpx::parallel::detail::less>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, RandIter3> merge(ExPolicy &&policy, RandIter1 first1, RandIter1 last1, RandIter2 first2, RandIter2 last2, RandIter3 dest, Comp &&comp = Comp())
```

Merges two sorted ranges `[first1, last1)` and `[first2, last2)` into one sorted range beginning at `dest`. The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. The destination range cannot overlap with either of the input ranges. Executed according to the policy.

The assignments in the parallel `merge` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `merge` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
Note: Complexity: Performs $O(\text{std::distance(first1, last1)} + \text{std::distance(first2, last2)})$ applications of the comparison \( \text{comp} \) and the each projection.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **RandIter1** – The type of the source iterators used (deduced) representing the first sorted range. This iterator type must meet the requirements of an random access iterator.

- **RandIter2** – The type of the source iterators used (deduced) representing the second sorted range. This iterator type must meet the requirements of an random access iterator.

- **RandIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an random access iterator.

- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \texttt{merge} requires \texttt{Comp} to meet the requirements of \texttt{CopyConstructible}. This defaults to \texttt{std::less<>

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first1** – Refers to the beginning of the first range of elements the algorithm will be applied to.

- **last1** – Refers to the end of the first range of elements the algorithm will be applied to.

- **first2** – Refers to the beginning of the second range of elements the algorithm will be applied to.

- **last2** – Refers to the end of the second range of elements the algorithm will be applied to.

- **dest** – Refers to the beginning of the destination range.

- **comp** – \texttt{comp} is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

  ```
  bool comp(const Type1 &a, const Type2 &b);
  ```

The signature does not need to have const\&, but the function must not modify the objects passed to it. The types \texttt{Type1} and \texttt{Type2} must be such that objects of types \texttt{RandIter1} and \texttt{RandIter2} can be dereferenced and then implicitly converted to both \texttt{Type1} and \texttt{Type2}

Returns The \texttt{merge} algorithm returns a \texttt{hpx::future<RandIter3>}, or if the execution policy is of type \texttt{sequenced_task_policy} or \texttt{parallel_task_policy} and returns \texttt{RandIter3} otherwise. The \texttt{merge} algorithm returns the destination iterator to the end of the \texttt{dest} range.

template<typename RandIter1, typename RandIter2, typename RandIter3, typename Comp = hpx::parallel::detail::less>
RandIter3 merge(RandIter1 first1, RandIter1 last1, RandIter2 first2, RandIter2 last2, RandIter3 dest, Comp &&comp = Comp())

Merges two sorted ranges \([\text{first1, last1})\) and \([\text{first2, last2})\) into one sorted range beginning at \texttt{dest}. The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. The destination range cannot overlap with either of the input ranges.
Note: Complexity: Performs $O(\text{std::distance}(\text{first1, last1}) + \text{std::distance}(\text{first2, last2}))$ applications of the comparison `comp` and the each projection.

**Template Parameters**

- **RandIter1** – The type of the source iterators used (deduced) representing the first sorted range. This iterator type must meet the requirements of a random access iterator.
- **RandIter2** – The type of the source iterators used (deduced) representing the second sorted range. This iterator type must meet the requirements of a random access iterator.
- **RandIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `merge` requires `Comp` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`

**Parameters**

- **first1** – Refers to the beginning of the first range of elements the algorithm will be applied to.
- **last1** – Refers to the end of the first range of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second range of elements the algorithm will be applied to.
- **last2** – Refers to the end of the second range of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **comp** – `comp` is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

  ```cpp
  bool comp(const Type1 &a, const Type2 &b);
  ```

  The signature does not have to have const&, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `RandIter1` and `RandIter2` can be dereferenced and then implicitly converted to both `Type1` and `Type2`.

**Returns** The `merge` algorithm returns a `RandIter3`. The `merge` algorithm returns the destination iterator to the end of the `dest` range.

```cpp
template<typename ExPolicy, typename RandIter, typename Comp = hpx::parallel::detail::less>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy> inplace_merge(ExPolicy &&policy, RandIter first,
RandIter middle, RandIter last,
Comp &&comp = Comp())
```

Merges two consecutive sorted ranges `[first, middle)` and `[middle, last)` into one sorted range `[first, last)`. The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. Executed according to the policy.

The assignments in the parallel `inplace_merge` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.
The assignments in the parallel `inplace_merge` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs $O(\text{std::distance}(\text{first}, \text{last}))$ applications of the comparison `comp` and the each projection.

## Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RandIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `inplace_merge` requires `Comp` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the first sorted range the algorithm will be applied to.
- **middle** – Refers to the end of the first sorted range and the beginning of the second sorted range the algorithm will be applied to.
- **last** – Refers to the end of the second sorted range the algorithm will be applied to.
- **comp** – `comp` is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```cpp
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `RandIter` can be dereferenced and then implicitly converted to both `Type1` and `Type2`.

### Returns

The `inplace_merge` algorithm returns a `hpx::future<void>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns void otherwise. The `inplace_merge` algorithm returns the source iterator `last`.

```cpp
template<typename RandIter, typename Comp = hpx::parallel::detail::less>
void inplace_merge(RandIter first, RandIter middle, RandIter last, Comp &&comp = Comp())
```

Merges two consecutive sorted ranges `[first, middle)` and `[middle, last)` into one sorted range `[first, last)`. The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range.

**Note:** Complexity: Performs $O(\text{std::distance}(\text{first}, \text{last}))$ applications of the comparison `comp` and the each projection.

## Template Parameters
• **RandIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an random access iterator.

• **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `inplace_merge` requires `Comp` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`

**Parameters**

• **first** – Refers to the beginning of the first sorted range the algorithm will be applied to.

• **middle** – Refers to the end of the first sorted range and the beginning of the second sorted range the algorithm will be applied to.

• **last** – Refers to the end of the second sorted range the algorithm will be applied to.

• **comp** – `comp` is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```cpp
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `RandIter` can be dereferenced and then implicitly converted to both `Type1` and `Type2`.

**Returns** The `inplace_merge` algorithm returns a `void`. The `inplace_merge` algorithm returns the source iterator `last`.

### `hpx/parallel/algorithms/minmax.hpp`

See [Public API](#) for a list of names and headers that are part of the public `HPX API`.

**namespace hpx**

**Functions**

```cpp
template<typename FwdIter, typename F = hpx::parallel::detail::less>
FwdIter min_element(FwdIter first, FwdIter last, F &&f)
```

Finds the smallest element in the range `[first, last)` using the given comparison function `f`.

The comparisons in the parallel `min_element` algorithm execute in sequential order in the calling thread.

**Note:** Complexity: Exactly `max(N-1, 0)` comparisons, where `N = std::distance(first, last)`.

**Template Parameters**

• **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

• **F** – The type of the function/function object to use (deduced).

**Parameters**

• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

• **f** – The binary predicate which returns true if the the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

**Returns** The `min_element` algorithm returns `FwdIter`. The `min_element` algorithm returns the iterator to the smallest element in the range `[first, last)`. If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```c++
template<typename ExPolicy, typename FwdIter, typename F = hpx::parallel::detail::less>
    hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> min_element(ExPolicy &&policy, FwdIter first, FwdIter last, F &&f)
```

Finds the smallest element in the range `[first, last)` using the given comparison function `f`. Executed according to the policy.

The comparisons in the parallel `min_element` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparisons in the parallel `min_element` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Exactly `max(N-1, 0)` comparisons, where `N = std::distance(first, last)`.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `min_element` requires `F` to meet the requirements of `CopyConstructible`.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **f** – The binary predicate which returns true if the the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:
The signature does not need to have const &\&, but the function must not modify the objects passed to it. The type \textit{Type1} must be such that objects of type \textit{FwdIter} can be dereferenced and then implicitly converted to \textit{Type1}.

**Returns** The \textit{min\_element} algorithm returns a \texttt{hpx::future<FwdIter>} if the execution policy is of type \texttt{sequenced\_task\_policy} or \texttt{parallel\_task\_policy} and returns \texttt{FwdIter} otherwise. The \textit{min\_element} algorithm returns the iterator to the smallest element in the range \([\texttt{first}, \texttt{last})\). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

\begin{verbatim}
template<typename FwdIter, typename F = hpx::parallel::detail::less>
FwdIter max_element(FwdIter first, FwdIter last, F &&f)

Finds the largest element in the range \([\texttt{first}, \texttt{last})\) using the given comparison function \(f\).
\end{verbatim}

The comparisons in the parallel \textit{min\_element} algorithm execute in sequential order in the calling thread.

**Note:** Complexity: Exactly \(\max(N-1, 0)\) comparisons, where \(N = \text{std::distance(\texttt{first}, \texttt{last})}\).

**Template Parameters**
- \textit{FwdIter} – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- \textit{F} – The type of the function/function object to use (deduced).

**Parameters**
- \texttt{first} – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- \texttt{last} – Refers to the end of the sequence of elements the algorithm will be applied to.
- \texttt{f} – The binary predicate which returns true if the This argument is optional and defaults to \texttt{std::less}. the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

\begin{verbatim}
bool pred(const Type1 &a, const Type1 &b);
\end{verbatim}

The signature does not need to have const &\&, but the function must not modify the objects passed to it. The type \textit{Type1} must be such that objects of type \textit{FwdIter} can be dereferenced and then implicitly converted to \textit{Type1}.

**Returns** The \textit{max\_element} algorithm returns \texttt{FwdIter}. The \textit{max\_element} algorithm returns the iterator to the smallest element in the range \([\texttt{first}, \texttt{last})\). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

\begin{verbatim}
template<typename ExPolicy, typename FwdIter, typename F = hpx::parallel::detail::less>
hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type max_element(ExPolicy &&policy, FwdIter first, FwdIter last, F &&f)

Removes all elements satisfying specific criteria from the range Finds the largest element in the range \([\texttt{first}, \texttt{last})\) using the given comparison function \(f\). Executed according to the policy.
\end{verbatim}
The comparisons in the parallel `max_element` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparisons in the parallel `max_element` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Exactly \(\max(N-1, 0)\) comparisons, where \(N = \text{std::distance}(\text{first, last})\).

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `max_element` requires \(F\) to meet the requirements of `CopyConstructible`.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the This argument is optional and defaults to `std::less`. The left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

  ```cpp
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

**Returns** The `max_element` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `max_element` algorithm returns the iterator to the smallest element in the range `[first, last)`. If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```cpp
template<typename FwdIter, typename F = hpx::parallel::detail::less>
minmax_element_result<FwdIter> minmax_element(FwdIter first, FwdIter last, F &&f)
```

Finds the largest element in the range `[first, last)` using the given comparison function \(f\).

The comparisons in the parallel `minmax_element` algorithm execute in sequential order in the calling thread.
Note: Complexity: At most \( \text{max}(\text{floor}(3/2 \cdot (N-1)), 0) \) applications of the predicate, where \( N = \text{std::distance}(\text{first}, \text{last}) \).

**Template Parameters**

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

- **F** – The type of the function/function object to use (deduced).

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **f** – The binary predicate which returns true if the the left argument is less than the right element. This argument is optional and defaults to std::less. The signature of the predicate function should be equivalent to the following:

```cpp
def pred(const Type1 &a, const Type1 &b):
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type **Type1** must be such that objects of type **FwdIter** can be dereferenced and then implicitly converted to **Type1**.

**Returns** The minmax_element algorithm returns a minmax_element_result< FwdIter >. The minmax_element algorithm returns a pair consisting of an iterator to the smallest element as the min element and an iterator to the largest element as the max element. Returns minmax_element_result< FwdIter >[first,first] if the range is empty. If several elements are equivalent to the smallest element, the iterator to the first such element is returned. If several elements are equivalent to the largest element, the iterator to the last such element is returned.

```cpp
template<typename ExPolicy, typename FwdIter, typename F = hpx::parallel::detail::less>
    hpx::parallel::util::detail::algorithm_result_t<ExPolicy, minmax_element_result<FwdIter>>
    minmax_element(ExPolicy &&policy, FwdIter first, FwdIter last, F &&f)
```

Finds the largest element in the range [first, last) using the given comparison function \( f \).

The comparisons in the parallel minmax_element algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The comparisons in the parallel minmax_element algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
Complexity: At most \( \max(\lfloor 3/2 \times (N-1) \rfloor, 0) \) applications of the predicate, where \( N = \text{std::distance(first, last)} \).

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `minmax_element` requires `F` to meet the requirements of `CopyConstructible`.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the the left argument is less than the right element. This argument is optional and defaults to `std::less`. The signature of the predicate function should be equivalent to the following:

  ```cpp
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

### Returns

The `minmax_element` algorithm returns a `hpx::future<minmax_element_result<FwdIter>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `minmax_element_result<FwdIter>` otherwise. The `minmax_element` algorithm returns a pair consisting of an iterator to the smallest element as the min element and an iterator to the largest element as the max element. Returns `std::make_pair(first,first)` if the range is empty. If several elements are equivalent to the smallest element, the iterator to the first such element is returned. If several elements are equivalent to the largest element, the iterator to the last such element is returned.

### hpx/parallel/algorithms/mismatch.hpp

See Public API for a list of names and headers that are part of the public HPX API.

namespace hpx
Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, std::pair<FwdIter1, FwdIter2>> mismatch(ExPolicy &&policy, 
FwdIter1 first1, 
FwdIter1 last1, 
FwdIter2 first2, 
FwdIter2 last2, 
Pred &&op)

Returns the first mismatching pair of elements from two ranges: one defined by \([\text{first1}, \text{last1})\) and another defined by \([\text{first2}, \text{last2})\). If last2 is not provided, it denotes \(\text{first2} + (\text{last1} - \text{first1})\). Executed according to the policy.

The comparison operations in the parallel \textit{mismatch} algorithm invoked with an execution policy object of type \textit{sequenced\_policy} execute in sequential order in the calling thread.

The comparison operations in the parallel \textit{mismatch} algorithm invoked with an execution policy object of type \textit{parallel\_policy} or \textit{parallel\_task\_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

\textbf{Note:} Complexity: At most min(last1 - first1, last2 - first2) applications of the predicate \texttt{op} or \texttt{operator==}. If \texttt{FwdIter1} and \texttt{FwdIter2} meet the requirements of \texttt{RandomAccessIterator} and \((\text{last1} - \text{first1}) \neq (\text{last2} - \text{first2})\) then no applications of the predicate \texttt{op} or \texttt{operator==} are made.

\textbf{Note:} The two ranges are considered mismatch if, for every iterator \(i\) in the range \([\text{first1},\text{last1})\), \(*i\) mismatches \(*(\text{first2} + (i - \text{first1})\)). This overload of mismatch uses \texttt{operator==} to determine if two elements are mismatch.

\textbf{Template Parameters}

\begin{itemize}
  \item \textbf{ExPolicy} – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
  \item \textbf{FwdIter1} – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
  \item \textbf{FwdIter2} – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
  \item \textbf{Pred} – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of \textit{mismatch} requires \texttt{Pred} to meet the requirements of \textit{CopyConstructible}. This defaults to \texttt{std::equal\_to}.
\end{itemize}

\textbf{Parameters}
• **policy** – The execution policy to use for the scheduling of the iterations.

• **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

• **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

• **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

• **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

• **op** – The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively.

### Returns

The `mismatch` algorithm returns a `hpx::future<std::pair<FwdIter1,FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `std::pair<FwdIter1,FwdIter2>` otherwise. If no mismatches are found when the comparison reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, std::pair<FwdIter1, FwdIter2>> mismatch(ExPolicy &&policy,
FwdIter1 first1,
FwdIter1 last1,
FwdIter2 first2,
FwdIter2 last2)
```

Returns the first mismatching pair of elements from two ranges: one defined by `[first1, last1)` and another defined by `[first2, last2)`. If last2 is not provided, it denotes `first2 + (last1 - first1)`. Executed according to the policy.

The comparison operations in the parallel `mismatch` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `mismatch` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most `min(last1 - first1, last2 - first2)` applications of `operator==`. If `FwdIter1` and `FwdIter2` meet the requirements of `RandomAccessIterator` and `(last1 - first1) != (last2 - first2)` then no
applications of `operator==` are made.

**Note:** The two ranges are considered mismatch if, for every iterator i in the range `[first1, last1)`, `*i mismatches *(first2 + (i - first1))`. This overload of mismatch uses `operator==` to determine if two elements are mismatch.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

**Returns** The `mismatch` algorithm returns a `hpx::future<std::pair<FwdIter1, FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `std::pair<FwdIter1, FwdIter2>` otherwise. If no mismatches are found when the comparison reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.
The comparison operations in the parallel `mismatch` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `mismatch` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most \( \text{last1} - \text{first1} \) applications of the predicate `op` or `operator==`. If `FwdIter1` and `FwdIter2` meet the requirements of `RandomAccessIterator` and \( (\text{last1} - \text{first1}) \neq (\text{last2} - \text{first2}) \) then no applications of the predicate `op` or `operator==` are made.

**Note:** The two ranges are considered mismatch if, for every iterator \( i \) in the range \([\text{first1},\text{last1})\), \( *i \) mismatches \( *(\text{first2} + (i - \text{first1})) \). This overload of mismatch uses `operator==` to determine if two elements are mismatch.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `mismatch` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

- **op** – The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

**Returns** The `mismatch` algorithm returns a `hpx::future<std::pair<FwdIter1,FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `std::pair<FwdIter1,FwdIter2>` otherwise. If no mismatches are found when the comparison
reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, std::pair<FwdIter1, FwdIter2>> mismatch(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1, FwdIter1 first2)
```

Returns the first mismatching pair of elements from two ranges: one defined by [first1, last1) and another defined by [first2,last2). If last2 is not provided, it denotes first2 + (last1 - first1). Executed according to the policy.

The comparison operations in the parallel mismatch algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The comparison operations in the parallel mismatch algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most last1 - first1 applications of operator==. If FwdIter1 and FwdIter2 meet the requirements of RandomAccessIterator and (last1 - first1) != (last2 - first2) then no applications of operator== are made.

**Note:** The two ranges are considered mismatch if, for every iterator i in the range [first1,last1), *(first2 + (i - first1)). This overload of mismatch uses operator== to determine if two elements are mismatch.

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of mismatch requires Pred to meet the requirements of CopyConstructible. This defaults to std::equal_to<>.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
• **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

• **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

**Returns** The *mismatch* algorithm returns a `hpx::future<std::pair<FwdIter1,FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `std::pair<FwdIter1,FwdIter2>` otherwise. If no mismatches are found when the comparison reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

```cpp
template<typename FwdIter1, typename FwdIter2, typename Pred>
std::pair<FwdIter1, FwdIter2> mismatch(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, Pred &&op)
```

Returns the first mismatching pair of elements from two ranges: one defined by [first1, last1) and another defined by [first2,last2). If last2 is not provided, it denotes first2 + (last1 - first1).

**Note:** Complexity: At most \(\min(last1 - first1, last2 - first2)\) applications of the predicate \(op\) or \(operator==\). If \(FwdIter1\) and \(FwdIter2\) meet the requirements of `RandomAccessIterator` and \(last1 - first1\) \(!=\) \(last2 - first2\) then no applications of the predicate \(op\) or \(operator==\) are made.

**Note:** The two ranges are considered mismatch if, for every iterator \(i\) in the range [first1,last1), \(*i\) mismatches \(*(first2 + (i - first1))\). This overload of mismatch uses \(operator==\) to determine if two elements are mismatch.

**Template Parameters**

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `mismatch` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`

**Parameters**

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

- **op** – The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:
bool pred(const Type1 &a, const Type2 &b);

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively.

**Returns** The `mismatch` algorithm returns a `std::pair<FwdIter1,FwdIter2>`. If no mismatches are found when the comparison reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

template<typename FwdIter1, typename FwdIter2>
std::pair<FwdIter1, FwdIter2> mismatch(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2)

Returns the first mismatching pair of elements from two ranges: one defined by [first1, last1) and another defined by [first2, last2). If last2 is not provided, it denotes first2 + (last1 - first1).

**Note:** Complexity: At most \( \min(last1 - first1, last2 - first2) \) applications of `operator==`. If `FwdIter1` and `FwdIter2` meet the requirements of `RandomAccessIterator` and \( (last1 - first1) != (last2 - first2) \) then no applications of `operator==` are made.

**Note:** The two ranges are considered mismatch if, for every iterator i in the range \([first1, last1)\), \(*i\) mismatches \(*(first2 + (i - first1))\). This overload of `mismatch` uses `operator==` to determine if two elements are mismatch.

**Template Parameters**

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

**Returns** The `mismatch` algorithm returns a `std::pair<FwdIter1,FwdIter2>`. If no mismatches are found when the comparison reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

template<typename FwdIter1, typename FwdIter2, typename Pred>
std::pair<FwdIter1, FwdIter2> mismatch(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, Pred &&op)

Returns the first mismatching pair of elements from two ranges: one defined by \([first1, last1)\) and another defined by \([first2, last2)\). If last2 is not provided, it denotes first2 + (last1 - first1).
Note: Complexity: At most last1 - first1 applications of the predicate \( \text{op} \) or \( \text{operator}== \). If \( \text{FwdIter1} \) and \( \text{FwdIter2} \) meet the requirements of \textit{RandomAccessIterator} and \((\text{last1} - \text{first1}) \neq (\text{last2} - \text{first2})\) then no applications of the predicate \( \text{op} \) or \( \text{operator}== \) are made.

Note: The two ranges are considered mismatch if, for every iterator \( i \) in the range \([\text{first1},\text{last1})\), \(*i\) mismatches \(*(\text{first2}+(i-\text{first1}))\). This overload of mismatch uses \( \text{operator}== \) to determine if two elements are mismatch.

Template Parameters

- \text{FwdIter1} – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- \text{FwdIter2} – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- \text{Pred} – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of \textit{mismatch} requires \text{Pred} to meet the requirements of \textit{CopyConstructible}. This defaults to \text{std::equal\_to<>>}

Parameters

- \text{first1} – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- \text{last1} – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- \text{first2} – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- \text{op} – The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

\[
\text{bool pred(}\text{const Type1 } &a, \text{ const Type2 } &b);\]

The signature does not need to have const &, but the function must not modify the objects passed to it. The types \textit{Type1} and \textit{Type2} must be such that objects of types \textit{FwdIter1} and \textit{FwdIter2} can be dereferenced and then implicitly converted to \textit{Type1} and \textit{Type2} respectively.

Returns The \textit{mismatch} algorithm returns a \textit{std::pair<FwdIter1,FwdIter2>>}. If no mismatches are found when the comparison reaches \text{last1} or \text{last2}, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

\[
\text{template<typename FwdIter1, typename FwdIter2> std::pair<FwdIter1, FwdIter2>> mismatch(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2)}
\]

Returns the first mismatching pair of elements from two ranges: one defined by \([\text{first1},\text{last1})\) and another defined by \([\text{first2},\text{last2})\). If \text{last2} is not provided, it denotes \text{first2} + (\text{last1} - \text{first1}).

Note: Complexity: At most last1 - first1 applications of \text{operator}==. If \text{FwdIter1} and \text{FwdIter2} meet the requirements of \textit{RandomAccessIterator} and \((\text{last1} - \text{first1}) \neq (\text{last2} - \text{first2})\) then no applications of \text{operator}== are made.
Note: The two ranges are considered mismatch if, for every iterator i in the range \([\text{first1}, \text{last1})\), \(*i\) mismatches \(*\text{(first2} + (i - \text{first1}))\). This overload of mismatch uses \(\text{operator==}\) to determine if two elements are mismatch.

Template Parameters

- **FwdIter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of mismatch requires Pred to meet the requirements of CopyConstructible. This defaults to std::equal_to<>

Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

Returns The mismatch algorithm returns a std::pair<FwdIter1,FwdIter2>. If no mismatches are found when the comparison reaches last1 or last2, whichever happens first, the pair holds the end iterator and the corresponding iterator from the other range.

**hpx/parallel/algorithms/move.hpp**

See Public API for a list of names and headers that are part of the public HPX API.

namespace hpx

## Functions

\[
\text{template<typename } \text{ExPolicy}, \text{typename FwdIter1, typename FwdIter2> hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> move(ExPolicy } \&\&\text{policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest)}
\]

Moves the elements in the range \([\text{first}, \text{last})\), to another range beginning at dest. After this operation the elements in the moved-from range will still contain valid values of the appropriate type, but not necessarily the same values as before the move. Executed according to the policy.

The move assignments in the parallel move algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The move assignments in the parallel move algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
Note: Complexity: Performs exactly last - first move assignments.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the move assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

Returns The move algorithm returns a hpx::future<FwdIter2> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter2 otherwise. The move algorithm returns the output iterator to the element in the destination range, one past the last element moved.

template<typename FwdIter1, typename FwdIter2>
FwdIter2 move(FwdIter1 first, FwdIter1 last, FwdIter2 dest)

Moves the elements in the range [first, last), to another range beginning at dest. After this operation the elements in the moved-from range will still contain valid values of the appropriate type, but not necessarily the same values as before the move.

Note: Complexity: Performs exactly last - first move assignments.

Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

Returns The move algorithm returns a FwdIter2. The move algorithm returns the output iterator to the element in the destination range, one past the last element moved.
hpx/parallel/algorithms/nth_element.hpp

See Public API for a list of names and headers that are part of the public HPX API.

namespace hpx

Functions

template<typename RandomIt, typename Pred = hpx::parallel::detail::less>
void nth_element(RandomIt first, RandomIt nth, RandomIt last, Pred &&pred = Pred())

nth_element is a partial sorting algorithm that rearranges elements in [first, last) such that the element
t point at by nth is changed to whatever element would occur in that position if [first, last) were sorted
and all of the elements before this new nth element are less than or equal to the elements after the new nth
element. Executed according to the policy.

The comparison operations in the parallel nth_element algorithm invoked without an execution policy ob-
ject execute in sequential order in the calling thread.

Note: Complexity: Linear in std::distance(first, last) on average. O(N) applications of the predicate, and
O(N log N) swaps, where N = last - first.

Template Parameters

• RandomIt – The type of the source begin, nth, and end iterators used (deduced). This
  iterator type must meet the requirements of a random access iterator.

• Pred – Comparison function object which returns true if the first argument is less than the
  second. This defaults to std::less<>.

Parameters

• first – Refers to the beginning of the sequence of elements the algorithm will be applied
to.

• nth – Refers to the iterator defining the sort partition point

• last – Refers to the end of the sequence of elements the algorithm will be applied to.

• pred – Specifies the comparison function object which returns true if the first argument
  is less than (i.e. is ordered before) the second. The signature of this comparison function
  should be equivalent to:

bool cmp(const Type1 &a, const Type2 &b);

The signature does not need to have const&, but the function must not modify the objects
passed to it. The type must be such that an object of type randomIt can be dereferenced
and then implicitly converted to Type. This defaults to std::less<>.

Returns The nth_element algorithms returns nothing.

template<typename ExPolicy, typename RandomIt, typename Pred = hpx::parallel::detail::less>
void nth_element(ExPolicy &&policy, RandomIt first, RandomIt nth, RandomIt last, Pred &&pred = Pred())

nth_element is a partial sorting algorithm that rearranges elements in [first, last) such that the element pointed at by nth is changed to whatever element would occur in that position if [first, last) were sorted and all of the elements before this new nth element are less than or equal to the elements after the new nth element.

The comparison operations in the parallel nth_element invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The assignments in the parallel nth_element algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Linear in std::distance(first, last) on average. O(N) applications of the predicate, and O(N log N) swaps, where N = last - first.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **RandomIt** – The type of the source begin, nth, and end iterators used (deduced). This iterator type must meet the requirements of a random access iterator.

- **Pred** – Comparison function object which returns true if the first argument is less than the second. This defaults to std::less<>.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **nth** – Refers to the iterator defining the sort partition point

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **pred** – Specifies the comparison function object which returns true if the first argument is less than (i.e. is ordered before) the second. The signature of this comparison function should be equivalent to:

```cpp
bool cmp(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type must be such that an object of type RandomIt can be dereferenced and then implicitly converted to Type. This defaults to std::less<>.

**Returns** The nth_element algorithms returns nothing.
namespace hpx

## Functions

```cpp
template<typename RandIter, typename Comp = hpx::parallel::detail::less>  
RandIter partial_sort(RandIter first, RandIter middle, RandIter last, Comp &&comp = Comp())
```

Places the first middle - first elements from the range [first, last) as sorted with respect to comp into the range [first, middle). The rest of the elements in the range [middle, last) are placed in an unspecified order.

**Note:** Complexity: Approximately (last - first) * log(middle - first) comparisons.

### Template Parameters

- **RandIter** – The type of the source begin, middle, and end iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Comp defaults to detail::less.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the middle of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. It defaults to detail::less.

### Returns

The `partial_sort` algorithm returns a `RandIter` that refers to `last`.

```cpp
template<typename ExPolicy, typename RandIter, typename Comp = hpx::parallel::detail::less>  
parallel::util::detail::algorithm_result_t<ExPolicy, RandIter> partial_sort(ExPolicy &&policy, RandIter first, RandIter middle, RandIter last, Comp &&comp = Comp())
```

Places the first middle - first elements from the range [first, last) as sorted with respect to comp into the range [first, middle). The rest of the elements in the range [middle, last) are placed in an unspecified order.

**Note:** Complexity: Approximately (last - first) * log(middle - first) comparisons.

### Template Parameters
• **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

• **RandIter** – The type of the source begin, middle, and end iterators used (deduced). This iterator type must meet the requirements of a random access iterator.

• **Comp** – The type of the function/function object to use (deduced). Comp defaults to detail::less.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the middle of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. It defaults to detail::less.

### Returns
The `partial_sort` algorithm returns a `hpx::future<RandIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `RandIter` otherwise. The iterator returned refers to `last`.

### hpx/parallel/algorithms/partial_sort_copy.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

```cpp
namespace hpx

# Functions

template<typename InIter, typename RandIter, typename Comp = hpx::parallel::detail::less>
RandIter partial_sort_copy(InIter first, InIter last, RandIter d_first, RandIter d_last, Comp &&comp = Comp())
```

Sorts some of the elements in the range [first, last) in ascending order, storing the result in the range [d_first, d_last). At most d_last - d_first of the elements are placed sorted to the range [d_first, d_first + n) where n is the number of elements to sort (n = min(last - first, d_last - d_first)).

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
**Note:** Complexity: \( O(N \log(\min(D,N))) \), where \( N = \text{std::distance(first, last)} \) and \( D = \text{std::distance(d_first, d_last)} \) comparisons.

**Template Parameters**

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.

- **RandIter** – The type of the destination iterators used (deduced). This iterator type must meet the requirements of an random iterator.

- **Comp** – The type of the function/function object to use (deduced). Comp defaults to detail::less.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **d_first** – Refers to the beginning of the destination range.

- **d_last** – Refers to the end of the destination range.

- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. This defaults to detail::less.

**Returns** The `partial_sort_copy` algorithm returns a `RandomIt`. The algorithm returns an iterator to the element defining the upper boundary of the sorted range i.e. \( d\_first + \min(last - first, d\_last - d\_first) \)

```
template<typename ExPolicy, typename FwdIter, typename RandIter, typename Comp = hpx::parallel::detail::less>
parallel::util::detail::algorithm_result_t<ExPolicy, RandIter> partial_sort_copy(ExPolicy &&policy,
FwdIter first, FwdIter last, RandIter d_first,
RandIter d_last, Comp &&comp = Comp())
```

Sorts some of the elements in the range \([\text{first}, \text{last})\) in ascending order, storing the result in the range \([d\_first, d\_last)\). At most \( d\_last - d\_first \) of the elements are placed sorted to the range \([d\_first, d\_first + n)\) where \( n \) is the number of elements to sort \( (n = \min(last - first, d\_last - d\_first)) \). Executed according to the policy.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: \( O(N \log(\min(D,N))) \), where \( N = \text{std::distance(first, last)} \) and \( D = \text{std::distance(d_first, d_last)} \) comparisons.
Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

- **RandIter** – The type of the destination iterators used (deduced). This iterator type must meet the requirements of an random iterator.

- **Comp** – The type of the function/function object to use (deduced). Comp defaults to detail::less.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **d_first** – Refers to the beginning of the destination range.

- **d_last** – Refers to the end of the destination range.

- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. This defaults to detail::less.

**Returns** The partial_sort_copy algorithm returns a hpx::future<RandomIt> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns RandomIt otherwise. The algorithm returns an iterator to the element defining the upper boundary of the sorted range i.e. d_first + min(last - first, d_last - d_first)

See Public API for a list of names and headers that are part of the public HPX API.

namespace hpx

**Functions**

template<typename FwdIter, typename Pred, typename Proj = hpx::identity>
FwdIter partition(FwdIter first, FwdIter last, Pred &&pred, Proj &&proj = Proj())

Reorders the elements in the range [first, last) in such a way that all elements for which the predicate pred returns true precede the elements for which the predicate pred returns false. Relative order of the elements is not preserved.

The assignments in the parallel partition algorithm invoked without an execution policy object execute in sequential order in the calling thread.
Note: Complexity: At most 2 * (last - first) swaps. Exactly last - first applications of the predicate and projection.

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `partition` requires `Pred` to meet the requirements of `Copy-Constructible`.

- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

  ```cpp
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Returns The `partition` algorithm returns returns `FwdIter`. The `partition` algorithm returns the iterator to the first element of the second group.

```cpp
template<typename ExPolicy, typename FwdIter, typename Pred, typename Proj = hpx::identity>
parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> partition(ExPolicy &&policy, FwdIter first, FwdIter last, Pred &&pred, Proj &&proj = Proj())
```

Reorders the elements in the range [first, last) in such a way that all elements for which the predicate `pred` returns true precede the elements for which the predicate `pred` returns false. Relative order of the elements is not preserved.

The assignments in the parallel `partition` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `partition` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: At most 2 * (last - first) swaps. Exactly last - first applications of the predicate and projection.
Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `partition` requires `Pred` to meet the requirements of `CopyConstructible`.

- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

  ```cpp
  bool pred(const Type &a);
  ```

  The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Returns The `partition` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `parallel_task_policy` and returns `FwdIter` otherwise. The `partition` algorithm returns the iterator to the first element of the second group.

```cpp
template<typename BidirIter, typename F, typename Proj = hpx::identity>
BidirIter stable_partition(BidirIter first, BidirIter last, F &&f, Proj &&proj = Proj())
```

Permutes the elements in the range `[first, last)` such that there exists an iterator `i` such that for every iterator `j` in the range `[first, i)` `INVOKE(f, INVOKE(proj, *j)) != false`, and for every iterator `k` in the range `[i, last)`, `INVOKE(f, INVOKE(proj, *k)) == false`.

The invocations of `f` in the parallel `stable_partition` algorithm invoked without an execution policy object executes in sequential order in the calling thread.

**Note:** Complexity: At most `(last - first) * log(last - first)` swaps, but only linear number of swaps if there is enough extra memory. Exactly `last - first` applications of the predicate and projection.

Template Parameters

- **BidirIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.
• **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `transform` requires `F` to meet the requirements of `CopyConstructible`.

• **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**

• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

• **f** – Unary predicate which returns true if the element should be ordered before other elements. Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. The signature of this predicate should be equivalent to:

```cpp
bool fun(const Type &a);
```

The signature does not need to have `const&`. The type `Type` must be such that an object of type `BidirIter` can be dereferenced and then implicitly converted to `Type`.

• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate `f` is invoked.

**Returns** The `stable_partition` algorithm returns an iterator `i` such that for every iterator `j` in the range `[first, i)`, `INVOKE(f, INVOKE(proj, *j)) != false`, and for every iterator `k` in the range `[i, last)`, `INVOKE(f, INVOKE(proj, *k)) == false`. The relative order of the elements in both groups is preserved.

```cpp
template<typename ExPolicy, typename BidirIter, typename F, typename Proj = hpx::identity>
parallel::util::detail::algorithm_result_t<ExPolicy, BidirIter> stable_partition(ExPolicy &&policy,
BidirIter first, BidirIter last, F &&f, Proj &&proj = Proj())
```

Permuting the elements in the range `[first, last)` such that there exists an iterator `i` such that for every iterator `j` in the range `[first, i)` `INVOKE(f, INVOKE(proj, *j)) != false`, and for every iterator `k` in the range `[i, last)`, `INVOKE(f, INVOKE(proj, *k)) == false`

The invocations of `f` in the parallel `stable_partition` algorithm invoked with an execution policy object of type `sequenced_policy` executes in sequential order in the calling thread.

The invocations of `f` in the parallel `stable_partition` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most `(last - first) * \log(last - first)` swaps, but only linear number of swaps if there is enough extra memory. Exactly `last - first` applications of the predicate and projection.

**Template Parameters**

• **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of `f`.
• **BidirIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.

• **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `transform` requires `F` to meet the requirements of `CopyConstructible`.

• **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**

• **policy** – The execution policy to use for the scheduling of the iterations.

• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

• **f** – Unary predicate which returns true if the element should be ordered before other elements. Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. The signature of this predicate should be equivalent to:

  ```cpp
  bool fun(const Type &a);
  ```

  The signature does not need to have `const&`. The type `Type` must be such that an object of type `BidirIter` can be dereferenced and then implicitly converted to `Type`.

• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate `f` is invoked.

**Returns** The `stable_partition` algorithm returns an iterator `i` such that for every iterator `j` in the range `[first, i)`, `f(*j) != false` `INVOKE(f, INVOKE(proj, *j)) != false`, and for every iterator `k` in the range `[i, last)`, `f(*k) == false` `INVOKE(f, INVOKE (proj, *k)) == false`. The relative order of the elements in both groups is preserved. If the execution policy is of type `parallel_task_policy` the algorithm returns a `future<>` referring to this iterator.

```cpp
template<typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred, typename Proj = hpx::identity>
std::pair<FwdIter2, FwdIter3> partition_copy(FwdIter1 first, FwdIter1 last, FwdIter2 dest_true, FwdIter3 dest_false, Pred &&pred, Proj &&proj = Proj())
```

Copies the elements in the range, defined by `[first, last)`, to two different ranges depending on the value returned by the predicate `pred`. The elements, that satisfy the predicate `pred` are copied to the range beginning at `dest_true`. The rest of the elements are copied to the range beginning at `dest_false`. The order of the elements is preserved.

The assignments in the parallel `partition_copy` algorithm invoked without an execution policy object execute in sequential order in the calling thread.

**Note:** Complexity: Performs not more than `last - first` assignments, exactly `last - first` applications of the predicate `pred`.

**Template Parameters**

• **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
• **FwdIter2** – The type of the iterator representing the destination range for the elements that satisfy the predicate `pred` (deduced). This iterator type must meet the requirements of an forward iterator.

• **FwdIter3** – The type of the iterator representing the destination range for the elements that don’t satisfy the predicate `pred` (deduced). This iterator type must meet the requirements of an forward iterator.

• **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `partition_copy` requires `Pred` to meet the requirements of `CopyConstructible`.

• **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**

• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

• **dest_true** – Refers to the beginning of the destination range for the elements that satisfy the predicate `pred`.

• **dest_false** – Refers to the beginning of the destination range for the elements that don’t satisfy the predicate `pred`.

• **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`.

• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate `is` invoked.

**Returns** The `partition_copy` algorithm returns `std::pair<OutIter1, OutIter2>` . The `partition_copy` algorithm returns the pair of the destination iterator to the end of the `dest_true` range, and the destination iterator to the end of the `dest_false` range.

template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred, typename Proj = hpx::identity>
Copies the elements in the range, defined by [first, last), to two different ranges depending on the value returned by the predicate `pred`. The elements that satisfy the predicate `pred` are copied to the range beginning at `dest_true`. The rest of the elements are copied to the range beginning at `dest_false`. The order of the elements is preserved.

The assignments in the parallel `partition_copy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `partition_copy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs not more than `last - first` assignments, exactly `last - first` applications of the predicate `pred`.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

- **FwdIter2** – The type of the iterator representing the destination range for the elements that satisfy the predicate `pred` (deduced). This iterator type must meet the requirements of an forward iterator.

- **FwdIter3** – The type of the iterator representing the destination range for the elements that don’t satisfy the predicate `pred` (deduced). This iterator type must meet the requirements of an forward iterator.

- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `partition_copy` requires `Pred` to meet the requirements of `CopyConstructible`.

- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`
Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest_true** – Refers to the beginning of the destination range for the elements that satisfy the predicate **pred**
- **dest_false** – Refers to the beginning of the destination range for the elements that don’t satisfy the predicate **pred**.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Returns

The **partition_copy** algorithm returns a `hpx::future<std::pair<OutIter1, OutIter2>>` if the execution policy is of type `parallel_task_policy` and returns `std::pair<OutIter1, OutIter2>` otherwise. The **partition_copy** algorithm returns the pair of the destination iterator to the end of the **dest_true** range, and the destination iterator to the end of the **dest_false** range.

### hpx/parallel/algorithms/reduce.hpp

See **Public API** for a list of names and headers that are part of the public **HPX** API.

namespace **hpx**

### Functions

```
template<typename ExPolicy, typename FwdIter, typename F, typename T = typename std::iterator_traits<FwdIter>::value_type>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, T> reduce(ExPolicy &&policy, FwdIter first, FwdIter last, T init, F &&f)
```

Returns **GENERALIZED_SUM(f, init, *first, ..., *(first + (last - first) - 1))**. Executed according to the policy.

The reduce operations in the parallel **reduce** algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The reduce operations in the parallel **copy_if** algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

2.8. API reference 439
The difference between `reduce` and `accumulate` is that the behavior of `reduce` may be non-deterministic for non-associative or non-commutative binary predicate.

**Note:** Complexity: $O(|last - first|)$ applications of the predicate $f$.

**Note:** `GENERALIZED_SUM(op, a1, ..., aN)` is defined as follows:
- $a1$ when $N$ is 1
- $op(GENERALIZED_SUM(op, b1, ..., bK), GENERALIZED_SUM(op, bM, ..., bN))$, where:
  - $b1, ..., bN$ may be any permutation of $a1, ..., aN$ and
  - $1 < K+1 = M <= N$.

Template Parameters
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `reduce` requires $F$ to meet the requirements of `CopyConstructible`.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is a binary predicate. The signature of this predicate should be equivalent to:

  ```cpp
  Ret fun(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have `const&`. The types `Type1 Ret` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to any of those types.

**Returns** The `reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns $T$ otherwise. The `reduce` algorithm returns the result of the generalized sum over the elements given by the input range `[first, last)`.

```cpp
template<typename ExPolicy, typename FwdIter, typename T = typename std::iterator_traits<FwdIter>::value_type>
```
util::detail::algorithm_result_t<ExPolicy, T> reduce(ExPolicy &&policy, FwdIter first, FwdIter last, T init)

Returns GENERALIZED_SUM(+, init, *first, ..., *(first + (last - first) - 1)). Executed according to the policy.

The reduce operations in the parallel reduce algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The reduce operations in the parallel copy_if algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between reduce and accumulate is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

**Note:** Complexity: O(last - first) applications of the operator+().

**Note:** GENERALIZED_SUM(+, a1, ..., aN) is defined as follows:
- a1 when N is 1
- op(GENERALIZED_SUM(+, b1, ..., bK), GENERALIZED_SUM(+, bM, ..., bN)), where:
  - b1, ..., bN may be any permutation of a1, ..., aN and
  - 1 < K+1 = M <= N.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.

**Returns** The reduce algorithm returns a `hpx::future<T>` if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns `T` otherwise. The reduce algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

```
template<
    typename ExPolicy,
    typename FwdIter
>
```
HPX Documentation, master

```cpp
hpx::parallel::util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<FwdIter>::value_type>::type reduce(ExPolicy &&policy, FwdIter first, FwdIter last)
```

Returns GENERALIZED_SUM(+, T(), *first, ..., *(first + (last - first) - 1)). Executed according to the policy.

The reduce operations in the parallel `reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The reduce operations in the parallel `reduce` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `reduce` and `accumulate` is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

**Note:** Complexity: $O(last - first)$ applications of the operator $+()$.

**Note:** The type of the initial value (and the result type) $T$ is determined from the value_type of the used `FwdIter`.

**Note:** GENERALIZED_SUM(+, a1, ..., aN) is defined as follows:

- $a1$ when $N$ is 1
- $op(GENERALIZED_SUM(+, b1, ..., bK), GENERALIZED_SUM(+, bM, ..., bN))$, where:
  - $b1, ..., bN$ may be any permutation of $a1, ..., aN$ and
  - $1 < K+1 = M <= N$.

**Template Parameters**

- `ExPolicy` – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter` – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

**Parameters**

- `policy` – The execution policy to use for the scheduling of the iterations.
- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements the algorithm will be applied to.
Returns

The `reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `T` otherwise (where `T` is the value_type of `FwdIter`). The `reduce` algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range `[first, last)`.

Template Parameters

- `FwdIter` – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- `F` – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `reduce` requires `F` to meet the requirements of `CopyConstructible`.
- `T` – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements the algorithm will be applied to.
- `init` – The initial value for the generalized sum.
- `f` – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`. The types `Type1 Ret` must be such that an object of type `InIter` can be dereferenced and then implicitly converted to any of those types.

Returns

The `reduce` algorithm returns `T`. The `reduce` algorithm returns the result of the generalized sum over the elements given by the input range `[first, last)`.

The difference between `reduce` and `accumulate` is that the behavior of `reduce` may be non-deterministic for non-associative or non-commutative binary predicate.

Note: Complexity: \(O(last - first)\) applications of the predicate \(f\).
template<typename FwdIter, typename T = typename std::iterator_traits<FwdIter>::value_type>
T reduce(FwdIter first, FwdIter last, T init)

Returns GENERALIZED_SUM(+, init, *first, …, *(first + (last - first) - 1)). Executed according to the policy.

The difference between reduce and accumulate is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note: Complexity: \(O(last - first)\) applications of the operator+().

Note: GENERALIZED_SUM(+, a1, …, aN) is defined as follows:
- \(a1\) when \(N\) is 1
- \(\text{op}(\text{GENERALIZED_SUM}(+, b1, …, bK), \text{GENERALIZED_SUM}(+, bM, …, bN))\), where:
  - \(b1, …, bN\) may be any permutation of \(a1, …, aN\) and
  - \(1 < K+1 = M \leq N\).

Template Parameters
- **FwdIter** – The type of the source begin and end iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **init** – The initial value for the generalized sum.

Returns The reduce algorithm returns a \(T\). The reduce algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range \([first, last)\).

template<typename FwdIter>
std::iterator_traits<FwdIter>::value_type reduce(FwdIter first, FwdIter last)

Returns GENERALIZED_SUM(+, T(), *first, …, *(first + (last - first) - 1)). Executed according to the policy.

The difference between reduce and accumulate is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note: Complexity: \(O(last - first)\) applications of the operator+().

Note: The type of the initial value (and the result type) \(T\) is determined from the value_type of the used FwdIter.
Note: GENERALIZED\_SUM(+, a_1, ..., a_N) is defined as follows:

- a_1 when N is 1
- op(GENERALIZED\_SUM(+, b_1, ..., b_K), GENERALIZED\_SUM(+, b_M, ..., b_N)), where:
  - b_1, ..., b_N may be any permutation of a_1, ..., a_N and
  - 1 < K+1 = M <= N.

Template Parameters **FwdIter** – The type of the source begin and end iterators used (deduced).
This iterator type must meet the requirements of an input iterator.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns The `reduce` algorithm returns `T` (where `T` is the value_type of `FwdIter`). The `reduce` algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range `[first, last)`.

**hpx/parallel/algorithms/reduce_by_key.hpp**

See **Public API** for a list of names and headers that are part of the public **HPX** API.

namespace **hpx**

namespace **experimental**

Top-level namespace.

**Functions**

template<typename ExPolicy, typename RanIter, typename RanIter2, typename FwdIter1,
typename FwdIter2, typename Compare = std::equal_to<typename
std::iterator_traits<RanIter>::value_type>, typename Func = std::plus<typename
std::iterator_traits<RanIter2>::value_type>>
Reduce by Key performs an inclusive scan reduction operation on elements supplied in key/value pairs. The algorithm produces a single output value for each set of equal consecutive keys in \([\text{key\_first, key\_last})\), the value being the \text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(\text{op, init, *first, \ldots, *(first + (i - result)))}. for the run of consecutive matching keys. The number of keys supplied must match the number of values.

\(comp\) has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type \text{sequenced\_policy} execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type \text{parallel\_policy} or \text{parallel\_task\_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: \(O(\text{last} - \text{first})\) applications of the predicate \(\text{op}\).

**Template Parameters**

- \text{ExPolicy} – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- \text{RanIter} – The type of the key iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- \text{RanIter2} – The type of the value iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- \text{FwdIter1} – The type of the iterator representing the destination key range (deduced).
- \text{FwdIter2} – The type of the iterator representing the destination value range (deduced).
This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the iterator representing the destination value range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Compare** – The type of the optional function/function object to use to compare keys (deduced). Assumed to be std::equal_to otherwise.
- **Func** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `reduce_by_key` requires `Func` to meet the requirements of `CopyConstructible`.

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **key_first** – Refers to the beginning of the sequence of key elements the algorithm will be applied to.
- **key_last** – Refers to the end of the sequence of key elements the algorithm will be applied to.
- **values_first** – Refers to the beginning of the sequence of value elements the algorithm will be applied to.
- **keys_output** – Refers to the start output location for the keys produced by the algorithm.
- **values_output** – Refers to the start output location for the values produced by the algorithm.
- **comp** – `comp` is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator.
- **func** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature of this predicate should be equivalent to:

```cpp
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`. The types `Type1 Ret` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to any of those types.

**Returns** The `reduce_by_key` algorithm returns a `hpx::future<pair<Iter1,Iter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `pair<Iter1,Iter2>` otherwise.

### `hpx/parallel/algorithms/remove.hpp`

See Public API for a list of names and headers that are part of the public HPX API.

### namespace hpx

#### Functions

```cpp
template<typename FwdIter, typename T = typename std::iterator_traits<FwdIter>::value_type>
FwdIter remove(FwdIter first, FwdIter last, T const &value)
```

Removes all elements satisfying specific criteria from the range [first, last) and returns a past-the-end iterator for the new end of the range. This version removes all elements that are equal to `value`.

The assignments in the parallel `remove` algorithm execute in sequential order in the calling thread.
Note: Complexity: Performs not more than last - first assignments, exactly last - first applications of the operator==().

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to remove (deduced). This value type must meet the requirements of CopyConstructible.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – Specifies the value of elements to remove.

Returns The remove algorithm returns a FwdIter. The remove algorithm returns the iterator to the new end of the range.

template<typename ExPolicy, typename FwdIter, typename T = typename std::iterator_traits<FwdIter>::value_type>

hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> remove(ExPolicy &&policy, FwdIter first, FwdIter last, T const &value)

Removes all elements satisfying specific criteria from the range [first, last) and returns a past-the-end iterator for the new end of the range. This version removes all elements that are equal to value. Executed according to the policy.

The assignments in the parallel remove algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The assignments in the parallel remove algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: Performs not more than last - first assignments, exactly last - first applications of the operator==().

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to remove (deduced). This value type must meet the requirements of CopyConstructible.
• **policy** – The execution policy to use for the scheduling of the iterations.
• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
• **value** – Specifies the value of elements to remove.

**Returns** The *remove* algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The *remove* algorithm returns the iterator to the new end of the range.

```cpp
template<typename FwdIter, typename Pred>
FwdIter remove_if(FwdIter first, FwdIter last, Pred &&pred)
```

Removes all elements satisfying specific criteria from the range `[first, last)` and returns a past-the-end iterator for the new end of the range. This version removes all elements for which predicate `pred` returns true.

The assignments in the parallel *remove_if* algorithm execute in sequential order in the calling thread.

**Note:** Complexity: Performs not more than `last - first` assignments, exactly `last - first` applications of the predicate `pred`.

**Template Parameters**

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *remove_if* requires `Pred` to meet the requirements of Copy-Constructible.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

**Returns** The *remove_if* algorithm returns a `FwdIter`. The *remove_if* algorithm returns the iterator to the new end of the range.

```cpp
template<typename ExPolicy, typename FwdIter, typename Pred>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> remove_if(ExPolicy &&policy, FwdIter first, FwdIter last, Pred &&pred)
```
Removes all elements satisfying specific criteria from the range \([\text{first}, \text{last})\) and returns a past-the-end iterator for the new end of the range. This version removes all elements for which predicate \(\text{pred}\) returns true. Executed according to the policy.

The assignments in the parallel `remove_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `remove_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs not more than \(\text{last} - \text{first}\) assignments, exactly \(\text{last} - \text{first}\) applications of the predicate \(\text{pred}\).

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `remove_if` requires \(\text{Pred}\) to meet the requirements of `CopyConstructible`.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\). This is an unary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type \(\text{Type}\) must be such that an object of type \(\text{FwdIter}\) can be dereferenced and then implicitly converted to \(\text{Type}\).

**Returns** The `remove_if` algorithm returns a `hpx::future<\text{FwdIter}>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns \(\text{FwdIter}\) otherwise. The `remove_if` algorithm returns the iterator to the new end of the range.
namespace hpx

Functions

template<typename InIter, typename OutIter, typename T = typename std::iterator_traits<InIter>::value_type>
OutIter remove_copy(InIter first, InIter last, OutIter dest, T const &value)

Copies the elements in the range, defined by [first, last), to another range beginning at dest. Copies only the elements for which the comparison operator returns false when compare to value. The order of the elements that are not removed is preserved.

Effects: Copies all the elements referred to by the iterator it in the range [first,last) for which the following corresponding conditions do not hold: *it == value

The assignments in the parallel remove_copy algorithm execute in sequential order in the calling thread.

Note: Complexity: Performs not more than last - first assignments, exactly last - first applications of the predicate pred, here comparison operator.

Template Parameters
- InIter – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- OutIter – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- T – The type that the result of dereferencing FwdIter1 is compared to.

Parameters
- first – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last – Refers to the end of the sequence of elements the algorithm will be applied to.
- dest – Refers to the beginning of the destination range.
- value – Value to be removed.

Returns The remove_copy algorithm returns an OutIter. The remove_copy algorithm returns the iterator to the element past the last element copied.
Copies the elements in the range, defined by \([\text{first}, \text{last})\), to another range beginning at \(\text{dest}\). Copies only the elements for which the comparison operator returns false when compare to value. The order of the elements that are not removed is preserved. Executed according to the policy.

**Effects:** Copies all the elements referred to by the iterator \(\text{it}\) in the range \([\text{first},\text{last})\) for which the following corresponding conditions do not hold: \(*\text{it} == \text{value}\)

The assignments in the parallel `remove_copy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `remove_copy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs not more than \(\text{last} - \text{first}\) assignments, exactly \(\text{last} - \text{first}\) applications of the predicate \(\text{pred}\), here comparison operator.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type that the result of dereferencing \(\text{FwdIter1}\) is compared to.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **value** – Value to be removed.

**Returns** The `remove_copy` algorithm returns a `hpx::future<\text{FwdIter2}>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns \(\text{FwdIter2}\) otherwise. The `remove_copy` algorithm returns the iterator to the element past the last element copied.

```
template<typename InIter, typename OutIter, typename Pred>
OutIter remove_copy_if(InIter first, InIter last, OutIter dest, Pred &&pred)
```

Copies the elements in the range, defined by \([\text{first}, \text{last})\), to another range beginning at \(\text{dest}\). Copies only the elements for which the predicate \(\text{pred}\) returns false. The order of the elements that are not removed is preserved.

**Effects:** Copies all the elements referred to by the iterator \(\text{it}\) in the range \([\text{first},\text{last})\) for which the following corresponding conditions do not hold: `INVOKE(p...true) != false`.
The assignments in the parallel `remove_copy_if` algorithm execute in sequential order in the calling thread.

**Note:** Complexity: Performs not more than `last - first` assignments, exactly `last - first` applications of the predicate `pred`.

**Template Parameters**
- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of the function/function object to use (deduced).

**Parameters**
- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements the algorithm will be applied to.
- `dest` – Refers to the beginning of the destination range.
- `pred` – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the elements to be removed. The signature of this predicate should be equivalent to:

  ```cpp
  bool pred(const Type &a);
  ```

  The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `InIter` can be dereferenced and then implicitly converted to `Type`.

**Returns** The `remove_copy_if` algorithm returns an `OutIter`. The `remove_copy_if` algorithm returns the iterator to the element past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> remove_copy_if(ExPolicy &&policy,
  FwdIter1 first,
  FwdIter1 last,
  FwdIter2 dest,
  Pred &&pred)
```

Copies the elements in the range, defined by `[first, last)`, to another range beginning at `dest`. Copies only the elements for which the predicate `pred` returns false. The order of the elements that are not removed is preserved. Executed according to the policy.

Effects: Copies all the elements referred to by the iterator `it` in the range `[first,last)` for which the following corresponding conditions do not hold: `INVOKE(pred, *it) != false`.

The assignments in the parallel `remove_copy_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `remove_copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
**Note:** Complexity: Performs not more than *last - first* assignments, exactly *last - first* applications of the predicate *pred*.

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *remove_copy_if* requires *Pred* to meet the requirements of *CopyConstructible*.

---

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by *first, last*. This is an unary predicate which returns *true* for the elements to be removed. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type *Type* must be such that an object of type *FwdIter1* can be dereferenced and then implicitly converted to *Type*.

**Returns** The *remove_copy_if* algorithm returns a *hpx::future<FwdIter2>* if the execution policy is of type *sequenced_task_policy* or *parallel_task_policy* and returns *FwdIter2* otherwise. The *remove_copy_if* algorithm returns the iterator to the element past the last element copied.

---

**hpx/parallel/algorithms/replace.hpp**

See *Public API* for a list of names and headers that are part of the public *HPX API*.

namespace *hpx*
Functions

template<
  typename InIter,
  typename T = typename std::iterator_traits<InIter>::value_type
>
void replace(InIter first, InIter last, T const &old_value, T const &new_value)

Replaces all elements satisfying specific criteria with new_value in the range [first, last).

Effects: Substitutes elements referred by the iterator it in the range [first, last) with new_value, when the
following corresponding conditions hold: *it == old_value

The assignments in the parallel replace algorithm execute in sequential order in the calling thread.

Note: Complexity: Performs exactly last - first assignments.

Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the
  requirements of an input iterator.
- **T** – The type of the old and new values to replace (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **old_value** – Refers to the old value of the elements to replace.
- **new_value** – Refers to the new value to use as the replacement.

Returns The replace algorithm returns a void.

template<
  typename ExPolicy,
  typename FwdIter,
  typename T = typename std::iterator_traits<FwdIter>::value_type
>
hp::parallel::util::detail::algorithm_result_t<ExPolicy, void> replace(ExPolicy &&policy, FwdIter first,
  FwdIter last, T const &old_value, T const &new_value)

Replaces all elements satisfying specific criteria with new_value in the range [first, last). Executed according to the policy.

Effects: Substitutes elements referred by the iterator it in the range [first, last) with new_value, when the
following corresponding conditions hold: *it == old_value

The assignments in the parallel replace algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The assignments in the parallel replace algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: Performs exactly last - first assignments.

Template Parameters
• **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

• **T** – The type of the old and new values to replace (deduced).

### Parameters

• **policy** – The execution policy to use for the scheduling of the iterations.

• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

• **old_value** – Refers to the old value of the elements to replace.

• **new_value** – Refers to the new value to use as the replacement.

### Returns

The replace algorithm returns a `hpx::future<void>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `void` otherwise.

```cpp
template<typename Iter, typename Pred, typename T = typename std::iterator_traits<Iter>::value_type>
void replace_if(Iter first, Iter last, Pred &&pred, T const &new_value)
```

Replaces all elements satisfying specific criteria (for which predicate `pred` returns true) with `new_value` in the range `[first, last).

Effects: Substitutes elements referred by the iterator it in the range [first, last) with new_value, when the following corresponding conditions hold: `INVOKE(f, *it) != false`

The assignments in the parallel `replace_if` algorithm execute in sequential order in the calling thread.

**Note:** Complexity: Performs exactly `last - first` applications of the predicate.

### Template Parameters

• **Iter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.

• **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible` (deduced).

• **T** – The type of the new values to replace (deduced).

### Parameters

• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

• **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the elements which need to replaced. The signature of this predicate should be equivalent to:
```cpp
bool pred(const Type &a);
```

The signature does not need to have &const, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `InIter` can be dereferenced and then implicitly converted to `Type`.

- **new_value** – Refers to the new value to use as the replacement.

**Returns** The `replace_if` algorithm returns `void`.

```cpp
template<typename ExPolicy, typename FwdIter, typename Pred, typename T = typename std::iterator_traits<FwdIter>::value_type>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, void> replace_if(ExPolicy &&policy, FwdIter first, FwdIter last, Pred &&pred, T const &new_value)
```

Replaces all elements satisfying specific criteria (for which predicate `f` returns true) with `new_value` in the range `[first, last)`. Executed according to the policy.

**Effects**: Substitutes elements referred by the iterator `it` in the range `[first, last)` with `new_value`, when the following corresponding conditions hold: `INVOKE(f, *it) != false`

The assignments in the parallel `replace_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `replace_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note**: Complexity: Performs exactly `last - first` applications of the predicate.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible` (deduced).

- **T** – The type of the new values to replace (deduced).

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last). This is an unary predicate which returns
true for the elements which need to replaced. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to Type.

- **new_value** – Refers to the new value to use as the replacement.

**Returns** The `replace_if` algorithm returns a `hpx::future<void>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `void` otherwise.

```cpp
template<typename InIter, typename OutIter, typename T = typename std::iterator_traits<OutIter>::value_type>
OutIter replace_copy(InIter first, InIter last, OutIter dest, T const &old_value, T const &new_value)
```

Copies the all elements from the range `[first, last)` to another range beginning at `dest` replacing all elements satisfying a specific criteria with `new_value`.

Effects: Assigns to every iterator `it` in the range `[result, result + (last - first))` either `new_value` or `*(first + (it - result))` depending on whether the following corresponding condition holds: `*(first + (i - result)) == old_value`

The assignments in the parallel `replace_copy` algorithm execute in sequential order in the calling thread.

**Note:** Complexity: Performs exactly `last - first` applications of the predicate.

**Template Parameters**

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **T** – The type of the old and new values (deduced).

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **old_value** – Refers to the old value of the elements to replace.
- **new_value** – Refers to the new value to use as the replacement.

**Returns** The `replace_copy` algorithm returns an `OutIter` The `replace_copy` algorithm returns the iterator to the element past the last element copied.
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> replace_copy(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest, T const &old_value, T const &new_value)

Copies the all elements from the range [first, last) to another range beginning at dest replacing all elements satisfying a specific criteria with new_value. Executed according to the policy.

Effects: Assigns to every iterator it in the range [result, result + (last - first)) either new_value or *(first + (it - result)) depending on whether the following corresponding condition holds: *(first + (i - result)) == old_value

The assignments in the parallel replace_copy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The assignments in the parallel replace_copy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: Performs exactly last - first applications of the predicate.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the old and new values (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **old_value** – Refers to the old value of the elements to replace.
- **new_value** – Refers to the new value to use as the replacement.

Returns The replace_copy algorithm returns a hpx::future<FwdIter2> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter2 otherwise. The replace_copy algorithm returns the Iterator to the element past the last element copied.
**OutIter** `replace_copy_if(InIter first, InIter last, OutIter dest, Pred &&pred, T const &new_value)`

Copies the all elements from the range `[first, last)` to another range beginning at `dest` replacing all elements satisfying a specific criteria with `new_value`.

Effects: Assigns to every iterator `it` in the range `[result, result + (last - first))` either `new_value` or `*(first + (it - result))` depending on whether the following corresponding condition holds: `INVOKE(f, *(first + (i - result)))` != false

The assignments in the parallel `replace_copy_if` algorithm execute in sequential order in the calling thread.

**Note:** Complexity: Performs exactly `last - first` applications of the predicate.

**Template Parameters**

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible` (deduced).
- **T** – The type of the new values to replace (deduced).

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the elements which need to replaced. The signature of this predicate should be equivalent to:

  ```cpp
  bool pred(const Type &a);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `InIter` can be dereferenced and then implicitly converted to `Type`.
- **new_value** – Refers to the new value to use as the replacement.

**Returns** The `replace_copy_if` algorithm returns an `OutIter`. The `replace_copy_if` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred, typename T = typename std::iterator_traits<FwdIter2>::value_type>
```
Copies all elements from the range [first, last) to another range beginning at dest replacing all elements satisfying a specific criteria with new_value.

Effects: Assigns to every iterator it in the range [result, result + (last - first)) either new_value or *(first + (it - result)) depending on whether the following corresponding condition holds: INVOKE(f, *(first + (i - result))) != false

The assignments in the parallel replace_copy_if algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The assignments in the parallel replace_copy_if algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: Performs exactly last - first applications of the predicate.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of replace_copy_if requires Pred to meet the requirements of CopyConstructible. (deduced).

- **T** – The type of the new values to replace (deduced).

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **dest** – Refers to the beginning of the destination range.

- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns true for the elements which need to replaced. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```
The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type FwdIter1 can be dereferenced and then implicitly converted to Type.

- new_value – Refers to the new value to use as the replacement.

Returns The replace_copy_if algorithm returns a hpx::future<FwdIter2> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter2 otherwise. The replace_copy_if algorithm returns the iterator to the element in the destination range, one past the last element copied.

See Public API for a list of names and headers that are part of the public HPX API.

namespace hpx

Functions

template<typename BidirIter>
void reverse(BidirIter first, BidirIter last)

Reverses the order of the elements in the range [first, last).Behaves as if applying std::iter_swap to every pair of iterators first+i, (last-i) - 1 for each non-negative i < (last-first)/2.

The assignments in the parallel reverse algorithm execute in sequential order in the calling thread.

Note: Complexity: Linear in the distance between first and last.

Template Parameters BidirIter – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.

Parameters

- first – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns The reverse algorithm returns void.

template<typename ExPolicy, typename BidirIter>

hpx::parallel::util::detail::algorithm_result_t<ExPolicy, void> reverse(ExPolicy &&policy, BidirIter first, BidirIter last)

Reverses the order of the elements in the range [first, last).Behaves as if applying std::iter_swap to every pair of iterators first+i, (last-i) - 1 for each non-negative i < (last-first)/2. Executed according to the policy.

The assignments in the parallel reverse algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.
The assignments in the parallel reverse algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Linear in the distance between first and last.

### Template Parameters
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **BidirIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.

### Parameters
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

### Returns
The reverse algorithm returns a hpx::future<void> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns void otherwise.

```
template<typename BidirIter, typename OutIter>
OutIter reverse_copy(BidirIter first, BidirIter last, OutIter dest)
```

Copies the elements from the range [first, last) to another range beginning at dest in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment *(dest + (last - first) - 1 - i) = *(first + i) once for each non-negative i < (last - first) If the source and destination ranges (that is, [first, last) and [dest, dest+(last-first)) respectively) overlap, the behavior is undefined.

The assignments in the parallel reverse_copy algorithm execute in sequential order in the calling thread.

**Note:** Complexity: Performs exactly last - first assignments.

### Template Parameters
- **BidirIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

### Parameters
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the begin of the destination range.

### Returns
The reverse_copy algorithm returns an OutIter. The reverse_copy algorithm returns the output iterator to the element in the destination range, one past the last element copied.
template<typename ExPolicy, typename BidirIter, typename FwdIter>

hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> reverse_copy(ExPolicy &&policy, 
BidirIter first, BidirIter last, FwdIter dest)

Copies the elements from the range [first, last) to another range beginning at dest in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment *(dest + (last - first) - 1 - i) = *(first + i) once for each non-negative i < (last - first) If the source and destination ranges (that is, [first, last) and [dest, dest+(last-first)) respectively) overlap, the behavior is undefined. Executed according to the policy.

The assignments in the parallel reverse_copy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The assignments in the parallel reverse_copy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs exactly last - first assignments.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **BidirIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a bidirectional iterator.

- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **dest** – Refers to the begin of the destination range.

**Returns** The reverse_copy algorithm returns a hpx::future<FwdIter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter otherwise. The reverse_copy algorithm returns the output iterator to the element in the destination range, one past the last element copied.
namespace hpx

Functions

template<typename FwdIter>
FwdIter rotate(FwdIter first, FwdIter new_first, FwdIter last)

Performs a left rotation on a range of elements. Specifically, rotate swaps the elements in the range \([first, last)\) in such a way that the element new_first becomes the first element of the new range and new_first - 1 becomes the last element.

The assignments in the parallel rotate algorithm execute in sequential order in the calling thread.

**Note:** Complexity: Linear in the distance between first and last.

**Note:** The type of dereferenced FwdIter must meet the requirements of MoveAssignable and MoveConstructible.

**Template Parameters** FwdIter – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **new_first** – Refers to the element that should appear at the beginning of the rotated range.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The rotate algorithm returns a FwdIter. The rotate algorithm returns the iterator to the new location of the element pointed by first, equal to first + (last - new_first).

template<typename ExPolicy, typename FwdIter>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> rotate(ExPolicy &&policy, FwdIter first,
FwdIter new_first, FwdIter last)

Performs a left rotation on a range of elements. Specifically, rotate swaps the elements in the range \([first, last)\) in such a way that the element new_first becomes the first element of the new range and new_first - 1 becomes the last element. Executed according to the policy.

The assignments in the parallel rotate algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The assignments in the parallel rotate algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
Note: Complexity: Linear in the distance between first and last.

Note: The type of dereferenced FwdIter must meet the requirements of MoveAssignable and MoveConstructible.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **new_first** – Refers to the element that should appear at the beginning of the rotated range.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns: The rotate algorithm returns a hpx::future<FwdIter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter otherwise. The rotate algorithm returns the iterator equal to first + (last - new_first).

```cpp
template<typename FwdIter, typename OutIter>
OutIter rotate_copy(FwdIter first, FwdIter new_first, FwdIter last, OutIter dest_first)
```

Copies the elements from the range [first, last), to another range beginning at dest_first in such a way, that the element new_first becomes the first element of the new range and new_first - 1 becomes the last element.

The assignments in the parallel rotate_copy algorithm execute in sequential order in the calling thread.

Note: Complexity: Performs exactly last - first assignments.

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **OutIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a output iterator.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **new_first** – Refers to the element that should appear at the beginning of the rotated range.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
• \textbf{dest_first} – Refers to the begin of the destination range.

\textbf{Returns} The \textit{rotate_copy} algorithm returns a output iterator, The \textit{rotate_copy} algorithm returns the output iterator to the element past the last element copied.

template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
\begin{verbatim}
 hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> rotate_copy(ExPolicy &&policy, 
        FwdIter1 first, FwdIter1 new_first, FwdIter1 last, 
        FwdIter2 dest_first)
\end{verbatim}

Copies the elements from the range \([\text{first}, \text{last})\), to another range beginning at \text{dest_first} in such a way, that the element \text{new_first} becomes the first element of the new range and \text{new_first} - 1 becomes the last element. Executed according to the policy.

The assignments in the parallel \textit{rotate_copy} algorithm execute in sequential order in the calling thread. The assignments in the parallel \textit{rotate_copy} algorithm execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

\textbf{Note:} Complexity: Performs exactly \text{last} - \text{first} assignments.

\textbf{Template Parameters}

\begin{itemize}
  \item \textbf{ExPolicy} – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
  \item \textbf{FwdIter1} – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
  \item \textbf{FwdIter2} – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
\end{itemize}

\textbf{Parameters}

\begin{itemize}
  \item \textbf{policy} – The execution policy to use for the scheduling of the iterations.
  \item \textbf{first} – Refers to the beginning of the sequence of elements the algorithm will be applied to.
  \item \textbf{new_first} – Refers to the element that should appear at the beginning of the rotated range.
  \item \textbf{last} – Refers to the end of the sequence of elements the algorithm will be applied to.
  \item \textbf{dest_first} – Refers to the begin of the destination range.
\end{itemize}

\textbf{Returns} The \textit{rotate_copy} algorithm returns a \texttt{hpx::future<FwdIter2>} if the execution policy is of type \texttt{parallel_task_policy} and returns \texttt{FwdIter2} otherwise. The \textit{rotate_copy} algorithm returns the output iterator to the element past the last element copied.
namespace hpx

**Functions**

```cpp
template<typename FwdIter, typename FwdIter2, typename Pred = parallel::detail::equal_to>
FwdIter search(FwdIter first, FwdIter last, FwdIter2 s_first, FwdIter2 s_last, Pred &&op = Pred())
```

Searches the range `[first, last)` for any elements in the range `[s_first, s_last)`. Uses a provided predicate to compare elements.

The comparison operations in the parallel `search` algorithm execute in sequential order in the calling thread.

**Note:** Complexity: at most \((S \cdot N)\) comparisons where \(S = \text{distance}(s\_first, s\_last)\) and \(N = \text{distance}(\text{first}, \text{last})\).

**Template Parameters**

- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `search` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`

**Parameters**

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
- **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const` &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.
Returns  The `search` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `search` algorithm returns an iterator to the beginning of the first subsequence `[s_first, s_last)` in range `[first, last)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, last)`, `last` is returned. Additionally if the size of the subsequence is empty `first` is returned. If no subsequence is found, `last` is returned.

```cpp
template<typename ExPolicy, typename FwdIter, typename FwdIter2, typename Pred = parallel::detail::equal_to>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> search(ExPolicy &&policy, FwdIter first, FwdIter last, FwdIter2 s_first, FwdIter2 s_last, Pred &&op = Pred())
```

Searches the range `[first, last)` for any elements in the range `[s_first, s_last)`. Uses a provided predicate to compare elements. Executed according to the policy.

The comparison operations in the parallel `search` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `search` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: at most \((S*N)\) comparisons where \(S = \text{distance}(s\_first, s\_last)\) and \(N = \text{distance}(first, last)\).

### Template Parameters
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `search` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`.

### Parameters
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.
• **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. The signature of the function should be equivalent to

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

**Returns** The `search` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `search` algorithm returns an iterator to the beginning of the first subsequence `[s_first, s_last)` in range `[first, last)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, last)`, `last` is returned. Additionally if the size of the subsequence is empty `first` is returned. If no subsequence is found, `last` is returned.

```cpp
template<typename FwdIter, typename FwdIter2, typename Pred = parallel::detail::equal_to>
FwdIter search_n(FwdIter first, std::size_t count, FwdIter2 s_first, FwdIter2 s_last, Pred &&op = Pred())
```

Searches the range `[first, last)` for any elements in the range `[s_first, s_last)`. Uses a provided predicate to compare elements.

The comparison operations in the parallel `search_n` algorithm execute in sequential order in the calling thread.

**Note:** Complexity: at most \((S*N)\) comparisons where \(S = \text{distance}(s\text{.first}, s\text{.last})\) and \(N = \text{count}\).
The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively.

**Returns** The search_n algorithm returns FwdIter. The search_n algorithm returns an iterator to the beginning of the last subsequence [s_first, s_last) in range [first, first+count). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, first+count), first is returned. Additionally if the size of the subsequence is empty or no subsequence is found, first is also returned.

```cpp
template<typename ExPolicy, typename FwdIter, typename FwdIter2, typename Pred = parallel::detail::equal_to>
hpx::parallel::util::algorithm_result_t<ExPolicy, FwdIter> search_n(ExPolicy &&policy, FwdIter first, std::size_t count, FwdIter2 s_first, FwdIter2 s_last, Pred &&op = Pred())
```

Searches the range [first, last) for any elements in the range [s_first, s_last). Uses a provided predicate to compare elements. Executed according to the policy.

The comparison operations in the parallel search_n algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The comparison operations in the parallel search_n algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: at most (S*N) comparisons where \( S = \text{distance}(s\_first, s\_last) \) and \( N = \text{count} \).

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of search_n requires Pred to meet the requirements of CopyConstructible. This defaults to std::equal_to<>.

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **count** – Refers to the range of elements of the first range the algorithm will be applied to.
- **s_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
• **s_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.

• **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. The signature of the function should be equivalent to

\[
\text{bool \ pred(const Type1 &a, const Type2 &b);}\]

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively.

**Returns** The search_n algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The search_n algorithm returns an iterator to the beginning of the last subsequence `[s_first, s_last)` in range `[first, first+count)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, first+count)`, *first* is returned. Additionally if the size of the subsequence is empty or no subsequence is found, *first* is also returned.

**hpx/parallel/algorithms/set_difference.hpp**

See *Public API* for a list of names and headers that are part of the public *HPX* API.

**namespace hpx**

**Functions**

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred = hpx::parallel::detail::less>
    hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter3> set_difference(ExPolicy &&policy,
        FwdIter1 first1,
        FwdIter1 last1,
        FwdIter2 first2,
        FwdIter2 last2,
        FwdIter3 dest,
        Pred &&op = Pred())
```

Constructs a sorted range beginning at *dest* consisting of all elements present in the range `[first1, last1)` and not present in the range `[first2, last2)`. This algorithm expects both input ranges to be sorted with the given binary predicate *pred*. Executed according to the policy.

Equivalent elements are treated individually, that is, if some element is found *m* times in `[first1, last1)` and *n* times in `[first2, last2)`, it will be copied to *dest* exactly std::max(*m*-*n*, 0) times. The resulting range cannot overlap with either of the input ranges. The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (*sequenced_policy*) or in a single new thread spawned from the current thread (*sequenced_task_policy*).
The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most $2*(N_1 + N_2 - 1)$ comparisons, where $N_1$ is the length of the first sequence and $N_2$ is the length of the second sequence.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

- **FwdIter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.

- **FwdIter2** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.

- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_difference` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

- **dest** – Refers to the beginning of the destination range.

- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

  ```cpp
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`

**Returns** The `set_difference` algorithm returns a `hpx::future<FwdIter3>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter3` otherwise. The `set_difference` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred = hpx::parallel::detail::less>
```
**FwdIter3 set_difference** *(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, FwdIter3 dest, Pred &&op = Pred())*

Constructs a sorted range beginning at `dest` consisting of all elements present in the range `[first1, last1)` and not present in the range `[first2, last2)`. This algorithm expects both input ranges to be sorted with the given binary predicate `pred`.

Equivalent elements are treated individually, that is, if some element is found `m` times in `[first1, last1)` and `n` times in `[first2, last2)`, it will be copied to `dest` exactly `std::max(m-n, 0)` times. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

**Note:** Complexity: At most $2*(N1 + N2 - 1)$ comparisons, where $N1$ is the length of the first sequence and $N2$ is the length of the second sequence.

**Template Parameters**

- **FwdIter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_difference` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`

**Parameters**

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

**Returns** The `set_difference` algorithm returns a `FwdIter3`. The `set_difference` algorithm returns the output iterator to the element in the destination range, one past the last element copied.
See Public API for a list of names and headers that are part of the public HPX API.

namespace hpx

Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred = hpx::parallel::detail::less>
    hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter3> set_intersection(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, FwdIter3 dest, Pred &&op = Pred())

Constructs a sorted range beginning at dest consisting of all elements present in both sorted ranges [first1, last1) and [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate pred. Executed according to the policy.

If some element is found \(m\) times in [first1, last1) and \(n\) times in [first2, last2), the first \(\min(m, n)\) elements will be copied from the first range to the destination range. The order of equivalent elements is preserved. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (sequenced_policy) or in a single new thread spawned from the current thread (for sequenced_task_policy).

The application of function objects in parallel algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: At most \(2^*(N1 + N2 - 1)\) comparisons, where \(N1\) is the length of the first sequence and \(N2\) is the length of the second sequence.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

- **FwdIter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.

- **FwdIter2** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
• **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator or output iterator with sequential execution.

• **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_intersection` requires `Pred` to meet the requirements of `Copy-Constructible`. This defaults to `std::less<>`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`

### Returns

The `set_intersection` algorithm returns a `hpx::future<FwdIter3>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter3` otherwise. The `set_intersection` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```
template<typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred = hpx::parallel::detail::less>
FwdIter3 set_intersection(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, FwdIter3 dest, 
Pred &&op = Pred())
```

Constructs a sorted range beginning at dest consisting of all elements present in both sorted ranges `[first1, last1)` and `[first2, last2)`. This algorithm expects both input ranges to be sorted with the given binary predicate `pred`.

If some element is found `m` times in `[first1, last1)` and `n` times in `[first2, last2)`, the first `std::min(m, n)` elements will be copied from the first range to the destination range. The order of equivalent elements is preserved. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

---

**Note:** Complexity: At most `2*(N1 + N2 - 1)` comparisons, where `N1` is the length of the first sequence and `N2` is the length of the second sequence.
Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator or output iterator with sequential execution.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_intersection` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>

Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

  ```cpp
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

Returns The `set_intersection` algorithm returns a `FwdIter3`. The `set_intersection` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

`hpx/parallel/algorithms/set_symmetric_difference.hpp`

See `Public API` for a list of names and headers that are part of the public `HPX` API.

namespace `hpx`
Functions

```cpp
template<
    typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3,
    typename Pred = hpx::parallel::detail::less>

hpx::parallel::util::detail::algorithm_result<
    ExPolicy, FwdIter3>::type set_symmetric_difference(
    ExPolicy &&policy,
    FwdIter1 first1, FwdIter1 last1,
    FwdIter2 first2, FwdIter2 last2,
    FwdIter3 dest,
    Pred &&op = Pred())
```

Constructs a sorted range beginning at `dest` consisting of all elements present in either of the sorted ranges `[first1, last1)` and `[first2, last2)`, but not in both of them are copied to the range beginning at `dest`. The resulting range is also sorted. This algorithm expects both input ranges to be sorted with the given binary predicate `pred`. Executed according to the policy.

If some element is found `m` times in `[first1, last1)` and `n` times in `[first2, last2)`, it will be copied to `dest` exactly \(\text{std::abs(m-n)}\) times. If \(m > n\), then the last \(m-n\) of those elements are copied from `[first1, last1)`, otherwise the last \(n-m\) elements are copied from `[first2, last2)`. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (``sequenced_policy``) or in a single new thread spawned from the current thread (for ``sequenced_task_policy``).

The application of function objects in parallel algorithm invoked with an execution policy object of type ``parallel_policy`` or ``parallel_task_policy`` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most \(2^*(N1 + N2 - 1)\) comparisons, where \(N1\) is the length of the first sequence and \(N2\) is the length of the second sequence.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

- **FwdIter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
• **FwdIter2** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.

• **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator or output iterator and sequential execution.

• **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_symmetric_difference` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`.

**Parameters**

• **policy** – The execution policy to use for the scheduling of the iterations.

• **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

• **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

• **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

• **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

• **dest** – Refers to the beginning of the destination range.

• **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

**Returns** The `set_symmetric_difference` algorithm returns a `hpx::future<FwdIter3>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter3` otherwise. The `set_symmetric_difference` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred = hpx::parallel::detail::less>
FwdIter3 set_symmetric_difference(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, FwdIter3 dest, Pred &&op = Pred())
```

Constructs a sorted range beginning at `dest` consisting of all elements present in either of the sorted ranges `[first1, last1)` and `[first2, last2)`, but not in both of them are copied to the range beginning at `dest`. The resulting range is also sorted. This algorithm expects both input ranges to be sorted with the given binary predicate `pred`.

If some element is found `m` times in `[first1, last1)` and `n` times in `[first2, last2)`, it will be copied to `dest` exactly `std::abs(m-n)` times. If `m>n`, then the last `m-n` of those elements are copied from `[first1, last1)`, otherwise the last `n-m` elements are copied from `[first2, last2)`. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.
Note: Complexity: At most $2(N1 + N2 - 1)$ comparisons, where $N1$ is the length of the first sequence and $N2$ is the length of the second sequence.

Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator or output iterator and sequential execution.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_symmetric_difference` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`

Parameters

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

Returns The `set_symmetric_difference` algorithm returns a `FwdIter3`. The `set_symmetric_difference` algorithm returns the output iterator to the element in the destination range, one past the last element copied.
namespace hpx

Functions

template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred = hpx::parallel::detail::less>
hpX::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter3> set_union(ExPolicy &&policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, FwdIter3 dest, Pred &&op = Pred())

Constructs a sorted range beginning at dest consisting of all elements present in one or both sorted ranges [first1, last1) and [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate pred. Executed according to the policy.

If some element is found \(m\) times in [first1, last1) and \(n\) times in [first2, last2), then all \(m\) elements will be copied from [first1, last1) to dest, preserving order, and then exactly std::max(\(n-m\), 0) elements will be copied from [first2, last2) to dest, also preserving order.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (sequenced_policy) or in a single new thread spawned from the current thread (for sequenced_task_policy).

The application of function objects in parallel algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most \(2*(N1 + N2 - 1)\) comparisons, where \(N1\) is the length of the first sequence and \(N2\) is the length of the second sequence.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator or output iterator and sequential execution.
• **Op** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_union` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

  ```cpp
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

### Returns

The `set_union` algorithm returns a `hpx::future<FwdIter3>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter3` otherwise. The `set_union` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename FwdIter1, typename FwdIter2, typename FwdIter3, typename Pred = hpx::parallel::detail::less>
FwdIter3 set_union(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter2 last2, FwdIter3 dest, Pred &&op = Pred())
```

Constructs a sorted range beginning at `dest` consisting of all elements present in one or both sorted ranges `[first1, last1)` and `[first2, last2)`. This algorithm expects both input ranges to be sorted with the given binary predicate `pred`. Executed according to the policy.

If some element is found `m` times in `[first1, last1)` and `n` times in `[first2, last2)`, then all `m` elements will be copied from `[first1, last1)` to `dest`, preserving order, and then exactly `std::max(n-m, 0)` elements will be copied from `[first2, last2)` to `dest`, also preserving order.

The resulting range cannot overlap with either of the input ranges.

---

**Note:** Complexity: At most $2^*(N1 + N2 - 1)$ comparisons, where $N1$ is the length of the first sequence and $N2$ is the length of the second sequence.

### Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
• **FwdIter2** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.

• **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator or output iterator and sequential execution.

• **Op** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_union` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`.

**Parameters**

• **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

• **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

• **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

• **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

• **dest** – Refers to the beginning of the destination range.

• **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &s, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

**Returns** The `set_union` algorithm returns a `FwdIter3`. The `set_union` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

### hpx/parallel/algorithms/shift_left.hpp

See Public API for a list of names and headers that are part of the public HPX API.

namespace hpx

**Functions**

```cpp
template<typename FwdIter, typename Size>
FwdIter shift_left(FwdIter first, FwdIter last, Size n)
```

Shifts the elements in the range `[first, last)` by `n` positions towards the beginning of the range. For every integer `i` in `[0, last - first - n)`, moves the element originally at position `first + n + i` to position `first + i`.

The assignment operations in the parallel `shift_left` algorithm invoked without an execution policy object will execute in sequential order in the calling thread.
Note: Complexity: At most (last - first) - n assignments.

Note: The type of dereferenced \textit{FwdIter} must meet the requirements of \textit{MoveAssignable}.

\textbf{Template Parameters}

- \textit{FwdIter} – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

- \textit{Size} – The type of the argument specifying the number of positions to shift by.

\textbf{Parameters}

- \textit{first} – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- \textit{last} – Refers to the end of the sequence of elements the algorithm will be applied to.

- \textit{n} – Refers to the number of positions to shift.

\textbf{Returns} The \textit{shift\_left} algorithm returns \textit{FwdIter}. The \textit{shift\_left} algorithm returns an iterator to the end of the resulting range.

\begin{verbatim}
template<typename ExPolicy, typename FwdIter, typename Size>
    hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter> shift_left(ExPolicy &&policy, FwdIter first, FwdIter last, Size n)
\end{verbatim}

Shifts the elements in the range \([\text{first}, \text{last})\) by \(n\) positions towards the beginning of the range. For every integer \(i\) in \([0, \text{last} - \text{first} - n)\), moves the element originally at position \(\text{first} + n + i\) to position \(\text{first} + i\). Executed according to the policy.

The assignment operations in the parallel \textit{shift\_left} algorithm invoked with an execution policy object of type \textit{sequenced\_policy} execute in sequential order in the calling thread.

The assignment operations in the parallel \textit{shift\_left} algorithm invoked with an execution policy object of type \textit{parallel\_policy} or \textit{parallel\_task\_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: At most (last - first) - n assignments.

Note: The type of dereferenced \textit{FwdIter} must meet the requirements of \textit{MoveAssignable}.

\textbf{Template Parameters}

- \textit{ExPolicy} – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- \textit{FwdIter} – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
• **Size** – The type of the argument specifying the number of positions to shift by.

**Parameters**

• **policy** – The execution policy to use for the scheduling of the iterations.

• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

• **n** – Refers to the number of positions to shift.

**Returns** The `shift_left` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `shift_left` algorithm returns an iterator to the end of the resulting range.

**Functions**

```cpp
template<typename FwdIter, typename Size>
FwdIter shift_right(FwdIter first, FwdIter last, Size n)
```

Shifts the elements in the range `[first, last)` by `n` positions towards the end of the range. For every integer `i` in `[0, last - first - n)`, moves the element originally at position `first + i` to position `first + n + i`.

The assignment operations in the parallel `shift_right` algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

**Note:** Complexity: At most `(last - first) - n` assignments.

**Note:** The type of dereferenced `FwdIter` must meet the requirements of `MoveAssignable`.

**Template Parameters**

• **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

• **Size** – The type of the argument specifying the number of positions to shift by.

**Parameters**

• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

• **n** – Refers to the number of positions to shift.
**Returns** The `shift_right` algorithm returns `FwdIter`. The `shift_right` algorithm returns an iterator to the end of the resulting range.

```
template<typename ExPolicy, typename FwdIter, typename Size>
    hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter> shift_right(ExPolicy &&policy, FwdIter first, FwdIter last, Size n)
```

Shifts the elements in the range `[first, last)` by `n` positions towards the end of the range. For every integer `i` in `[0, last - first - n)`, moves the element originally at position `first + i` to position `first + n + i`. Executed according to the policy.

The assignment operations in the parallel `shift_right` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignment operations in the parallel `shift_right` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most `(last - first) - n` assignments.

**Note:** The type of dereferenced `FwdIter` must meet the requirements of `MoveAssignable`.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of positions to shift by.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **n** – Refers to the number of positions to shift.

**Returns** The `shift_right` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `shift_right` algorithm returns an iterator to the end of the resulting range.
namespace hpx

## Functions

template<typename RandomIt, typename Comp = hpx::parallel::detail::less, typename Proj = hpx::identity>
void sort(RandomIt first, RandomIt last, Comp &&comp, Proj &&proj = Proj())

Sorts the elements in the range [first, last) in ascending order. The order of equal elements is not guaranteed to be preserved. The function uses the given comparison function object comp (defaults to using operator<()).

A sequence is sorted with respect to a comparator comp and a projection proj if for every iterator i pointing to the sequence and every non-negative integer n such that i + n is a valid iterator pointing to an element of the sequence, and INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false. comp has to induce a strict weak ordering on the values.

The assignments in the parallel sort algorithm invoked without an execution policy object execute in sequential order in the calling thread.

**Note:** Complexity: O(N log(N)), where N = std::distance(first, last) comparisons.

### Template Parameters

- **RandomIt** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to hpx::identity.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate comp is invoked.

### Returns

The sort algorithm returns void.

template<typename ExPolicy, typename RandomIt, typename Comp = hpx::parallel::detail::less, typename Proj = hpx::identity>
**hpx::parallel::util::detail::algorithm_result_t<ExPolicy> sort(ExPolicy &&policy, RandomIt first, RandomIt last, Comp &&comp, Proj &&proj)**

Sorts the elements in the range [first, last) in ascending order. The order of equal elements is not guaranteed to be preserved. The function uses the given comparison function object comp (defaults to using operator<()). Executed according to the policy.

A sequence is sorted with respect to a comparator `comp` and a projection `proj` if for every iterator `i` pointing to the sequence and every non-negative integer `n` such that `i + n` is a valid iterator pointing to an element of the sequence, and `INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false`.

`comp` has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: O(N log(N)), where N = std::distance(first, last) comparisons.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

- **RandomIt** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.

- **Comp** – The type of the function/function object to use (deduced).

- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **comp** – `comp` is a callable object. The return value of the INVOKE operation applied to an object of type `Comp`, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator.

- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate `comp` is invoked.

**Returns** The `sort` algorithm returns a `hpx::future<void>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `void` otherwise.
See Public API for a list of names and headers that are part of the public HPX API.

namespace hpx

namespace experimental
    Top-level namespace.

Functions

template<typename ExPolicy, typename KeyIter, typename ValueIter, typename Compare = detail::less>
util::detail::algorithm_result_t<ExPolicy, sort_by_key_result<KeyIter, ValueIter>> sort_by_key(ExPolicy &&policy, KeyIter key_first, KeyIter key_last, ValueIter value_first, Compare &&comp = Compare())

Sorts one range of data using keys supplied in another range. The key elements in the range [key_first, key_last) are sorted in ascending order with the corresponding elements in the value range moved to follow the sorted order. The algorithm is not stable, the order of equal elements is not guaranteed to be preserved. The function uses the given comparison function object comp (defaults to using operator<()). Executed according to the policy.

A sequence is sorted with respect to a comparator comp if for every iterator i pointing to the sequence and every non-negative integer n such that i + n is a valid iterator pointing to an element of the sequence, and INVOKE(comp, *(i + n), *i) == false.

comp has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: \(O(N \log(N))\), where \(N = \text{std::distance(first, last)}\) comparisons.

Template Parameters
• **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

• **KeyIter** – The type of the key iterators used (deduced). This iterator type must meet the requirements of a random access iterator.

• **ValueIter** – The type of the value iterators used (deduced). This iterator type must meet the requirements of a random access iterator.

• **Compare** – The type of the function/function object to use (deduced).

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **key_first** – Refers to the beginning of the sequence of key elements the algorithm will be applied to.
- **key_last** – Refers to the end of the sequence of key elements the algorithm will be applied to.
- **value_first** – Refers to the beginning of the sequence of value elements the algorithm will be applied to, the range of elements must match \([key\_first, key\_last)\)
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.

**Returns**  The `sort_by_key` algorithm returns a `hpx::future<sort_by_key_result<KeyIter,ValueIter>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `otherwise`. The algorithm returns a pair holding an iterator pointing to the first element after the last element in the input key sequence and an iterator pointing to the first element after the last element in the input value sequence.

`hpx/parallel/algorithms/stable_sort.hpp`

See **Public API** for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

**Functions**

```cpp
template<typename RandomIt, typename Comp = hpx::parallel::detail::less, typename Proj = hpx::identity>
void stable_sort(RandomIt first, RandomIt last, Comp &&comp = Comp(), Proj &&proj = Proj())
```

Sorts the elements in the range \([first, last)\) in ascending order. The relative order of equal elements is preserved. The function uses the given comparison function object `comp` (defaults to using `operator<()`).

A sequence is sorted with respect to a comparator `comp` and a projection `proj` if for every iterator `i` pointing to the sequence and every non-negative integer `n` such that `i + n` is a valid iterator pointing to an element of the sequence, and `INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *))` == false.

`comp` has to induce a strict weak ordering on the values.

The assignments in the parallel `stable_sort` algorithm invoked without an execution policy object execute in sequential order in the calling thread.

**Note:** Complexity: \(O(N \log(N))\), where \(N = \text{std::distance}(first, last)\) comparisons.
Template Parameters

- **RandomIt** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a random access iterator.

- **Comp** – The type of the function/function object to use (deduced).

- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.

- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate `comp` is invoked.

Returns The `stable_sort` algorithm returns `void`.

```cpp
template<typename ExPolicy, typename RandomIt, typename Comp = hpx::parallel::detail::less, typename Proj = hpx::identity>
    hpx::parallel::util::detail::algorithm_result_t<ExPolicy> stable_sort(ExPolicy &&policy, RandomIt first, RandomIt last, Comp &&comp = Comp(), Proj &&proj = Proj())
```

Sorts the elements in the range `[first, last)` in ascending order. The relative order of equal elements is preserved. The function uses the given comparison function object `comp` (defaults to using `operator<()`). Executed according to the policy.

A sequence is sorted with respect to a comparator `comp` and a projection `proj` if for every iterator `i` pointing to the sequence and every non-negative integer `n` such that `i + n` is a valid iterator pointing to an element of the sequence, and `INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false`.

`comp` has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: $O(N \log(N))$, where $N = \text{std::distance(first, last)}$ comparisons.
Comp – The type of the function/function object to use (deduced).

Proj – The type of an optional projection function. This defaults to hpx::identity.

Parameters

 policy – The execution policy to use for the scheduling of the iterations.

 first – Refers to the beginning of the sequence of elements the algorithm will be applied to.

 last – Refers to the end of the sequence of elements the algorithm will be applied to.

 comp – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.

 proj – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate comp is invoked.

Returns The stable_sort algorithm returns a hpx::future<void> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns void otherwise.

hpx/parallel/algorithms/starts_with.hpp

See Public API for a list of names and headers that are part of the public HPX API.

namespace hpx

Functions

template<typename InIter1, typename InIter2, typename Pred = hpx::parallel::detail::equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
bool starts_with(InIter1 first1, InIter1 last1, InIter2 first2, InIter2 last2, Pred &&pred = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())

Checks whether the second range defined by [first1, last1) matches the prefix of the first range defined by [first2, last2)

The assignments in the parallel starts_with algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Note: Complexity: Linear: at most min(N1, N2) applications of the predicate and both projections.

Template Parameters

 InIter1 – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.

 InIter2 – The type of the destination iterators used (deduced). This iterator type must meet the requirements of an input iterator.

 Pred – The binary predicate that compares the projected elements. This defaults to hpx::parallel::detail::equal_to.
• **Proj1** – The type of an optional projection function for the source range. This defaults to `hpx::identity`.

• **Proj2** – The type of an optional projection function for the destination range. This defaults to `hpx::identity`.

**Parameters**

• **first1** – Refers to the beginning of the source range.

• **last1** – Sentinel value referring to the end of the source range.

• **first2** – Refers to the beginning of the destination range.

• **last2** – Sentinel value referring to the end of the destination range.

• **pred** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the in two ranges projected by `proj1` and `proj2` respectively.

• **proj1** – Specifies the function (or function object) which will be invoked for each of the elements in the source range as a projection operation before the actual predicate `pred` is invoked.

• **proj2** – Specifies the function (or function object) which will be invoked for each of the elements in the destination range as a projection operation before the actual predicate `pred` is invoked.

**Returns** The `starts_with` algorithm returns `bool`. The `starts_with` algorithm returns a boolean with the value true if the second range matches the prefix of the first range, false otherwise.

```cpp
template<typename ExPolicy, typename InIter1, typename InIter2, typename Pred = hpx::parallel::detail::equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> starts_with(ExPolicy &&policy, InIter1 first1, InIter1 last1, InIter2 first2, InIter2 last2, Pred &&pred = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Checks whether the second range defined by `[first1, last1)` matches the prefix of the first range defined by `[first2, last2)`. Executed according to the policy.

The assignments in the parallel `starts_with` algorithm invoked without an execution policy object execute in sequential order in the calling thread.

**Note:** Complexity: Linear: at most \( \min(N1, N2) \) applications of the predicate and both projections.

**Template Parameters**

• **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **InIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.

• **InIter2** – The type of the destination iterators used (deduced). This iterator type must meet the requirements of an input iterator.
• **Pred** – The binary predicate that compares the projected elements. This defaults to `hpx::parallel::detail::equal_to`.

• **Proj1** – The type of an optional projection function for the source range. This defaults to `hpx::identity`.

• **Proj2** – The type of an optional projection function for the destination range. This defaults to `hpx::identity`.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the source range.
- **last1** – Sentinel value referring to the end of the source range.
- **first2** – Refers to the beginning of the destination range.
- **last2** – Sentinel value referring to the end of the destination range.
- **pred** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the two ranges projected by `proj1` and `proj2` respectively.
- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements in the source range as a projection operation before the actual predicate `pred` is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements in the destination range as a projection operation before the actual predicate `pred` is invoked.

### Returns

The `starts_with` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `starts_with` algorithm returns a boolean with the value true if the second range matches the prefix of the first range, false otherwise.

### hpX/parallel/algorithms/swap_ranges.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

```cpp
namespace hpx {

Functions

template<typename FwdIter1, typename FwdIter2>
FwdIter2 swap_ranges(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2)

Exchanges elements between range [first1, last1) and another range starting at first2.

The swap operations in the parallel `swap_ranges` algorithm invoked without an execution policy object execute in sequential order in the calling thread.

**Note:** Complexity: Linear in the distance between `first1` and `last1`.

Template Parameters
```
• **FwdIter1** – The type of the first range of iterators to swap (deduced). This iterator type must meet the requirements of a forward iterator.

• **FwdIter2** – The type of the second range of iterators to swap (deduced). This iterator type must meet the requirements of a forward iterator.

**Parameters**

• **first1** – Refers to the beginning of the first sequence of elements the algorithm will be applied to.

• **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.

• **first2** – Refers to the beginning of the second sequence of elements the algorithm will be applied to.

**Returns**

The `swap_ranges` algorithm returns `FwdIter2`. The `swap_ranges` algorithm returns iterator to the element past the last element exchanged in the range beginning with `first2`.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
auto swap_ranges(ExPolicy&& policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2) {
    Exchanges elements between range [first1, last1) and another range starting at first2. Executed according to the policy.
}
```

The swap operations in the parallel `swap_ranges` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The swap operations in the parallel `swap_ranges` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Linear in the distance between `first1` and `last1`.

**Template Parameters**

• **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the swap operations.

• **FwdIter1** – The type of the first range of iterators to swap (deduced). This iterator type must meet the requirements of a forward iterator.

• **FwdIter2** – The type of the second range of iterators to swap (deduced). This iterator type must meet the requirements of a forward iterator.

**Parameters**

• **policy** – The execution policy to use for the scheduling of the iterations.

• **first1** – Refers to the beginning of the first sequence of elements the algorithm will be applied to.

• **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
• **first2** – Refers to the beginning of the second sequence of elements the algorithm will be applied to.

**Returns** The `swap_ranges` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `parallel_task_policy` and returns `FwdIter2` otherwise. The `swap_ranges` algorithm returns iterator to the element past the last element exchanged in the range beginning with `first2`.

### hpx/parallel/algorithms/transform.hpp

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace **hpx**

#### Functions

```cpp
template<typename FwdIter1, typename FwdIter2, typename F>
FwdIter2 transform(FwdIter1 first, FwdIter1 last, FwdIter2 dest, F &&f)
```

Applies the given function `f` to the range `[first, last)` and stores the result in another range, beginning at `dest`.

**Note:** Complexity: Exactly `last - first` applications of `f`

#### Template Parameters

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `transform` requires `F` to meet the requirements of `CopyConstructible`.

#### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`). This is an unary predicate. The signature of this predicate should be equivalent to:

```cpp
Ret fun(const Type &a);
```

The signature does not need to have `const&`. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`. The type `Ret` must be such that an object of type `FwdIter2` can be dereferenced and assigned a value of type `Ret`. 

---

Chapter 2. What’s so special about HPX?
Returns The transform algorithm returns a `FwdIter2`. The transform algorithm returns a tuple holding an iterator referring to the first element after the input sequence and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename F>
parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> transform(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest, F &&f)
```

Applies the given function \( f \) to the range \([\text{first}, \text{last})\) and stores the result in another range, beginning at \( \text{dest} \). Executed according to the policy.

The invocations of \( f \) in the parallel transform algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The invocations of \( f \) in the parallel transform algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Exactly \( \text{last} - \text{first} \) applications of \( f \)

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of \( f \).
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `transform` requires \( F \) to meet the requirements of `CopyConstructible`.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\). This is an unary predicate. The signature of this predicate should be equivalent to:

```cpp
Ret fun(const Type &a);
```

The signature does not need to have const&. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`. The type `Ret` must be such that an object of type `FwdIter2` can be dereferenced and assigned a value of type `Ret`.

2.8. API reference 497
Returns  The `transform` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `parallel_task_policy` and returns `FwdIter2` otherwise. The `transform` algorithm returns a tuple holding an iterator referring to the first element after the input sequence and the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename FwdIter1, typename FwdIter2, typename FwdIter3, typename F>
FwdIter3 transform(FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, FwdIter3 dest, F &&f)
```

Applies the given function `f` to pairs of elements from two ranges: one defined by `[first1, last1)` and the other beginning at `first2`, and stores the result in another range, beginning at `dest`.

Note:  Complexity: Exactly `last - first` applications of `f`

Template Parameters

- **FwdIter1** – The type of the source iterators for the first range used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the source iterators for the second range used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `transform` requires `F` to meet the requirements of `CopyConstructible`.

Parameters

- **first1** – Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is a binary predicate. The signature of this predicate should be equivalent to:

```cpp
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively. The type `Ret` must be such that an object of type `FwdIter3` can be dereferenced and assigned a value of type `Ret`.

Returns  The `transform` algorithm returns a `FwdIter3`. The `transform` algorithm returns a tuple holding an iterator referring to the first element after the first input sequence, an iterator referring to the first element after the second input sequence, and the output iterator referring to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename FwdIter3, typename F>
```
Applies the given function $f$ to pairs of elements from two ranges: one defined by $[\text{first1}, \text{last1})$ and the other beginning at $\text{first2}$, and stores the result in another range, beginning at $\text{dest}$. Executed according to the policy.

The invocations of $f$ in the parallel transform algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The invocations of $f$ in the parallel transform algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Exactly $\text{last} - \text{first}$ applications of $f$
to Type1 and Type2 respectively. The type Ret must be such that an object of type FwdIter3 can be dereferenced and assigned a value of type Ret.

Returns The transform algorithm returns a hpx::future<FwdIter3> if the execution policy is of type parallel_task_policy and returns FwdIter3 otherwise. The transform algorithm returns a tuple holding an iterator referring to the first element after the first input sequence, an iterator referring to the first element after the second input sequence, and the output iterator referring to the element in the destination range, one past the last element copied.

hpx/parallel/algorithms/transform_exclusive_scan.hpp

See Public API for a list of names and headers that are part of the public HPX API.

namespace hpx

Functions

template<typename InIter, typename OutIter, typename BinOp, typename UnOp, typename T = typename std::iterator_traits<InIter>::value_type>
OutIter transform_exclusive_scan(InIter first, InIter last, OutIter dest, T init, BinOp &&binary_op, UnOp &&unary_op)

Transforms each element in the range [first, last) with unary_op, then computes an exclusive prefix sum operation using binary_op over the resulting range, with init as the initial value, and writes the results to the range beginning at dest. “exclusive” means that the i-th input element is not included in the i-th sum. Formally, assigns through each iterator i in [dest, d_first + (last - first)) the value of the generalized noncommutative sum of init, unary_op(*j)... for every j in [first, first + (i - d_first)) over binary_op, where generalized noncommutative sum GNSUM(op, a1, ..., a N) is defined as follows:

• if N=1, a1
• if N > 1, op(GNSUM(op, a1, ..., aK), GNSUM(op, aM, ..., aN)) for any K where 1 < K+1 = M <= N

In other words, the summation operations may be performed in arbitrary order, and the behavior is nondeterministic if binary_op is not associative.

The reduce operations in the parallel transform_exclusive_scan algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Neither unary_op nor binary_op shall invalidate iterators or sub-ranges, or modify elements in the ranges [first, last) or [result, result + (last - first)).

The behavior of transform_exclusive_scan may be non-deterministic for a non-associative predicate.

Note: Complexity: O(last - first) applications of each of binary_op and unary_op.
Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **BinOp** – The type of `binary_op`.
- **UnOp** – The type of `unary_op`.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.
- **binary_op** – Binary `FunctionObject` that will be applied to the result of `unary_op`, the results of other `binary_op`, and `init`.
- **unary_op** – Unary `FunctionObject` that will be applied to each element of the input range. The return type must be acceptable as input to `binary_op`.

Returns

The `transform_exclusive_scan` algorithm returns a returns `OutIter`. The `transform_exclusive_scan` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename BinOp, typename UnOp,
    typename T = typename std::iterator_traits<FwdIter1>::value_type>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type transform_exclusive_scan(ExPolicy &&policy,
    FwdIter1 first, FwdIter1 last, FwdIter2 dest, T init, BinOp &&binary_op,
    UnOp &&unary_op)
```

Assigns through each iterator `i` in `[result, result + (last - first))` the value of `GENERALIZED_NONCOMMUTATIVE_SUM(binary_op, init, conv(*first), ..., conv(*(first + (i - result) - 1)))`. Executed according to the policy.

The reduce operations in the parallel `transform_exclusive_scan` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.
The reduce operations in the parallel `transform_exclusive_scan` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither `unary_op` nor `binary_op` shall invalidate iterators or sub-ranges, or modify elements in the ranges `[first,last)` or `[result, result + (last - first))].

The behavior of `transform_exclusive_scan` may be non-deterministic for a non-associative predicate.

**Note:** Complexity: O(last - first) applications of each of `binary_op` and `unary_op`.

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN)` is defined as:

- a1 when N is 1
- op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN)) where 1 < K+1 = M <= N.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **BinOp** – The type of `binary_op`.
- **UnOp** – The type of `unary_op`.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.
- **binary_op** – Binary `FunctionObject` that will be applied in to the result of `unary_op`, the results of other `binary_op`, and `init`.
- **unary_op** – Unary `FunctionObject` that will be applied to each element of the input range. The return type must be acceptable as input to `binary_op`.

**Returns** The `transform_exclusive_scan` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `transform_exclusive_scan` algorithm returns the output iterator to the element in the destination range, one past the last element copied.
namespace hpx

**Functions**

```cpp
template<typename InIter, typename OutIter, typename BinOp, typename UnOp>
OutIter transform_inclusive_scan(InIter first, InIter last, OutIter dest, BinOp &&binary_op, UnOp &&unary_op)
```

Assigns through each iterator i in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(op, conv(*first), ..., conv(*(first + (i - result)))).

The reduce operations in the parallel `transform_inclusive_scan` algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Neither `binary_op` nor `unary_op` shall invalidate iterators or sub-ranges, or modify elements in the ranges [first,last) or [result,result + (last - first)).

The difference between `inclusive_scan` and `transform_inclusive_scan` is that `transform_inclusive_scan` includes the ith input element in the ith sum.

**Note:** Complexity: O(last - first) applications of each of `binary_op` and `unary_op`.

**Note:** GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN) is defined as:
- a1 when N is 1
- op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN)) where 1 < K+1 = M <= N.

**Template Parameters**
- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **BinOp** – The type of `binary_op`.
- **UnOp** – The type of `unary_op`.

**Parameters**
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **binary_op** – Binary *FunctionObject* that will be applied in to the result of *unary_op*, the results of other *binary_op*, and *init* if provided.

- **unary_op** – Unary *FunctionObject* that will be applied to each element of the input range.
  The return type must be acceptable as input to *binary_op*.

**Returns** The *transform_inclusive_scan* algorithm returns a returns *OutIter*. The *transform_inclusive_scan* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename BinOp, typename UnOp>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type transform_inclusive_scan(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest, BinOp &&binary_op, UnOp &&unary_op)
```

Assigns through each iterator *i* in 
[result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(op, conv(*first), ..., conv(*(first + (i - result)))). Executed according to the policy.

The reduce operations in the parallel *transform_inclusive_scan* algorithm invoked with an execution policy object of type *sequenced_policy* execute in sequential order in the calling thread.

The reduce operations in the parallel *transform_inclusive_scan* algorithm invoked with an execution policy object of type *parallel_policy* or *parallel_task_policy* are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither *binary_op* nor *unary_op* shall invalidate iterators or sub-ranges, or modify elements in the ranges [first,last) or [result,result + (last - first)).

The difference between *inclusive_scan* and *transform_inclusive_scan* is that *transform_inclusive_scan* includes the ith input element in the ith sum.

**Note:** Complexity: O(last - first) applications of each of *binary_op* and *unary_op*.

**Note:** GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN) is defined as:

- a1 when N is 1

- op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN)) where 1 < K+1 = M <= N.

**Template Parameters**
• **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

• **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

• **BinOp** – The type of `binary_op`.

• **UnOp** – The type of `unary_op`.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **dest** – Refers to the beginning of the destination range.

- **binary_op** – Binary `FunctionObject` that will be applied in to the result of `unary_op`, the results of other `binary_op`, and `init` if provided.

- **unary_op** – Unary `FunctionObject` that will be applied to each element of the input range. The return type must be acceptable as input to `binary_op`.

**Returns** The `transform_inclusive_scan` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `transform_inclusive_scan` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename InIter, typename OutIter, typename BinOp, typename UnOp, typename T = typename std::iterator_traits<InIter>::value_type>
OutIter transform_inclusive_scan(InIter first, InIter last, OutIter dest, BinOp &&binary_op, UnOp &&unary_op, T init)
```

Assigns through each iterator \( i \) in \( [\text{result}, \text{result} + (\text{last} - \text{first})) \) the value of \( \text{GENERALIZED_NONCOMMUTATIVE\_SUM}(\text{op, init}, \text{conv}(\text{*first}), \ldots, \text{conv}(\text{*(first + (i - result))}) \).

The reduce operations in the parallel `transform_inclusive_scan` algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Neither `binary_op` nor `unary_op` shall invalidate iterators or sub-ranges, or modify elements in the ranges \([\text{first}, \text{last})\) or \([\text{result}, \text{result} + (\text{last} - \text{first}))\).

The difference between `inclusive_scan` and `transform_inclusive_scan` is that `transform_inclusive_scan` includes the \( i \)th input element in the \( i \)th sum. If `binary_op` is not mathematically associative, the behavior of `transform_inclusive_scan` may be non-deterministic.

**Note:** Complexity: \( O(\text{last} - \text{first}) \) applications of each of `binary_op` and `unary_op`.

**Note:** `GENERALIZED_NONCOMMUTATIVE\_SUM(op, a1, \ldots, aN)` is defined as:
Transform inclusive scan

The transform_inclusive_scan algorithm returns a returns OutIter. The transform_inclusive_scan algorithm returns the output iterator to the element in the destination range, one past the last element copied.

template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename BinOp, typename UnOp, typename T = typename std::iterator_traits<FwdIter1>::value_type>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter2>::type transform_inclusive_scan(ExPolicy &&policy, FwdIter1 first, FwdIter1 last, FwdIter2 dest, BinOp &&binary_op, UnOp &&unary_op, T init)

Assigns through each iterator \(i\) in \([\text{result}, \text{result} + (\text{last} - \text{first}))\) the value of GENERALIZED_NONCOMMUTATIVE_SUM(op, init, \(\text{conv}(*\text{first}), \ldots, \text{conv}(*(\text{first} + (i - \text{result})))\)). Executed according to the policy.
The reduce operations in the parallel `transform_inclusive_scan` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The reduce operations in the parallel `transform_inclusive_scan` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Neither `binary_op` nor `unary_op` shall invalidate iterators or sub-ranges, or modify elements in the ranges `[first,last)` or `[result,result + (last - first))].

The difference between `inclusive_scan` and `transform_inclusive_scan` is that `transform_inclusive_scan` includes the ith input element in the ith sum. If `binary_op` is not mathematically associative, the behavior of `transform_inclusive_scan` may be non-deterministic.

**Note:** Complexity: O(last - first) applications of each of `binary_op` and `unary_op`.

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN)` is defined as:
- \( a_1 \) when \( N = 1 \)
- \( \text{op} (\text{GENERALIZED_NONCOMMUTATIVE_SUM}(\text{op}, a_1, ..., a_K), \text{GENERALIZED_NONCOMMUTATIVE_SUM}(\text{op}, a_{M}, ..., a_N)) \) where \( 1 < K + 1 = M \leq N \).

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **BinOp** – The type of `binary_op`.
- **UnOp** – The type of `unary_op`.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **binary_op** – Binary `FunctionObject` that will be applied in to the result of `unary_op`, the results of other `binary_op`, and `init` if provided.
- **unary_op** – Unary `FunctionObject` that will be applied to each element of the input range. The return type must be acceptable as input to `binary_op`.
- **init** – The initial value for the generalized sum.
Returns The `transform_inclusive_scan` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `transform_inclusive_scan` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

`hpx/parallel/algorithms/transform_reduce.hpp`

See Public API for a list of names and headers that are part of the public HPX API.

namespace hpx

Functions

template<typename ExPolicy, typename FwdIter, typename T, typename Reduce, typename Convert>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, T> transform_reduce(ExPolicy &&policy, FwdIter first, FwdIter last, T init, Reduce &&red_op, Convert &&conv_op)

Returns GENERALIZED_SUM(red_op, init, conv_op(*first), ..., conv_op(*(first + (last - first) - 1))). Executed according to the policy.

The reduce operations in the parallel `transform_reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread. The reduce operations in the parallel `transform_reduce` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `transform_reduce` and `accumulate` is that the behavior of transform_reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note: Complexity: $O(last - first)$ applications of the predicates `red_op` and `conv_op`.

Note: GENERALIZED_SUM(op, a1, ..., aN) is defined as follows:

- $a1$ when N is 1
- $op(GENERALIZED_SUM(op, b1, ..., bK), GENERALIZED_SUM(op, bM, ..., bN))$, where:
  - $b1, ..., bN$ may be any permutation of $a1, ..., aN$ and
  - $1 < K+1 = M <= N$.

Template Parameters

- ExPolicy – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

• **T** – The type of the value to be used as initial (and intermediate) values (deduced).

• **Reduce** – The type of the binary function object used for the reduction operation.

• **Convert** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

**Parameters**

• **policy** – The execution policy to use for the scheduling of the iterations.

• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

• **init** – The initial value for the generalized sum.

• **red_op** – Specifies the function (or function object) which will be invoked for each of the values returned from the invocation of `conv_op`. This is a binary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types `Type1`, `Type2`, and `Ret` must be such that an object of a type as returned from `conv_op` can be implicitly converted to any of those types.

• **conv_op** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is a unary predicate. The signature of this predicate should be equivalent to:

  ```
  R fun(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`. The type `R` must be such that an object of this type can be implicitly converted to `T`.

**Returns** The `transform_reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `parallel_task_policy` and returns `T` otherwise. The `transform_reduce` algorithm returns the result of the generalized sum over the values returned from `conv_op` when applied to the elements given by the input range `[first, last)`.

```
template<typename InIter, typename T, typename Reduce, typename Convert>
T transform_reduce(InIter first, InIter last, T init, Reduce &&red_op, Convert &&&conv_op)
```

Returns `GENERALIZED_SUM(red_op, init, conv_op(*first), ..., conv_op(*first + (last - first) - 1))`.

The difference between `transform_reduce` and `accumulate` is that the behavior of `transform_reduce` may be non-deterministic for non-associative or non-commutative binary predicate.

**Note:** Complexity: \(O(last - first)\) applications of the predicates `red_op` and `conv_op`.

**Note:** `GENERALIZED_SUM(op, a1, ..., aN)` is defined as follows:
• a1 when N is 1
• \text{op}(\text{GENERALIZED\_SUM}(\text{op}, b_1, \ldots, b_K), \text{GENERALIZED\_SUM}(\text{op}, b_M, \ldots, b_N)), where:
  – b_1, \ldots, b_N may be any permutation of a_1, \ldots, a_N and
  – 1 < K+1 = M \leq N.

**Template Parameters**

• **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.

• **T** – The type of the value to be used as initial (and intermediate) values (deduced).

• **Reduce** – The type of the binary function object used for the reduction operation.

• **Convert** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

**Parameters**

• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

• **init** – The initial value for the generalized sum.

• **red_op** – Specifies the function (or function object) which will be invoked for each of the values returned from the invocation of \textit{conv\_op}. This is a binary predicate. The signature of this predicate should be equivalent to:

\[
\text{Ret} \ fun(\text{const Type1} &a, \text{const Type2} &b);
\]

The signature does not need to have const&, but the function must not modify the objects passed to it. The types \textit{Type1}, \textit{Type2}, and \textit{Ret} must be such that an object of a type as returned from \textit{conv\_op} can be implicitly converted to any of those types.

• **conv_op** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \text{[first, last)}. This is a unary predicate. The signature of this predicate should be equivalent to:

\[
\text{R} \ fun(\text{const Type} &a);
\]

The signature does not need to have const&, but the function must not modify the objects passed to it. The type \textit{Type} must be such that an object of type \textit{InIter} can be dereferenced and then implicitly converted to Type. The type \textit{R} must be such that an object of this type can be implicitly converted to \textit{T}.

**Returns** The \textit{transform\_reduce} algorithm returns a \textit{T}. The \textit{transform\_reduce} algorithm returns the result of the generalized sum over the values returned from \textit{conv\_op} when applied to the elements given by the input range \text{[first, last)].

\[
\text{template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename T> hpx::parallel::util::detail::algorithm_result_t<ExPolicy, T> transform_reduce(ExPolicy \&&policy, FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, T init)}
\]

Returns the result of accumulating \textit{init} with the inner products of the pairs formed by the elements of two ranges starting at \textit{first1} and \textit{first2}. Executed according to the policy.
The operations in the parallel `transform_reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The operations in the parallel `transform_reduce` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: O(last - first) applications each of `reduce` and `transform`.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter1** – The type of the first source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

- **FwdIter2** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

- **T** – The type of the value to be used as return) values (deduced).

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first1** – Refers to the beginning of the first sequence of elements the result will be calculated with.

- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.

- **first2** – Refers to the beginning of the second sequence of elements the result will be calculated with.

- **init** – The initial value for the sum.

**Returns** The `transform_reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `T` otherwise.

```cpp
template<typename InIter1, typename InIter2, typename T>
T transform_reduce(InIter1 first1, InIter1 last1, InIter2 first2, T init)
```

Returns the result of accumulating init with the inner products of the pairs formed by the elements of two ranges starting at `first1` and `first2`.

**Note:** Complexity: O(last - first) applications each of `reduce` and `transform`.

**Template Parameters**

- **InIter1** – The type of the first source iterators used (deduced). This iterator type must meet the requirements of an input iterator.

- **InIter2** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of an input iterator.

- **T** – The type of the value to be used as return) values (deduced).
Parameters

- **first1** – Refers to the beginning of the first sequence of elements the result will be calculated with.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the result will be calculated with.
- **init** – The initial value for the sum.

Returns

The `transform_reduce` algorithm returns a `T`.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename T, typename Reduce, typename Convert>
    hpx::parallel::util::detail::algorithm_result_t<ExPolicy, T> transform_reduce(ExPolicy &&policy,
        FwdIter1 first1, FwdIter1 last1, FwdIter2 first2, T init,
        Reduce &&red_op, Convert &&conv_op)
```

Returns the result of accumulating `init` with the inner products of the pairs formed by the elements of two ranges starting at `first1` and `first2`. Executed according to the policy.

The operations in the parallel `transform_reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The operations in the parallel `transform_reduce` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: $O(last - first)$ applications each of `reduce` and `transform`.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the first source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **T** – The type of the value to be used as return) values (deduced).
- **Reduce** – The type of the binary function object used for the multiplication operation.
- **Convert** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the first sequence of elements the result will be calculated with.

Chapter 2. What’s so special about HPX?
• **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.

• **first2** – Refers to the beginning of the second sequence of elements the result will be calculated with.

• **init** – The initial value for the sum.

• **red_op** – Specifies the function (or function object) which will be invoked for the initial value and each of the return values of **conv_op**. This is a binary predicate. The signature of this predicate should be equivalent to:

```cpp
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Ret` must be such that it can be implicitly converted to a type of `T`.

• **conv_op** – Specifies the function (or function object) which will be invoked for each of the input values of the sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```cpp
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Ret` must be such that it can be implicitly converted to an object for the second argument type of `red_op`.

**Returns**

The **transform_reduce** algorithm returns a `hpx::future<T>` if the execution policy is of type **sequenced_task_policy** or **parallel_task_policy** and returns `T` otherwise.

```cpp
template<typename InIter1, typename InIter2, typename T, typename Reduce, typename Convert>
T transform_reduce(ExPolicy &&policy, InIter1 first1, InIter1 last1, InIter2 first2, T init, Reduce &&red_op, Convert &&conv_op)
```

Returns the result of accumulating `init` with the inner products of the pairs formed by the elements of two ranges starting at `first1` and `first2`.

**Note:** Complexity: \(O(last - first)\) applications each of `reduce` and `transform`.

**Template Parameters**

- **InIter1** – The type of the first source iterators used (deduced). This iterator type must meet the requirements of an input iterator.

- **InIter2** – The type of the second source iterators used (deduced). This iterator type must meet the requirements of an input iterator.

- **T** – The type of the value to be used as return) values (deduced).

- **Reduce** – The type of the binary function object used for the multiplication operation.

- **Convert** – The type of the unary function object used to transform the elements of the input sequence before invoking the reduce function.

**Parameters**

- **first1** – Refers to the beginning of the first sequence of elements the result will be calculated with.
• last1 – Refers to the end of the first sequence of elements the algorithm will be applied to.

• first2 – Refers to the beginning of the second sequence of elements the result will be calculated with.

• init – The initial value for the sum.

• red_op – Specifies the function (or function object) which will be invoked for the initial value and each of the return values of conv_op. This is a binary predicate. The signature of this predicate should be equivalent to:

```cpp
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type Ret must be such that it can be implicitly converted to a type of T.

• conv_op – Specifies the function (or function object) which will be invoked for each of the input values of the sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```cpp
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type Ret must be such that it can be implicitly converted to an object for the second argument type of red_op.

**Returns** The `transform_reduce` algorithm returns a T.

**hpx/parallel/algorithms/transform_reduce_binary.hpp**

See [Public API](#) for a list of names and headers that are part of the public HPX API.

**hpx/parallel/algorithms/uninitialized_copy.hpp**

See [Public API](#) for a list of names and headers that are part of the public HPX API.

namespace `hpx`

### Functions

```cpp
template<typename InIter, typename FwdIter>
FwdIter uninitialized_copy(InIter first, InIter last, FwdIter dest)
```

Copies the elements in the range, defined by [first, last), to an uninitialized memory area beginning at dest. If an exception is thrown during the copy operation, the function has no effects.

The assignments in the parallel `uninitialized_copy` algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

**Note:** Complexity: Performs exactly last - first assignments.
Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.

- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **dest** – Refers to the beginning of the destination range.

Returns

The `uninitialized_copy` algorithm returns `FwdIter`. The `uninitialized_copy` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> uninitialized_copy(
    ExPolicy &&policy,
    FwdIter1 first,
    FwdIter1 last,
    FwdIter2 dest)
```

Copies the elements in the range, defined by [first, last), to an uninitialized memory area beginning at dest. If an exception is thrown during the copy operation, the function has no effects. Executed according to the policy.

The assignments in the parallel `uninitialized_copy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `uninitialized_copy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: Performs exactly last - first assignments.
• **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
• **dest** – Refers to the beginning of the destination range.

**Returns** The *uninitialized_copy* algorithm returns a `hpx::future<FwdIter2>`, if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The *uninitialized_copy* algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename InIter, typename Size, typename FwdIter>
FwdIter uninitialized_copy_n(InIter first, Size count, FwdIter dest)
```
Copies the elements in the range `[first, first + count)`, starting from first and proceeding to `first + count - 1`, to another range beginning at `dest`. If an exception is thrown during the copy operation, the function has no effects.

The assignments in the parallel `uninitialized_copy_n` algorithm invoked without an execution policy object execute in sequential order in the calling thread.

**Note:** Complexity: Performs exactly `count` assignments, if `count > 0`, no assignments otherwise.

**Template Parameters**
• **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
• **Size** – The type of the argument specifying the number of elements to apply `f` to.
• **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

**Parameters**
• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **count** – Refers to the number of elements starting at `first` the algorithm will be applied to.
• **dest** – Refers to the beginning of the destination range.

**Returns** The `uninitialized_copy_n` algorithm returns a returns `FwdIter`. The `uninitialized_copy_n` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename Size, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> uninitialized_copy_n(ExPolicy &&policy,
  FwdIter1 first,
  Size count,
  FwdIter2 dest)
```
Copies the elements in the range `[first, first + count)`, starting from first and proceeding to `first + count - 1`, to another range beginning at `dest`. If an exception is thrown during the copy operation, the function has no effects.

The assignments in the parallel `uninitialized_copy_n` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.
The assignments in the parallel `uninitialized_copy_n` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs exactly `count` assignments, if `count > 0`, no assignments otherwise.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

- **Size** – The type of the argument specifying the number of elements to apply `f` to.

- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **count** – Refers to the number of elements starting at `first` the algorithm will be applied to.

- **dest** – Refers to the beginning of the destination range.

**Returns** The `uninitialized_copy_n` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `uninitialized_copy_n` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

**Functions**

```cpp
template<typename FwdIter>
void uninitialized_default_construct(FwdIter first, FwdIter last)
```

Constructs objects of type `typename iterator_traits<ForwardIt>::value_type` in the uninitialized storage designated by the range by default-initialization. If an exception is thrown during the initialization, the function has no effects.

The assignments in the parallel `uninitialized_default_construct` algorithm invoked without an execution policy object will execute in sequential order in the calling thread.
**Note:** Complexity: Performs exactly last - first assignments.

**Template Parameters** **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The `uninitialized_default_construct` algorithm returns nothing.

```cpp
template<typename ExPolicy, typename FwdIter>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy> uninitialized_default_construct(ExPolicy &&policy, FwdIter first, FwdIter last)
```

Constructs objects of type typename iterator_traits<ForwardIt>::value_type in the uninitialized storage designated by the range by default-initialization. If an exception is thrown during the initialization, the function has no effects. Executed according to the policy.

The assignments in the parallel `uninitialized_default_construct` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `uninitialized_default_construct` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs exactly last - first assignments.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The `uninitialized_default_construct` algorithm returns a `hpx::future<void>`, if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns nothing otherwise.
template<typename FwdIter, typename Size>
FwdIter uninitialized_default_construct_n(FwdIter first, Size count)

Constructs objects of type typename iterator_traits<ForwardIt>::value_type in the uninitialized storage designated by the range [first, first + count) by default-initialization. If an exception is thrown during the initialization, the function has no effects.

Note: Complexity: Performs exactly count assignments, if count > 0, no assignments otherwise.

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply \( f \) to.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at first the algorithm will be applied to.

Returns The uninitialized_default_construct_n algorithm returns a returns FwdIter. The uninitialized_default_construct_n algorithm returns the iterator to the element in the source range, one past the last element constructed.

template<typename ExPolicy, typename FwdIter, typename Size>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> uninitialized_default_construct_n(ExPolicy \&&policy, FwdIter first, Size count)

Constructs objects of type typename iterator_traits<ForwardIt>::value_type in the uninitialized storage designated by the range [first, first + count) by default-initialization. If an exception is thrown during the initialization, the function has no effects. Executed according to the policy.

The assignments in the parallel uninitialized_default_construct_n algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The assignments in the parallel uninitialized_default_construct_n algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: Performs exactly count assignments, if count > 0, no assignments otherwise.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

• **Size** – The type of the argument specifying the number of elements to apply \( f \) to.

**Parameters**

• **policy** – The execution policy to use for the scheduling of the iterations.

• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **count** – Refers to the number of elements starting at \( \text{first} \) the algorithm will be applied to.

**Returns** The \texttt{uninitialized_default_construct_n} algorithm returns a \texttt{hpx::future\:<\:FwdIter>} if the execution policy is of type \texttt{sequenced_task_policy} or \texttt{parallel_task_policy} and returns \texttt{FwdIter} otherwise. The \texttt{uninitialized_default_construct_n} algorithm returns the iterator to the element in the source range, one past the last element constructed.

### hpx/parallel/algorithms/uninitialized_fill.hpp

See \textit{Public API} for a list of names and headers that are part of the public HPX API.

**namespace** \texttt{hpx}

**Functions**

\begin{verbatim}
template<typename FwdIter, typename T>
void uninitialized_fill(FwdIter first, FwdIter last, T const &value)

Copies the given \texttt{value} to an uninitialized memory area, defined by the range \([\text{first}, \text{last})\). If an exception is thrown during the initialization, the function has no effects.

\textbf{Note:} Complexity: Linear in the distance between \texttt{first} and \texttt{last}
\end{verbatim}

**Template Parameters**

• **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

• **T** – The type of the value to be assigned (deduced).

**Parameters**

• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

• **value** – The value to be assigned.

**Returns** The \texttt{uninitialized_fill} algorithm returns nothing
Copies the given value to an uninitialized memory area, defined by the range [first, last). If an exception is thrown during the initialization, the function has no effects. Executed according to the policy.

The initializations in the parallel uninitialized_fill algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The initializations in the parallel uninitialized_fill algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Linear in the distance between first and last

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **T** – The type of the value to be assigned (deduced).

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to be assigned.

**Returns** The uninitialized_fill algorithm returns a hpx::future<void>, if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns nothing otherwise.

Copies the given value value to the first count elements in an uninitialized memory area beginning at first. If an exception is thrown during the initialization, the function has no effects.

**Note:** Complexity: Performs exactly count assignments, if count > 0, no assignments otherwise.

**Template Parameters**

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply f to.
- **T** – The type of the value to be assigned (deduced).
Parameters

• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **count** – Refers to the number of elements starting at first the algorithm will be applied to.
• **value** – The value to be assigned.

Returns The uninitialized_fill_n algorithm returns a returns FwdIter. The uninitialized_fill_n algorithm returns the output iterator to the element in the range, one past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter, typename Size, typename T>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> uninitialized_fill_n(ExPolicy &&policy, FwdIter first, Size count, T const &value)
```

Copies the given value value to the first count elements in an uninitialized memory area beginning at first. If an exception is thrown during the initialization, the function has no effects. Executed according to the policy.

The initializations in the parallel uninitialized_fill_n algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The initializations in the parallel uninitialized_fill_n algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs exactly count assignments, if count > 0, no assignments otherwise.

Template Parameters

• **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
• **Size** – The type of the argument specifying the number of elements to apply f to.
• **T** – The type of the value to be assigned (deduced).

Parameters

• **policy** – The execution policy to use for the scheduling of the iterations.
• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **count** – Refers to the number of elements starting at first the algorithm will be applied to.
• **value** – The value to be assigned.

Returns The uninitialized_fill_n algorithm returns a hpx::future<FwdIter>, if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter otherwise.
The `uninitialized_fill_n` algorithm returns the output iterator to the element in the range, one past the last element copied.

**hpx/parallel/algorithms/uninitialized_move.hpp**

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace hpx

**Functions**

```cpp
template<typename InIter, typename FwdIter>
FwdIter uninitialized_move(InIter first, InIter last, FwdIter dest)
```

Moves the elements in the range, defined by `[first, last)`, to an uninitialized memory area beginning at `dest`. If an exception is thrown during the initialization, some objects in `[first, last)` are left in a valid but unspecified state.

**Template Parameters**

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The `uninitialized_move` algorithm returns `FwdIter`. The `uninitialized_move` algorithm returns the output iterator to the element in the destination range, one past the last element moved.

```cpp
template<typename ExPolicy, typename FwdIter1, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> uninitialized_move(ExPolicy &&policy,
    FwdIter1 first, FwdIter1 last, FwdIter2 dest)
```

Moves the elements in the range, defined by `[first, last)`, to an uninitialized memory area beginning at `dest`. If an exception is thrown during the initialization, some objects in `[first, last)` are left in a valid but unspecified state. Executed according to the policy.

The assignments in the parallel `uninitialized_move` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.
The assignments in the parallel `uninitialized_move` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs exactly last - first assignments.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns** The `uninitialized_move` algorithm returns a `hpx::future<FwdIter2>`, if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `uninitialized_move` algorithm returns the output iterator to the element in the destination range, one past the last element moved.

```cpp
template<typename InIter, typename Size, typename FwdIter>
std::pair<InIter, FwdIter> uninitialized_move_n(InIter first, Size count, FwdIter dest)
```

Moves the elements in the range [first, first + count), starting from first and proceeding to first + count - 1., to another range beginning at dest. If an exception is thrown during the initialization, some objects in [first, first + count) are left in a valid but unspecified state.

**Note:** Complexity: Performs exactly count movements, if count > 0, no move operations otherwise.
• **dest** – Refers to the beginning of the destination range.

**Returns** The `uninitialized_move_n` algorithm returns a returns `std::pair<InIter,FwdIter>`. The `uninitialized_move_n` algorithm returns a pair whose first element is an iterator to the element past the last element moved in the source range, and whose second element is an iterator to the element past the last element moved in the destination range.

```
template<typename ExPolicy, typename FwdIter1, typename Size, typename FwdIter2>
parallel::util::detail::algorithm_result<ExPolicy, std::pair<FwdIter1, FwdIter2>>::type uninitialized_move_n(ExPolicy &&policy, FwdIter1 first, Size count, FwdIter2 dest)
```

Moves the elements in the range `[first, first + count)`, starting from first and proceeding to `first + count - 1`, to another range beginning at dest. If an exception is thrown during the initialization, some objects in `[first, first + count)` are left in a valid but unspecified state. Executed according to the policy.

The assignments in the parallel `uninitialized_move_n` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `uninitialized_move_n` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs exactly `count` movements, if `count > 0`, no move operations otherwise.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

- **Size** – The type of the argument specifying the number of elements to apply `f` to.

- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **count** – Refers to the number of elements starting at `first` the algorithm will be applied to.

- **dest** – Refers to the beginning of the destination range.

**Returns** The `uninitialized_move_n` algorithm returns a `hpx::future<std::pair<FwdIter1,FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns
std::pair<FwdIter1, FwdIter2> otherwise. The uninitialized_move_n algorithm returns a pair whose first element is an iterator to the element past the last element moved in the source range, and whose second element is an iterator to the element past the last element moved in the destination range.

hpx/parallel/algorithms/uninitialized_value_construct.hpp

See Public API for a list of names and headers that are part of the public HPX API.

namespace hpx

## Functions

```cpp
template<typename FwdIter>
void uninitialized_value_construct(FwdIter first, FwdIter last)
```

Constructs objects of type typename iterator_traits<ForwardIt>::value_type in the uninitialized storage designated by the range by value-initialization. If an exception is thrown during the initialization, the function has no effects.

**Note:** Complexity: Performs exactly last - first assignments.

### Template Parameters FwdIter – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

### Returns

The uninitialized_value_construct algorithm returns nothing.

```cpp
template<typename ExPolicy, typename FwdIter>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy> uninitialized_value_construct(ExPolicy &&policy,
FwdIter first,
FwdIter last)
```

Constructs objects of type typename iterator_traits<ForwardIt>::value_type in the uninitialized storage designated by the range by value-initialization. If an exception is thrown during the initialization, the function has no effects. Executed according to the policy.

The assignments in the parallel uninitialized_value_construct algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The assignments in the parallel uninitialized_value_construct algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs exactly last - first assignments.
Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns The `uninitialized_value_construct` algorithm returns a `hpx::future<void>`, if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns nothing otherwise.

```
template<typename FwdIter, typename Size>
FwdIter uninitialized_value_construct_n(FwdIter first, Size count)

Constructs objects of type typename iterator_traits<ForwardIt>::value_type in the uninitialized storage designated by the range [first, first + count) by value-initialization. If an exception is thrown during the initialization, the function has no effects.
```

Note: Complexity: Performs exactly `count` assignments, if `count > 0`, no assignments otherwise.

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

- **Size** – The type of the argument specifying the number of elements to apply `f` to.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **count** – Refers to the number of elements starting at `first` the algorithm will be applied to.

Returns The `uninitialized_value_construct_n` algorithm returns a returns `FwdIter`. The `uninitialized_value_construct_n` algorithm returns the iterator to the element in the source range, one past the last element constructed.

```
template<typename ExPolicy, typename FwdIter, typename Size>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> uninitialized_value_construct_n(ExPolicy &&policy, FwdIter first, Size count)

Constructs objects of type typename iterator_traits<ForwardIt>::value_type in the uninitialized storage
```

2.8. API reference 527
designated by the range [first, first + count) by value-initialization. If an exception is thrown during the
initialization, the function has no effects.

The assignments in the parallel `uninitialized_value_construct_n` algorithm invoked with an execution policy
object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `uninitialized_value_construct_n` algorithm invoked with an execution policy
object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in
unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs exactly `count` assignments, if `count` > 0, no assignments otherwise.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner
  in which the execution of the algorithm may be parallelized and the manner in which it
  executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet
  the requirements of a forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply `f` to.

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied
  to.
- **count** – Refers to the number of elements starting at `first` the algorithm will be applied to.

**Returns** The `uninitialized_value_construct_n` algorithm returns a `hpx::future<FwdIter>` if the
execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns
`FwdIter` otherwise. The `uninitialized_value_construct_n` algorithm returns the iterator to the
element in the source range, one past the last element constructed.

`hpx/parallel/algorithms/unique.hpp`

See Public API for a list of names and headers that are part of the public HPX API.

namespace `hpx`

**Functions**

```cpp
template<typename FwdIter, typename Pred = hpx::parallel::detail::equal_to, typename Proj = hpx::identity>
FwdIter unique(FwdIter first, FwdIter last, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Eliminates all but the first element from every consecutive group of equivalent elements from the range
[first, last) and returns a past-the-end iterator for the new logical end of the range.
**Note:** Complexity: Performs not more than last - first assignments, exactly last - first - 1 applications of the predicate `pred` and no more than twice as many applications of the projection `proj`.

**Template Parameters**

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `unique` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an binary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

  ```cpp
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to both `Type1` and `Type2`.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate `pred` is invoked.

**Returns** The `unique` algorithm returns `FwdIter`. The `unique` algorithm returns the iterator to the new end of the range.

```cpp
template<typename ExPolicy, typename FwdIter, typename Pred = hpx::parallel::detail::equal_to,
          typename Proj = hpx::identity>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type unique(ExPolicy &&policy, FwdIter first,
  FwdIter last, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Eliminates all but the first element from every consecutive group of equivalent elements from the range `[first, last)` and returns a past-the-end iterator for the new logical end of the range. Executed according to the policy.

The assignments in the parallel `unique` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `unique` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
Note: Complexity: Performs not more than last - first assignments, exactly last - first - 1 applications of the predicate pred and no more than twice as many applications of the projection proj.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of unique requires Pred to meet the requirements of CopyConstructible. This defaults to std::equal_to<>
- **Proj** – The type of an optional projection function. This defaults to hpx::identity.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an binary predicate which returns true for the required elements. The signature of this predicate should be equivalent to:

  ```cpp
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types FwdIter can be dereferenced and then implicitly converted to both Type1 and Type2
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate pred is invoked.

Returns The unique algorithm returns a hpx::future<FwdIter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter otherwise. The unique algorithm returns the iterator to the new end of the range.

template<typename InIter, typename OutIter, typename Pred = hpx::parallel::detail::equal_to, typename Proj = hpx::identity>

```cpp
OutIter unique_copy(InIter first, InIter last, OutIter dest, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Copies the elements from the range [first, last), to another range beginning at dest in such a way that there are no consecutive equal elements. Only the first element of each group of equal elements is copied.

Note: Complexity: Performs not more than last - first assignments, exactly last - first - 1 applications of the predicate pred and no more than twice as many applications of the projection proj

Template Parameters
• **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.

• **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

• **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `unique_copy` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`

• **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**

• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

• **dest** – Refers to the beginning of the destination range.

• **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an binary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a, const Type &b);
  ```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate `pred` is invoked.

**Returns** The `unique_copy` algorithm returns a returns `OutIter`. The `unique_copy` algorithm returns the destination iterator to the end of the `dest` range.

```
template<typename ExPolicy, typename FwdIter1, typename FwdIter2, typename Pred = hpx::parallel::detail::equal_to, typename Proj = hpx::identity>
paralell::util::detail::algorithm_result<ExPolicy, FwdIter2>::type unique_copy(ExPolicy &&policy,
  FwdIter1 first, FwdIter1 last,
  FwdIter2 dest, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Copies the elements from the range `[first, last)`, to another range beginning at `dest` in such a way that there are no consecutive equal elements. Only the first element of each group of equal elements is copied. Executed according to the policy.

The assignments in the parallel `unique_copy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `unique_copy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs not more than `last - first` assignments, exactly `last - first` - 1 applications of the predicate `pred` and no more than twice as many applications of the projection `proj`
Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.

- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of a forward iterator.

- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `unique_copy` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`

- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **dest** – Refers to the beginning of the destination range.

- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an binary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a, const Type &b);
  ```

  The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate `pred` is invoked.

Returns

The `unique_copy` algorithm returns a `hpx::future<FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter2` otherwise. The `unique_copy` algorithm returns the pair of the source iterator to `last`, and the destination iterator to the end of the `dest` range.

See [Public API](#) for a list of names and headers that are part of the public `HPX` API.

```
namespace hpx

namespace ranges
```
Functions

template<typename FwdIter1, typename FwdIter2, typename Sent>
FwdIter2 adjacent_difference(FwdIter1 first, Sent last, FwdIter2 dest)

Searches the range [first, last) for two consecutive identical elements.

Note: Complexity: Exactly the smaller of (result - first) + 1 and (last - first) - 1 application of the predicate where result is the value returned

Template Parameters
- FwdIter1 – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- FwdIter2 – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- Sent – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.

Parameters
- first – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- last – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- dest – Refers to the beginning of the destination range.

Returns The adjacent_difference algorithm returns an iterator to the first of the identical elements. If no such elements are found, last is returned.

template<typename Rng, typename FwdIter2>
FwdIter2 adjacent_difference(Rng &&rng, FwdIter2 dest)

Searches the rng for two consecutive identical elements.

Note: Complexity: Exactly the smaller of (result - first) + 1 and (last - first) - 1 application of the predicate where result is the value returned

Template Parameters
- FwdIter2 – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- Rng – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

Parameters
- rng – Refers to the sequence of elements the algorithm will be applied to.
- dest – Refers to the beginning of the destination range.

Returns The adjacent_difference algorithm returns an iterator to the first of the identical elements.

template<typename ExPolicy, typename FwdIter1, typename Sent, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> adjacent_difference(ExPolicy &&policy, FwdIter1 first, Sent last, FwdIter2 dest)

Searches the range [first, last) for two consecutive identical elements.
Note:  Complexity: Exactly the smaller of (result - first) + 1 and (last - first) - 1 application of the predicate where result is the value returned

**Template Parameters**
- `ExPolicy` – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter1` – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- `FwdIter2` – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- `Sent` – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.

**Parameters**
- `policy` – The execution policy to use for the scheduling of the iterations.
- `first` – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- `dest` – Refers to the beginning of the destination range.

**Returns**  The adjacent_difference algorithm returns an iterator to the first of the identical elements. If no such elements are found, last is returned.

```cpp
template<typename ExPolicy, typename Rng, typename FwdIter2>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> adjacent_difference(ExPolicy &&policy, Rng &&rng, FwdIter2 dest)
```

Searches the rng for two consecutive identical elements.

Note:  Complexity: Exactly the smaller of (result - first) + 1 and (last - first) - 1 application of the predicate where result is the value returned

**Template Parameters**
- `ExPolicy` – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Rng` – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

**Parameters**
- `policy` – The execution policy to use for the scheduling of the iterations.
- `rng` – Refers to the sequence of elements the algorithm will be applied to.
- `dest` – Refers to the beginning of the destination range.

**Returns**  The adjacent_difference algorithm returns an iterator to the first of the identical elements.

```cpp
template<typename FwdIter1, typename Sent, typename FwdIter2, typename Op>
```
**FwdIter2 adjacent_difference** *(FwdIter1 first, Sent last, FwdIter2 dest, Op &&op)*

Searches the range [first, last) for two consecutive identical elements.

**Note:** Complexity: Exactly the smaller of (result - first) + 1 and (last - first) - 1 application of the predicate where result is the value returned

**Template Parameters**
- **FwdIter1** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **Op** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of adjacent_difference requires Op to meet the requirements of CopyConstructible.

**Parameters**
- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Binary operation function object that will be applied. The signature of the function should be equivalent to the following:

```cpp
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &. The types Type1 and Type2 must be such that an object of type iterator_traits<InputIt>::value_type can be implicitly converted to both of them. The type Ret must be such that an object of type OutputIt can be dereferenced and assigned a value of type Ret.

**Returns** The adjacent_difference algorithm returns an iterator to the first of the identical elements. If no such elements are found, last is returned.

template<typename Rng, typename FwdIter2, typename Op>
**FwdIter2 adjacent_difference** *(Rng &&rng, FwdIter2 dest, Op &&op)*

Searches the rng for two consecutive identical elements.

**Template Parameters**
- **FwdIter2** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Op** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of adjacent_difference requires Op to meet the requirements of CopyConstructible.

**Parameters**
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Binary operation function object that will be applied. The signature of the function should be equivalent to the following:

```cpp
Ret fun(const Type1 &a, const Type2 &b);
```
The signature does not need to have const &. The types Type1 and Type2 must be such that an object of type `iterator_traits<InputIt>::value_type` can be implicitly converted to both of them. The type Ret must be such that an object of type `OutputIt` can be dereferenced and assigned a value of type Ret?.

**Returns** The `adjacent_difference` algorithm returns an iterator to the first of the identical elements.

```cpp
template<typename ExPolicy, typename FwdIter1, typename Sent, typename FwdIter2, typename Op>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> adjacent_difference(ExPolicy &&policy, FwdIter1 first, Sent last, FwdIter2 dest, Op &&&op)
```

Searches the range `[first, last)` for two consecutive identical elements.

**Note:** Complexity: Exactly the smaller of `(result - first) + 1` and `(last - first) - 1` application of the predicate where `result` is the value returned

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **Op** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `adjacent_difference` requires `Op` to meet the requirements of `CopyConstructible`.

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Binary operation function object that will be applied. The signature of the function should be equivalent to the following:

```cpp
Ret fun(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &. The types Type1 and Type2 must be such that an object of type `iterator_traits<InputIt>::value_type` can be implicitly converted to both of them. The type Ret must be such that an object of type `OutputIt` can be dereferenced and assigned a value of type Ret?.

**Returns** The `adjacent_difference` algorithm returns an iterator to the first of the identical elements. If no such elements are found, `last` is returned.
template<typename ExPolicy, typename Rng, typename FwdIter2, typename Op>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter2> adjacent_difference(ExPolicy &&policy, Rng &&rng, FwdIter2 dest, Op &&op)

Searches the rng for two consecutive identical elements.

**Note:** Complexity: Exactly the smaller of (result - first) + 1 and (last - first) - 1 application of the predicate where result is the value returned

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter2** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Op** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of adjacent_difference requires Op to meet the requirements of CopyConstructible.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Binary operation function object that will be applied. The signature of the function should be equivalent to the following:

\[
\text{Ret fun(const Type1 &a, const Type2 &b);}\]

The signature does not need to have const &. The types Type1 and Type2 must be such that an object of type iterator_traits<InputIt>::value_type can be implicitly converted to both of them. The type Ret must be such that an object of type OutputIt can be dereferenced and assigned a value of type Ret.

**Returns** The adjacent_difference algorithm returns an iterator to the first of the identical elements.

**hpx/parallel/container_algorithms/adjacent_find.hpp**

See **Public API** for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**
Functions

template<typename FwdIter, typename Sent, typename Proj = hpx::identity, typename Pred = detail::equal_to>
FwdIter adjacent_find(FwdIter first, Sent last, Pred &&pred = Pred(), Proj &&proj = Proj())

Searches the range [first, last) for two consecutive identical elements.

Note: Complexity: Exactly the smaller of (result - first) + 1 and (last - first) - 1 application of the predicate where result is the value returned.

Template Parameters

- **FwdIter** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **Proj** – The type of an optional projection function. This defaults to hpx::identity
- **Pred** – The type of an optional function/function object to use.

Parameters

- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **pred** – The binary predicate which returns true if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 must be such that objects of type FwdIter can be dereferenced and then implicitly converted to Type1.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Returns The adjacent_find algorithm returns an iterator to the first of the identical elements. If no such elements are found, last is returned.

template<typename ExPolicy, typename FwdIter, typename Sent, typename Proj = hpx::identity, typename Pred = detail::equal_to>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type adjacent_find(ExPolicy &&policy, FwdIter first, Sent last, Pred &&pred = Pred(), Proj &&proj = Proj())

Searches the range [first, last) for two consecutive identical elements. This version uses the given binary predicate pred.

The comparison operations in the parallel adjacent_find invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The comparison operations in the parallel adjacent_find invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
This overload of `adjacent_find` is available if the user decides to provide their algorithm their own binary predicate `pred`.

**Note:** Complexity: Exactly the smaller of \((\text{result} - \text{first}) + 1\) and \((\text{last} - \text{first}) - 1\) application of the predicate where `result` is the value returned.

**Template Parameters**
- `ExPolicy` – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter` – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- `Sent` – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `InIter`.
- `Proj` – The type of an optional projection function. This defaults to `hpx::identity`.
- `Pred` – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>

**Parameters**
- `policy` – The execution policy to use for the scheduling of the iterations.
- `first` – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- `pred` – The binary predicate which returns `true` if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.
- `proj` – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `adjacent_find` algorithm returns a `hpx::future<InIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `InIter` otherwise. The `adjacent_find` algorithm returns an iterator to the first of the identical elements. If no such elements are found, `last` is returned.

```cpp
template<typename Rng, typename Proj = hpx::identity, typename Pred = detail::equal_to>
hpx::traits::range_traits<Rng>::iterator_type adjacent_find(Rng &&rng, Pred &&&pred = Pred(), Proj &&&proj = Proj())
```

Searches the range `rng` for two consecutive identical elements.

**Note:** Complexity: Exactly the smaller of \((\text{result} - \text{std::begin(rng)}) + 1\) and \((\text{std::begin(rng)} - \text{std::end(rng)}) - 1\) applications of the predicate where `result` is the value returned.

**Template Parameters**
- `Rng` – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- `Proj` – The type of an optional projection function. This defaults to `hpx::identity`.
- `Pred` – The type of an optional function/function object to use.
Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – The binary predicate which returns `true` if the elements should be treated as equal.
  
  The signature should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Returns

The `adjacent_find` algorithm returns an iterator to the first of the identical elements. If no such elements are found, `last` is returned.

```
template<typename ExPolicy, typename Rng, typename Proj = hpx::identity, typename Pred = detail::equal_to>
parallel::util::detail::algorithm_result<ExPolicy, typename hpx::traits::range_traits<Rng>::iterator_type>::type
adjacent_find(
  ExPolicy &&policy,
  Rng &&rng,
  Pred &&pred = Pred(),
  Proj &&proj = Proj())
```
• **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – The binary predicate which returns `true` if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `adjacent_find` algorithm returns a `hpx::future<InIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `InIter` otherwise. The `adjacent_find` algorithm returns an iterator to the first of the identical elements. If no such elements are found, `last` is returned.

`hpx/parallel/container_algorithms/all_any_none.hpp`

See *Public API* for a list of names and headers that are part of the public *HPX API*.

namespace `hpx`

namespace `ranges`

**Functions**

```cpp
template<typename ExPolicy, typename Rng, typename F, typename Proj = hpx::identity>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> none_of(ExPolicy &&policy, Rng &&rng, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate `f` returns true for no elements in the range `rng`.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate `f`.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
• **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

• **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `none_of` requires `F` to meet the requirements of `CopyConstructible`.

• **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

### Returns

The `none_of` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `none_of` algorithm returns true if the unary predicate `f` returns true for no elements in the range, false otherwise. It returns true if the range is empty.

```cpp
template<
    typename ExPolicy, typename Iter, typename Sent, typename F, typename Proj = hpx::identity>

hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> none_of(
    ExPolicy &&policy, Iter first, Sent last, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate `f` returns true for no elements in the range `[first, last)`.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

### Note:

Complexity: At most `last - first` applications of the predicate `f`

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

- **Iter** – The type of the source iterators used for the range (deduced).

- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `InIter`.

- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `none_of` requires `F` to meet the requirements of `CopyConstructible`.

- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`
• **policy** – The execution policy to use for the scheduling of the iterations.
• **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
• **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
• **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `none_of` algorithm returns `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `none_of` algorithm returns true if the unary predicate `f` returns true for no elements in the range, false otherwise. It returns true if the range is empty.

```cpp
template<typename Rng, typename F, typename Proj = hpx::identity>
bool none_of(Rng &rng, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate `f` returns true for no elements in the range `rng`.

**Note:** Complexity: At most std::distance(begin(rng), end(rng)) applications of the predicate `f`.

**Template Parameters**

• **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
• **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `none_of` requires `F` to meet the requirements of `CopyConstructible`.
• **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**

• **rng** – Refers to the sequence of elements the algorithm will be applied to.
• **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `none_of` algorithm returns true if the unary predicate `f` returns true for no elements in the range, false otherwise. It returns true if the range is empty.

```cpp
template<typename Iter, typename Sent, typename F, typename Proj = hpx::identity>
bool none_of(Iter first, Sent last, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate `f` returns true for no elements in the range `[first, last)`. 
Template Parameters

- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `none_of` requires `F` to meet the requirements of `Copy-Constructible`.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

Parameters

- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Returns

The `none_of` algorithm returns true if the unary predicate `f` returns true for no elements in the range, false otherwise. It returns true if the range is empty.

```cpp
template<typename ExPolicy, typename Rng, typename F, typename Proj = hpx::identity>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> any_of(ExPolicy &&policy, Rng &&rng, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate `f` returns true for at least one element in the range `rng`.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate `f`
Constructible.

- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

### Returns

The `any_of` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `any_of` algorithm returns true if the unary predicate `f` returns true for at least one element in the range, false otherwise. It returns false if the range is empty.

```cpp
template<typename ExPolicy, typename Iter, typename Sent, typename F, typename Proj = hpx::identity>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> any_of(ExPolicy &&policy, Iter first, Sent last, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate `f` returns true for at least one element in the range `rng`.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most std::distance(begin(rng), end(rng)) applications of the predicate `f`

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `InIter`.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `none_of` requires `F` to meet the requirements of `CopyConstructible`.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
• **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.

• **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type Type must be such that an object of type FwdIter can be dereferenced and then implicitly converted to Type.

• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `any_of` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `any_of` algorithm returns true if the unary predicate `f` returns true for at least one element in the range, false otherwise. It returns false if the range is empty.

```cpp
template<typename Rng, typename F, typename Proj = hpx::identity>
bool any_of(Rng &&rng, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate `f` returns true for at least one element in the range `rng`.

**Note:** Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate `f`

**Template Parameters**

• **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

• **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `none_of` requires `F` to meet the requirements of Copy-Constructible.

• **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**

• **rng** – Refers to the sequence of elements the algorithm will be applied to.

• **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type Type must be such that an object of type FwdIter can be dereferenced and then implicitly converted to Type.

• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `any_of` algorithm returns true if the unary predicate `f` returns true for at least one element in the range, false otherwise. It returns false if the range is empty.

```cpp
template<typename Iter, typename Sent, typename F, typename Proj = hpx::identity>
bool any_of(Iter first, Sent last, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate `f` returns true for at least one element in the range `rng`.

**Note:** Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate `f`
Template Parameters
- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `none_of` requires `F` to meet the requirements of `CopyConstructible`.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

Parameters
- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. The signature of this predicate should be equivalent to:

  ```cpp
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Returns
The `any_of` algorithm returns true if the unary predicate `f` returns true for at least one element in the range, false otherwise. It returns false if the range is empty.

```cpp
template<typename ExPolicy, typename Rng, typename F, typename Proj = hpx::identity>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> any_of(ExPolicy &&policy, Rng &&rng, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate `f` returns true for all elements in the range `rng`.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate `f`.

Template Parameters
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `none_of` requires `F` to meet the requirements of `CopyConstructible`.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

Parameters
- **policy** – The execution policy to use for the scheduling of the iterations.
• **rng** – Refers to the sequence of elements the algorithm will be applied to.
• **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `all_of` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `all_of` algorithm returns true if the unary predicate `f` returns true for all elements in the range, false otherwise. It returns true if the range is empty.

```cpp
template<typename ExPolicy, typename Iter, typename Sent, typename F, typename Proj = hpx::identity>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> all_of(ExPolicy &&policy, Iter first, Sent last, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate `f` returns true for all elements in the range `rng`.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most `std::distance(begin(rng), end(rng))` applications of the predicate `f`

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `InIter`.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `none_of` requires `F` to meet the requirements of `CopyConstructible`.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. The signature of this predicate should be equivalent to:
bool pred(const Type &a);

The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type FwdIter can be dereferenced and then implicitly converted to Type.

- proj – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The all_of algorithm returns a hpx::future<bool> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns bool otherwise. The all_of algorithm returns true if the unary predicate f returns true for all elements in the range, false otherwise. It returns true if the range is empty.

```cpp
template<typename Rng, typename F, typename Proj = hpx::identity>
bool all_of(Rng &&rng, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate f returns true for all elements in the range rng.

**Note:** Complexity: At most std::distance(begin(rng), end(rng)) applications of the predicate f

**Template Parameters**
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of none_of requires F to meet the requirements of Copy-Constructible.
- **Proj** – The type of an optional projection function. This defaults to hpx::identity

**Parameters**
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type FwdIter can be dereferenced and then implicitly converted to Type.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The all_of algorithm returns true if the unary predicate f returns true for all elements in the range, false otherwise. It returns true if the range is empty.

```cpp
template<typename Iter, typename Sent, typename F, typename Proj = hpx::identity>
bool all_of(Iter first, Sent last, F &&f, Proj &&proj = Proj())
```

Checks if unary predicate f returns true for all elements in the range rng.

**Note:** Complexity: At most std::distance(begin(rng), end(rng)) applications of the predicate f

**Template Parameters**
- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
• **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `none_of` requires `F` to meet the requirements of `CopyConstructible`.

• **Proj** – The type of an optional projection function. This defaults to `hpx::identity`  

**Parameters**

• **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.

• **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.

• **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `all_of` algorithm returns true if the unary predicate `f` returns true for all elements in the range, false otherwise. It returns true if the range is empty.

### hpx/parallel/container_algorithms/copy.hpp

See "Public API" for a list of names and headers that are part of the public HPX API.

```
namespace hpx

namespace ranges

Functions

template<typename ExPolicy, typename FwdIter1, typename Sent1, typename FwdIter>
parallel::util::detail::algorithm_result<ExPolicy, ranges::copy_result<FwdIter1, FwdIter>>::type copy(ExPolicy &&policy, FwdIter1 iter, Sent1 sent, FwdIter dest)
```

Copies the elements in the range, defined by [first, last), to another range beginning at `dest`.

The assignments in the parallel `copy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `copy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
Note: Complexity: Performs exactly last - first assignments.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **iter** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns**
The copy algorithm returns a `hpx::future<ranges::copy_result<FwdIter1, FwdIter>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::copy_result<FwdIter1, FwdIter>` otherwise. The copy algorithm returns the pair of the input iterator last and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename Rng, typename FwdIter>
parallel::util::detail::algorithm_result<ExPolicy, ranges::copy_result<typename hpx::traits::range_traits<Rng>::iterator_type, FwdIter>> copy(
    ExPolicy &&policy,
    Rng &&rng,
    FwdIter dest)
```

Copies the elements in the range rng to another range beginning at dest.

The assignments in the parallel copy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The assignments in the parallel copy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: Performs exactly std::distance(begin(rng), end(rng)) assignments.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

Returns The copy algorithm returns a `hpx::future<ranges::copy_result<iterator_t<Rng>, FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::copy_result<iterator_t<Rng>, FwdIter2>` otherwise.

The copy algorithm returns the pair of the input iterator `last` and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename FwdIter1, typename Sentinel1, typename FwdIter>
ranges::copy_result<FwdIter1, FwdIter> copy(FwdIter1 iter, Sentinel1 sent, FwdIter dest)
```

Copies the elements in the range, defined by `[first, last)`, to another range beginning at `dest`.

Note: Complexity: Performs exactly `last - first` assignments.

Template Parameters

- **FwdIter1** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sentinel1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **iter** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

Returns The copy algorithm returns the pair of the input iterator `last` and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename Rng, typename FwdIter>
ranges::copy_result<typename hpx::traits::range_traits<Rng>::iterator_type, FwdIter> copy(Rng &&rng, FwdIter dest)
```

Copies the elements in the range `rng` to another range beginning at `dest`.

Note: Complexity: Performs exactly `std::distance(begin(rng), end(rng))` assignments.

Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

Returns The copy algorithm returns the pair of the input iterator `last` and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename FwdIter1, typename Size, typename FwdIter2>
```
Copies the elements in the range \([\text{first}, \text{first} + \text{count})\), starting from \text{first} and proceeding to \text{first} + \text{count} - 1, to another range beginning at \text{dest}.

The assignments in the parallel \texttt{copy\_n} algorithm invoked with an execution policy object of type \texttt{sequenced\_policy} execute in sequential order in the calling thread.

The assignments in the parallel \texttt{copy\_n} algorithm invoked with an execution policy object of type \texttt{parallel\_policy} or \texttt{parallel\_task\_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

\textbf{Note:} Complexity: Performs exactly \texttt{count} assignments, if \texttt{count} > 0, no assignments otherwise.

\textbf{Template Parameters}
- \texttt{ExPolicy} – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- \texttt{FwdIter1} – The type of the source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- \texttt{Size} – The type of the argument specifying the number of elements to apply \(f\) to.
- \texttt{FwdIter2} – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

\textbf{Parameters}
- \texttt{policy} – The execution policy to use for the scheduling of the iterations.
- \texttt{first} – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- \texttt{count} – Refers to the number of elements starting at \texttt{first} the algorithm will be applied to.
- \texttt{dest} – Refers to the beginning of the destination range.

\textbf{Returns} The \texttt{copy\_n} algorithm returns a \texttt{hpx::future<ranges::copy\_n\_result<FwdIter1, FwdIter2> >} if the execution policy is of type \texttt{sequenced\_task\_policy} or \texttt{parallel\_task\_policy} and returns \texttt{ranges::copy\_n\_result<FwdIter1, FwdIter2> otherwise}. The \texttt{copy} algorithm returns the pair of the input iterator forwarded to the first element after the last in the input sequence and the output iterator to the element in the destination range, one past the last element copied.

\textbf{Note:} Complexity: Performs exactly \texttt{count} assignments, if \texttt{count} > 0, no assignments otherwise.
Template Parameters
- **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply \( f \) to.
- **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at \( \text{first} \) the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

Returns The \( \text{copy} \) algorithm returns the pair of the input iterator forwarded to the first element after the last in the input sequence and the output iterator to the element in the destination range, one past the last element copied.

```cpp
#include <hpx/parallel/util/detail/algorithm_result.hpp>
#include <hpx/parallel/util/detail/algorithm_result.hpp>
#include <ranges/algorithm_result.hpp>

template<typename ExPolicy, typename FwdIter1, typename Sent1, typename FwdIter, typename Pred, typename Proj = hpx::identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, ranges::copy_if_result<FwdIter1, FwdIter>> copy_if(ExPolicy &&policy, FwdIter1 first, Sent1 last, FwdIter dest, Pred &&pred, Proj &&proj = Proj())
```

Copies the elements in the range, defined by \([\text{first}, \text{last})\) to another range beginning at \( \text{dest} \). The order of the elements that are not removed is preserved.

The assignments in the parallel \( \text{copy_if} \) algorithm invoked with an execution policy object of type \( \text{sequenced_policy} \) execute in sequential order in the calling thread.

The assignments in the parallel \( \text{copy_if} \) algorithm invoked with an execution policy object of type \( \text{parallel_policy} \) or \( \text{parallel_task_policy} \) are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Template Parameters
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for \( \text{FwdIter1} \).
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of an optional function/function object to use.
- **Proj** – The type of an optional projection function. This defaults to \( \text{hpx::identity} \)
Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **iter** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – The binary predicate which returns `true` if the elements should be treated as equal.

The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `copy_if` algorithm returns a `hpx::future<ranges::copy_if_result<iterator_t<Rng>>, FwdIter2>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::copy_if_result<iterator_t<Rng>>, FwdIter2>` otherwise. The `copy_if` algorithm returns the pair of the input iterator `last` and the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename Rng, typename FwdIter, typename Pred, typename Proj = hpx::identity>
    hpx::parallel::util::detail::algorithm_result<ExPolicy, ranges::copy_if_result<typename hpx::traits::range_traits<Rng>::iterator_type, FwdIter>> copy_if(ExPolicy &&policy, Rng &&rng, FwdIter dest, Pred &&pred, Proj &&proj = Proj())
```

Copies the elements in the range, defined by `rng` to another range beginning at `dest`. The order of the elements that are not removed is preserved.

The assignments in the parallel `copy_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
• **Pred** – The type of an optional function/function object to use.
• **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – The binary predicate which returns `true` if the elements should be treated as equal.
  The signature should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

### Returns

The `copy_if` algorithm returns a `hpx::future<ranges::copy_if_result<iterator_t<Rng>, FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::copy_if_result<iterator_t<Rng>, FwdIter2>` otherwise. The `copy_if` algorithm returns the pair of the input iterator `last` and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename FwdIter1, typename Sent1, typename FwdIter, typename Pred, typename Proj = hpx::identity>
ranges::copy_if_result<FwdIter1, FwdIter> copy_if(FwdIter1 iter, Sent1 sent, FwdIter dest, Pred &&pred, Proj &&proj = Proj())
```

Copies the elements in the range, defined by `[first, last)` to another range beginning at `dest`. The order of the elements that are not removed is preserved.

### Template Parameters

- **FwdIter1** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for `FwdIter1`.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of an optional function/function object to use.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

### Parameters

- **iter** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – The binary predicate which returns `true` if the elements should be treated as equal.
  The signature should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

### Returns

The `copy_if` algorithm returns the pair of the input iterator `last` and the output iterator to the element in the destination range, one past the last element copied.
template<
    typename Rng,
    typename FwdIter,
    typename Pred,
    typename Proj = hpx::identity>

ranges::copy_if_result<typename hpx::traits::range_traits<Rng>::iterator_type,
    FwdIter>

    copy_if
    (Rng &&rng,
    FwdIter dest,
    Pred &&pred,
    Proj &&proj
    = Proj())

Copies the elements in the range, defined by rng to another range beginning at dest. The order of the elements that are not removed is preserved.

**Template Parameters**
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of an optional function/function object to use.
- **Proj** – The type of an optional projection function. This defaults to hpx::identity

**Parameters**
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – The binary predicate which returns true if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 must be such that objects of type FwdIter can be dereferenced and then implicitly converted to Type1.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The copy_if algorithm returns the pair of the input iterator last and the output iterator to the element in the destination range, one past the last element copied.

Functions

template<typename ExPolicy, typename Rng, typename Proj = hpx::identity, typename T = typename hpx::parallel::traits::projected<hpx::traits::range_iterator_t<Rng>, Proj>::value_type>

hpx::parallel::util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<typename hpx::traits::range_traits<Rng>::iterator_type>::difference_type>::type
count(
ExPolicy&& policy,
Rng&& rng,
T const& value,
Proj&& proj = Proj())

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts the elements that are equal to the given value.

The comparisons in the parallel count algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note:** Complexity: Performs exactly last - first comparisons.

**Note:** The comparisons in the parallel count algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the comparisons.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **T** – The type of the value to search for (deduced).
- **Proj** – The type of an optional projection function. This defaults to hpx::identity

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **value** – The value to search for.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The count algorithm returns a hpx::future<difference_type> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns difference_type otherwise (where difference_type is defined by std::iterator_traits<FwdIter>::difference_type. The count algorithm returns the number of elements satisfying the given criteria.

template<typename ExPolicy, typename Iter, typename Sent, typename Proj = hpx::identity, typename T = typename hpx::parallel::traits::projected<Iter, Proj>::value_type>
Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts the elements that are equal to the given value.

The comparisons in the parallel count algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

**Note:** Complexity: Performs exactly last - first comparisons.

**Note:** The comparisons in the parallel count algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the comparisons.
- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **T** – The type of the value to search for (deduced).
- **Proj** – The type of an optional projection function. This defaults to hpx::identity

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to search for.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns**

The count algorithm returns a hpx::future<difference_type> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns difference_type otherwise (where difference_type is defined by std::iterator_traits<FwdIter>::difference_type. The count algorithm returns the number of elements satisfying the given criteria.
std::iterator_traits<typename hpx::traits::range_traits<Rng>::iterator_type>::difference_type count(Rng &&rng, T const &value, Proj &&proj = Proj())

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts the elements that are equal to the given value.

**Note:** Complexity: Performs exactly last - first comparisons.

**Template Parameters**
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **T** – The type of the value to search for (deduced).
- **Proj** – The type of an optional projection function. This defaults to hpx::identity

**Parameters**
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **value** – The value to search for.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The count algorithm returns the number of elements satisfying the given criteria.

template<typename Iter, typename Sent, typename Proj = hpx::identity, typename T = typename hpx::parallel::traits::projected<Iter, Proj>::value_type>
std::iterator_traits<Iter>::difference_type count(Iter first, Sent last, T const &value, Proj &&proj = Proj())

Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts the elements that are equal to the given value.

**Note:** Complexity: Performs exactly last - first comparisons.

**Template Parameters**
- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **T** – The type of the value to search for (deduced).
- **Proj** – The type of an optional projection function. This defaults to hpx::identity

**Parameters**
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – The value to search for.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The count algorithm returns the number of elements satisfying the given criteria.

template<typename ExPolicy, typename Rng, typename F, typename Proj = hpx::identity>
Returns the number of elements in the range [first, last) satisfying a specific criteria. This version counts elements for which predicate \( f \) returns true.

**Note:** Complexity: Performs exactly \( last - first \) applications of the predicate.

**Note:** The assignments in the parallel `count_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note:** The assignments in the parallel `count_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the comparisons.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `count_if` requires \( F \) to meet the requirements of `CopyConstructible`.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([first, last)\). This is an unary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

### Returns

The `count_if` algorithm returns `hpx::future<difference_type>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `difference_type` otherwise (where `difference_type` is defined by
The `count` algorithm returns the number of elements satisfying the given criteria.

```cpp
template<typename ExPolicy, typename Iter, typename Sent, typename F, typename Proj = hpx::identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<Iter>::difference_type>::type
count_if(
    ExPolicy&& policy,
    Iter first,
    Sent last,
    F&& f,
    Proj&& proj = Proj()
)
```

Returns the number of elements in the range `[first, last)` satisfying a specific criteria. This version counts elements for which predicate `f` returns true.

**Note:** Complexity: Performs exactly `last - first` applications of the predicate.

**Note:** The assignments in the parallel `count_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

**Note:** The assignments in the parallel `count_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Template Parameters**
- `ExPolicy` – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the comparisons.
- `Iter` – The type of the source iterators used for the range (deduced).
- `Sent` – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `InIter`.
- `F` – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `count_if` requires `F` to meet the requirements of `CopyConstructible`.
- `Proj` – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**
- `policy` – The execution policy to use for the scheduling of the iterations.
- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements the algorithm will be applied to.
- `f` – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:
```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `count_if` algorithm returns `hpx::future<difference_type>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `difference_type` otherwise (where `difference_type` is defined by `std::iterator_traits<FwdIter>::difference_type`). The `count` algorithm returns the number of elements satisfying the given criteria.

```cpp
template<typename Rng, typename F, typename Proj = hpx::identity>
std::iterator_traits<typename hpx::traits::range_traits<Rng>::iterator_type>::difference_type count_if(Rng &&rng, F &&f, Proj &&proj = Proj())
```

Returns the number of elements in the range `[first, last)` satisfying a specific criteria. This version counts elements for which predicate `f` returns true.

**Note:** Complexity: Performs exactly `last - first` applications of the predicate.

**Template Parameters**
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `count_if` requires `F` to meet the requirements of Copy-Constructible.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `count` algorithm returns the number of elements satisfying the given criteria.

```cpp
template<typename Iter, typename Sent, typename F, typename Proj = hpx::identity>
std::iterator_traits<Iter>::difference_type count_if(Iter first, Sent last, F &&f, Proj &&proj = Proj())
```

Returns the number of elements in the range `[first, last)` satisfying a specific criteria. This version counts elements for which predicate `f` returns true.
Template Parameters

- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `InIter`.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `count_if` requires `F` to meet the requirements of `CopyConstructible`.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Returns

The `count` algorithm returns the number of elements satisfying the given criteria.

---

**Note:** Complexity: Performs exactly `last - first` applications of the predicate.

---

**Public API** for a list of names and headers that are part of the public `HPX` API.

```cpp
namespace hpx

namespace ranges

Functions

template<
    typename ExPolicy, typename Rng>
hpx::parallel::util::detail::algorithm_result<ExPolicy, hpx::traits::range_iterator_t<Rng>>
destroy(ExPolicy &&policy,
    Rng &&rng)
```

Destroys objects of type `typename range_traits<ForwardIt>::value_type` in the range `[first, last)`. The operations in the parallel `destroy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.
The operations in the parallel destroy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: Performs exactly last - first operations.

Template Parameters
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

Parameters
- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.

Returns The destroy algorithm returns a hpx::future<void>, if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns void otherwise.

template<typename ExPolicy, typename Iter, typename Sent>
  hpx::parallel::util::detail::algorithm_result_t<ExPolicy, Iter> destroy(ExPolicy &&policy, Iter first, Sent last)

Destroys objects of type typename iterator_traits<ForwardIt>::value_type in the range [first, last).

The operations in the parallel destroy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The operations in the parallel destroy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: Performs exactly last - first operations.

Template Parameters
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.

Parameters
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns The destroy algorithm returns a hpx::future<void>, if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns void otherwise.

template<typename Rng>
  hpx::traits::range_iterator<Rng>::type destroy(Rng &&rng)

Destroys objects of type typename iterator_traits<ForwardIt>::value_type in the range [first, last).
Note: Complexity: Performs exactly last - first operations.

**Template Parameters**
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.

**Returns** The destroy algorithm returns void.

template<typename Iter, typename Sent>
Iter destroy(Iter first, Sent last)

Destroys objects of type typename iterator_traits<ForwardIt>::value_type in the range [first, last).

Note: Complexity: Performs exactly last - first operations.

**Template Parameters**
- **Iter** – The type of the source iterators used for the range (deduced).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.

**Parameters**
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The destroy algorithm returns void.

template<typename ExPolicy, typename FwdIter, typename Size>
hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type destroy_n(ExPolicy &&policy, FwdIter first, Size count)

Destroys objects of type typename iterator_traits<ForwardIt>::value_type in the range [first, first + count).

The operations in the parallel destroy_n algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The operations in the parallel destroy_n algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: Performs exactly count operations, if count > 0, no assignments otherwise.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply this algorithm to.

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **count** – Refers to the number of elements starting at first the algorithm will be applied to.

**Returns** The destroy_n algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The destroy_n algorithm returns the iterator to the element in the source range, one past the last element constructed.

```cpp
template<typename FwdIter, typename Size>
FwdIter destroy_n(FwdIter first, Size count)
```

Destroys objects of type `typename iterator_traits<ForwardIt>::value_type` in the range `[first, first + count)`.

**Note:** Complexity: Performs exactly `count` operations, if `count > 0`, no assignments otherwise.

**Template Parameters**
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply this algorithm to.

**Parameters**
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at first the algorithm will be applied to.

**Returns** The destroy_n algorithm returns the iterator to the element in the source range, one past the last element constructed.

### hpx/parallel/container_algorithms/ends_with.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

```cpp
namespace hpx

namespace ranges

Functions
```

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Pred = ranges::equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
bool ends_with(Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Pred &&pred = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Checks whether the second range defined by `[first1, last1)` matches the suffix of the first range defined by `[first2, last2)`

The assignments in the parallel ends_with algorithm invoked without an execution policy object execute in sequential order in the calling thread.
Note: Complexity: Linear: at most min(N1, N2) applications of the predicate and both projections.

Template Parameters

- **Iter1** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2** – The type of the begin destination iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Sent2** – The type of the end destination iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter2.
- **Pred** – The binary predicate that compares the projected elements.
- **Proj1** – The type of an optional projection function for the source range. This defaults to hpx::identity
- **Proj2** – The type of an optional projection function for the destination range. This defaults to hpx::identity

Parameters

- **first1** – Refers to the beginning of the source range.
- **last1** – Sentinel value referring to the end of the source range.
- **first2** – Refers to the beginning of the destination range.
- **last2** – Sentinel value referring to the end of the destination range.
- **pred** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the in two ranges projected by proj1 and proj2 respectively.
- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements in the source range as a projection operation before the actual predicate is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements in the destination range as a projection operation before the actual predicate is invoked.

Returns

The ends_with algorithm returns bool. The ends_with algorithm returns a boolean with the value true if the second range matches the suffix of the first range, false otherwise.

```cpp
template<typename ExPolicy, typename FwdIter1, typename Sent1, typename FwdIter2, typename Sent2, typename Pred = ranges::equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
parallel::util::detail::algorithm_result<ExPolicy, bool>::type ends_with(ExPolicy &&policy, FwdIter1 first1, Sent1 last1, FwdIter2 first2, Sent2 last2, Pred &&pred = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Checks whether the second range defined by [first1, last1) matches the suffix of the first range defined by [first2, last2)

The assignments in the parallel ends_with algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The assignments in the parallel ends_with algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
Note: Complexity: Linear: at most \(\min(N1, N2)\) applications of the predicate and both projections.

Template Parameters
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of a sentinel for Iter1.
- **FwdIter2** – The type of the begin destination iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Sent2** – The type of the end destination iterators used (deduced). This iterator type must meet the requirements of a sentinel for Iter2.
- **Pred** – The binary predicate that compares the projected elements.
- **Proj1** – The type of an optional projection function for the source range. This defaults to `hpx::identity`
- **Proj2** – The type of an optional projection function for the destination range. This defaults to `hpx::identity`

Parameters
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the source range.
- **last1** – Sentinel value referring to the end of the source range.
- **first2** – Refers to the beginning of the destination range.
- **last2** – Sentinel value referring to the end of the destination range.
- **pred** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the two ranges projected by proj1 and proj2 respectively.
- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements in the source range as a projection operation before the actual predicate is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements in the destination range as a projection operation before the actual predicate is invoked.

Returns The `ends_with` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `ends_with` algorithm returns a boolean with the value true if the second range matches the suffix of the first range, false otherwise.

```cpp
template<typename Rng1, typename Rng2, typename Pred = ranges::equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
bool ends_with(Rng1 &&rng1, Rng2 &&rng2, Pred &&pred = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Checks whether the second range `rng2` matches the suffix of the first range `rng1`.

The assignments in the parallel `ends_with` algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Note: Complexity: Linear: at most \(\min(N1, N2)\) applications of the predicate and both projections.
• **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.

• **Rng2** – The type of the destination range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.

• **Pred** – The binary predicate that compares the projected elements.

• **Proj1** – The type of an optional projection function for the source range. This defaults to `hpx::identity`

• **Proj2** – The type of an optional projection function for the destination range. This defaults to `hpx::identity`

**Parameters**

• **rng1** – Refers to the source range.

• **rng2** – Refers to the destination range.

• **pred** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the in two ranges projected by proj1 and proj2 respectively.

• **proj1** – Specifies the function (or function object) which will be invoked for each of the elements in the source range as a projection operation before the actual predicate is invoked.

• **proj2** – Specifies the function (or function object) which will be invoked for each of the elements in the destination range as a projection operation before the actual predicate is invoked.

**Returns**

The `ends_with` algorithm returns `bool`. The `ends_with` algorithm returns a boolean with the value true if the second range matches the suffix of the first range, false otherwise.

```cpp
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred = ranges::equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
  hpx::parallel::util::detail::algorithm_result<ExPolicy, bool>::type ends_with(ExPolicy &&policy, Rng1 &&rng1, Rng2 &&rng2, Pred &&pred = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Checks whether the second range `rng2` matches the suffix of the first range `rng1`.

The assignments in the parallel `ends_with` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `ends_with` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Linear: at most min(N1, N2) applications of the predicate and both projections.

**Template Parameters**

• **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.

• **Rng2** – The type of the destination range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.

• **Pred** – The binary predicate that compares the projected elements.
- **Proj1** – The type of an optional projection function for the source range. This defaults to `hpx::identity`
- **Proj2** – The type of an optional projection function for the destination range. This defaults to `hpx::identity`

### Parameters
- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the source range.
- **rng2** – Refers to the destination range.
- **pred** – Specifies the binary predicate function (or function object) which will be invoked for comparison of the elements in the two ranges projected by proj1 and proj2 respectively.
- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements in the source range as a projection operation before the actual predicate is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements in the destination range as a projection operation before the actual predicate is invoked.

### Returns
The `ends_with` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `ends_with` algorithm returns a boolean with the value true if the second range matches the suffix of the first range, false otherwise.

---

**hpx/parallel/container_algorithms/equal.hpp**

See Public API for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

### Functions

```cpp
template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2,
         typename Pred = equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
    hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> equal(ExPolicy &&policy, Iter1 first1,
    Sent1 last1, Iter2 first2, Sent2 last2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2
    &&proj2 = Proj2())
```

Returns true if the range [first1, last1) is equal to the range [first2, last2), and false otherwise.

The comparison operations in the parallel `equal` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `equal` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most min(last1 - first1, last2 - first2) applications of the predicate f.
Note: The two ranges are considered equal if, for every iterator i in the range [first1,last1), *i equals *(first2 + (i - first1)). This overload of equal uses operator== to determine if two elements are equal.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the source iterators used for the end of the first range (deduced).
- **Iter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the source iterators used for the end of the second range (deduced).
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`
- **Proj1** – The type of an optional projection function applied to the first range. This defaults to `hpx::identity`
- **Proj2** – The type of an optional projection function applied to the second range. This defaults to `hpx::identity`

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as equal.

The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate is invoked.

**Returns**
The `equal` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `equal` algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range `[first1, last1)` does not equal the length of the range `[first2, last2)`, it returns false.

```cpp
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred = equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
```
\texttt{hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> equal(ExPolicy &&policy, Rng1 &&rng1, Rng2 &&rng2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())}

Returns true if the range \([\text{first1}, \text{last1})\) is equal to the range starting at \text{first2}, and false otherwise.

The comparison operations in the parallel \texttt{equal} algorithm invoked with an execution policy object of type \texttt{sequenced\_policy} execute in sequential order in the calling thread.

The comparison operations in the parallel \texttt{equal} algorithm invoked with an execution policy object of type \texttt{parallel\_policy} or \texttt{parallel\_task\_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

\textbf{Note:} Complexity: At most \(\text{last1} - \text{first1}\) applications of the predicate \(f\).

\textbf{Note:} The two ranges are considered equal if, for every iterator \(i\) in the range \([\text{first1},\text{last1})\), \(*i\) equals \(*(\text{first2} + (i - \text{first1})).\) This overload of equal uses operator\texttt{==} to determine if two elements are equal.

\textbf{Template Parameters}
- \textbf{ExPolicy} – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- \textbf{Rng1} – The type of the first source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- \textbf{Rng2} – The type of the second source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- \textbf{Pred} – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of \texttt{equal} requires \texttt{Pred} to meet the requirements of \texttt{CopyConstructible}. This defaults to \texttt{std::equal\_to<>}
- \textbf{Proj1} – The type of an optional projection function applied to the first range. This defaults to \texttt{hpx::identity}
- \textbf{Proj2} – The type of an optional projection function applied to the second range. This defaults to \texttt{hpx::identity}

\textbf{Parameters}
- \textbf{policy} – The execution policy to use for the scheduling of the iterations.
- \textbf{rng1} – Refers to the first sequence of elements the algorithm will be applied to.
- \textbf{rng2} – Refers to the second sequence of elements the algorithm will be applied to.
- \textbf{op} – The binary predicate which returns true if the elements should be treated as equal.
  The signature of the predicate function should be equivalent to the following:

\begin{verbatim}
bool pred(const Type1 &a, const Type2 &b);
\end{verbatim}

The signature does not need to have \texttt{const \&}, but the function must not modify the objects passed to it. The types \texttt{Type1} and \texttt{Type2} must be such that objects of types \texttt{FwdIter1} and \texttt{FwdIter2} can be dereferenced and then implicitly converted to \texttt{Type1} and \texttt{Type2} respectively.
- \textbf{proj1} – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate \texttt{is} invoked.
- \textbf{proj2} – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate \texttt{is} invoked.
**Returns**  The `equal` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `equal` algorithm returns true if the elements in the two ranges are equal, otherwise it returns false.

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Pred = equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
bool equal(Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Returns true if the range `[first1, last1)` is equal to the range `[first2, last2)`, and false otherwise.

**Note:** Complexity: At most min(last1 - first1, last2 - first2) applications of the predicate \(f\).

**Note:** The two ranges are considered equal if, for every iterator \(i\) in the range `[first1,last1)`, \(*i\) equals \(*(*(first2 + (i - first1)))\). This overload of `equal` uses `operator==` to determine if two elements are equal.

**Template Parameters**
- `Iter1` – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- `Sent1` – The type of the source iterators used for the end of the first range (deduced).
- `Iter2` – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- `Sent2` – The type of the source iterators used for the end of the second range (deduced).
- `Pred` – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to`.
- `Proj1` – The type of an optional projection function applied to the first range. This defaults to `hpx::identity`.
- `Proj2` – The type of an optional projection function applied to the second range. This defaults to `hpx::identity`.

**Parameters**
- `first1` – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- `last1` – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- `first2` – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- `last2` – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- `op` – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

- `proj1` – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate is invoked.
- `proj2` – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate is invoked.
Returns The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false. If the length of the range \([\text{first}_1, \text{last}_1)\) does not equal the length of the range \([\text{first}_2, \text{last}_2)\), it returns false.

```cpp
template<typename Rng1, typename Rng2, typename Pred = equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
bool equal(Rng1 &&rng1, Rng2 &&rng2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Returns true if the range \([\text{first}_1, \text{last}_1)\) is equal to the range starting at \(\text{first}_2\), and false otherwise.

**Note:** Complexity: At most \(\text{last}_1 - \text{first}_1\) applications of the predicate \(f\).

**Note:** The two ranges are considered equal if, for every iterator \(i\) in the range \([\text{first}_1, \text{last}_1)\), \(*i\) equals \(*(\text{first}_2 + (i - \text{first}_1))\). This overload of equal uses operator== to determine if two elements are equal.

**Template Parameters**
- **Rng1** – The type of the first source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Rng2** – The type of the second source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *equal* requires \(\text{Pred}\) to meet the requirements of *CopyConstructible*. This defaults to std::equal_to<>
- **Proj1** – The type of an optional projection function applied to the first range. This defaults to \(\text{hpx}::\text{identity}\)
- **Proj2** – The type of an optional projection function applied to the second range. This defaults to \(\text{hpx}::\text{identity}\)

**Parameters**
- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types *Type1* and *Type2* must be such that objects of types *FwdIter1* and *FwdIter2* can be dereferenced and then implicitly converted to *Type1* and *Type2* respectively.

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate is invoked.

**Returns** The *equal* algorithm returns true if the elements in the two ranges are equal, otherwise it returns false.
namespace hpx
namespace ranges

Functions

template<typename InIter, typename Sent, typename OutIter, typename T = typename std::iterator_traits<InIter>::value_type, typename Op = std::plus<T>>
exclusive_scan_result<InIter, OutIter> exclusive_scan(InIter first, Sent last, OutIter dest, T init, Op &&op = Op())

Assigns through each iterator \(i\) in \([\text{result}, \text{result} + (\text{last} - \text{first}))\) the value of \(\text{GENERALIZED_NONCOMMUTATIVE_SUM}(\text{binary}_\text{op}, \text{init}, \star\text{first}, \ldots, \star(\text{first} + (i - \text{result}) - 1))\).

The difference between exclusive_scan and inclusive_scan is that inclusive_scan includes the \(i\)th input element in the \(i\)th sum. If \(\text{op}\) is not mathematically associative, the behavior of inclusive_scan may be non-deterministic.

Note: Complexity: \(O(\text{last} - \text{first})\) applications of the predicate \(\text{op}\).

Note: \(\text{GENERALIZED_NONCOMMUTATIVE_SUM}(\text{op}, a_1, \ldots, a_N)\) is defined as:
- \(a_1\) when \(N\) is 1
- \(\text{op}(\text{GENERALIZED_NONCOMMUTATIVE_SUM}(\text{op}, a_1, \ldots, a_K), \text{GENERALIZED_NONCOMMUTATIVE_SUM}(\text{op}, a_M, \ldots, a_N))\) where \(1 < K+1 = M <= N\).

Template Parameters
- FwdIter1 – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- Sent – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter1.
- FwdIter2 – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- T – The type of the value to be used as initial (and intermediate) values (deduced).
- Op – The type of the binary function object used for the reduction operation.

Parameters
- first – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- dest – Refers to the beginning of the destination range.
- init – The initial value for the generalized sum.
- op – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:
```cpp
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types `Type1` and `Ret` must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

**Returns** The `exclusive_scan` algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename Sent, typename FwdIter2, typename T = typename std::iterator_traits<FwdIter1>::value_type, typename Op = std::plus<T>>
parallel::util::detail::algorithm_result<ExPolicy, exclusive_scan_result<FwdIter1, FwdIter2>>::type exclusive_scan(ExPolicy &&policy, FwdIter1 first, Sent last, FwdIter2 dest, T init, Op &&op = Op())
```

Assigns through each iterator `i` in `[result, result + (last - first))` the value of `GENERALIZED_NONCOMMUTATIVE_SUM(binary_op, init, *first, ..., *(first + (i - result) - 1))`.

The reduce operations in the parallel `exclusive_scan` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The reduce operations in the parallel `exclusive_scan` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `exclusive_scan` and `inclusive_scan` is that `inclusive_scan` includes the `i`th input element in the `i`th sum. If `op` is not mathematically associative, the behavior of `inclusive_scan` may be non-deterministic.

**Note:** Complexity: $O(last - first)$ applications of the predicate `op`.

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN)` is defined as:

- `a1` when `N` is 1
- `op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN))` where `1 < K+1 = M <= N`.

**Template Parameters**
HPX Documentation, master

• **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **FwdIter1** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

• **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter1.

• **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

• **T** – The type of the value to be used as initial (and intermediate) values (deduced).

• **Op** – The type of the binary function object used for the reduction operation.

### Parameters

• **policy** – The execution policy to use for the scheduling of the iterations.

• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.

• **dest** – Refers to the beginning of the destination range.

• **init** – The initial value for the generalized sum.

• **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

\[
\text{Ret } \text{fun}(\text{const } \text{Type1 } &a, \text{ const } \text{Type1 } &b);
\]

The signature does not need to have const&, but the function must not modify the objects passed to it. The types Type1 and Ret must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

### Returns

The `exclusive_scan` algorithm returns a `hpx::future<util::in_out_result<FwdIter1, FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `util::in_out_result<FwdIter1, FwdIter2>` otherwise. The `exclusive_scan` algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

\[
\text{template<typename } \text{Rng, typename } \text{O, typename } \text{T = typename std::iterator_traits<hpx::traits::range_iterator_t<\text{Rng}}>::value_type, typename } \text{Op = std::plus<T> } \text{exclusive_scan_result<traits::range_iterator_t<\text{Rng}>, } \text{O} \text{ exclusive_scan}(\text{Rng } \&\&\text{rng}, \text{ O dest, T init, Op } \&\&\&\text{op = Op()})
\]

Assigns through each iterator \(i\) in \([\text{result, result + (last - first)})\) the value of GENERALIZED_NONCOMMUTATIVE_SUM(+, init, *first, ... , *(first + (i - result) - 1))

The difference between `exclusive_scan` and `inclusive_scan` is that `inclusive_scan` includes the ith input element in the ith sum.

**Note:** Complexity: \(O(last - first)\) applications of the predicate `std::plus<T>`.  

**Note:** GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ... , aN) is defined as:

- \(a1\) when \(N\) is 1
- GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ... , aK)
  - GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, ... , aN) where \(1 < K+1 = M \leq N\).
Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **O** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
- **Op** – The type of the binary function object used for the reduction operation.

Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **init** – The initial value for the generalized sum.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types Type1 and Ret must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

Returns The exclusive_scan algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename Rng, typename O, typename T = typename std::iterator_traits<hpx::traits::range_iterator_t<Rng>>::value_type, typename Op = std::plus<T>>
parallel::util::detail::algorithm_result<ExPolicy, exclusive_scan_result<trait==range_iterator_t<Rng>, O>> exclusive_scan(ExPolicy&& policy, Rng&& rng, O dest, T init, Op&& op = Op())
```

Assigns through each iterator i in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(+, init, *first, ..., *(first + (i - result) - 1))

The reduce operations in the parallel exclusive_scan algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The reduce operations in the parallel exclusive_scan algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between exclusive_scan and inclusive_scan is that inclusive_scan includes the ith input element in the ith sum.
Note: Complexity: O(last - first) applications of the predicate std::plus<T>.

Note: GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ..., aN) is defined as:
  • a1 when N is 1
  • GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ..., aK)
    – GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, ..., aN) where 1 < K+1 = M <= N.

Template Parameters
  • ExPolicy – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
  • Rng – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
  • O – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
  • T – The type of the value to be used as initial (and intermediate) values (deduced).
  • Op – The type of the binary function object used for the reduction operation.

Parameters
  • policy – The execution policy to use for the scheduling of the iterations.
  • rng – Refers to the sequence of elements the algorithm will be applied to.
  • dest – Refers to the beginning of the destination range.
  • init – The initial value for the generalized sum.
  • op – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types Type1 and Ret must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

Returns The exclusive_scan algorithm returns a hpx::future<util::in_out_result <traits::range_iterator_t<Rng>, O>> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns util::in_out_result <traits::range_iterator_t<Rng>, O> otherwise. The exclusive_scan algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

hpx/parallel/container_algorithms/fill.hpp

See Public API for a list of names and headers that are part of the public HPX API.

namespace hpx

namespace ranges
Assigns the given value to the elements in the range [first, last).

The comparisons in the parallel fill algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The comparisons in the parallel fill algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs exactly last - first assignments.

### Template Parameters
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **T** – The type of the value to be assigned (deduced).

### Parameters
- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **value** – The value to be assigned.

### Returns
The fill algorithm returns a hpx::future<void> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns difference_type otherwise (where difference_type is defined by void).

Assigns the given value to the elements in the range [first, last).

The comparisons in the parallel fill algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The comparisons in the parallel fill algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
Note: Complexity: Performs exactly last-first assignments.

Template Parameters
- ExPolicy – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- Iter – The type of the source iterators used for the range (deduced).
- Sent – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- T – The type of the value to be assigned (deduced).

Parameters
- policy – The execution policy to use for the scheduling of the iterations.
- first – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
- last – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
- value – The value to be assigned.

Returns
The fill algorithm returns a hpx::future<void> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns difference_type otherwise (where difference_type is defined by void).

```
template<typename Rng, typename T = typename std::iterator_traits<hpx::traits::range_iterator_t<Rng>>::value_type>
    hpx::traits::range_iterator_t<Rng> fill(Rng &&rng, T const &value)
```
Assigns the given value to the elements in the range [first, last).

Note: Complexity: Performs exactly last-first assignments.

Template Parameters
- Rng – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- T – The type of the value to be assigned (deduced).

Parameters
- rng – Refers to the sequence of elements the algorithm will be applied to.
- value – The value to be assigned.

Returns
The fill algorithm returns void.

```
template<typename Iter, typename Sent, typename T = typename std::iterator_traits<Iter>::value_type>
    Iter fill(Iter first, Sent last, T const &value)
```
Assigns the given value to the elements in the range [first, last).

Note: Complexity: Performs exactly last-first assignments.
• **first** – Refers to the beginning of the sequence of elements of the range the algorithm will be applied to.
• **last** – Refers to the end of the sequence of elements of the range the algorithm will be applied to.
• **value** – The value to be assigned.

**Returns**
The `fill` algorithm returns `void`.

```cpp
template<typename ExPolicy, typename Rng, typename T = typename
         std::iterator_traits<hpx::traits::range_iterator_t<Rng>>::value_type>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, hpx::traits::range_iterator_t<Rng>>
fill_n(ExPolicy &&policy,
      Rng &&rng,
      T const &value)
```

Assigns the given value value to the first count elements in the range beginning at first if count > 0. Does nothing otherwise.

The comparisons in the parallel `fill_n` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparisons in the parallel `fill_n` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **T** – The type of the value to be assigned (deduced).

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **value** – The value to be assigned.

**Returns**
The `fill_n` algorithm returns a `hpx::future<void>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `difference_type` otherwise (where `difference_type` is defined by `void`).

```cpp
template<typename ExPolicy, typename FwdIter, typename Size, typename T = typename
         std::iterator_traits<FwdIter>::value_type>
hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type
fill_n(ExPolicy &&policy,
      FwdIter first, Size count,
      T const &value)
```

Assigns the given value value to the first count elements in the range beginning at first if count > 0. Does nothing otherwise.

The comparisons in the parallel `fill_n` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparisons in the parallel `fill_n` algorithm invoked with an execution policy object of type `para-
allel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs exactly count assignments, for count > 0.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply \( f \) to.
- **T** – The type of the value to be assigned (deduced).

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements starting at first the algorithm will be applied to.
- **value** – The value to be assigned.

**Returns**

The fill_n algorithm returns a hpx::future<void> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns difference_type otherwise (where difference_type is defined by void).

```cpp
template<typename Rng, typename T = typename std::iterator_traits<hpx::traits::range_iterator_t<Rng>>::value_type>
std::traits::range_traits<Rng>::iterator_type fill_n(Rng &&rng, T const &value)
```
Assigns the given value value to the first count elements in the range beginning at first if count > 0. Does nothing otherwise.

**Template Parameters**

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **T** – The type of the value to be assigned (deduced).

**Parameters**

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **value** – The value to be assigned.

**Returns**

The fill_n algorithm returns an output iterator that compares equal to last.

```cpp
template<typename FwdIter, typename Size, typename T = typename std::iterator_traits<FwdIter>::value_type>
FwdIter fill_n(Iterator first, Size count, T const &value)
```
Assigns the given value value to the first count elements in the range beginning at first if count > 0. Does nothing otherwise.

**Note:** Complexity: Performs exactly count assignments, for count > 0.

**Template Parameters**

- **Iterator** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Size** – The type of the argument specifying the number of elements to apply \( f \) to.
- **T** – The type of the value to be assigned (deduced).

**Parameters**
• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **count** – Refers to the number of elements starting at first the algorithm will be applied to.
• **value** – The value to be assigned.

**Returns** The `fill_n` algorithm returns an output iterator that compares equal to last.

**hpx/parallel/container_algorithms/find.hpp**

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace *hpx*

namespace *ranges*

**Functions**

```cpp
template<typename ExPolicy, typename Iter, typename Sent, typename Proj = hpx::identity,
         typename T = typename hpx::parallel::traits::projected<Iter, Proj>::value_type>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, Iter> find(ExPolicy &&policy, Iter first, Sent last,
         T const &val, Proj &&proj = Proj())
```

Returns the first element in the range `[first, last)` that is equal to `value`.

The comparison operations in the parallel `find` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `find` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most last - first applications of the operator==().

**Template Parameters**

• `ExPolicy` – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• `Iter` – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
• `Sent` – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for `Iter`.
• `T` – The type of the value to find (deduced).
• `Proj` – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**

• `policy` – The execution policy to use for the scheduling of the iterations.
• `first` – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
• `last` – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
• **val** – the value to compare the elements to
• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `find` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `find` algorithm returns the first element in the range `[first, last)` that is equal to `val`. If no such element in the range of `[first, last)` is equal to `val`, then the algorithm returns `last`.

```cpp
template<typename ExPolicy, typename Rng, typename Proj = hpx::identity, typename T = typename hpx::parallel::traits::projected<hpx::traits::range_iterator_t<Rng>, Proj>::value_type>
find(ExPolicy &&policy,
     Rng &&rng,
     T const &val,
     Proj &&proj = Proj())
```

Returns the first element in the range `[first, last)` that is equal to `val`.

The comparison operations in the parallel `find` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `find` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most last - first applications of the operator `==`().

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **T** – The type of the value to find (deduced).
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`
Iter `find` (Iter first, Sent last, T const &val, Proj &&proj = Proj())

Returns the first element in the range [first, last) that is equal to value.

**Note:** Complexity: At most last - first applications of the operator==().

**Template Parameters**
- **Iter** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter.
- **T** – The type of the value to find (deduced).
- **Proj** – The type of an optional projection function. This defaults to hpx::identity.

**Parameters**
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **val** – the value to compare the elements to
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `find` algorithm returns the first element in the range [first, last) that is equal to val. If no such element in the range of [first,last) is equal to val, then the algorithm returns last.

template<typename Rng, typename Proj = hpx::identity, typename T = typename hpx::parallel::traits::projected<hpx::traits::range_iterator_t<Rng>, Proj>::value_type>

hpx::traits::range_iterator_t<Rng> find (Rng &&rng, T const &val, Proj &&proj = Proj())

Returns the first element in the range [first, last) that is equal to value.

The comparison operations in the parallel `find` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `find` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most last - first applications of the operator==().

**Template Parameters**
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **T** – The type of the value to find (deduced).
- **Proj** – The type of an optional projection function. This defaults to hpx::identity.

**Parameters**
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **val** – the value to compare the elements to
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `find` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `find` algorithm returns the first element in the range [first,last) that is equal to val. If no such
element in the range of \([first, last)\) is equal to \(val\), then the algorithm returns \(last\).

```cpp
template<typename ExPolicy, typename Iter, typename Sent, typename Pred, typename Proj = hpx::identity>
  hpx::parallel::util::detail::algorithm_result_t<ExPolicy, Iter> find_if(ExPolicy &&policy, Iter first, Sent last, Pred &&pred, Proj &&proj = Proj())
```

Returns the first element in the range \([first, last)\) for which predicate \(pred\) returns true.

The comparison operations in the parallel \(find\_if\) algorithm invoked with an execution policy object of type \(sequenced\_policy\) execute in sequential order in the calling thread.

The comparison operations in the parallel \(find\_if\) algorithm invoked with an execution policy object of type \(parallel\_policy\) or \(parallel\_task\_policy\) are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most last - first applications of the predicate.

### Template Parameters
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires \(F\) to meet the requirements of `CopyConstructible`.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

### Parameters
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **pred** – The unary predicate which returns true for the required element. The signature of the predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

### Returns
The `find_if` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `find_if` algorithm returns the first element in the range \([first, last)\) that satisfies the predicate \(f\). If no such element exists that satisfies the predicate \(f\), the algorithm returns \(last\).

```cpp
template<typename ExPolicy, typename Rng, typename Pred, typename Proj = hpx::identity>
```
`hpx::parallel::util::detail::algorithm_result<ExPolicy, hpx::traits::range_iterator_t<Rng>> find_if(ExPolicy &&policy, Rng &&rng, Pred &&pred, Proj &&proj = Proj())`  

Returns the first element in the range `rng` for which predicate `pred` returns true.

The comparison operations in the parallel `find_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `find_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most last - first applications of the predicate.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `F` to meet the requirements of `CopyConstructible`.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – The unary predicate which returns true for the required element. The signature of the predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns**

The `find_if` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `find_if` algorithm returns the first element in the range `[first, last)` that satisfies the predicate `f`. If no such element exists that satisfies the predicate `f`, the algorithm returns `last`.

```template<typename Iter, typename Sent, typename Pred, typename Proj = hpx::identity>
Iter find_if(Iter first, Sent last, Pred &&pred, Proj &&proj = Proj())
```  

Returns the first element in the range `[first, last)` for which predicate `pred` returns true.
**Template Parameters**

- **Iter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `F` to meet the requirements of `CopyConstructible`.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **pred** – The unary predicate which returns true for the required element. The signature of the predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `find_if` algorithm returns the first element in the range [first,last) that satisfies the predicate `f`. If no such element exists that satisfies the predicate `f`, the algorithm returns `last`.

```cpp
template<typename Rng, typename Pred, typename Proj = hpx::identity>
hpx::traits::range_iterator_t<
Rng> find_if(Rng &&rng, Pred &&pred, Proj &&proj = Proj())
```

Returns the first element in the range `rng` for which predicate `pred` returns true

**Note:** Complexity: At most last - first applications of the predicate.
and then implicitly converted to Type.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `find_if` algorithm returns the first element in the range [first, last) that satisfies the predicate f. If no such element exists that satisfies the predicate f, the algorithm returns last.

```cpp
template<typename ExPolicy, typename Iter, typename Sent, typename Pred, typename Proj = hpx::identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, Iter>::type find_if_not(ExPolicy &&policy,
    Iter first, Sent last, Pred &&pred, Proj &&proj
    = Proj())
```

Returns the first element in the range [first, last) for which predicate f returns false.

The comparison operations in the parallel `find_if_not` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `find_if_not` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most last - first applications of the predicate.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `F` to meet the requirements of `CopyConstructible`.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **pred** – The unary predicate which returns false for the required element. The signature of the predicate should be equivalent to:

  ```cpp
  bool pred(const Type &a);
  ```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

---

2.8. API reference 591
The `find_if_not` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `find_if_not` algorithm returns the first element in the range `[first, last)` that does not satisfy the predicate `f`. If no such element exists that does not satisfy the predicate `f`, the algorithm returns `last`.

```cpp
template<typename ExPolicy, typename Rng, typename Pred, typename Proj = hpx::identity>
  hpx::parallel::util::detail::algorithm_result<ExPolicy, hpx::traits::range_iterator_t<Rng>> find_if_not(ExPolicy &&policy, Rng &&rng, Pred &&pred, Proj &&proj = Proj())
```

Returns the first element in the range `rng` for which predicate `f` returns false.

The comparison operations in the parallel `find_if_not` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `find_if_not` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most last - first applications of the predicate.

**Template Parameters**
- `ExPolicy` – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Rng` – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- `Pred` – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `F` to meet the requirements of `CopyConstructible`.
- `Proj` – The type of an optional projection function. This defaults to `hpx::identity`.

**Parameters**
- `policy` – The execution policy to use for the scheduling of the iterations.
- `rng` – Refers to the sequence of elements the algorithm will be applied to.
- `pred` – The unary predicate which returns false for the required element. The signature of the predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- `proj` – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.
Returns The find_if_not algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The find_if_not algorithm returns the first element in the range [first, last) that does not satisfy the predicate f. If no such element exists that does not satisfy the predicate f, the algorithm returns last.

```cpp
template<typename Iter, typename Sent, typename Pred, typename Proj = hpx::identity>
Iter find_if_not(Iter first, Sent last, Pred &&pred, Proj &&proj = Proj())
```

Returns the first element in the range [first, last) for which predicate f returns false

**Note:** Complexity: At most last - first applications of the predicate.

### Template Parameters
- **Iter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of equal requires F to meet the requirements of CopyConstructible.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

### Parameters
- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **pred** – The unary predicate which returns false for the required element. The signature of the predicate should be equivalent to:

  ```cpp
  bool pred(const Type &a);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Returns The find_if_not algorithm returns the first element in the range [first, last) that does not satisfy the predicate f. If no such element exists that does not satisfy the predicate f, the algorithm returns last.

```cpp
template<typename Rng, typename Pred, typename Proj = hpx::identity>
hpx::traits::range_iterator_t<Rng> find_if_not(Rng &&rng, Pred &&pred, Proj &&proj = Proj())
```

Returns the first element in the range rng for which predicate f returns false

**Note:** Complexity: At most last - first applications of the predicate.

### Template Parameters
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of equal requires F to meet the requirements of CopyConstructible.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`
Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – The unary predicate which returns false for the required element. The signature of the predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Returns The `find_if_not` algorithm returns the first element in the range `[first, last)` that does not satisfy the predicate `f`. If no such element exists that does not satisfy the predicate `f`, the algorithm returns `last`.

```cpp
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred = equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, hpx::traits::range_iterator_t<Rng1>> find_end(ExPolicy &&policy,
Rng1 &&rng1,
Rng2 &&rng2,
Pred &&pred = Pred(),
Proj1 &&proj1 = Proj1(),
Proj2 &&proj2 = Proj2())
```

Returns the last subsequence of elements `rng2` found in the range `rng` using the given predicate `f` to compare elements.

The comparison operations in the parallel `find_end` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `find_end` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of `find_end` is available if the user decides to provide the algorithm their own predicate `op`.

**Note:** Complexity: at most $S^* (N-S+1)$ comparisons where $S = \text{distance} (\text{begin}(rng2), \text{end}(rng2))$ and
$N = \text{distance} (\text{begin}(\text{rng}), \text{end}(\text{rng}))$.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1** – The type of the first source range (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **Rng2** – The type of the second source range (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `replace` requires `Pred` to meet the requirements of `Copy-Constructible`. This defaults to `std::equal_to<>
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `hpx::identity`
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `hpx::identity`

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **op** – The binary predicate which returns `true` if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `iterator_t<Rng>` and `iterator_t<Rng2>` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.
- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range of type dereferenced `iterator_t<Rng1>` as a projection operation before the function `op` is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range of type dereferenced `iterator_t<Rng2>` as a projection operation before the function `op` is invoked.

**Returns**
The `find_end` algorithm returns a `hpx::future<iterator_t<Rng>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `iterator_t<Rng>` otherwise. The `find_end` algorithm returns an iterator to the beginning of the last subsequence `rng2` in range `rng`. If the length of the subsequence `rng2` is greater than the length of the range `rng`, `end(rng)` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `end(rng)` is also returned.

```cpp
template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Pred = equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, Iter1> find_end(ExPolicy &&policy, Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Returns the last subsequence of elements `[first2, last2)` found in the range `[first1, last1)` using the given predicate `f` to compare elements.
The comparison operations in the parallel `find_end` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `find_end` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of `find_end` is available if the user decides to provide the algorithm their own predicate `op`.

**Note:** Complexity: at most $S^*(N-S+1)$ comparisons where $S = \text{distance}(\text{first2}, \text{last2})$ and $N = \text{distance}(\text{first1}, \text{last1})$.

---

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter1** – The type of the begin source iterators for the first sequence used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the end source iterators for the first sequence used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2** – The type of the begin source iterators for the second sequence used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the end source iterators for the second sequence used (deduced). This iterator type must meet the requirements of an sentinel for Iter2.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `replace` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `hpx::identity`
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `hpx::identity`

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the algorithm will be applied to.
- **last2** – Refers to the end of the second sequence of elements the algorithm will be applied to.
- **op** – The binary predicate which returns `true` if the elements should be treated as equal. The signature should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `iterator_t<Rng>` and `iterator_t<Rng2>` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.
• **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range of type dereferenced `iterator_t<Rng1>` as a projection operation before the function `op` is invoked.

• **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range of type dereferenced `iterator_t<Rng2>` as a projection operation before the function `op` is invoked.

**Returns** The `find_end` algorithm returns a `hpx::future<iterator_t<Rng>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `iterator_t<Rng>` otherwise. The `find_end` algorithm returns an iterator to the beginning of the last subsequence `rng2` in range `rng`. If the length of the subsequence `rng2` is greater than the length of the range `rng`, `end(rng)` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `end(rng)` is also returned.

template<typename Rng1, typename Rng2, typename Pred = std::equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
`hpx::traits::range_iterator_t<Rng1>` find_end(Rng1 &&rng1, Rng2 &&rng2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())

Returns the last subsequence of elements `rng2` found in the range `rng` using the given predicate `f` to compare elements.

This overload of `find_end` is available if the user decides to provide the algorithm their own predicate `op`.

**Note:** Complexity: at most \( S^*(N-S+1) \) comparisons where \( S = \text{distance(begin(rng2), end(rng2))} \) and \( N = \text{distance(begin(rng), end(rng))} \).

**Template Parameters**
- **Rng1** – The type of the first source range (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **Rng2** – The type of the second source range (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `replace` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `hpx::identity`
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `hpx::identity`

**Parameters**
- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **op** – The binary predicate which returns `true` if the elements should be treated as equal.
  The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `iterator_t<Rng>` and `iterator_t<Rng2>` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

• **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range of type dereferenced `iterator_t<Rng1>` as a projection
operation before the function \( op \) is invoked.

- \textbf{proj2} – Specifies the function (or function object) which will be invoked for each of the elements of the second range of type dereferenced \texttt{iterator_t<Rng2>} as a projection operation before the function \( op \) is invoked.

\textbf{Returns} The \texttt{find_end} algorithm returns an iterator to the beginning of the last subsequence \( rng2 \) in range \( rng \). If the length of the subsequence \( rng2 \) is greater than the length of the range \( rng \), \texttt{end(rng)} is returned. Additionally if the size of the subsequence is empty or no subsequence is found, \texttt{end(rng)} is also returned.

```
template<typename \texttt{Iter1}, typename \texttt{Sent1}, typename \texttt{Iter2}, typename \texttt{Sent2}, typename \texttt{Pred} = \texttt{equal_to}, typename \texttt{Proj1} = \texttt{hpx::identity}, typename \texttt{Proj2} = \texttt{hpx::identity}>
\texttt{Iter1} \texttt{find_end(Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())}
```

Returns the last subsequence of elements \([\texttt{first2}, \texttt{last2})\) found in the range \([\texttt{first1}, \texttt{last1})\) using the given predicate \( f \) to compare elements.

This overload of \texttt{find_end} is available if the user decides to provide the algorithm their own predicate \( op \).

\textbf{Note:} Complexity: at most \( S*(N-S+1) \) comparisons where \( S = \text{distance(}\texttt{first2}, \texttt{last2}) \) and \( N = \text{distance(}\texttt{first1}, \texttt{last1}) \).

\textbf{Template Parameters}

- \texttt{Iter1} – The type of the begin source iterators for the first sequence used (deduced). This iterator type must meet the requirements of an forward iterator.
- \texttt{Sent1} – The type of the end source iterators for the first sequence used (deduced). This iterator type must meet the requirements of an sentinel for \texttt{Iter1}.
- \texttt{Iter2} – The type of the begin source iterators for the second sequence used (deduced). This iterator type must meet the requirements of an forward iterator.
- \texttt{Sent2} – The type of the end source iterators for the second sequence used (deduced). This iterator type must meet the requirements of an sentinel for \texttt{Iter2}.
- \texttt{Pred} – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of \texttt{replace} requires \texttt{Pred} to meet the requirements of \texttt{CopyConstructible}. This defaults to \texttt{std::equal_to<}>.
- \texttt{Proj1} – The type of an optional projection function applied to the first sequence. This defaults to \texttt{hpx::identity}.
- \texttt{Proj2} – The type of an optional projection function applied to the second sequence. This defaults to \texttt{hpx::identity}.

\textbf{Parameters}

- \texttt{first1} – Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- \texttt{last1} – Refers to the end of the first sequence of elements the algorithm will be applied to.
- \texttt{first2} – Refers to the beginning of the second sequence of elements the algorithm will be applied to.
- \texttt{last2} – Refers to the end of the second sequence of elements the algorithm will be applied to.
- \texttt{op} – The binary predicate which returns \texttt{true} if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool \texttt{pred(const Type1 \&a, const Type2 \&b);}
```
The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types iterator_t<Rng> and iterator_t<Rng2> can be dereferenced and then implicitly converted to Type1 and Type2 respectively.

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range of type dereferenced iterator_t<Rng1> as a projection operation before the function op is invoked.

- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range of type dereferenced iterator_t<Rng2> as a projection operation before the function op is invoked.

**Returns** The find_end algorithm returns an iterator to the beginning of the last subsequence rng2 in range rng. If the length of the subsequence rng2 is greater than the length of the range rng, end(rng) is returned. Additionally if the size of the subsequence is empty or no subsequence is found, end(rng) is also returned.

```
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred = equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
{hpx::parallel::util::detail::algorithm_result<ExPolicy, hpx::traits::range_iterator_t<Rng1>> find_first_of(ExPolicy &&policy, Rng1 &&rng1, Rng2 &&rng2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Searches the range rng1 for any elements in the range rng2. Uses binary predicate p to compare elements.

The comparison operations in the parallel find_first_of algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The comparison operations in the parallel find_first_of algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of find_first_of is available if the user decides to provide the algorithm their own predicate op.

**Note:** Complexity: at most (S*N) comparisons where S = distance(begin(rng2), end(rng2)) and N = distance(begin(rng1), end(rng1)).
Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1** – The type of the first source range (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **Rng2** – The type of the second source range (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `replace` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`.
- **Proj1** – The type of an optional projection function. This defaults to `hpx::identity` and is applied to the elements in `rng1`.
- **Proj2** – The type of an optional projection function. This defaults to `hpx::identity` and is applied to the elements in `rng2`.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **op** – The binary predicate which returns `true` if the elements should be treated as equal. The signature should be equivalent to the following:

```
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `iterator_t<Rng1>` and `iterator_t<Rng2>` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `iterator_t<Rng1>` before the function `op` is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `iterator_t<Rng2>` before the function `op` is invoked.

Returns

The `find_end` algorithm returns a `hpx::future<iterator_t<Rng1>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `iterator_t<Rng1>` otherwise. The `find_first_of` algorithm returns an iterator that is equal to an element from the range `rng2`. If the length of the subsequence `rng2` is greater than the length of the range `rng1`, `end(rng1)` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `end(rng1)` is also returned.

```cpp
template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Pred = equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, Iter1> find_first_of(ExPolicy &&policy,
  Iter1 first1, Sent1 last1,
  Iter2 first2, Sent2 last2,
  Pred &&op = Pred(),
  Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Searches the range `[first1, last1)` for any elements in the range `[first2, last2)`. Uses binary predicate `p` to compare elements.

The comparison operations in the parallel `find_first_of` algorithm invoked with an execution policy
object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `find_first_of` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

This overload of `find_first_of` is available if the user decides to provide the algorithm their own predicate `op`.

**Note:** Complexity: at most \((S*N)\) comparisons where \(S = \text{distance}(\text{first2}, \text{last2})\) and \(N = \text{distance}(\text{first1}, \text{last1})\).

**Template Parameters**

- `ExPolicy` – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Iter1` – The type of the begin source iterators for the first sequence used (deduced). This iterator type must meet the requirements of an forward iterator.
- `Sent1` – The type of the end source iterators for the first sequence used (deduced). This iterator type must meet the requirements of an sentinel for `Iter1`.
- `Iter2` – The type of the begin source iterators for the second sequence used (deduced). This iterator type must meet the requirements of an forward iterator.
- `Sent2` – The type of the end source iterators for the second sequence used (deduced). This iterator type must meet the requirements of an sentinel for `Iter2`.
- `Pred` – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `replace` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>
- `Proj1` – The type of an optional projection function. This defaults to `hpx::identity` and is applied to the elements in `rng1`.
- `Proj2` – The type of an optional projection function. This defaults to `hpx::identity` and is applied to the elements in `rng2`.

**Parameters**

- `policy` – The execution policy to use for the scheduling of the iterations.
- `first1` – Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- `last1` – Refers to the end of the first sequence of elements the algorithm will be applied to.
- `first2` – Refers to the beginning of the second sequence of elements the algorithm will be applied to.
- `last2` – Refers to the end of the second sequence of elements the algorithm will be applied to.
- `op` – The binary predicate which returns `true` if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `iterator_t<Rng1>` and `iterator_t<Rng2>` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.
- `proj1` – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `iterator_t<Rng1>` before the function `op` is invoked.
• proj2 – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced iterator_t<Rng2> before the function op is invoked.

Returns
The find_end algorithm returns a hpx::future<iterator_t<Rng1>> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns iterator_t<Rng1> otherwise. The find_first_of algorithm returns an iterator to the first element in the range rng1 that is equal to an element from the range rng2. If the length of the subsequence rng2 is greater than the length of the range rng1, end(rng1) is returned. Additionally if the size of the subsequence is empty or no subsequence is found, end(rng1) is also returned.

```cpp
template<typename Rng1, typename Rng2, typename Pred = equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
hpx::traits::range_iterator_t<Rng1> find_first_of(Rng1 &&rng1, Rng2 &&rng2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Searches the range rng1 for any elements in the range rng2. Uses binary predicate p to compare elements

This overload of find_first_of is available if the user decides to provide the algorithm their own predicate op.

Note: Complexity: at most (S*N) comparisons where \( S = \text{distance}(\text{begin(rng2)}, \text{end(rng2)}) \) and \( N = \text{distance}(\text{begin(rng1)}, \text{end(rng1)}) \).

Template Parameters
- Rng1 – The type of the first source range (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- Rng2 – The type of the second source range (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- Pred – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of replace requires Pred to meet the requirements of CopyConstructible. This defaults to std::equal_to>
- Proj1 – The type of an optional projection function. This defaults to hpx::identity and is applied to the elements in rng1.
- Proj2 – The type of an optional projection function. This defaults to hpx::identity and is applied to the elements in rng2.

Parameters
- rng1 – Refers to the first sequence of elements the algorithm will be applied to.
- rng2 – Refers to the second sequence of elements the algorithm will be applied to.
- op – The binary predicate which returns true if the elements should be treated as equal. The signature should be equivalent to the following:
  ```cpp
  bool pred(const Type1 &a, const Type2 &b);
  ```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types iterator_t<Rng1> and iterator_t<Rng2> can be dereferenced and then implicitly converted to Type1 and Type2 respectively.

- proj1 – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced iterator_t<Rng1> before the function op is invoked.
- proj2 – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced iterator_t<Rng2> before the function op is invoked.
Returns

The `find_first_of` algorithm returns an iterator to the first element in the range `rng1` that is equal to an element from the range `rng2`. If the length of the subsequence `rng2` is greater than the length of the range `rng1`, `end(rng1)` is returned. Additionally, if the size of the subsequence is empty or no subsequence is found, `end(rng1)` is also returned.

```cpp
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Pred = equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
Iter1 find_first_of(Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Searches the range `[first1, last1)` for any elements in the range `[first2, last2)`. Uses binary predicate \( p \) to compare elements.

This overload of `find_first_of` is available if the user decides to provide the algorithm their own predicate \( op \).

**Note:** Complexity: at most \((S*N)\) comparisons where \( S = \text{distance}(first2, last2) \) and \( N = \text{distance}(first1, last1) \).

Template Parameters

- **Iter1** – The type of the begin source iterators for the first sequence used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the end source iterators for the first sequence used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2** – The type of the begin source iterators for the second sequence used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the end source iterators for the second sequence used (deduced). This iterator type must meet the requirements of an sentinel for Iter2.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `replace` requires `Pred` to meet the requirements of Copy-Constructible. This defaults to `std::equal_to<>

- **Proj1** – The type of an optional projection function. This defaults to `hpx::identity` and is applied to the elements in `rng1`.
- **Proj2** – The type of an optional projection function. This defaults to `hpx::identity` and is applied to the elements in `rng2`.

Parameters

- **first1** – Refers to the beginning of the first sequence of elements the algorithm will be applied to.
- **last1** – Refers to the end of the first sequence of elements the algorithm will be applied to.
- **first2** – Refers to the beginning of the second sequence of elements the algorithm will be applied to.
- **last2** – Refers to the end of the second sequence of elements the algorithm will be applied to.
- **op** – The binary predicate which returns `true` if the elements should be treated as equal. The signature should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `iterator_t<Rng1>` and `iterator_t<Rng2>` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.
• **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `iterator_t<Rng1>` before the function `op` is invoked.
• **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `iterator_t<Rng2>` before the function `op` is invoked.

**Returns**  The `find_first_of` algorithm returns an iterator to the first element in the range `rng1` that is equal to an element from the range `rng2`. If the length of the subsequence `rng2` is greater than the length of the range `rng1`, `end(rng1)` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `end(rng1)` is also returned.

```cpp
hpx/parallel/container_algorithms/for_each.hpp
```

See *Public API* for a list of names and headers that are part of the public `HPX` API.

namespace **hpx**

namespace **ranges**

### Functions

template<typename **InIter**, typename **Sent**, typename **F**, typename **Proj** = hpx::identity>
for_each_result<**InIter**, **F**> **for_each**(**InIter** first, **Sent** last, **F** &f, **Proj** &&proj = Proj())

Applies `f` to the result of dereferencing every iterator in the range `[first, last)`. If `f` returns a result, the result is ignored.

If the type of `first` satisfies the requirements of a mutable iterator, `f` may apply non-constant functions through the dereferenced iterator.

**Note:** Complexity: Applies `f` exactly `last - first` times.

### Template Parameters

- **InIter** – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `InIter`.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `for_each` requires `F` to meet the requirements of `CopyConstructible`.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. The signature of this predicate should be equivalent to:

```cpp
<ignored> pred(const Type &a);
```
The signature does not need to have const&. The type `Type` must be such that an object of type `InIter` can be dereferenced and then implicitly converted to `Type`.

- `proj` – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Returns \{last, HPX_MOVE(f)\} where last is the iterator corresponding to the input sentinel last.

```
template<typename Rng, typename F, typename Proj = hpx::identity>
for_each_result<hpx::traits::range_iterator_t<Rng>, F> for_each(Rng &&rng, F &&f, Proj &&proj = Proj())
```

Applies `f` to the result of dereferencing every iterator in the given range `rng`.

If `f` returns a result, the result is ignored.

If the type of `first` satisfies the requirements of a mutable iterator, `f` may apply non-constant functions through the dereferenced iterator.

Note: Complexity: Applies `f` exactly size(rng) times.

### Template Parameters

- `Rng` – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- `F` – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `for_each` requires `F` to meet the requirements of `Copy-Constructible`.
- `Proj` – The type of an optional projection function. This defaults to `hpx::identity`.

### Parameters

- `rng` – Refers to the sequence of elements the algorithm will be applied to.
- `f` – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. The signature of this predicate should be equivalent to:

```
<ignored> pred(const Type &a);
```

The signature does not need to have const&. The type `Type` must be such that an object of type `InIter` can be dereferenced and then implicitly converted to `Type`.

- `proj` – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Returns \{std::end(rng), HPX_MOVE(f)\}

```
template<typename ExPolicy, typename FwdIter, typename Sent, typename F, typename Proj = hpx::identity>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> for_each(ExPolicy &&policy, FwdIter first, Sent last, F &&f, Proj &&proj = Proj())
```

Applies `f` to the result of dereferencing every iterator in the range `[first, last)`.

If `f` returns a result, the result is ignored.

If the type of `first` satisfies the requirements of a mutable iterator, `f` may apply non-constant functions through the dereferenced iterator.
Unlike its sequential form, the parallel overload of `for_each` does not return a copy of its `Function` parameter, since parallelization may not permit efficient state accumulation.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Applies \( f \) exactly \( last - first \) times.

### Template Parameters
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **FwdIter** – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `InIter`.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `for_each` requires \( F \) to meet the requirements of `CopyConstructible`.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

### Parameters
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `for_each` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. It returns `last`.

```cpp
template<typename ExPolicy, typename Rng, typename F, typename Proj = hpx::identity>``
Applies \( f \) to the result of dereferencing every iterator in the given range \( \text{rng} \).

If \( f \) returns a result, the result is ignored.

If the type of first satisfies the requirements of a mutable iterator, \( f \) may apply non-constant functions through the dereferenced iterator.

Unlike its sequential form, the parallel overload of \texttt{for_each} does not return a copy of its Function parameter, since parallelization may not permit efficient state accumulation.

The application of function objects in parallel algorithm invoked with an execution policy object of type \texttt{sequenced_policy} execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type \texttt{parallel_policy} or \texttt{parallel_task_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Applies \( f \) exactly size(rng) times.

**Template Parameters**

- \texttt{ExPolicy} – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- \texttt{Rng} – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- \texttt{F} – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \texttt{for_each} requires \( F \) to meet the requirements of \texttt{CopyConstructible}.
- \texttt{Proj} – The type of an optional projection function. This defaults to \texttt{hpx::identity}

**Parameters**

- \texttt{policy} – The execution policy to use for the scheduling of the iterations.
- \texttt{rng} – Refers to the sequence of elements the algorithm will be applied to.
- \texttt{f} – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

\[
\texttt{\langle ignored\rangle pred(const Type &a);}\]

The signature does not need to have \texttt{const}. The type \texttt{Type} must be such that an object of type \texttt{InIter} can be dereferenced and then implicitly converted to \texttt{Type}. 

---

2.8. API reference 607
proj – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Returns The for_each algorithm returns a hpx::future<FwdIter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter otherwise. It returns last.

template<
typename InIter, typename Size, typename F, typename Proj = hpx::identity>
for_each_n_result<
InIter, F>
for_each_n(InIter first, Size count, F &&f, Proj &&proj = Proj())
Applies f to the result of dereferencing every iterator in the range [first, first + count), starting from first and proceeding to first + count - 1.

If f returns a result, the result is ignored.

If the type of first satisfies the requirements of a mutable iterator, f may apply non-constant functions through the dereferenced iterator.

Unlike its sequential form, the parallel overload of for_each does not return a copy of its Function parameter, since parallelization may not permit efficient state accumulation.

Note: Complexity: Applies f exactly count times.

Template Parameters
• InIter – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an input iterator.
• Size – The type of the argument specifying the number of elements to apply f to.
• F – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of for_each requires F to meet the requirements of Copy-Constructible.
• Proj – The type of an optional projection function. This defaults to hpx::identity

Parameters
• first – Refers to the beginning of the sequence of elements the algorithm will be applied to.
• count – Refers to the number of elements starting at first the algorithm will be applied to.
• f – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

  \[ \text{pred(const Type &a);} \]

  The signature does not need to have const&. The type Type must be such that an object of type InIter can be dereferenced and then implicitly converted to Type.

• proj – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Returns It returns last.

template<
typename ExPolicy, typename FwdIter, typename Size, typename F, typename Proj = hpx::identity>

hpx::parallel::util::detail::algorithm_result<
ExPolicy, FwdIter>::type
for_each_n(ExPolicy &&policy,
FwdIter first, Size count, F &&f, Proj &&proj = Proj())
Applies f to the result of dereferencing every iterator in the range [first, first + count), starting from first and proceeding to first + count - 1.
If \( f \) returns a result, the result is ignored.

If the type of \( \text{first} \) satisfies the requirements of a mutable iterator, \( f \) may apply non-constant functions through the dereferenced iterator.

Unlike its sequential form, the parallel overload of \texttt{for_each} does not return a copy of its \texttt{Function} parameter, since parallelization may not permit efficient state accumulation.

The application of function objects in parallel algorithm invoked with an execution policy object of type \texttt{sequenced_policy} execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type \texttt{parallel_policy} or \texttt{parallel_task_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

\textbf{Note:} Complexity: Applies \( f \) exactly \texttt{count} times.

\textbf{Template Parameters}

- \texttt{ExPolicy} – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- \texttt{FwdIter} – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- \texttt{Size} – The type of the argument specifying the number of elements to apply \( f \) to.
- \texttt{F} – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \texttt{for_each} requires \( F \) to meet the requirements of \texttt{CopyConstructible}.
- \texttt{Proj} – The type of an optional projection function. This defaults to \texttt{hpx::identity}

\textbf{Parameters}

- \texttt{policy} – The execution policy to use for the scheduling of the iterations.
- \texttt{first} – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- \texttt{count} – Refers to the number of elements starting at \texttt{first} the algorithm will be applied to.
- \( f \) – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \texttt{[first, last)}. The signature of this predicate should be equivalent to:

\begin{verbatim}
<ignored> pred(const Type &a);
\end{verbatim}

The signature does not need to have \texttt{const&}. The type \texttt{Type} must be such that an object of type \texttt{InIter} can be dereferenced and then implicitly converted to \texttt{Type}.
- \texttt{proj} – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

\textbf{Returns} The \texttt{for_each} algorithm returns a \texttt{hpx::future<FwdIter>} if the execution policy is of type \texttt{sequenced_task_policy} or \texttt{parallel_task_policy} and returns \texttt{FwdIter} otherwise. It returns \texttt{last}.

Functions

template<typename ExPolicy, typename Iter, typename Sent, typename ...Args>
hpx::parallel::util::detail::algorithm_result<ExPolicy>::type for_loop(ExPolicy &&policy, Iter first, Sent last, Args&&... args)

The for_loop implements loop functionality over a range specified by iterator bounds. These algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

Requires: Iter shall meet the requirements of a forward iterator type. The args parameter pack shall have at least one element, comprising objects returned by invocations of reduction and/or induction function templates followed by exactly one element invocable element-access function, f. f shall meet the requirements of MoveConstructible.

Effects: Applies f to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the args parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by first. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the args parameter pack excluding f, an additional argument is passed to each application of f as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of f in the input sequence.

Complexity: Applies f exactly once for each element of the input sequence.

Remarks: If f returns a result, the result is ignored.

Note: As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

Note: The order of the elements of the input sequence is important for determining ordinal position of an application of f, even though the applications themselves may be unordered.
Template Parameters
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Iter** – The type of the iteration variable (forward iterator).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for Iter.
- **Args** – A parameter pack, it’s last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

Parameters
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:

  ```cpp
  <ignored> pred(Iter const& a, ...);
  ```

  The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

Returns
The for_loop algorithm returns a `hpx::future<void>` if the execution policy is of type `hpx::execution::sequenced_task_policy` or `hpx::execution::parallel_task_policy` and returns `void` otherwise.

```cpp
template<typename Iter, typename Sent, typename ...Args>
void for_loop(Iter first, Sent last, Args&&... args)
```

The for_loop implements loop functionality over a range specified by iterator bounds. These algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of for_loop without specifying an execution policy is equivalent to specifying `hpx::execution::seq` as the execution policy.

Requires: Iter shall meet the requirements of an input iterator type. The args parameter pack shall have at least one element, comprising objects returned by invocations of reduction and/or induction function templates followed by exactly one element invocable element-access function, f. f shall meet the requirements of MoveConstructible.

Effects: Applies f to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the args parameter pack. The length of the input sequence is last - first.

The first element in the input sequence is specified by first. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the args parameter pack excluding f, an additional argument is passed to each application of f as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then
the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of \( f \) in the input sequence.

Complexity: Applies \( f \) exactly once for each element of the input sequence.

Remarks: If \( f \) returns a result, the result is ignored.

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of \( f \), even though the applications themselves may be unordered.

**Template Parameters**
- \( \text{Iter} \) – The type of the iteration variable (input iterator).
- \( \text{Sent} \) – The type of the source sentinel (deduced). This sentinel type must be a sentinel for \( \text{Iter} \).
- \( \text{Args} \) – A parameter pack, it’s last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**
- \( \text{first} \) – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- \( \text{last} \) – Refers to the end of the sequence of elements the algorithm will be applied to.
- \( \text{args} \) – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\) should expose a signature equivalent to:

\[
<\text{ignored}> \text{pred}(\text{Iter const}& \text{a}, ...);
\]

The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

template<typename ExPolicy, typename R, typename ...Args>

\( \text{hpx::parallel::util::detail::algorithm_result<ExPolicy>:type for_loop(ExPolicy &&policy, R &&rng, Args&&... args)} \)

The for_loop implements loop functionality over a range specified by a range. These algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

Requires: \( \text{Rng::iterator} \) shall meet the requirements of a forward iterator type. The \( \text{args} \) parameter pack shall have at least one element, comprising objects returned by invocations of reduction and/or induction function templates followed by exactly one element invocable element-access function, \( f \), \( f \) shall meet the requirements of MoveConstructible.

Effects: Applies \( f \) to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the \( \text{args} \) parameter pack. The length of the input sequence is last - first.
The first element in the input sequence is specified by \textit{first}. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the \textit{args} parameter pack excluding \textit{f}, an additional argument is passed to each application of \textit{f} as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of \textit{f} in the input sequence.

Complexity: Applies \textit{f} exactly once for each element of the input sequence.

Remarks: If \textit{f} returns a result, the result is ignored.

\textbf{Note:} As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

\textbf{Note:} The order of the elements of the input sequence is important for determining ordinal position of an application of \textit{f}, even though the applications themselves may be unordered.

\textbf{Template Parameters}
- \textbf{ExPolicy} – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- \textbf{R} – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- \textbf{Args} – A parameter pack, it’s last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

\textbf{Parameters}
- \textbf{policy} – The execution policy to use for the scheduling of the iterations.
- \textbf{rng} – Refers to the sequence of elements the algorithm will be applied to.
- \textbf{args} – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\) should expose a signature equivalent to:

\begin{verbatim}
<ignored> pred(Rng::iterator const & a, ...);
\end{verbatim}

The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

\textbf{Returns} The \texttt{for_loop} algorithm returns a \texttt{hpx::future<void>} if the execution policy is of type \texttt{hpx::execution::sequenced_task_policy} or \texttt{hpx::execution::parallel_task_policy} and returns \texttt{void} otherwise.

\begin{verbatim}
template<typename Rng, typename ...Args>
void for_loop(Rng &&rng, Args &&... args)
\end{verbatim}

The \texttt{for_loop} implements loop functionality over a range specified by a range. These algorithms resemble \texttt{for_each} from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.
The execution of `for_loop` without specifying an execution policy is equivalent to specifying `hpx::execution::seq` as the execution policy.

Requires: `Rng::iterator` shall meet the requirements of an input iterator type. The `args` parameter pack shall have at least one element, comprising objects returned by invocations of `reduction` and/or `induction` function templates followed by exactly one element invocable element-access function. `f` shall meet the requirements of `MoveConstructible`.

Effects: Applies `f` to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the `args` parameter pack. The length of the input sequence is `last - first`.

The first element in the input sequence is specified by `first`. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the `args` parameter pack excluding `f`, an additional argument is passed to each application of `f` as follows:

- If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object.
- If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of `f` in the input sequence.

Complexity: Applies `f` exactly once for each element of the input sequence.

Remarks: If `f` returns a result, the result is ignored.

---

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using `advance` and `distance`.

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of `f`, even though the applications themselves may be unordered.

---

**Template Parameters**

- `Rng` – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- `Args` – A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**

- `rng` – Refers to the sequence of elements the algorithm will be applied to.
- `args` – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)` should expose a signature equivalent to:

```cpp
<ignored> pred(Rng::iterator const& a, ...);
```

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

```cpp
template<
    typename ExPolicy,
    typename Iter,
    typename Sent,
    typename S,
    typename ...Args
>
```
The `for_loop_strided` implements loop functionality over a range specified by iterator bounds. These algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

Requires: `Iter` shall meet the requirements of a forward iterator type. The `args` parameter pack shall have at least one element, comprising objects returned by invocations of `reduction` and/or `induction` function templates followed by exactly one element invocable element-access function, `f`. `f` shall meet the requirements of `MoveConstructible`.

Effects: Applies `f` to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the `args` parameter pack. The length of the input sequence is `last - first`.

The first element in the input sequence is specified by `first`. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the `args` parameter pack excluding `f`, an additional argument is passed to each application of `f` as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of `f` in the input sequence.

Complexity: Applies `f` exactly once for each element of the input sequence.

Remarks: If `f` returns a result, the result is ignored.

---

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using `advance` and `distance`.

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of `f`, even though the applications themselves may be unordered.

---

**Template Parameters**

- `ExPolicy` – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- `Iter` – The type of the iteration variable (forward iterator).
- `Sent` – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `Iter`.
- `S` – The type of the stride variable. This should be an integral type.
- `Args` – A parameter pack, it’s last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**

- `policy` – The execution policy to use for the scheduling of the iterations.
- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
• **stride** – Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if Iter meets the requirements a bidirectional iterator.
• **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last) should expose a signature equivalent to:
  ```cpp
  <ignored> pred(Iter const& a, ...);
  ```
  The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

**Returns** The `for_loop_strided` algorithm returns a `hpx::future<void>` if the execution policy is of type `hpx::execution::sequenced_task_policy` or `hpx::execution::parallel_task_policy` and returns `void` otherwise.

```cpp
template<typename Iter, typename Sent, typename S, typename ...Args>
void for_loop_strided(Iter first, Sent last, S stride, Args&&... args)
```

The `for_loop_strided` implements loop functionality over a range specified by iterator bounds. These algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of `for_loop_strided` without specifying an execution policy is equivalent to specifying `hpx::execution::seq` as the execution policy.

**Requires:** `Iter` shall meet the requirements of an input iterator type. The `args` parameter pack shall have at least one element, comprising objects returned by invocations of `reduction` and/or `induction` function templates followed by exactly one element invocable element-access function, `f`. `f` shall meet the requirements of `MoveConstructible`.

**Effects:** Applies `f` to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the `args` parameter pack. The length of the input sequence is `last - first`.

The first element in the input sequence is specified by `first`. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the `args` parameter pack excluding `f`, an additional argument is passed to each application of `f` as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of `f` in the input sequence.

**Complexity:** Applies `f` exactly once for each element of the input sequence.

**Remarks:** If `f` returns a result, the result is ignored.

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using `advance` and `distance`.
**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of \( f \), even though the applications themselves may be unordered.

**Template Parameters**

- **Iter** – The type of the iteration variable (input iterator).
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for \( \text{Iter} \).
- **S** – The type of the stride variable. This should be an integral type.
- **Args** – A parameter pack, it’s last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **stride** – Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if \( \text{Iter} \) meets the requirements a bidirectional iterator.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\) should expose a signature equivalent to:

\[
<\text{ignored}> \quad \text{pred}(\text{Iter \ const}&\ a, ...);
\]

The signature does not need to have \( \text{const} \& \). It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

```cpp
template<typename \text{ExPolicy}, \text{typename Rng}, \text{typename S, typename ...Args}>
\text{hpx::parallel::util::detail::algorithm_result_t<ExPolicy>} \text{for_loop_strided(ExPolicy \ &\&policy,}
\text{Rng \ &\&rng, \ S \ stride,}
\text{Args\&\&... \ args)}
```

The `for_loop_strided` implements loop functionality over a range specified by a range. These algorithms resemble `for_each` from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

Requires: `Rng::iterator` shall meet the requirements of a forward iterator type. The `args` parameter pack shall have at least one element, comprising objects returned by invocations of `reduction` and/or `induction` function templates followed by exactly one element invocable element-access function, \( f \). \( f \) shall meet the requirements of `MoveConstructible`.

Effects: Applies \( f \) to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the `args` parameter pack. The length of the input sequence is \( \text{last} - \text{first} \).

The first element in the input sequence is specified by `first`. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the `args` parameter pack excluding \( f \), an additional argument is passed to each application of \( f \) as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then
the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of \( f \) in the input sequence.

Complexity: Applies \( f \) exactly once for each element of the input sequence.

Remarks: If \( f \) returns a result, the result is ignored.

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using advance and distance.

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of \( f \), even though the applications themselves may be unordered.

Template Parameters
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **S** – The type of the stride variable. This should be an integral type.
- **Args** – A parameter pack, its last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

Parameters
- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the of the sequence of elements the algorithm will be applied to.
- **stride** – Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if Rng::iterator meets the requirements a bidirectional iterator.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by (first, last) should expose a signature equivalent to:

  ```cpp
  <ignored> pred(Rng::iterator const& a, ...);
  ```

  The signature does not need to have const&. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

Returns The for_loop_strided algorithm returns a hpx::future&lt;void&gt; if the execution policy is of type hpx::execution::sequenced_task_policy or hpx::execution::parallel_task_policy and returns void otherwise.

template<typename Rng, typename S, typename ...Args>
void for_loop_strided(Rng &&rng, S stride, Args&&... args)

The for_loop_strided implements loop functionality over a range specified by a range. These algorithms resemble for_each from the Parallelism TS, but leave to the programmer when and if to dereference the iterator.

The execution of for_loop_strided without specifying an execution policy is equivalent to specifying hpx::execution::seq as the execution policy.
Requires: `Rng::iterator` shall meet the requirements of an input iterator type. The `args` parameter pack shall have at least one element, comprising objects returned by invocations of `reduction` and/or `induction` function templates followed by exactly one element invocable element-access function, `f`. `f` shall meet the requirements of `MoveConstructible`.

Effects: Applies `f` to each element in the input sequence, with additional arguments corresponding to the reductions and inductions in the `args` parameter pack. The length of the input sequence is `last - first`.

The first element in the input sequence is specified by `first`. Each subsequent element is generated by incrementing the previous element.

Along with an element from the input sequence, for each member of the `args` parameter pack excluding `f`, an additional argument is passed to each application of `f` as follows:

If the pack member is an object returned by a call to a reduction function listed in section, then the additional argument is a reference to a view of that reduction object. If the pack member is an object returned by a call to induction, then the additional argument is the induction value for that induction object corresponding to the position of the application of `f` in the input sequence.

Complexity: Applies `f` exactly once for each element of the input sequence.

Remarks: If `f` returns a result, the result is ignored.

**Note:** As described in the C++ standard, arithmetic on non-random-access iterators is performed using `advance` and `distance`.

**Note:** The order of the elements of the input sequence is important for determining ordinal position of an application of `f`, even though the applications themselves may be unordered.

**Template Parameters**
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **S** – The type of the stride variable. This should be an integral type.
- **Args** – A parameter pack, it’s last element is a function object to be invoked for each iteration, the others have to be either conforming to the induction or reduction concept.

**Parameters**
- **rng** – Refers to the of the sequence of elements the algorithm will be applied to.
- **stride** – Refers to the stride of the iteration steps. This shall have non-zero value and shall be negative only if `Rng::iterator` meets the requirements a bidirectional iterator.
- **args** – The last element of this parameter pack is the function (object) to invoke, while the remaining elements of the parameter pack are instances of either induction or reduction objects. The function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)` should expose a signature equivalent to:

```cpp
<ignored> pred(Rng::iterator const& a, ...);
```

The signature does not need to have `const&`. It will receive the current value of the iteration variable and one argument for each of the induction or reduction objects passed to the algorithms, representing their current values.

\text{template<typename ExPolicy, typename Rng, typename F>
\text{hpx::parallel::util::detail::algorithm_result<ExPolicy, hpx::traits::range_iterator_t<Rng>> generate(ExPolicy &&policy, Rng &&rng, F &&f)}
\]

Assign each element in range [first, last) a value generated by the given function object f

The assignments in the parallel generate algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The assignments in the parallel generate algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: Exactly distance(first, last) invocations of f and assignments.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of equal requires F to meet the requirements of CopyConstructible.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – generator function that will be called. signature of function should be equivalent to the following:

\[
\text{Ret fun();}
\]

The type Ret must be such that an object of type FwdIter can be dereferenced and assigned a value of type Ret.

Returns The replace_if algorithm returns a hpx::future<FwdIter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter otherwise. It returns last.
template<typename ExPolicy, typename Iter, typename Sent, typename F>

hpx::parallel::util::detail::algorithm_result_t<ExPolicy, Iter> generate(ExPolicy &&policy, Iter first, Sent last, F &&f)

Assign each element in range [first, last) a value generated by the given function object f.

The assignments in the parallel generate algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The assignments in the parallel generate algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: Exactly distance(first, last) invocations of f and assignments.

Template Parameters
- ExPolicy – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- Iter – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- Sent – The type of the source end iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- F – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of equal requires F to meet the requirements of CopyConstructible.

Parameters
- policy – The execution policy to use for the scheduling of the iterations.
- first – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last – Refers to the end of the sequence of elements the algorithm will be applied to.
- f – generator function that will be called. signature of function should be equivalent to the following:

  ```
  Ret fun();
  ```

The type Ret must be such that an object of type FwdIter can be dereferenced and assigned a value of type Ret.

Returns The replace_if algorithm returns a hpx::future<FwdIter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter otherwise. It returns last.

template<typename Rng, typename F>

hpx::traits::range_iterator_t<Rng> generate(Rng &&rng, F &&f)

Assign each element in range [first, last) a value generated by the given function object f.

Note: Complexity: Exactly distance(first, last) invocations of f and assignments.

Template Parameters
- Rng – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- F – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of equal requires F to meet the requirements of CopyConstructible.

Parameters
• **rng** – Refers to the sequence of elements the algorithm will be applied to.
• **f** – generator function that will be called. signature of function should be equivalent to the following:

```cpp
Ret fun();
```

The type `Ret` must be such that an object of type `FwdIter` can be dereferenced and assigned a value of type `Ret`.

**Returns** The `replace_if` algorithm returns `last`.

```cpp
template<typename Iter, typename Sent, typename F>
Iter generate(Iter first, Sent last, F &&f)
```

Assign each element in range `[first, last)` a value generated by the given function object `f`.

**Note:** Complexity: Exactly `distance(first, last)` invocations of `f` and assignments.

---

**Template Parameters**
- **Iter** – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source end iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `F` to meet the requirements of `CopyConstructible`.

**Parameters**
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – generator function that will be called. signature of function should be equivalent to the following:

```cpp
Ret fun();
```

The type `Ret` must be such that an object of type `FwdIter` can be dereferenced and assigned a value of type `Ret`.

**Returns** The `replace_if` algorithm returns `last`.

```cpp
template<typename ExPolicy, typename FwdIter, typename Size, typename F>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> generate_n(ExPolicy &&policy,
   FwdIter first, Size count, F &&f)
```

Assigns each element in range `[first, first+count)` a value generated by the given function object `g`.

The assignments in the parallel `generate_n` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `generate_n` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Exactly `count` invocations of `f` and assignments, for `count > 0`.

---

**Template Parameters**
• **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

• **Size** – The type of the argument specifying the number of elements to apply $f$ to.

• **$F$** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of $equal$ requires $F$ to meet the requirements of $CopyConstructible$.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **count** – Refers to the number of elements in the sequence the algorithm will be applied to.
- **$f$** – Refers to the generator function object that will be called. The signature of the function should be equivalent to

  ```
  Ret fun();
  ```

  The type $Ret$ must be such that an object of type $OutputIt$ can be dereferenced and assigned a value of type $Ret$.

### Returns

The $replace_if$ algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. It returns `last`.

```
template<typename FwdIter, typename Size, typename F>
FwdIter generate_n(FwdIter first, Size count, F &&f)
```

Assigns each element in range `[first, first+count)` a value generated by the given function object $g$.

### Note:

Complexity: Exactly $count$ invocations of $f$ and assignments, for $count > 0$.

### Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.

- **Size** – The type of the argument specifying the number of elements to apply $f$ to.

- **$F$** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of $equal$ requires $F$ to meet the requirements of $CopyConstructible$.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **count** – Refers to the number of elements in the sequence the algorithm will be applied to.

- **$f$** – Refers to the generator function object that will be called. The signature of the function should be equivalent to

  ```
  Ret fun();
  ```

  The type $Ret$ must be such that an object of type $OutputIt$ can be dereferenced and assigned a value of type $Ret$.

### Returns

The $replace_if$ algorithm returns `last`.
namespace hpx

namespace ranges

Functions

template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Pred = hpx::parallel::detail::less, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>

hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> includes(ExPolicy &&policy, Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())

Returns true if every element from the sorted range [first2, last2) is found within the sorted range [first1, last1). Also returns true if [first2, last2) is empty. The version expects both ranges to be sorted with the user supplied binary predicate $f$.

The comparison operations in the parallel includes algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The comparison operations in the parallel includes algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: At most $2^{*(N1+N2-1)}$ comparisons, where $N1 = \text{std::distance(first1, last1)}$ and $N2 = \text{std::distance(first2, last2)}$.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2** – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for Iter2.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of includes requires Pred to meet the requirements of Copy-Constructible. This defaults to std::less<>.
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to hpx::identity
• **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `hpx::identity`.

**Parameters**

• **policy** – The execution policy to use for the scheduling of the iterations.
• **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
• **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
• **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
• **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
• **op** – The binary predicate which returns true if the elements should be treated as includes. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

• **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.
• **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

**Returns**
The `includes` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `includes` algorithm returns true every element from the sorted range `[first2, last2)` is found within the sorted range `[first1, last1)`. Also returns true if `[first2, last2)` is empty. The version expects both ranges to be sorted with the user supplied binary predicate `f`.

```
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Pred = hpx::parallel::detail::less, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
bool includes(Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Returns true if every element from the sorted range `[first2, last2)` is found within the sorted range `[first1, last1)`. Also returns true if `[first2, last2)` is empty. The version expects both ranges to be sorted with the user supplied binary predicate `f`.

**Note:** At most `2*(N1+N2-1)` comparisons, where `N1 = std::distance(first1, last1)` and `N2 = std::distance(first2, last2)`.

**Template Parameters**

• **Iter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
• **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for `Iter1`.
• **Iter2** – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
• **Sent2** – The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for `Iter2`.
• **Pred** – The type of an optional function/function object to use. Unlike its sequential implementation.
form, the parallel overload of `includes` requires `Pred` to meet the requirements of `Copy-Constructible`. This defaults to `std::less<>

- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `hpx::identity`
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `hpx::identity`

**Parameters**

- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as includes. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

**Returns**
The `includes` algorithm returns true every element from the sorted range `[first2, last2)` is found within the sorted range `[first1, last1)`. Also returns true if `[first2, last2)` is empty.

```cpp
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred = hpx::parallel::detail::less, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
    hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> includes(ExPolicy &&policy, Rng1 &&rng1, Rng2 &&rng2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Returns true if every element from the sorted range `[first2, last2)` is found within the sorted range `[first1, last1)`. Also returns true if `[first2, last2)` is empty. The version expects both ranges to be sorted with the user supplied binary predicate `f`.

The comparison operations in the parallel `includes` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `includes` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** At most \(2^{(N1+N2-1)}\) comparisons, where \(N1 = \text{std::distance}(first1, last1)\) and \(N2 =
std::distance(first2, last2).

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of includes requires Pred to meet the requirements of Copy-Constructible. This defaults to std::less<>
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to hpx::identity
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to hpx::identity

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as includes. The signature of the predicate function should be equivalent to the following:

```cpp
class bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const & but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively
- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate op is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate op is invoked.

Returns The includes algorithm returns a hpx::future<bool> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns bool otherwise. The includes algorithm returns true every element from the sorted range [first2, last2) is found within the sorted range [first1, last1). Also returns true if [first2, last2) is empty. The version expects both ranges to be sorted with the user supplied binary predicate f.

Note: At most 2*(N1+N2-1) comparisons, where N1 = std::distance(first1, last1) and N2 = std::distance(first2, last2).

Template Parameters
• **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
• **Rng2** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
• **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of *includes* requires *Pred* to meet the requirements of *CopyConstructible*. This defaults to `std::less<>`
• **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `hpx::identity`
• **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `hpx::identity`

### Parameters
• **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
• **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
• **op** – The binary predicate which returns true if the elements should be treated as includes. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.
• **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate *op* is invoked.
• **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate *op* is invoked.

### Returns
The *includes* algorithm returns true every element from the sorted range `[first2, last2)` is found within the sorted range `[first1, last1)`. Also returns true if `[first2, last2)` is empty.

`hpx/parallel/container_algorithms/inclusive_scan.hpp`

See Public API for a list of names and headers that are part of the public *HPX* API.

namespace `hpx`

namespace `ranges`

### Functions

```cpp
template<
  typename InIter, typename Sent, typename OutIter,
  typename Op = std::plus<typename std::iterator_traits<InIter>::value_type>>
inclusive_scan_result<InIter, OutIter> inclusive_scan(InIter first, Sent last, OutIter dest, Op &&op)
```

Assigns through each iterator *i* in [result, result + (last - first)) the value of `GENERALIZED_NONCOMMUTATIVE_SUM(op, *(first + i - result)))`. 

628 Chapter 2. What’s so special about *HPX*?
The reduce operations in the parallel `inclusive_scan` algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between `exclusive_scan` and `inclusive_scan` is that `inclusive_scan` includes the ith input element in the ith sum.

**Note:** Complexity: O(last - first) applications of the predicate op.

**Note:** GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ..., aN) is defined as:
- a1 when N is 1
- GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ..., aK) - GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, ..., aN) where 1 < K+1 = M <= N.

**Template Parameters**
- `InIter` – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- `Sent` – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `InIter`.
- `OutIter` – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- `Op` – The type of the binary function object used for the reduction operation.

**Parameters**
- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last` – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- `dest` – Refers to the beginning of the destination range.
- `op` – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Ret` must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

**Returns** The `inclusive_scan` algorithm returns `util::in_out_result<InIter, OutIter>`. The `inclusive_scan` algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename Sent, typename FwdIter2, typename Op = std::plus<typename std::iterator_traits<FwdIter1>::value_type>>
```
Assigns through each iterator $i$ in $[\text{result}, \text{result} + (\text{last} - \text{first}))$ the value of \text{GENERALIZED_NONCOMMUTATIVE_SUM}(\text{op}, \ast\text{first}, \ldots, \ast(\text{first} + (i - \text{result}))).$

The reduce operations in the parallel \text{inclusive_scan} algorithm invoked with an execution policy object of type \text{sequenced_policy} execute in sequential order in the calling thread.

The reduce operations in the parallel \text{inclusive_scan} algorithm invoked with an execution policy object of type \text{parallel_policy} or \text{parallel_task_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between \text{exclusive_scan} and \text{inclusive_scan} is that \text{inclusive_scan} includes the $i$th input element in the $i$th sum.

\textbf{Note:} Complexity: $O(\text{last} - \text{first})$ applications of the predicate $\text{op}$.

\textbf{Note:} \text{GENERALIZED_NONCOMMUTATIVE_SUM}(+, a_1, \ldots, a_N) is defined as:

\begin{itemize}
  \item $a_1$ when $N$ is 1
  \item \text{GENERALIZED_NONCOMMUTATIVE_SUM}(\text{op}, a_1, \ldots, a_K)
  \begin{itemize}
    \item \text{GENERALIZED_NONCOMMUTATIVE_SUM}(+, a_M, \ldots, a_N) where $1 < K+1 = M \leq N$
  \end{itemize}
\end{itemize}

\textbf{Template Parameters}

\begin{itemize}
  \item \textbf{ExPolicy} – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
  \item \textbf{FwdIter1} – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
  \item \textbf{Sent} – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
  \item \textbf{FwdIter2} – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
  \item \textbf{Op} – The type of the binary function object used for the reduction operation.
\end{itemize}

\textbf{Parameters}

\begin{itemize}
  \item \textbf{policy} – The execution policy to use for the scheduling of the iterations.
  \item \textbf{first} – Refers to the beginning of the sequence of elements the algorithm will be applied to.
  \item \textbf{last} – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
  \item \textbf{dest} – Refers to the beginning of the destination range.
\end{itemize}
• **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```cpp
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types `Type1` and `Ret` must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

**Returns** The `inclusive_scan` algorithm returns a `hpx::future<util::in_out_result<FwdIter1, FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `util::in_out_result<FwdIter1, FwdIter2>` otherwise. The `inclusive_scan` algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename Rng, typename O, typename Op = std::plus<typename hpx::traits::range_traits<Rng>::value_type>>
inclusive_scan_result<hpx::traits::range_iterator_t<Rng>, O> inclusive_scan(Rng &&rng, O dest, Op &&op)
```

Assigns through each iterator \(i\) in \([\text{result}, \text{result} + (\text{last} - \text{first}))\) the value of `GENERALIZED_NONCOMMUTATIVE_SUM(op, *first, ..., *(first + (i - result)))`.

The reduce operations in the parallel `inclusive_scan` algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between `exclusive_scan` and `inclusive_scan` is that `inclusive_scan` includes the \(i\)th input element in the \(i\)th sum.

**Note:** Complexity: \(O(\text{last} - \text{first})\) applications of the predicate `op`.

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(+, a_1, \ldots, a_N)` is defined as:

- \(a_1\) when \(N = 1\)
- `GENERALIZED_NONCOMMUTATIVE_SUM(+, a_1, \ldots, a_K)`
  - `GENERALIZED_NONCOMMUTATIVE_SUM(+, a_M, \ldots, a_N)` where \(1 < K+1 = M \leq N\).

**Template Parameters**
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **O** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Op** – The type of the binary function object used for the reduction operation.

**Parameters**
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```cpp
Ret fun(const Type1 &a, const Type1 &b);
```
The signature does not need to have const&, but the function must not modify the objects passed to it. The types Type1 and Ret must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

**Returns** The `inclusive_scan` algorithm returns `util::in_out_result<traits::range_iterator_t<Rng>, O>`. The `inclusive_scan` algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename Rng, typename O, typename Op = std::plus<typename hpx::traits::range_traits<Rng>::value_type>>
parallel::util::detail::algorithm_result<ExPolicy, inclusive_scan_result<hpx::traits::range_iterator_t<Rng>, O>> inclusive_scan(ExPolicy&& policy, Rng&& rng, O dest, Op&& op)
```

Assigns through each iterator \(i\) in \([\text{result}, \text{result} + (\text{last} - \text{first}))\) the value of `GENERALIZED_NONCOMMUTATIVE_SUM(op, *first, ..., *(first + (i - result))))`.

The reduce operations in the parallel `inclusive_scan` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The reduce operations in the parallel `inclusive_scan` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `exclusive_scan` and `inclusive_scan` is that `inclusive_scan` includes the \(i\)th input element in the \(i\)th sum.

**Note:** Complexity: \(O(\text{last} - \text{first})\) applications of the predicate `op`.

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(+, a1, ..., aN)` is defined as:
- a1 when \(N\) is 1
- `GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK)
  = GENERALIZED_NONCOMMUTATIVE_SUM(+, aM, ..., aN)` where \(1 < K+1 = M \leq N\).

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **O** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Op** – The type of the binary function object used for the reduction operation.

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
• **rng** – Refers to the sequence of elements the algorithm will be applied to.
• **dest** – Refers to the beginning of the destination range.
• **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```cpp
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types Type1 and Ret must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.

**Returns** The `inclusive_scan` algorithm returns a `hpx::future<util::in_out_result<traits::range_iterator_t<Rng>, O>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `util::in_out_result<traits::range_iterator_t<Rng>, O>` otherwise. The `inclusive_scan` algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename InIter, typename Sent, typename OutIter, typename Op, typename T = typename std::iterator_traits<InIter>::value_type>
inclusive_scan_result<InIter, OutIter> inclusive_scan(InIter first, Sent last, OutIter dest, Op &&op, T init)
```

Assigns through each iterator \( i \) in \( [\text{result}, \text{result} + (\text{last} - \text{first})) \) the value of `GENERALIZED_NONCOMMUTATIVE_SUM(op, \text{init}, *\text{first}, \ldots, *(\text{first} + (i - \text{result})))`.

The reduce operations in the parallel `inclusive_scan` algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between `exclusive_scan` and `inclusive_scan` is that `inclusive_scan` includes the \( i \)th input element in the \( i \)th sum. If `op` is not mathematically associative, the behavior of `inclusive_scan` may be non-deterministic.

**Note:** Complexity: \( O(\text{last} - \text{first}) \) applications of the predicate `op`.

**Note:** `GENERALIZED_NONCOMMUTATIVE_SUM(op, a_1, \ldots, a_N)` is defined as:

- \( a_1 \) when \( N = 1 \)
- \( \text{op}(\text{GENERALIZED_NONCOMMUTATIVE_SUM(op, a_1, \ldots, a_K), \text{GENERALIZED_NONCOMMUTATIVE_SUM(op, a_M, \ldots, a_N)}) \) where \( 1 < K+1 = M \leq N \).

**Template Parameters**

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Op** – The type of the binary function object used for the reduction operation.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).
HPX Documentation,  master

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **dest** – Refers to the beginning of the destination range.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

  ```
  Ret fun(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The types Type1 and Ret must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.
- **init** – The initial value for the generalized sum.

  **Returns** The inclusive_scan algorithm returns util::in_out_result<InIter, OutIter>. The inclusive_scan algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

  template<
typename ExPolicy,
typename FwdIter1,
typename Sent,
typename FwdIter2,
typename Op,
typename T = typename std::iterator_traits<FwdIter1>::value_type>

  parallel::util::detail::algorithm_result<ExPolicy, inclusive_scan_result<FwdIter1, FwdIter2>>::type inclusive_scan(
      ExPolicy &&policy,
      InIter first,
      Sent last,
      OutIter dest,
      Op &&op,
      T init)

Assigns through each iterator i in [result, result + (last - first)) the value of GENERALIZED_NONCOMMUTATIVE_SUM(op, init, *first, ..., *(first + (i - result))).

  The reduce operations in the parallel inclusive_scan algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

  The reduce operations in the parallel inclusive_scan algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

  The difference between exclusive_scan and inclusive_scan is that inclusive_scan includes the ith input element in the ith sum. If op is not mathematically associative, the behavior of inclusive_scan may be non-deterministic.

  **Note:** Complexity: O(last - first) applications of the predicate op.
Note: GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN) is defined as:

- a1 when N is 1
- op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN)) where 1 < K + 1 = M <= N.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Op** – The type of the binary function object used for the reduction operation.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **dest** – Refers to the beginning of the destination range.
- **op** – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

\[
\text{Ret fun(const Type1 &a, const Type1 &b);}\]

The signature does not need to have const&, but the function must not modify the objects passed to it. The types Type1 and Ret must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.
- **init** – The initial value for the generalized sum.

**Returns** The **inclusive_scan** algorithm returns a hpx::future<util::in_out_result<InIter, OutIter>> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns util::in_out_result<InIter, OutIter> otherwise. The inclusive_scan algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename Rng, typename O, typename Op, typename T = typename std::iterator_traits<hpx::traits::range_iterator_t<Rng>>::value_type>
inclusive_scan_result<hpx::traits::range_iterator_t<Rng>, O> inclusive_scan(Rng &&rng, O dest, Op &&op, T init)
```

Assigns through each iterator \( i \) in \( [\text{result, result + (last - first))} \) the value of GENERALIZED_NONCOMMUTATIVE_SUM(op, init, *first, ..., *(first + (i - result))).

The reduce operations in the parallel inclusive_scan algorithm invoked without an execution policy object will execute in sequential order in the calling thread.

The difference between exclusive_scan and inclusive_scan is that inclusive_scan includes the \( i \)th input

2.8. API reference 635
element in the \(i\)th sum. If \(op\) is not mathematically associative, the behavior of \(inclusive\_scan\) may be non-deterministic.

**Note:** Complexity: \(O(\text{last} - \text{first})\) applications of the predicate \(op\).

**Note:** \(\text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(op, a_1, \ldots, a_N)\) is defined as:
- \(a_1\) when \(N = 1\)
- \(op(\text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(op, a_1, \ldots, a_K), \text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(op, a_M, \ldots, a_N))\) where \(1 < K + 1 = M <= N\).

**Template Parameters**
- \(\text{Rng}\) – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- \(\text{O}\) – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- \(\text{Op}\) – The type of the binary function object used for the reduction operation.
- \(\text{T}\) – The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**
- \(\text{rng}\) – Refers to the sequence of elements the algorithm will be applied to.
- \(\text{dest}\) – Refers to the beginning of the destination range.
- \(\text{op}\) – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

\[
\text{Ret} \quad \text{fun}(\text{const} \text{ Type1} \&a, \text{ const} \text{ Type1} \&b);
\]

The signature does not need to have const\&, but the function must not modify the objects passed to it. The types \(\text{Type1}\) and \(\text{Ret}\) must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.
- \(\text{init}\) – The initial value for the generalized sum.

**Returns** The \(\text{inclusive\_scan}\) algorithm returns \(\text{util}\::\text{in\_out\_result}<\text{traits}\::\text{range\_iterator\_t}<\text{Rng}>\), \(\text{O}\) > The \(\text{inclusive\_scan}\) algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

\[
\text{template<!\text{typename }\text{ExPolicy}, \text{typename }\text{Rng}, \text{typename }\text{O, typename }\text{Op, typename }\text{T} = \text{typename std}\::\text{iterator\_traits}<\text{hpx}\::\text{traits}\::\text{range\_iterator\_t}<\text{Rng}>\::\text{value\_type}> parallel::util::detail::algorithm\_result<\text{ExPolicy}, inclusive\_scan\_result<\text{hpx}\::\text{traits}\::\text{range\_iterator\_t}<\text{Rng}>\>, O>> inclusive\_scan
\]

Assigns through each iterator \(i\) in \([\text{result}, \text{result} + (\text{last} - \text{first}))\) the value of \(\text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(op, \text{init}, *\text{first}, \ldots, *(\text{first} + (i - \text{result})))\).
The reduce operations in the parallel inclusive_scan algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The reduce operations in the parallel inclusive_scan algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between exclusive_scan and inclusive_scan is that inclusive_scan includes the ith input element in the ith sum. If op is not mathematically associative, the behavior of inclusive_scan may be non-deterministic.

Note: Complexity: O(last - first) applications of the predicate op.

Note: GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN) is defined as:
• a1 when N is 1
• op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK), GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN)) where 1 < K+1 = M <= N.

Template Parameters
• ExPolicy – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• Rng – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
• O – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
• Op – The type of the binary function object used for the reduction operation.
• T – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters
• policy – The execution policy to use for the scheduling of the iterations.
• rng – Refers to the sequence of elements the algorithm will be applied to.
• dest – Refers to the beginning of the destination range.
• op – Specifies the function (or function object) which will be invoked for each of the values of the input sequence. This is a binary predicate. The signature of this predicate should be equivalent to:

```
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types Type1 and Ret must be such that an object of a type as given by the input sequence can be implicitly converted to any of those types.
• init – The initial value for the generalized sum.

Returns The inclusive_scan algorithm returns a hpx::future<util::in_out_result_traits::range_iterator_t<Rng>, O> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns util::in_out_result_traits::range_iterator_t<Rng>, O> otherwise. The inclusive_scan algorithm returns an input iterator to the point denoted by the sentinel and an output iterator to the element in the destination range, one past the last element copied.

Functions

template<typename ExPolicy, typename Rng, typename Comp = hpx::parallel::detail::less, typename Proj = hpx::identity>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> is_heap(ExPolicy &&policy, Rng &&rng, Comp &&comp = Comp(), Proj &&proj = Proj())

Returns whether the range is max heap. That is, true if the range is max heap, false otherwise. The function uses the given comparison function object comp (defaults to using operator<()).

comp has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: Performs at most N applications of the comparison comp, at most 2 * N applications of the projection proj, where N = last - first.

Template Parameters
- ExPolicy – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- Rng – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- Comp – The type of the function/function object to use (deduced).
- Proj – The type of an optional projection function. This defaults to hpx::identity

Parameters
- policy – The execution policy to use for the scheduling of the iterations.
- rng – Refer to the sequence of elements the algorithm will be applied to.
- comp – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.
- proj – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Returns The is_heap algorithm returns a hpx::future<bool> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns bool otherwise. The is_heap algorithm returns whether the range is max heap. That is, true if the range is max heap, false otherwise.
template<typename ExPolicy, typename Iter, typename Sent, typename Comp = hpx::parallel::detail::less, typename Proj = hpx::identity>

hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> is_heap(ExPolicy &&policy, Iter first, Sent last, Comp &&comp = Comp(), Proj &&proj = Proj())

Returns whether the range is max heap. That is, true if the range is max heap, false otherwise. The function uses the given comparison function object \textit{comp} (defaults to using operator\textless()\textgreater).

\textit{comp} has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type \texttt{sequenced\_policy} execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type \texttt{parallel\_policy} or \texttt{parallel\_task\_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

\textbf{Note:} Complexity: Performs at most \(N\) applications of the comparison \textit{comp}, at most \(2 \times N\) applications of the projection \textit{proj}, where \(N = \text{last - first}\).

\textbf{Template Parameters}

- \textit{ExPolicy} – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- \textit{Iter} – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- \textit{Sent} – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for \texttt{Iter1}.
- \textit{Comp} – The type of the function/function object to use (deduced).
- \textit{Proj} – The type of an optional projection function. This defaults to \texttt{hpx::identity}

\textbf{Parameters}

- \textit{policy} – The execution policy to use for the scheduling of the iterations.
- \textit{first} – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- \textit{last} – Refers to the end of the sequence of elements the algorithm will be applied to.
- \textit{comp} – \textit{comp} is a callable object. The return value of the INVOKE operation applied to an object of type \textit{Comp}, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that \textit{comp} will not apply any non-constant function through the dereferenced iterator.
- \textit{proj} – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate \textit{is} is invoked.

\textbf{Returns} The \textit{is\_heap} algorithm returns a \texttt{hpx::future<bool>} if the execution policy is of type \texttt{sequenced\_task\_policy} or \texttt{parallel\_task\_policy} and returns \texttt{bool} otherwise. The \textit{is\_heap} algorithm returns whether the range is max heap. That is, true if the range is max heap, false otherwise.

template<typename Rng, typename Comp = hpx::parallel::detail::less, typename Proj = hpx::identity>

bool is_heap(Rng &&rng, Comp &&comp = Comp(), Proj &&proj = Proj())

Returns whether the range is max heap. That is, true if the range is max heap, false otherwise. The function uses the given comparison function object \textit{comp} (defaults to using operator\textless()\textgreater).

\textit{comp} has to induce a strict weak ordering on the values.

\textbf{Note:} Complexity: Performs at most \(N\) applications of the comparison \textit{comp}, at most \(2 \times N\) applica-
tions of the projection \( proj \), where \( N = \text{last} - \text{first} \).

**Template Parameters**
- **\( \text{Rng} \)** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- **\( \text{Comp} \)** – The type of the function/function object to use (deduced).
- **\( \text{Proj} \)** – The type of an optional projection function. This defaults to \( \text{hpx::identity} \)

**Parameters**
- **\( \text{rng} \)** – Refers to the sequence of elements the algorithm will be applied to.
- **\( \text{comp} \)** – \( \text{comp} \) is a callable object. The return value of the INVOKE operation applied to an object of type \( \text{Comp} \), when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that \( \text{comp} \) will not apply any non-constant function through the dereferenced iterator.
- **\( \text{proj} \)** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns**
The \( \text{is_heap} \) algorithm returns \( \text{bool} \). The \( \text{is_heap} \) algorithm returns whether the range is max heap. That is, true if the range is max heap, false otherwise.

```cpp
template<typename \text{Iter}, typename \text{Sent}, typename \text{Comp} = \text{hpx::parallel::detail::less}, typename \text{Proj} = \text{hpx::identity}>
\text{bool is_heap}(\text{Iter} \text{first}, \text{Sent} \text{last}, \text{Comp} &&\text{comp} = \text{Comp}(), \text{Proj} &&\text{proj} = \text{Proj}())
```

Returns whether the range is max heap. That is, true if the range is max heap, false otherwise. The function uses the given comparison function object \( \text{comp} \) (defaults to using operator\( <() \)).

\( \text{comp} \) has to induce a strict weak ordering on the values.

**Note:** Complexity: Performs at most \( N \) applications of the comparison \( \text{comp} \), at most \( 2 \ast N \) applications of the projection \( \text{proj} \), where \( N = \text{last} - \text{first} \).

**Template Parameters**
- **\( \text{Iter} \)** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **\( \text{Sent} \)** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for \( \text{Iter} \).
- **\( \text{Comp} \)** – The type of the function/function object to use (deduced).
- **\( \text{Proj} \)** – The type of an optional projection function. This defaults to \( \text{hpx::identity} \)

**Parameters**
- **\( \text{first} \)** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **\( \text{last} \)** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **\( \text{comp} \)** – \( \text{comp} \) is a callable object. The return value of the INVOKE operation applied to an object of type \( \text{Comp} \), when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that \( \text{comp} \) will not apply any non-constant function through the dereferenced iterator.
- **\( \text{proj} \)** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns**
The \( \text{is_heap} \) algorithm returns \( \text{bool} \). The \( \text{is_heap} \) algorithm returns whether the range is max heap. That is, true if the range is max heap, false otherwise.

```cpp
template<typename \text{ExPolicy}, typename \text{Rng}, typename \text{Comp} = \text{hpx::parallel::detail::less}, typename \text{Proj} = \text{hpx::identity}>
```

Chapter 2. What’s so special about HPX?
`hpx::parallel::util::detail::algorithm_result<ExPolicy, hpx::traits::range_iterator_t<Rng>> is_heap_until(ExPolicy &&policy, Rng &&rng, Comp &&comp = Comp(), Proj &&proj = Proj())`

Returns the upper bound of the largest range beginning at `first` which is a max heap. That is, the last iterator `it` for which range `[first, it)` is a max heap. The function uses the given comparison function object `comp` (defaults to using `operator<()`). `comp` has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs at most N applications of the comparison `comp`, at most 2 * N applications of the projection `proj`, where N = last - first.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **comp** – `comp` is a callable object. The return value of the INVOKE operation applied to an object of type `Comp`, when contextually converted to `bool`, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns**
The `is_heap_until` algorithm returns a `hpx::future<RandIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `RandIter` otherwise. The `is_heap_until` algorithm returns the upper bound of the largest range beginning at first which is a max heap. That is, the last iterator `it` for which range `[first, it)` is a max heap.

```
template<typename ExPolicy, typename Iter, typename Sent, typename Comp = hpx::parallel::detail::less, typename Proj = hpx::identity>
```
Returns the upper bound of the largest range beginning at `first` which is a max heap. That is, the last iterator `it` for which range `[first, it)` is a max heap. The function uses the given comparison function object `comp` (defaults to using `operator<()`).

`comp` has to induce a strict weak ordering on the values.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: Performs at most N applications of the comparison `comp`, at most 2 * N applications of the projection `proj`, where N = last - first.

**Template Parameters**

- `ExPolicy` – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Iter` – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- `Sent` – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for `Iter1`.
- `Comp` – The type of the function/function object to use (deduced).
- `Proj` – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**

- `policy` – The execution policy to use for the scheduling of the iterations.
- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements the algorithm will be applied to.
- `comp` – `comp` is a callable object. The return value of the INVOKE operation applied to an object of type `Comp`, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator.
- `proj` – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `is_heap_until` algorithm returns a `hpx::future<RandIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `RandIter` otherwise. The `is_heap_until` algorithm returns the upper bound of the largest range beginning at first which is a max heap. That is, the last iterator `it` for which range `[first, it)` is a max heap.

```cpp
template<typename Rng, typename = hpx::parallel::detail::less, typename = hpx::identity>
hpx::traits::range_iterator_t<Rng> is_heap_until(Rng &&rng, Comp &&comp = Comp(), Proj &&proj = Proj())
```

Returns the upper bound of the largest range beginning at `first` which is a max heap. That is, the last iterator `it` for which range `[first, it)` is a max heap. The function uses the given comparison function object `comp` (defaults to using `operator<()`).

`comp` has to induce a strict weak ordering on the values.
**Note:** Complexity: Performs at most N applications of the comparison *comp*, at most 2 * N applications of the projection *proj*, where N = last - first.

**Template Parameters**
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **comp** – *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that *comp* will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `is_heap_until` algorithm returns *RandIter*. The `is_heap_until` algorithm returns the upper bound of the largest range beginning at first which is a max heap. That is, the last iterator *it* for which range [first, it) is a max heap.

```cpp
template<typename Iter, typename Sent, typename Comp = hpx::parallel::detail::less, typename Proj = hpx::identity>
Iter is_heap_until(Iter first, Sent last, Comp &comp = Comp(), Proj &proj = Proj())
```

Returns the upper bound of the largest range beginning at first which is a max heap. That is, the last iterator *it* for which range [first, it) is a max heap. The function uses the given comparison function object *comp* (defaults to using operator<()).

*comp* has to induce a strict weak ordering on the values.

**Note:** Complexity: Performs at most N applications of the comparison *comp*, at most 2 * N applications of the projection *proj*, where N = last - first.

**Template Parameters**
- **Iter** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – *comp* is a callable object. The return value of the INVOKE operation applied to an object of type *Comp*, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that *comp* will not apply any non-constant function through the dereferenced iterator.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `is_heap_until` algorithm returns *RandIter*. The `is_heap_until` algorithm returns the upper bound of the largest range beginning at first which is a max heap. That is, the last iterator *it* for which range [first, it) is a max heap.

## Functions

```cpp
template<typename FwdIter, typename Sent, typename Pred, typename Proj = hpx::identity>
bool is_partitioned(FwdIter first, Sent last, Pred &&pred, Proj &&proj = Proj())
```

Determines if the range [first, last) is partitioned.

**Note:** Complexity: at most \((N)\) predicate evaluations where \(N = \text{distance}(\text{first}, \text{last})\).

### Template Parameters

- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter.
- **Pred** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

### Parameters

- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the unary predicate which returns true for elements expected to be found in the beginning of the range. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

### Returns

The `is_partitioned` algorithm returns `bool`. The `is_partitioned` algorithm returns true if each element in the sequence for which pred returns true precedes those for which pred returns false. Otherwise `is_partitioned` returns false. If the range [first, last) contains less than two elements, the function is always true.
The predicate operations in the parallel `is_partitioned` algorithm invoked with an execution policy object of type `sequenced_policy` executes in sequential order in the calling thread.

The comparison operations in the parallel `is_partitioned` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: at most (N) predicate evaluations where \( N = \text{distance}(\text{first, last}) \).

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `FwdIter`.
- **Pred** – The type of the function/function object to use (deduced). `Pred` must be `Copy-Constructible` when using a parallel policy.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the unary predicate which returns true for elements expected to be found in the beginning of the range. The signature of the function should be equivalent to

\[
\text{bool pred(const Type &a);}
\]

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate `is` invoked.

**Returns** The `is_partitioned` algorithm returns a `hpx::future<bool>` if the execution policy is of type `task_execution_policy` and returns `bool` otherwise. The `is_partitioned` algorithm returns true if each element in the sequence for which `pred` returns true precedes those for which `pred` returns false. Otherwise `is_partitioned` returns false. If the range `[first, last)` contains less than two elements, the function is always true.

```cpp
template<typename Rng, typename Pred, typename Proj = hpx::identity>
bool is_partitioned(Rng &&rng, Pred &&pred, Proj &&proj = Proj())
```

Determines if the range `rng` is partitioned.

**Note:** Complexity: at most (N) predicate evaluations where \( N = \text{std::size(rng)} \).

**Template Parameters**
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

2.8. API reference 645
Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Refers to the unary predicate which returns true for elements expected to be found in the beginning of the range. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Returns

The `is_partitioned` algorithm returns `bool`. The `is_partitioned` algorithm returns true if each element in the sequence for which `pred` returns true precedes those for which `pred` returns false. Otherwise `is_partitioned` returns false. If the range `rng` contains less than two elements, the function is always true.

```cpp
template<typename ExPolicy, typename Rng, typename Pred = hpx::identity>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool>
is_partitioned(ExPolicy &&policy,
Rng &&rng, Pred &&pred,
Proj &&proj = Proj())
```

Determines if the range [first, last) is partitioned.

The predicate operations in the parallel `is_partitioned` algorithm invoked with an execution policy object of type `sequenced_policy` executes in sequential order in the calling thread.

The comparison operations in the parallel `is_partitioned` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: at most (N) predicate evaluations where N = std::size(rng).

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). `Pred` must be `CopyConstructible` when using a parallel policy.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Refers to the unary predicate which returns true for elements expected to be found in the beginning of the range. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.
• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `is_partitioned` algorithm returns a `hpx::future<bool>` if the execution policy is of type `task_execution_policy` and returns `bool` otherwise. The `is_partitioned` algorithm returns `true` if each element in the sequence for which `pred` returns `true` precedes those for which `pred` returns `false`. Otherwise `is_partitioned` returns `false`. If the range `rng` contains less than two elements, the function is always `true`.

```cpp
hpx/parallel/container_algorithms/is_sorted.hpp
```

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace **hpx**

namespace **ranges**

**Functions**

```cpp
template<typename FwdIter, typename Sent, typename Pred = hpx::parallel::detail::less, typename Proj = hpx::identity>
bool is_sorted(FwdIter first, Sent last, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Determines if the range `[first, last)` is sorted. Uses `pred` to compare elements.

The comparison operations in the parallel `is_sorted` algorithm executes in sequential order in the calling thread.

**Note:** Complexity: at most \((N+S-1)\) comparisons where \(N = \text{distance}(\text{first}, \text{last})\). \(S = \text{number of partitions}\)

**Template Parameters**

- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter.
- **Pred** – The type of an optional function/function object to use.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**

- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns `true` if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a, const Type &b);
```
The signature does not need to have const &, but the function must not modify the objects passed to it. The type Type must be such that objects of types FwdIter can be dereferenced and then implicitly converted to Type.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The is_sorted algorithm returns a bool. The is_sorted algorithm returns true if each element in the sequence [first, last) satisfies the predicate passed. If the range [first, last) contains less than two elements, the function always returns true.

```cpp
template<typename ExPolicy, typename FwdIter, typename Sent, typename Pred = std::less<>, typename Proj = std::identity> hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> is_sorted(ExPolicy &&policy, FwdIter first, Sent last, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Determines if the range [first, last) is sorted. Uses pred to compare elements.

The comparison operations in the parallel is_sorted algorithm invoked with an execution policy object of type sequenced_policy executes in sequential order in the calling thread.

The comparison operations in the parallel is_sorted algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: at most (N+S-1) comparisons where \( N = \text{distance(first, last)} \). \( S = \text{number of partitions} \)

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of is_sorted requires Pred to meet the requirements of Copy-Constructible. This defaults to std::less<>
- **Proj** – The type of an optional projection function. This defaults to hpx::identity

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a, const Type &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type Type must be such that objects of types FwdIter can be dereferenced.
and then implicitly converted to Type.

- **proj** – Specifies the function (or function object) which will be invoked for each of the
  elements as a projection operation before the actual predicate is invoked.

**Returns** The *is_sorted* algorithm returns a `hpx::future<bool>` if the execution policy is of

- type `task_execution_policy` and returns `bool` otherwise. The *is_sorted* algorithm returns a
  bool if each element in the sequence [first, last) satisfies the predicate passed. If the range
  [first, last) contains less than two elements, the function always returns true.

```cpp
template<typename Rng, typename Pred = hpx::parallel::detail::less, typename Proj = hpx::identity>
bool is_sorted(Rng &&rng, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Determines if the range rng is sorted. Uses pred to compare elements.

The comparison operations in the parallel *is_sorted* algorithm executes in sequential order in the calling
thread.

**Note:** Complexity: at most 

\[ (N + S - 1) \] comparisons where \( N = \text{size(rng)} \), \( S = \text{number of partitions} \)

**Template Parameters**

- **Rng** – The type of the source range used (deduced). The iterators extracted from this
  range type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should
  be treated as less than the second argument. The signature of the function should be
  equivalent to

```cpp
bool pred(const Type &, const Type &);
```

The signature does not need to have const &., but the function must not modify the objects
passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced
and then implicitly converted to Type.

- **proj** – Specifies the function (or function object) which will be invoked for each of the
  elements as a projection operation before the actual predicate is invoked.

**Returns** The *is_sorted* algorithm returns a `bool`. The *is_sorted* algorithm returns true if each

- element in the rng satisfies the predicate passed. If the range rng contains less than two
  elements, the function always returns true.

```cpp
template<typename ExPolicy, typename Rng, typename Pred = hpx::parallel::detail::less, typename Proj = hpx::identity>

hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> is_sorted(ExPolicy &&policy, Rng &&rng, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Determines if the range rng is sorted. Uses pred to compare elements.

The comparison operations in the parallel *is_sorted* algorithm invoked with an execution policy object
of type `sequenced_policy` executes in sequential order in the calling thread.

The comparison operations in the parallel *is_sorted* algorithm invoked with an execution policy object
of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in
unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: at most (N+S-1) comparisons where \(N = \text{size(rng)}\). \(S = \text{number of partitions}\)

**Template Parameters**
- `ExPolicy` – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Rng` – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- `Pred` – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `is_sorted` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>
- `Proj` – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**
- `policy` – The execution policy to use for the scheduling of the iterations.
- `rng` – Refers to the sequence of elements the algorithm will be applied to.
- `pred` – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a, const Type &b);
```

The signature does not have to have const &, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- `proj` – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `is_sorted` algorithm returns a `hpx::future<bool>` if the execution policy is of type `task_execution_policy` and returns `bool` otherwise. The `is_sorted` algorithm returns a bool if each element in the range `rng` satisfies the predicate passed. If the range `rng` contains less than two elements, the function always returns true.

```cpp
template<typename FwdIter, typename Sent, typename Pred = hpx::parallel::detail::less, typename Proj = hpx::identity>
FwdIter is_sorted_until(FwdIter first, Sent last, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Returns the first element in the range `[first, last)` that is not sorted. Uses a predicate to compare elements or the less than operator.

The comparison operations in the parallel `is_sorted_until` algorithm execute in sequential order in the calling thread.

**Note:** Complexity: at most (N+S-1) comparisons where \(N = \text{distance(first, last)}\). \(S = \text{number of partitions}\)

**Template Parameters**
- `FwdIter` – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- `Sent` – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `FwdIter`.
- `Pred` – The type of an optional function/function object to use.
• **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

**Parameters**

• **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.

• **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.

• **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a, const Type &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.

• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns**

The `is_sorted_until` algorithm returns an `FwdIter`. The `is_sorted_until` algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, last is returned.

```cpp
template<typename ExPolicy, typename FwdIter, typename Sent, typename Pred = hpx::parallel::detail::less, typename Proj = hpx::identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type is_sorted_until(ExPolicy &&policy,
FwdIter first,
Sent last,
Pred &&pred = Pred(), Proj &&proj = Proj())
```

Returns the first element in the range `[first, last)` that is not sorted. Uses a predicate to compare elements or the less than operator.

The comparison operations in the parallel `is_sorted_until` algorithm invoked with an execution policy object of type `sequenced_policy` executes in sequential order in the calling thread.

The comparison operations in the parallel `is_sorted_until` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: at most (N+S-1) comparisons where N = distance(first, last). S = number of partitions

**Template Parameters**

• **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.

• **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter.
• **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `is_sorted_until` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`

• **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements of that the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of that the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a, const Type &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

### Returns

The `is_sorted_until` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `is_sorted_until` algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, `last` is returned.

```cpp
template<typename Rng, typename Pred = hpx::parallel::detail::less, typename Proj = hpx::identity>
hpx::traits::range_iterator_t<Rng> is_sorted_until(Rng &&rng, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Returns the first element in the range `rng` that is not sorted. Uses a predicate to compare elements or the less than operator.

---

**Note:** Complexity: at most \(N+S-1\) comparisons where \(N = \text{size}(rng)\). \(S = \text{number of partitions}\)

### Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `is_sorted_until` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

### Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a, const Type &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.
**Returns** The `is_sorted_until` returns `FwdIter`. The `is_sorted_until` algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, last is returned.

```
template<typename ExPolicy, typename Rng, typename Pred = hpx::parallel::detail::less, typename Proj = hpx::identity>
  hpx::parallel::util::detail::algorithm_result<ExPolicy, hpx::traits::range_iterator_t<Rng>> is_sorted_until(ExPolicy &&policy,
            Rng &&rng, Pred &&pred = Pred(), Proj &&proj = Proj())
```

Returns the first element in the range `rng` that is not sorted. Uses a predicate to compare elements or the less than operator.

The comparison operations in the parallel `is_sorted_until` algorithm invoked with an execution policy object of type `sequenced_policy` executes in sequential order in the calling thread.

The comparison operations in the parallel `is_sorted_until` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: at most (N+S-1) comparisons where N = `size(rng)`. S = number of partitions

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `is_sorted_until` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second argument. The signature of the function should be equivalent to

```cpp
bool pred(const Type &a, const Type &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `FwdIter` can be dereferenced and then implicitly converted to `Type`.

2.8. API reference 653
• proj – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Returns: The is_sorted_until algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The is_sorted_until algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, last is returned.

The algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The is_sorted_until algorithm returns the first unsorted element. If the sequence has less than two elements or the sequence is sorted, last is returned.

`hpx/parallel/container_algorithms/lexicographical_compare.hpp`

See `Public API` for a list of names and headers that are part of the public `HPX` API.

namespace hpx

namespace ranges

Functions

```cpp
template<typename InIter1, typename Sent1, typename InIter2, typename Sent2, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity, typename Pred = hpx::parallel::detail::less>
bool lexicographical_compare(InIter1 first1, Sent1 last1, InIter2 first2, Sent2 last2, Pred &&pred = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Checks if the first range `[first1, last1)` is lexicographically less than the second range `[first2, last2)`. Uses a provided predicate to compare elements.

The comparison operations in the parallel `lexicographical_compare` algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Note: Complexity: At most 2 * min(N1, N2) applications of the comparison operation, where N1 = std::distance(first1, last) and N2 = std::distance(first2, last2).

Note: Lexicographical comparison is an operation with the following properties
• Two ranges are compared element by element
• The first mismatching element defines which range is lexicographically less or greater than the other
• If one range is a prefix of another, the shorter range is lexicographically less than the other
• If two ranges have equivalent elements and are of the same length, then the ranges are lexicographically equal
• An empty range is lexicographically less than any non-empty range
• Two empty ranges are lexicographically equal

Template Parameters
• InIter1 – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an input iterator.
• Sent1 – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter1.
• InIter2 – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an input iterator.
• **Sent2** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter2.

• **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `lexicographical_compare` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>

• **Proj1** – The type of an optional projection function for FwdIter1. This defaults to `hpx::identity`

• **Proj2** – The type of an optional projection function for FwdIter2. This defaults to `hpx::identity`

**Parameters**

• **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

• **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

• **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

• **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

• **pred** – Refers to the comparison function that the first and second ranges will be applied to

• **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate is invoked.

• **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate is invoked.

**Returns** The `lexicographically_compare` algorithm returns `bool`. The `lexicographically_compare` algorithm returns true if the first range is lexicographically less, otherwise it returns false. range [first2, last2), it returns false.

```
template<typename ExPolicy, typename FwdIter1, typename Sent1, typename FwdIter2, typename Sent2, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity, typename Pred = hpx::parallel::detail::less>

hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> lexicographical_compare(ExPolicy &&policy, FwdIter1 first1, Sent1 last1, FwdIter2 first2, Sent2 last2, Pred &&pred = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Checks if the first range [first1, last1) is lexicographically less than the second range [first2, last2). uses a provided predicate to compare elements.

The comparison operations in the parallel `lexicographical_compare` algorithm invoked with an execu-
tion policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `lexicographical_compare` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most $2 \times \min(N1, N2)$ applications of the comparison operation, where $N1 = \text{std::distance}(first1, last)$ and $N2 = \text{std::distance}(first2, last2)$.

**Note:** Lexicographical comparison is an operation with the following properties

- Two ranges are compared element by element
- The first mismatching element defines which range is lexicographically *less* or *greater* than the other
- If one range is a prefix of another, the shorter range is lexicographically *less* than the other
- If two ranges have equivalent elements and are of the same length, then the ranges are lexicographically *equal*
- An empty range is lexicographically *less* than any non-empty range
- Two empty ranges are lexicographically *equal*

**Template Parameters**

- `ExPolicy` – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter1` – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- `Sent1` – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `FwdIter1`.
- `FwdIter2` – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- `Sent2` – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `FwdIter2`.
- `Pred` – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `lexicographical_compare` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>
- `Proj1` – The type of an optional projection function for `FwdIter1`. This defaults to `hpx::identity`
- `Proj2` – The type of an optional projection function for `FwdIter2`. This defaults to `hpx::identity`

**Parameters**

- `policy` – The execution policy to use for the scheduling of the iterations.
- `first1` – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- `last1` – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- `first2` – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- `last2` – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- `pred` – Refers to the comparison function that the first and second ranges will be applied to.
- `proj1` – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate is invoked.
• **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate is invoked.

**Returns**
The `lexicographically_compare` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `lexicographically_compare` algorithm returns true if the first range is lexicographically less, otherwise it returns false. range `[first2, last2)`, it returns false.

```cpp
template<typename Rng1, typename Rng2, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity, typename Pred = hpx::parallel::detail::less>
bool lexicographical_compare(Rng1 &&rng1, Rng2 &&rng2, Pred &&pred = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Checks if the first range `rng1` is lexicographically less than the second range `rng2`. uses a provided predicate to compare elements.

The comparison operations in the parallel `lexicographical_compare` algorithm invoked without an execution policy object execute in sequential order in the calling thread.

**Note:** Complexity: At most 2 * min(N1, N2) applications of the comparison operation, where N1 = `std::distance(std::begin(rng1), std::end(rng1))` and N2 = `std::distance(std::begin(rng2), std::end(rng2))`.

**Note:**
Lexicographical comparison is an operation with the following properties

• Two ranges are compared element by element
• The first mismatching element defines which range is lexicographically less or greater than the other
• If one range is a prefix of another, the shorter range is lexicographically less than the other
• If two ranges have equivalent elements and are of the same length, then the ranges are lexicographically equal
• An empty range is lexicographically less than any non-empty range
• Two empty ranges are lexicographically equal

**Template Parameters**

• **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
• **Rng2** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
• **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `lexicographical_compare` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`
• **Proj1** – The type of an optional projection function for elements of the first range. This defaults to `hpx::identity`
• **Proj2** – The type of an optional projection function for elements of the second range. This defaults to `hpx::identity`

**Parameters**

• **rng1** – Refers to the sequence of elements the algorithm will be applied to.
• **rng2** – Refers to the sequence of elements the algorithm will be applied to.
• **pred** – Refers to the comparison function that the first and second ranges will be applied to
• **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate is invoked.
• **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate is invoked.

**Returns** The `lexicographically_compare` algorithm returns `bool`. The `lexicographically_compare` algorithm returns true if the first range is lexicographically less, otherwise it returns false. range `[first2, last2)`, it returns false.

```cpp
template<typename ExPolicy, typename Rng1, typename Rng2, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity, typename Pred = hpx::parallel::detail::less>
  hpx::parallel::util::detail::algorithm_result_t<ExPolicy, bool> lexicographical_compare(ExPolicy &&policy, Rng1 &&rng1, Rng2 &&rng2, Pred &&pred = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Checks if the first range `rng1` is lexicographically less than the second range `rng2`. uses a provided predicate to compare elements.

The comparison operations in the parallel `lexicographical_compare` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparison operations in the parallel `lexicographical_compare` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most \(2 \times \min(N1, N2)\) applications of the comparison operation, where \(N1 = \text{std::distance}(	ext{std::begin(rng1)}, \text{std::end(rng1)})\) and \(N2 = \text{std::distance}(	ext{std::begin(rng2)}, \text{std::end(rng2)})\).

**Note:** Lexicographical comparison is an operation with the following properties

- Two ranges are compared element by element
- The first mismatching element defines which range is lexicographically less or greater than the other
- If one range is a prefix of another, the shorter range is lexicographically less than the other
- If two ranges have equivalent elements and are of the same length, then the ranges are lexicographically equal
- An empty range is lexicographically less than any non-empty range
- Two empty ranges are lexicographically equal

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it
executes the assignments.

- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `lexicographical_compare` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`
- **Proj1** – The type of an optional projection function for elements of the first range. This defaults to `hpx::identity`
- **Proj2** – The type of an optional projection function for elements of the second range. This defaults to `hpx::identity`

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Refers to the comparison function that the first and second ranges will be applied to.
- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate is invoked.

**Returns**
The `lexicographically_compare` algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The `lexicographically_compare` algorithm returns true if the first range is lexicographically less, otherwise it returns false. range `[first2, last2)`, it returns false.

```cpp
hpx/parallel/container_algorithms/make_heap.hpp
```

See *Public API* for a list of names and headers that are part of the public *HPX* API.

namespace hpx

namespace ranges

**Functions**

```cpp
template<typename ExPolicy, typename Iter, typename Sent, typename Comp, typename Proj = hpx::identity>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, Iter> make_heap(ExPolicy &&policy, Iter first,
  Sent last, Comp &&comp,
  Proj &&proj = Proj{})
```

Constructs a *max heap* in the range `[first, last)`.

The predicate operations in the parallel `make_heap` algorithm invoked with an execution policy object of type `sequential_execution_policy` executes in sequential order in the calling thread.

The comparison operations in the parallel `make_heap` algorithm invoked with an execution policy object of type `parallel_execution_policy` or `parallel_task_execution_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
Note: Complexity: at most (3*N) comparisons where N = distance(first, last).

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second. The signature of the function should be equivalent to

```cpp
bool comp(const Type &a, const Type &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `RndIter` can be dereferenced and then implicitly converted to `Type`.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate `comp` is invoked.

**Returns** The `make_heap` algorithm returns a `hpx::future<Iter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `Iter` otherwise. It returns `last`.

```cpp
hpx::parallel::util::detail::algorithm_result<ExPolicy, hpx::traits::range_iterator_t<Rng>> make_heap(ExPolicy &&policy, Rng &&rng, Comp &&comp, Proj &&proj = Proj{})
```

Constructs a max heap in the range [first, last).

The predicate operations in the parallel `make_heap` algorithm invoked with an execution policy object of type `sequential_execution_policy` executes in sequential order in the calling thread.

The comparison operations in the parallel `make_heap` algorithm invoked with an execution policy object of type `parallel_execution_policy` or `parallel_task_execution_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
Note: Complexity: at most (3*N) comparisons where \( N = \text{distance}(\text{first}, \text{last}) \).

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **comp** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second. The signature of the function should be equivalent to

```cpp
bool comp(const Type &a, const Type &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `RndIter` can be dereferenced and then implicitly converted to `Type`.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate `comp` is invoked.

Returns The `make_heap` algorithm returns a `hpx::future<Iter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `Iter` otherwise. It returns `last`.

```cpp
template<typename ExPolicy, typename Iter, typename Sent, typename Proj = hpx::identity>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, Iter> make_heap(ExPolicy &&policy, Iter first, Sent last, Proj &&proj = Proj{})
```

Constructs a max heap in the range `[first, last)`.

The predicate operations in the parallel `make_heap` algorithm invoked with an execution policy object of type `sequential_execution_policy` executes in sequential order in the calling thread.

The comparison operations in the parallel `make_heap` algorithm invoked with an execution policy object of type `parallel_execution_policy` or `parallel_task_execution_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: at most (3*N) comparisons where \( N = \text{distance}(\text{first}, \text{last}) \).
Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate \( \text{comp} \) is invoked.

**Returns** The `make_heap` algorithm returns a `hpx::future<Iter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `Iter` otherwise. It returns `last`.

```cpp
template<typename ExPolicy, typename Rng, typename Proj = hpx::identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, hpx::traits::range_iterator_t<Rng>> make_heap(ExPolicy &&policy, Rng &&rng, Proj &&proj = Proj{})
```

Constructs a **max heap** in the range `[first, last)`.

The predicate operations in the parallel `make_heap` algorithm invoked with an execution policy object of type `sequential_execution_policy` executes in sequential order in the calling thread.

The comparison operations in the parallel `make_heap` algorithm invoked with an execution policy object of type `parallel_execution_policy` or `parallel_task_execution_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: at most \((3*N)\) comparisons where \(N = \text{distance(}first, last)\).

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate \( \text{comp} \) is invoked.

**Returns** The `make_heap` algorithm returns a `hpx::future<Iter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `Iter` otherwise. It returns `last`.

```cpp
template<typename Iter, typename Sent, typename Comp, typename Proj = hpx::identity>
Iter make_heap(Iter first, Sent last, Comp &&comp, Proj &&proj = Proj{})
```

Constructs a **max heap** in the range `[first, last)`.
Template Parameters

- **Iter** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Comp** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **comp** – Refers to the binary predicate which returns true if the first argument should be treated as less than the second. The signature of the function should be equivalent to

  ```cpp
def bool comp(const Type &a, const Type &b);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that objects of types `RndIter` can be dereferenced and then implicitly converted to `Type`.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate `comp` is invoked.

Returns The `make_heap` algorithm returns `Iter`. It returns `last`.

```cpp
template<typename Iter, typename Sent, typename Proj = hpx::identity>
Iter make_heap(Iter first, Sent last, Proj &&proj = Proj{})
``` Constructs a max heap in the range [first, last).

---

Note: Complexity: at most (3*N) comparisons where N = distance(first, last).

---
Note: Complexity: at most (3*N) comparisons where \(N = \text{distance(} \text{first, last)}\).

**Template Parameters**
- **Iter** – The type of the begin source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate \(\text{comp}\) is invoked.

**Returns** The `make_heap` algorithm returns `Iter`. It returns `last`.

```cpp
template<typename Rng, typename Proj = hpx::identity>
hpx::traits::range_iterator_t<Rng> make_heap(Rng &&rng, Proj &&proj = Proj{})
```

Constructs a max heap in the range `[first, last)`.

Note: Complexity: at most (3*N) comparisons where \(N = \text{distance(} \text{first, last)}\).

**Template Parameters**
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate \(\text{comp}\) is invoked.

**Returns** The `make_heap` algorithm returns `Iter`. It returns `last`.

\text{hpx::ranges::less},
\text{Proj1} = \text{hpx::identity},
\text{Proj2} = \text{hpx::identity}>
\text{hpx::parallel::util::detail::algorithm_result<ExPolicy, hpx::ranges::merge_result<hpx::traits::range_iterator_t<Rng1>, hpx::traits::}}$

Merges two sorted ranges \([\text{first1}, \text{last1})\) and \([\text{first2}, \text{last2})\) into one sorted range beginning at \text{dest}. The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. The destination range cannot overlap with either of the input ranges.

The assignments in the parallel \text{merge} algorithm invoked with an execution policy object of type \text{sequenced_policy} execute in sequential order in the calling thread.

The assignments in the parallel \text{merge} algorithm invoked with an execution policy object of type \text{parallel_policy} or \text{parallel_task_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

\text{Note:} Complexity: Performs \(O(\text{std::distance(first1, last1)} + \text{std::distance(first2, last2)})\) applications of the comparison \text{comp} and the each projection.

\text{Template Parameters}
\begin{itemize}
\item \text{ExPolicy} – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
\item \text{Rng1} – The type of the first source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
\item \text{Rng2} – The type of the second source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
\item \text{Iter3} – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an random access iterator.
\item \text{Comp} – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \text{merge} requires \text{Comp} to meet the requirements of \text{Copy-}
\end{itemize}
Constructible. This defaults to std::less<>

- **Proj1** – The type of an optional projection function to be used for elements of the first range. This defaults to `hpx::identity`
- **Proj2** – The type of an optional projection function to be used for elements of the second range. This defaults to `hpx::identity`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the first range of elements the algorithm will be applied to.
- **rng2** – Refers to the second range of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **comp** – `comp` is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```cpp
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `Iter1` and `Iter2` can be dereferenced and then implicitly converted to both `Type1` and `Type2`

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual comparison `comp` is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual comparison `comp` is invoked.

### Returns

The `merge` algorithm returns a `hpx::future<merge_result<Iter1, Iter2, Iter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `merge_result<Iter1, Iter2, Iter3>` otherwise. The `merge` algorithm returns the tuple of the source iterator `last1`, the source iterator `last2`, the destination iterator to the end of the `dest` range.

```cpp
template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3, typename Comp = hpx::ranges::less, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
```

Chapter 2. What’s so special about HPX?
hpx::parallel::util::detail::algorithm_result<ExPolicy, hpx::ranges::merge_result<Iter1, Iter2, Iter3>>::type merge(ExPolicy &&policy, Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Iter3 dest, Comp &&comp = Comp(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())

Merges two sorted ranges [first1, last1) and [first2, last2) into one sorted range beginning at dest. The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. The destination range cannot overlap with either of the input ranges.

The assignments in the parallel merge algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The assignments in the parallel merge algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: Performs $O(\text{std::distance(first1, last1)} + \text{std::distance(first2, last2)})$ applications of the comparison `comp` and the each projection.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an random access iterator.
- **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2** – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an random access iterator.
- **Sent2** – The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for Iter2.
Iter3 – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an random access iterator.

Comp – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `merge` requires `Comp` to meet the requirements of `CopyConstructible`. This defaults to std::less<>

Proj1 – The type of an optional projection function to be used for elements of the first range. This defaults to hpx::identity

Proj2 – The type of an optional projection function to be used for elements of the second range. This defaults to hpx::identity

Parameters

- policy – The execution policy to use for the scheduling of the iterations.
- first1 – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- last1 – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- first2 – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- last2 – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- dest – Refers to the beginning of the destination range.
- comp – `comp` is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```cpp
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `Iter1` and `Iter2` can be dereferenced and then implicitly converted to both `Type1` and `Type2`

- proj1 – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual comparison `comp` is invoked.
- proj2 – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual comparison `comp` is invoked.

Returns The `merge` algorithm returns a `hpx::future<merge_result<Iter1, Iter2, Iter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `merge_result<Iter1, Iter2, Iter3>` otherwise. The `merge` algorithm returns the tuple of the source iterator `last1`, the source iterator `last2`, the destination iterator to the end of the `dest` range.

```cpp
template<typename Rng1, typename Rng2, typename Iter3, typename Comp = hpx::ranges::less, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
```
Merges two sorted ranges [first1, last1) and [first2, last2) into one sorted range beginning at dest. The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. The destination range cannot overlap with either of the input ranges.

**Note:** Complexity: Performs $O(\text{std::distance(first1, last1)} + \text{std::distance(first2, last2)})$ applications of the comparison `comp` and the each projection.

**Template Parameters**
- **Rng1** – The type of the first source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- **Rng2** – The type of the second source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `merge` requires `Comp` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>
- **Proj1** – The type of an optional projection function to be used for elements of the first range. This defaults to `hpx::identity`
- **Proj2** – The type of an optional projection function to be used for elements of the second range. This defaults to `hpx::identity`

**Parameters**
- **rng1** – Refers to the first range of elements the algorithm will be applied to.
- **rng2** – Refers to the second range of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **comp** – `comp` is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```cpp
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `Iter1` and `Iter2` can be dereferenced and then implicitly converted to both `Type1` and `Type2`
- **proj1** – Specifies the function (or function object) which will be invoked for each of the
elements of the first range as a projection operation before the actual comparison `comp` is invoked.

- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual comparison `comp` is invoked.

**Returns** The `merge` algorithm returns `merge_result<Iter1, Iter2, Iter3>`. The `merge` algorithm returns the tuple of the source iterator `last1`, the source iterator `last2`, the destination iterator to the end of the `dest` range.

```cpp
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3, typename Comp = hpx::ranges::less, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>

hpx::ranges::merge_result<Iter1, Iter2, Iter3> merge(Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Iter3 dest, Comp &&comp = Comp(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Merges two sorted ranges `[first1, last1)` and `[first2, last2)` into one sorted range beginning at `dest`. The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range. The destination range cannot overlap with either of the input ranges.

**Note:** Complexity: Performs O(std::distance(first1, last1) + std::distance(first2, last2)) applications of the comparison `comp` and the each projection.

**Template Parameters**
- **Iter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an random access iterator.
- **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for `Iter1`.
- **Iter2** – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of a random access iterator.
- **Sent2** – The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for `Iter2`.
- **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `merge` requires `Comp` to meet the requirements of `CopyConstructible`. This defaults to std::less<>
- **Proj1** – The type of an optional projection function to be used for elements of the first range. This defaults to `hpx::identity`
- **Proj2** – The type of an optional projection function to be used for elements of the second range. This defaults to `hpx::identity`

**Parameters**
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **comp** – `comp` is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:
bool comp(const Type1 &a, const Type2 &b);

The signature does not need to have const&, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types Iter1 and Iter2 can be dereferenced and then implicitly converted to both Type1 and Type2.

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual comparison comp is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual comparison comp is invoked.

**Returns** The merge algorithm returns merge_result<Iter1, Iter2, Iter3>. The merge algorithm returns the tuple of the source iterator last1, the source iterator last2, the destination iterator to the end of the dest range.

template<typename ExPolicy, typename Rng, typename Iter, typename Comp = hpx::ranges::less, typename Proj = hpx::identity>

hpx::parallel::util::detail::algorithm_result_t<ExPolicy, Iter, Rng> inplace_merge(ExPolicy &&policy, Rng &&rng, Iter middle, Comp &&comp = Comp(), Proj &&proj = Proj())

Merges two consecutive sorted ranges [first, middle) and [middle, last) into one sorted range [first, last). The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range.

The assignments in the parallel inplace_merge algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The assignments in the parallel inplace_merge algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs O(std::distance(first, last)) applications of the comparison comp and the each projection.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- **Iter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of inplace_merge requires Comp to meet the requirements of CopyConstructible. This defaults to std::less<>
- **Proj** – The type of an optional projection function. This defaults to hpx::identity

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the range of elements the algorithm will be applied to.
• \textbf{middle} – Refers to the end of the first sorted range and the beginning of the second sorted range the algorithm will be applied to.
• \textbf{comp} – \textit{comp} is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

\begin{verbatim}
bool comp(const Type1 &a, const Type2 &b);
\end{verbatim}

The signature does not need to have \texttt{const\&}, but the function must not modify the objects passed to it. The types \texttt{Type1} and \texttt{Type2} must be such that objects of types \texttt{Iter} can be dereferenced and then implicitly converted to both \texttt{Type1} and \texttt{Type2}.

• \textbf{proj} – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

\textbf{Returns} The \textit{inplace_merge} algorithm returns a \textit{hpx::future<Iter>} if the execution policy is of type \textit{sequenced_task_policy} or \textit{parallel_task_policy} and returns \textit{Iter} otherwise. The \textit{inplace_merge} algorithm returns the source iterator \textit{last}.

```cpp
template<typename ExPolicy, typename Iter, typename Sent, typename Comp = hpx::ranges::less, typename Proj = hpx::identity>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, Iter> inplace_merge(ExPolicy &&policy, Iter first, Iter middle, Sent last, Comp &&comp = Comp(), Proj &&proj = Proj())
```

Merges two consecutive sorted ranges \([\texttt{first}, \texttt{middle})\) and \([\texttt{middle}, \texttt{last})\) into one sorted range \([\texttt{first}, \texttt{last})\). The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range.

The assignments in the parallel \textit{inplace_merge} algorithm invoked with an execution policy object of type \textit{sequenced_policy} execute in sequential order in the calling thread.

The assignments in the parallel \textit{inplace_merge} algorithm invoked with an execution policy object of type \textit{parallel_policy} or \textit{parallel_task_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

\textbf{Note:} Complexity: Performs \(O(\text{std::distance(first, last)})\) applications of the comparison \textit{comp} and the each projection.

\textbf{Template Parameters}
• \textbf{ExPolicy} – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• \textbf{Iter} – The type of the source iterators used (deduced). This iterator type must meet the requirements of an random access iterator.
• \textbf{Sent} – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for \texttt{Iter1}.
• \textbf{Comp} – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \textit{inplace_merge} requires \texttt{Comp} to meet the requirements of \texttt{CopyConstructible}. This defaults to \texttt{std::less<>
• \textbf{Proj} – The type of an optional projection function. This defaults to \texttt{hpx::identity}

\textbf{Parameters}
• \textbf{policy} – The execution policy to use for the scheduling of the iterations.
• \textbf{first} – Refers to the beginning of the first sorted range the algorithm will be applied to.
• **middle** – Refers to the end of the first sorted range and the beginning of the second sorted range the algorithm will be applied to.
• **last** – Refers to the end of the second sorted range the algorithm will be applied to.
• **comp** – *comp* is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```cpp
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `Iter` can be dereferenced and then implicitly converted to both `Type1` and `Type2`.

• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns**
The `inplace_merge` algorithm returns a `hpx::future<Iter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `Iter` otherwise. The `inplace_merge` algorithm returns the source iterator `last`.

```cpp
template<typename Rng, typename Iter, typename Comp = hpx::ranges::less, typename Proj = hpx::identity>
Iter inplace_merge(Rng &&rng, Iter middle, Comp &&comp = Comp(), Proj &&proj = Proj())

Merges two consecutive sorted ranges `[first, middle)` and `[middle, last)` into one sorted range `[first, last)`. The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range.

**Note:** Complexity: Performs $O(\text{std::distance}(\text{first}, \text{last}))$ applications of the comparison `comp` and the each projection.

**Template Parameters**
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- **Iter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an random access iterator.
- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `inplace_merge` requires `Comp` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**
- **rng** – Refers to the range of elements the algorithm will be applied to.
- **middle** – Refers to the end of the first sorted range and the beginning of the second sorted range the algorithm will be applied to.
- **comp** – *comp* is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```cpp
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `Iter` can be dereferenced and then implicitly converted to both `Type1` and `Type2`.

• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `inplace_merge` algorithm returns `Iter`. The `inplace_merge` algorithm returns the source iterator `last`.

2.8. API reference 673
template<typename Iter, typename Sent, typename Comp = hpx::ranges::less, typename Proj = hpx::identity>

Iter inplace_merge(Iter first, Iter middle, Sent last, Comp &&comp = Comp(), Proj &&proj = Proj())

Merges two consecutive sorted ranges [first, middle) and [middle, last) into one sorted range [first, last). The order of equivalent elements in the each of original two ranges is preserved. For equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range.

**Note:** Complexity: Performs O(std::distance(first, last)) applications of the comparison `comp` and the each projection.

**Template Parameters**

- **Iter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an random access iterator.
- **Sent** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter.
- **Comp** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `inplace_merge` requires `Comp` to meet the requirements of CopyConstructible. This defaults to std::less<>.
- **Proj** – The type of an optional projection function. This defaults to hpx::identity

**Parameters**

- **first** – Refers to the beginning of the first sorted range the algorithm will be applied to.
- **middle** – Refers to the end of the first sorted range and the beginning of the second sorted range the algorithm will be applied to.
- **last** – Refers to the end of the second sorted range the algorithm will be applied to.
- **comp** – `comp` is a callable object which returns true if the first argument is less than the second, and false otherwise. The signature of this comparison should be equivalent to:

```cpp
bool comp(const Type1 &a, const Type2 &b);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `Iter` can be dereferenced and then implicitly converted to both `Type1` and `Type2`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `inplace_merge` algorithm `Iter`. The `inplace_merge` algorithm returns the source iterator `last`
namespace hpx

**Functions**

```cpp
template<typename FwdIter, typename Sent, typename F = hpx::parallel::detail::less, typename Proj = hpx::identity>
FwdIter min_element(FwdIter first, Sent last, F &&f = F(), Proj &&proj = Proj())
```

Finds the smallest element in the range [first, last) using the given comparison function f. The comparisons in the parallel min_element algorithm execute in sequential order in the calling thread.

**Note:** Complexity: Exactly $\max(N-1, 0)$ comparisons, where $N = \text{std::distance}(\text{first}, \text{last})$.

**Template Parameters**

- **FwdIter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for FwdIter.
- **F** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to hpx::identity.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type Type1 must be such that objects of type FwdIter can be dereferenced and then implicitly converted to Type1.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The min_element algorithm returns FwdIter. The min_element algorithm returns the iterator to the smallest element in the range [first, last). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```cpp
template<typename Rng, typename F = hpx::parallel::detail::less, typename Proj = hpx::identity>
```
**hpx::traits::range_iterator_t<Rng> min_element(Rng &&rng, F &&f = F(), Proj &&proj = Proj())**

Finds the smallest element in the range `[first, last)` using the given comparison function \( f \).

The comparisons in the parallel `min_element` algorithm execute in sequential order in the calling thread.

**Note:** Complexity: Exactly \( \max(N-1, 0) \) comparisons, where \( N = \text{std::distance}(\text{first, last}) \).

**Template Parameters**

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced).
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

  ```
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `min_element` algorithm returns a `hpx::traits::range_iterator<Rng>::type` otherwise. The `min_element` algorithm returns the iterator to the smallest element in the range `[first, last)`. If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```
template<typename ExPolicy, typename FwdIter, typename Sent, typename F = hpx::parallel::detail::less, typename Proj = hpx::identity>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> min_element(ExPolicy &&policy, FwdIter first, Sent last, F &&f = F(), Proj &&proj = Proj())
```

Finds the smallest element in the range `[first, last)` using the given comparison function \( f \).

The comparisons in the parallel `min_element` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparisons in the parallel `min_element` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Exactly \( \max(N-1, 0) \) comparisons, where \( N = \text{std::distance}(\text{first, last}) \).
Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an forward iterator.

- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for FwdIter.

- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `min_element` requires `F` to meet the requirements of `CopyConstructible`.

- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **f** – The binary predicate which returns true if the the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

  ```cpp
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Returns The `min_element` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `min_element` algorithm returns the iterator to the smallest element in the range `[first, last)`. If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns `last` if the range is empty.

template<typename ExPolicy, typename Rng, typename F = hpx::parallel::detail::less, typename Proj = hpx::identity>

```cpp
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, hpx::traits::range_iterator_t<Rng>> min_element(ExPolicy
&&policy,
Rng
&&rng,
F
&&f
= F(),
Proj
&&proj
= Proj())
```
Finds the smallest element in the range [first, last) using the given comparison function \( f \).

The comparisons in the parallel \texttt{min\_element} algorithm invoked with an execution policy object of type \texttt{sequenced\_policy} execute in sequential order in the calling thread.

The comparisons in the parallel \texttt{min\_element} algorithm invoked with an execution policy object of type \texttt{parallel\_policy} or \texttt{parallel\_task\_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

\textbf{Note:} Complexity: Exactly \( \max(N-1, 0) \) comparisons, where \( N = \text{std\::distance(first, last)} \).

\section*{Template Parameters}

- \texttt{ExPolicy} – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- \texttt{Rng} – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.

- \( F \) – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \texttt{min\_element} requires \( F \) to meet the requirements of \texttt{CopyConstructible}.

- \texttt{Proj} – The type of an optional projection function. This defaults to \texttt{hpx::identity}

\section*{Parameters}

- \texttt{policy} – The execution policy to use for the scheduling of the iterations.

- \texttt{rng} – Refers to the sequence of elements the algorithm will be applied to.

- \( f \) – The binary predicate which returns true if the the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

\begin{verbatim}
bool pred(const Type1 &a, const Type1 &b);
\end{verbatim}

The signature does not need to have \texttt{const &}, but the function must not modify the objects passed to it. The type \texttt{Type1} must be such that objects of type \texttt{FwdIter} can be dereferenced and then implicitly converted to \texttt{Type1}.

- \texttt{proj} – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

\section*{Returns}

The \texttt{min\_element} algorithm returns a \texttt{hpx::future<hpx::traits::range\_iterator<Rng>::type>} if the execution policy is of type \texttt{sequenced\_task\_policy} or \texttt{parallel\_task\_policy} and returns \texttt{FwdIter} otherwise. The \texttt{min\_element} algorithm returns the iterator to the smallest element in the range \([\text{first}, \text{last})\). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

\begin{verbatim}
template<typename FwdIter, typename Sent, typename F = hpx::parallel::detail::less, typename Proj = hpx::identity>
FwdIter max_element(FwdIter first, Sent last, F &&f = F(), Proj &&proj = Proj())
\end{verbatim}

Finds the greatest element in the range \([\text{first}, \text{last})\) using the given comparison function \( f \).
The comparisons in the parallel `max_element` algorithm execute in sequential order in the calling thread.

**Note:** Complexity: Exactly `max(N-1, 0)` comparisons, where `N = std::distance(first, last)`.

**Template Parameters**

- **FwdIter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an forward iterator.

- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for `FwdIter`.

- **F** – The type of the function/function object to use (deduced).

- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

- **f** – The binary predicate which returns true if the This argument is optional and defaults to `std::less`. the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `max_element` algorithm returns a `FwdIter`. The `max_element` algorithm returns the iterator to the smallest element in the range `[first, last)`. If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```cpp
template<typename Rng, typename F = hpx::parallel::detail::less, typename Proj = hpx::identity>
hpx::traits::range_iterator_t<Rng> max_element(Rng &&rng, F &&f = F(), Proj &&proj = Proj())
```

Finds the greatest element in the range `[first, last)` using the given comparison function `f`.

The comparisons in the parallel `max_element` algorithm execute in sequential order in the calling thread.

**Note:** Complexity: Exactly `max(N-1, 0)` comparisons, where `N = std::distance(first, last)`.

**Template Parameters**

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.

- **F** – The type of the function/function object to use (deduced).
• **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**

• **rng** – Refers to the sequence of elements the algorithm will be applied to.

• **f** – The binary predicate which returns true if the This argument is optional and defaults to `std::less`. the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```cpp
def pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `max_element` algorithm returns a `hpx::traits::range_iterator<Rng>::type` otherwise. The `max_element` algorithm returns the iterator to the smallest element in the range `[first,last)`. If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns `last` if the range is empty.

```cpp
template<typename ExPolicy, typename FwdIter, typename Sent, typename F = hpx::parallel::detail::less, typename Proj = hpx::identity>
    hpx::parallel::util::detail::algorithm_result_t<ExPolicy, FwdIter> max_element(ExPolicy &&policy, FwdIter first, Sent last, F &&f = F(), Proj &&proj = Proj())
```

Finds the greatest element in the range `[first, last)` using the given comparison function `f`.

The comparisons in the parallel `max_element` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The comparisons in the parallel `max_element` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Exactly `max(N-1, 0)` comparisons, where `N = std::distance(first, last)`.

**Template Parameters**

• **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **FwdIter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an forward iterator.

• **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for FwdIter.

• **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `max_element` requires `F` to meet the requirements of `CopyConstructible`.

• **Proj** – The type of an optional projection function. This defaults to `hpx::identity`
Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the This argument is optional and defaults to std::less. the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

  ```cpp
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type Type1 must be such that objects of type FwdIter can be dereferenced and then implicitly converted to Type1.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Returns

The max_element algorithm returns a hpx::future<FwdIter> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns FwdIter otherwise. The max_element algorithm returns the iterator to the smallest element in the range [first, last). If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns last if the range is empty.

```cpp
template<typename ExPolicy, typename Rng, typename F = hpx::parallel::detail::less, typename Proj = hpx::identity>
  hpx::parallel::util::detail::algorithm_result_t<ExPolicy, hpx::traits::range_iterator_t<Rng>>
  max_element(ExPolicy &&policy, Rng &&rng, F &&f = F(), Proj &&proj = Proj())
```

Finds the greatest element in the range [first, last) using the given comparison function f.

The comparisons in the parallel max_element algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The comparisons in the parallel max_element algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Exactly max(N-1, 0) comparisons, where N = std::distance(first, last).

Template Parameters
• **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.

• **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `max_element` requires `F` to meet the requirements of `CopyConstructible`.

• **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

### Parameters

• **policy** – The execution policy to use for the scheduling of the iterations.

• **rng** – Refers to the sequence of elements the algorithm will be applied to.

• **f** – The binary predicate which returns true if the left argument is less than the right element. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

### Returns

The `max_element` algorithm returns a `hpx::future<hpx::traits::range_iterator<Rng>::type>` if the execution policy is of type `seqeunced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `max_element` algorithm returns the iterator to the smallest element in the range `[first, last)`. If several elements in the range are equivalent to the smallest element, returns the iterator to the first such element. Returns `last` if the range is empty.

```cpp
template<typename FwdIter, typename Sent, typename F = hpx::parallel::detail::less, typename Proj = hpx::identity>
minmax_element_result<FwdIter> minmax_element(FwdIter first, Sent last, F &&f = F(), Proj &&proj = Proj())
```

Finds the greatest element in the range `[first, last)` using the given comparison function `f`.

The assignments in the parallel `minmax_element` algorithm execute in sequential order in the calling thread.

**Note:** Complexity: At most \( \max(\text{floor}(3/2^*(N-1)), 0) \) applications of the predicate, where \( N = \text{std::distance(first, last)} \).

### Template Parameters

• **FwdIter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an forward iterator.

• **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for `FwdIter`. 

---
• **F** – The type of the function/function object to use (deduced).

• **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**

• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

• **f** – The binary predicate which returns true if the left argument is less than the right element. This argument is optional and defaults to `std::less`. The signature of the predicate function should be equivalent to the following:

```cpp
def pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `minmax_element` algorithm returns a `minmax_element_result<FwdIter, FwdIter>`

The `minmax_element` algorithm returns a `min_max_result` consisting of an iterator to the smallest element as the min element and an iterator to the greatest element as the max element. Returns `minmax_element_result{first, first}` if the range is empty. If several elements are equivalent to the smallest element, the iterator to the first such element is returned. If several elements are equivalent to the largest element, the iterator to the last such element is returned.

```cpp
template<typename Rng, typename F = hpx::parallel::detail::less, typename Proj = hpx::identity>
minmax_element_result<hpx::traits::range_iterator_t<Rng>> minmax_element(Rng &&rng, F &&f = F(), Proj &&proj = Proj())
```

Finds the greatest element in the range `[first, last)` using the given comparison function `f`.

The assignments in the parallel `minmax_element` algorithm execute in sequential order in the calling thread.

**Note:** Complexity: At most `max(floor(3/2*(N-1)), 0)` applications of the predicate, where `N = std::distance(first, last)`.

**Template Parameters**

• **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.

• **F** – The type of the function/function object to use (deduced).

• **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**

• **rng** – Refers to the sequence of elements the algorithm will be applied to.

• **f** – The binary predicate which returns true if the the left argument is less than the right element. This argument is optional and defaults to `std::less`. The signature of the predicate function should be equivalent to the following:
bool pred(const Type1 &a, const Type1 &b);

The signature does not need to have const &, but the function must not modify the objects passed to it. The type Type1 must be such that objects of type FwdIter can be dereferenced and then implicitly converted to Type1.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The minmax_element algorithm returns a minmax_element_result type consisting of an range iterator to the smallest element as the min element and an range iterator to the greatest element as the max element. If several elements are equivalent to the smallest element, the iterator to the first such element is returned. If several elements are equivalent to the largest element, the iterator to the last such element is returned.

```cpp
template<
    typename ExPolicy, 
    typename FwdIter, 
    typename Sent, 
    typename F = hpx::parallel::detail::less, 
    typename Proj = hpx::identity>

hpx::parallel::util::detail::algorithm_result_t<ExPolicy, minmax_element_result<FwdIter>> minmax_element(ExPolicy &&policy, 
    FwdIter first, 
    Sent last, 
    F &&f = F(), 
    Proj &&proj = Proj())
```

Finds the greatest element in the range [first, last) using the given comparison function \( f \).

The comparisons in the parallel minmax_element algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The comparisons in the parallel minmax_element algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most \( \max(\text{floor}(3/2*(N-1)), 0) \) applications of the predicate, where \( N = \text{std::distance}(\text{first}, \text{last}) \).

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- **FwdIter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an forward iterator.
The parallel overload of `minmax_element` requires `F` to meet the requirements of `CopyConstructible`.

- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – The binary predicate which returns true if the the left argument is less than the right element. This argument is optional and defaults to `std::less`. The signature of the predicate function should be equivalent to the following:

  ```cpp
  bool pred(const Type1 &a, const Type1 &b);
  ```

  The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `FwdIter` can be dereferenced and then implicitly converted to `Type1`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

### Returns

The `minmax_element` algorithm returns a `minmax_element_result<FwdIter, FwdIter>`

The `minmax_element` algorithm returns a min_max_result consisting of an iterator to the smallest element as the min element and an iterator to the greatest element as the max element. Returns `minmax_element_result{first, first}` if the range is empty. If several elements are equivalent to the smallest element, the iterator to the first such element is returned. If several elements are equivalent to the largest element, the iterator to the last such element is returned.

Finds the greatest element in the range `[first, last)` using the given comparison function `f`.

The comparisons in the parallel `minmax_element` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.
The comparisons in the parallel \texttt{minmax_element} algorithm invoked with an execution policy object of type parallel\_policy or parallel\_task\_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

\textbf{Note:} Complexity: At most \( \max(\floor{3/2*(N-1)}, 0) \) applications of the predicate, where \( N = \) \texttt{std\::distance}\( (\text{first}, \text{last}) \).

\textbf{Template Parameters}

- \texttt{ExPolicy} – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

- \texttt{Rng} – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.

- \texttt{F} – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \texttt{minmax_element} requires \texttt{F} to meet the requirements of \texttt{CopyConstructible}.

- \texttt{Proj} – The type of an optional projection function. This defaults to \texttt{hpx::identity}

\textbf{Parameters}

- \texttt{policy} – The execution policy to use for the scheduling of the iterations.

- \texttt{rng} – Refers to the sequence of elements the algorithm will be applied to.

- \texttt{f} – The binary predicate which returns true if the the left argument is less than the right element. This argument is optional and defaults to \texttt{std::less}. The signature of the predicate function should be equivalent to the following:

\begin{verbatim}
bool pred(const Type1 &a, const Type1 &b);
\end{verbatim}

The signature does not need to have const &, but the function must not modify the objects passed to it. The type \texttt{Type1} must be such that objects of type \texttt{FwdIter} can be dereferenced and then implicitly converted to \texttt{Type1}.

- \texttt{proj} – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

\textbf{Returns} The \texttt{minmax_element} algorithm returns a \texttt{minmax_element_result<rhp::traits::range_iterator<Rng>::type, hpx::traits::range_iterator<Rng>::type>} The \texttt{minmax_element} algorithm returns a \texttt{min_max_result} consisting of an range iterator to the smallest element as the min element and an range iterator to the greatest element as the max element. If several elements are equivalent to the smallest element, the iterator to the first such element is returned. If several elements are equivalent to the largest element, the iterator to the last such element is returned.
hpx/parallel/container_algorithms/mismatch.hpp

See Public API for a list of names and headers that are part of the public HPX API.

namespace hpx

namespace ranges

Functions

template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Pred = equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, mismatch_result<Iter1, Iter2>>::type mismatch(ExPolicy &&policy, Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())

Returns true if the range [first1, last1) is mismatch to the range [first2, last2), and false otherwise.

The comparison operations in the parallel mismatch algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The comparison operations in the parallel mismatch algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: At most min(last1 - first1, last2 - first2) applications of the predicate f. If FwdIter1 and FwdIter2 meet the requirements of RandomAccessIterator and (last1 - first1) != (last2 - first2) then no applications of the predicate f are made.

Note: The two ranges are considered mismatch if, for every iterator i in the range [first1,last1), *i
mismatchs *(first2 + (i - first1)). This overload of mismatch uses operator== to determine if two elements are mismatch.

Template Parameters
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the source iterators used for the end of the first range (deduced).
- **Iter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the source iterators used for the end of the second range (deduced).
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of mismatch requires Pred to meet the requirements of Copy-Constructible. This defaults to std::equal_to<>.
- **Proj1** – The type of an optional projection function applied to the first range. This defaults to hpx::identity.
- **Proj2** – The type of an optional projection function applied to the second range. This defaults to hpx::identity.

Parameters
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.
- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate is invoked.

Returns The mismatch algorithm returns a `hpx::future<bool>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `bool` otherwise. The mismatch algorithm returns true if the elements in the two ranges are mismatch, otherwise it returns false. If the length of the range [first1, last1) does not mismatch the length of the range [first2, last2), it returns false.

```
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred = equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
```
Returns std::pair with iterators to the first two non-equivalent elements.

The comparison operations in the parallel mismatch algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The comparison operations in the parallel mismatch algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most last1 - first1 applications of the predicate \( f \).

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1** – The type of the first source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Rng2** – The type of the second source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of mismatch requires Pred to meet the requirements of Copy Constructible. This defaults to std::equal_to<>.
- **Proj1** – The type of an optional projection function applied to the first range. This defaults to hpx::identity
- **Proj2** – The type of an optional projection function applied to the second range. This defaults to hpx::identity

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:
bool pred(const Type1 &a, const Type2 &b);

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively.

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate is invoked.

**Returns**: The `mismatch` algorithm returns a `hpx::future<std::pair<FwdIter1, FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `std::pair<FwdIter1, FwdIter2>` otherwise. The `mismatch` algorithm returns the first mismatching pair of elements from two ranges: one defined by `[first1, last1)` and another defined by `[first2, last2)`.

```cpp
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Pred = equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
mismatch_result<Iter1, Iter2> mismatch(Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Returns true if the range `[first1, last1)` is mismatch to the range `[first2, last2)`, and false otherwise.

**Note**: Complexity: At most min(last1 - first1, last2 - first2) applications of the predicate f. If FwdIter1 and FwdIter2 meet the requirements of `RandomAccessIterator` and (last1 - first1) != (last2 - first2) then no applications of the predicate f are made.

**Note**: The two ranges are considered mismatch if, for every iterator i in the range `[first1,last1)`, *i mismatches *(first2 + (i - first1)). This overload of mismatch uses operator== to determine if two elements are mismatch.

**Template Parameters**
- **Iter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the source iterators used for the end of the first range (deduced).
- **Iter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the source iterators used for the end of the second range (deduced).
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `mismatch` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`
- **Proj1** – The type of an optional projection function applied to the first range. This defaults to `hpx::identity`
- **Proj2** – The type of an optional projection function applied to the second range. This defaults to `hpx::identity`

**Parameters**
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
• **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

• **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

• **op** – The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

• **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate is invoked.

• **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate is invoked.

**Returns** The `mismatch` algorithm returns `bool`. The `mismatch` algorithm returns true if the elements in the two ranges are mismatch, otherwise it returns false. If the length of the range `[first1, last1)` does not mismatch the length of the range `[first2, last2)`, it returns false.

```cpp
template<typename Rng1, typename Rng2, typename Pred = std::equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
mismatch_result<typename hpx::traits::range_traits<Rng1>::iterator_type, typename hpx::traits::range_traits<Rng2>::iterator_type>
mismatch(Rng1 &&rng1, Rng2 &&rng2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Returns `std::pair` with iterators to the first two non-equivalent elements.

**Note:** Complexity: At most `last1 - first1` applications of the predicate $f$.

**Template Parameters**

• **Rng1** – The type of the first source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.

• **Rng2** – The type of the second source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.

• **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `mismatch` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`

• **Proj1** – The type of an optional projection function applied to the first range. This
defaults to `hpx::identity`

- **Proj2** – The type of an optional projection function applied to the second range. This defaults to `hpx::identity`

### Parameters

- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **op** – The binary predicate which returns true if the elements should be treated as mismatch. The signature of the predicate function should be equivalent to the following:

```cpp
template<typename Type1, typename Type2>
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first range as a projection operation before the actual predicate is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second range as a projection operation before the actual predicate is invoked.

### Returns

The `mismatch` algorithm returns `std::pair<FwdIter1, FwdIter2>`. The `mismatch` algorithm returns the first mismatching pair of elements from two ranges: one defined by `[first1, last1)` and another defined by `[first2, last2)`.

### hpx/parallel/container_algorithms/move.hpp

See **Public API** for a list of names and headers that are part of the public **HPX** API.

```cpp
namespace hpx

namespace ranges

Functions

template<
  typename ExPolicy,
  typename Iter1,
  typename Sent1,
  typename Iter2>

hpx::parallel::util::detail::algorithm_result<ExPolicy, move_result<Iter1, Iter2>>::type
move(ExPolicy &&policy,
     Iter1 first,
     Sent1 last,
     Iter2 dest)

Moves the elements in the range `rng` to another range beginning at `dest`. After this operation the elements in the moved-from range will still contain valid values of the appropriate type, but not necessarily the same values as before the move.

The assignments in the parallel `copy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `copy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
Note: Complexity: Performs exactly std::distance(begin(rng), end(rng)) assignments.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the source iterators used for the end of the first range (deduced).
- **Iter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.

**Returns**
The move algorithm returns a `hpx::future<ranges::move_result<iterator_t<Rng>, FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::move_result<iterator_t<Rng>, FwdIter2>` otherwise. The move algorithm returns the pair of the input iterator `last` and the output iterator to the element in the destination range, one past the last element moved.

```
template<typename ExPolicy, typename Rng, typename Iter2>
hpx::parallel::util::detail::algorithm_result<ExPolicy, move_result<hpx::traits::range_iterator_t<Rng>, Iter2>>::type move(ExPolicy&& policy, Rng&& rng, Iter2 dest)
```

Moves the elements in the range `rng` to another range beginning at `dest`. After this operation the elements in the moved-from range will still contain valid values of the appropriate type, but not necessarily the same values as before the move.

The assignments in the parallel copy algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel copy algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: Performs exactly std::distance(begin(rng), end(rng)) assignments.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
• **Iter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

• **policy** – The execution policy to use for the scheduling of the iterations.
• **rng** – Refers to the sequence of elements the algorithm will be applied to.
• **dest** – Refers to the beginning of the destination range.

**Returns** The move algorithm returns a `hpx::future<ranges::move_result<iterator_t<Rng>, FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::move_result<iterator_t<Rng>, FwdIter2>` otherwise. The move algorithm returns the pair of the input iterator `last` and the output iterator to the element in the destination range, one past the last element moved.

```cpp
template<typename Iter1, typename Sent1, typename Iter2>
move_result<Iter1, Iter2> move(Iter1 first, Sent1 last, Iter2 dest)
```

Moves the elements in the range `rng` to another range beginning at `dest`. After this operation the elements in the moved-from range will still contain valid values of the appropriate type, but not necessarily the same values as before the move.

**Note:** Complexity: Performs exactly `std::distance(begin(rng), end(rng))` assignments.

**Template Parameters**

• **Iter1** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
• **Sent1** – The type of the source iterators used for the end of the first range (deduced).
• **Iter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
• **dest** – Refers to the beginning of the destination range.

**Returns** The move algorithm returns `ranges::move_result<iterator_t<Rng>, FwdIter2>`.

The move algorithm returns the pair of the input iterator `last` and the output iterator to the element in the destination range, one past the last element moved.

```cpp
template<typename Rng, typename Iter2>
move_result<hpx::traits::range_iterator_t<Rng>, Iter2> move(Rng &&rng, Iter2 dest)
```

Moves the elements in the range `rng` to another range beginning at `dest`. After this operation the elements in the moved-from range will still contain valid values of the appropriate type, but not necessarily the same values as before the move.

**Note:** Complexity: Performs exactly `std::distance(begin(rng), end(rng))` assignments.

**Template Parameters**

• **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
• **Iter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

• **rng** – Refers to the sequence of elements the algorithm will be applied to.
• **dest** – Refers to the beginning of the destination range.

**Returns** The move algorithm returns a `ranges::move_result<iterator_t<Rng>, FwdIter2>`. 

694 Chapter 2. What’s so special about HPX?
The move algorithm returns the pair of the input iterator last and the output iterator to the element in the destination range, one past the last element moved.

**hpx/parallel/container_algorithms/nth_element.hpp**

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace hpx

namespace ranges

**Functions**

```cpp
template<typename RandomIt, typename Sent, typename Pred = hpx::parallel::detail::less, typename Proj = hpx::identity>
RandomIt nth_element(RandomIt first, RandomIt nth, Sent last, Pred &&pred = Pred(), Proj &&proj = Proj())
```

nth_element is a partial sorting algorithm that rearranges elements in [first, last) such that the element pointed at by nth is changed to whatever element would occur in that position if [first, last) were sorted and all of the elements before this new nth element are less than or equal to the elements after the new nth element.

The comparison operations in the parallel nth_element algorithm invoked without an execution policy object execute in sequential order in the calling thread.

**Note:** Complexity: Linear in std::distance(first, last) on average. O(N) applications of the predicate, and O(N log N) swaps, where N = last - first.

**Template Parameters**

- **RandomIt** – The type of the source begin, nth, and end iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for RandomIt.
- **Pred** – Comparison function object which returns true if the first argument is less than the second.
- **Proj** – The type of an optional projection function. This defaults to hpx::identity

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **nth** – Refers to the iterator defining the sort partition point
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **pred** – Specifies the comparison function object which returns true if the first argument is less than (i.e. is ordered before) the second. The signature of this comparison function should be equivalent to:

  ```cpp
  bool cmp(const Type1 &a, const Type2 &b);
  ```
The signature does not need to have const&, but the function must not modify the objects passed to it. The type must be such that an object of type `randomIt` can be dereferenced and then implicitly converted to Type. This defaults to std::less<>.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked. This defaults to hpx::identity.

**Returns** The `nth_element` algorithm returns returns `RandomIt`. The `nth_element` algorithm returns an iterator equal to last.

```cpp
template<typename ExPolicy, typename RandomIt, typename Sent, typename Pred = hpx::parallel::detail::less, typename Proj = hpx::identity>
parallel::util::detail::algorithm_result_t<ExPolicy, RandomIt> nth_element(ExPolicy &&policy, RandomIt first, RandomIt nth, Sent last, Pred &&pred = Pred(), Proj &&proj = Proj())```

`nth_element` is a partial sorting algorithm that rearranges elements in `[first, last)` such that the element pointed at by `nth` is changed to whatever element would occur in that position if `[first, last)` were sorted and all of the elements before this new `nth` element are less than or equal to the elements after the new `nth` element.

The comparison operations in the parallel `nth_element` invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `nth_element` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Linear in std::distance(first, last) on average. O(N) applications of the predicate, and O(N log N) swaps, where N = last - first.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RandomIt** – The type of the source begin, nth, and end iterators used (deduced). This iterator type must meet the requirements of a random access iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `RandomIt`.
- **Pred** – Comparison function object which returns true if the first argument is less than the second.
- **Proj** – The type of an optional projection function. This defaults to hpx::identity

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **nth** – Refers to the iterator defining the sort partition point
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **pred** – Specifies the comparison function object which returns true if the first argument is less than (i.e. is ordered before) the second. The signature of this comparison function should be equivalent to:
bool cmp(const Type1 &a, const Type2 &b);

The signature does not need to have const&, but the function must not modify the objects passed to it. The type must be such that an object of type randomIt can be dereferenced and then implicitly converted to Type. This defaults to std::less<>

- proj – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked. This defaults to hpx::identity.

Returns The partition algorithm returns a hpx::future<RandomIt> if the execution policy is of type parallel_task_policy and returns RandomIt otherwise. The nth_element algorithm returns an iterator equal to last.

nth_element is a partial sorting algorithm that rearranges elements in [first, last) such that the element pointed at by nth is changed to whatever element would occur in that position if [first, last) were sorted and all of the elements before this new nth element are less than or equal to the elements after the new nth element.

Note: Complexity: Linear in std::distance(first, last) on average. O(N) applications of the predicate, and O(N log N) swaps, where N = last - first.

Template Parameters
- Rng – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- Pred – Comparison function object which returns true if the first argument is less than the second.
- Proj – The type of an optional projection function. This defaults to hpx::identity

Parameters
- rng – Refers to the sequence of elements the algorithm will be applied to.
- nth – Refers to the iterator defining the sort partition point
- pred – Specifies the comparison function object which returns true if the first argument is less than (i.e. is ordered before) the second. The signature of this comparison function should be equivalent to:

bool cmp(const Type1 &a, const Type2 &b);

The signature does not need to have const&, but the function must not modify the objects passed to it. The type must be such that an object of type randomIt can be dereferenced and then implicitly converted to Type. This defaults to std::less<>

- proj – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked. This defaults to hpx::identity.

Returns The nth_element algorithm returns returns hpx::traits::range_iterator_t<Rng>. The nth_element algorithm returns an iterator equal to last.
nth_element is a partial sorting algorithm that rearranges elements in [first, last) such that the element pointed at by nth is changed to whatever element would occur in that position if [first, last) were sorted and all of the elements before this new nth element are less than or equal to the elements after the new nth element.

The comparison operations in the parallel nth_element invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The assignments in the parallel nth_element algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Linear in std::distance(first, last) on average. O(N) applications of the predicate, and O(N log N) swaps, where N = last - first.

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an random access iterator.
- **Pred** – Comparison function object which returns true if the first argument is less than the second.
- **Proj** – The type of an optional projection function. This defaults to hpx::identity

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **nth** – Refers to the iterator defining the sort partition point
- **pred** – Specifies the comparison function object which returns true if the first argument is less than (i.e. is ordered before) the second. The signature of this comparison function should be equivalent to:

  ```cpp
  bool cmp(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type must be such that an object of type randomIt can be dereferenced and then implicitly converted to Type. This defaults to std::less<>.
• proj – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked. This defaults to hpx::identity.

Returns The partition algorithm returns a hpx::future<hpx::traits::range_iterator_t<Rng>> if the execution policy is of type parallel_task_policy and returns hpx::traits::range_iterator_t<Rng> otherwise. The nth_element algorithm returns an iterator equal to last.

hpx/parallel/container_algorithms/partial_sort.hpp

See Public API for a list of names and headers that are part of the public HPX API.

namespace hpx

namespace ranges

Functions

template<typename RandomIt, typename Sent, typename Comp = ranges::less, typename Proj = hpx::identity>
RandomIt partial_sort(RandomIt first, RandomIt middle, Sent last, Comp &&comp = Comp(), Proj &&proj = Proj())

Places the first middle - first elements from the range [first, last) as sorted with respect to comp into the range [first, middle). The rest of the elements in the range [middle, last) are placed in an unspecified order.

The assignments in the parallel partial_sort algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Note: Complexity: Approximately (last - first) * log(middle - first) comparisons.

Template Parameters
• RandomIt – The type of the source iterators used (deduced). This iterator type must meet the requirements of an random iterator.
• Sent – The type of the source sentinel (deduced). This sentinel type must be a sentinel for RandomIt.
• Comp – The type of the function/function object to use (deduced). Comp defaults to detail::less.
• Proj – The type of an optional projection function. This defaults to hpx::identity

Parameters
• first – Refers to the beginning of the sequence of elements the algorithm will be applied to.
• middle – Refers to the middle of the sequence of elements the algorithm will be applied to.
• last – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
• comp – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that
comp will not apply any non-constant function through the dereferenced iterator. Comp defaults to detail::less.

- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate `comp` is invoked.

**Returns** The `partial_sort` algorithm returns `RandomIt`. The algorithm returns an iterator pointing to the first element after the last element in the input sequence.

```cpp
template<
typename ExPolicy, 
typename RandomIt, 
typename Sent, 
typename Comp = std::less, 
typename Proj = hpx::identity>
parallel::util::detail::algorithm_result<ExPolicy, RandomIt>::type
partial_sort(ExPolicy &&policy, 
RandomIt first, 
RandomIt middle, 
Sent last, 
Comp &&comp = Comp(), 
Proj &&proj = Proj())
```

Places the first middle - first elements from the range [first, last) as sorted with respect to comp into the range [first, middle). The rest of the elements in the range [middle, last) are placed in an unspecified order.

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Approximately (last - first) * log(middle - first) comparisons.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **RandomIt** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an random iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for RandomIt.
- **Comp** – The type of the function/function object to use (deduced). Comp defaults to detail::less.
- **Proj** – The type of an optional projection function. This defaults to hpx::identity

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the middle of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. Comp defaults to detail::less.
• proj – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate comp is invoked.

Returns The partial_sort algorithm returns a hpx::future<RandomIt> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns RandomIt otherwise. The algorithm returns an iterator pointing to the first element after the last element in the input sequence.

```cpp
template<typename Rng, typename Comp = ranges::less, typename Proj = hpx::identity>
hpx::traits::range_iterator_t<Rng> partial_sort(Rng &&rng, hpx::traits::range_iterator_t<Rng> middle, Comp &&comp = Comp(), Proj &&proj = Proj())
```

Places the first middle - first elements from the range [first, last) as sorted with respect to comp into the range [first, middle). The rest of the elements in the range [middle, last) are placed in an unspecified order.

The assignments in the parallel partial_sort algorithm invoked without an execution policy object execute in sequential order in the calling thread.

**Note:** Complexity: Approximately (last - first) * log(middle - first) comparisons.

### Template Parameters
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Comp** – The type of the function/function object to use (deduced). Comp defaults to detail::less.
- **Proj** – The type of an optional projection function. This defaults to hpx::identity

### Parameters
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the middle of the sequence of elements the algorithm will be applied to.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. Comp defaults to detail::less.
- **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate comp is invoked.

Returns The partial_sort algorithm returns hpx::traits::range_iterator_t<Rng>. It returns last.

```cpp
template<typename ExPolicy, typename Rng, typename Comp = ranges::less, typename Proj = hpx::identity>
```
Sorts the elements in the range [first, last) in ascending order. The relative order of equal elements is preserved. The function uses the given comparison function object comp (defaults to using operator<()).

A sequence is sorted with respect to a comparator comp and a projection proj if for every iterator i pointing to the sequence and every non-negative integer n such that i + n is a valid iterator pointing to an element of the sequence, and INVOKE(comp, INVOKE(proj, *(i + n)), INVOKE(proj, *i)) == false.

The application of function objects in parallel algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: O(N log(N)), where N = std::distance(first, last) comparisons.

Template Parameters
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Comp** – The type of the function/function object to use (deduced). Comp defaults to detail::less;
- **Proj** – The type of an optional projection function. This defaults to hpx::identity

Parameters
- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the middle of the sequence of elements the algorithm will be applied to.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that
comp will not apply any non-constant function through the dereferenced iterator. Comp defaults to detail::less.

• **proj** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate `comp` is invoked.

**Returns** The `partial_sort` algorithm returns a `hpx::future<hpx::traits::range_iterator_t<Rng>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `hpx::traits::range_iterator_t<Rng>` otherwise. It returns `last`.

### hpx/parallel/container_algorithms/partial_sort_copy.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

```cpp
namespace hpx

namespace ranges

Functions

template<typename InIter, typename Sent1, typename RandIter, typename Sent2, typename Comp = ranges::less, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>

partial_sort_copy_result<InIter, RandIter> partial_sort_copy(InIter first, Sent1 last, RandIter r_first, Sent2 r_last, Comp &&comp = Comp(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Sorts some of the elements in the range [first, last) in ascending order, storing the result in the range [r_first, r_last). At most `r_last - r_first` of the elements are placed sorted to the range [r_first, r_first + n) where n is the number of elements to sort (n = min(last - first, r_last - r_first)).

The assignments in the parallel `partial_sort_copy` algorithm invoked without an execution policy object execute in sequential order in the calling thread.

**Note:** Complexity: O(N log(min(D,N))), where N = std::distance(first, last) and D = std::distance(r_first, r_last) comparisons.

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Sent1** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for InIter.
- **RandIter** – The type of the destination iterators used (deduced). This iterator type must meet the requirements of an random iterator.
- **Sent2** – The type of the destination sentinel (deduced). This sentinel type must be a sentinel for RandIter.
- **Comp** – The type of the function/function object to use (deduced). Comp defaults to detail::less.
- **Proj1** – The type of an optional projection function for the input range. This defaults to `hpx::identity`.
- **Proj2** – The type of an optional projection function for the output range. This defaults to `hpx::identity`. 
Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the sentinel value denoting the end of the sequence of elements the algorithm will be applied to.
- **r_first** – Refers to the beginning of the destination range.
- **r_last** – Refers to the sentinel denoting the end of the destination range.
- **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. This defaults to detail::less.
- **proj1** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate comp is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation after the actual predicate comp is invoked.

Returns

The **partial_sort_copy** algorithm returns a returns **partial_sort_copy_result<InIter, RandIter>**. The algorithm returns {last, result_first + N}.

```cpp
template<typename ExPolicy, typename FwdIter, typename Sent1, typename RandIter, typename Sent2, typename Comp = ranges::less, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity> parallel::util::detail::algorithm_result_t<ExPolicy, partial_sort_copy_result<FwdIter, RandIter>> partial_sort_copy(ExPolicy&& policy, FwdIter first, Sent1 last, RandIter r_first, Sent2 r_last, Comp&& comp = Comp(), Proj1&& proj1 = Proj1(), Proj2&& proj2 = Proj2())
```

Sorts some of the elements in the range [first, last) in ascending order, storing the result in the range [r_first, r_last). At most r_last - r_first of the elements are placed sorted to the range [r_first, r_first + n) where n is the number of elements to sort (n = min(last - first, r_last - r_first)).

The application of function objects in parallel algorithm invoked with an execution policy object of type **sequenced_policy** execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type **parallel_policy** or **parallel_task_policy** are permitted to execute in an unordered fashion in unspecified
threads, and indeterminately sequenced within each thread.

**Note:** Complexity: \( O(N \log(\min(D,N))) \), where \( N = \text{std::distance}(\text{first, last}) \) and \( D = \text{std::distance}(\text{r_first, r_last}) \) comparisons.

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter.
- **RandIter** – The type of the destination iterators used (deduced). This iterator type must meet the requirements of an random iterator.
- **Sent2** – The type of the destination sentinel (deduced). This sentinel type must be a sentinel for RandIter.
- **Comp** – The type of the function/function object to use (deduced). Comp defaults to `detail::less`.
- **Proj1** – The type of an optional projection function for the input range. This defaults to `hpx::identity`.
- **Proj2** – The type of an optional projection function for the output range. This defaults to `hpx::identity`.

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the sentinel value denoting the end of the sequence of elements the algorithm will be applied to.
- **r_first** – Refers to the beginning of the destination range.
- **r_last** – Refers to the sentinel denoting the end of the destination range.
- **comp** – `comp` is a callable object. The return value of the `INVOKE` operation applied to an object of type `Comp`, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that `comp` will not apply any non-constant function through the dereferenced iterator. This defaults to `detail::less`.
- **proj1** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate `comp` is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation after the actual predicate `comp` is invoked.

### Returns

The `partial_sort_copy` algorithm returns a `hpx::future<partial_sort_copy_result<FwdIter, RandIter>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `partial_sort_copy_result<FwdIter, RandIter>` otherwise. The algorithm returns `{last, result_first + N}`.
partial_sort_copy_result<hpx::traits::range_iterator_t<Rng1>, hpx::traits::range_iterator_t<Rng2>> partial_sort_copy(
Rng1 &&rng1, Rng2 &&rng2, Comp &&comp = Comp(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())

Sorts some of the elements in the range [first, last) in ascending order, storing the result in the range [r_first, r_last). At most r_last - r_first of the elements are placed sorted to the range [r_first, r_first + n) where n is the number of elements to sort (n = min(last - first, r_last - r_first)).

The assignments in the parallel partial_sort_copy algorithm invoked without an execution policy object execute in sequential order in the calling thread.

Note: Complexity: \(O(N \log(\min(D,N)))\), where \(N = \text{std::distance(first, last)}\) and \(D = \text{std::distance(r_first, r_last)}\) comparisons.

Template Parameters
- \(Rng1\) – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a input iterator.
- \(Rng2\) – The type of the destination range used (deduced). The iterators extracted from this range type must meet the requirements of a random iterator.
- \(Comp\) – The type of the function/function object to use (deduced). \(Comp\) defaults to detail::less.
- \(Proj1\) – The type of an optional projection function for the input range. This defaults to hpx::identity.
- \(Proj2\) – The type of an optional projection function for the output range. This defaults to hpx::identity.

Parameters
- \(rng1\) – Refers to the source range.
- \(rng2\) – Refers to the destination range.
- \(comp\) – \(comp\) is a callable object. The return value of the INVOKE operation applied to an object of type \(Comp\), when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that \(comp\) will not apply any non-constant function through the dereferenced iterator. This defaults to detail::less.
- \(proj1\) – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate \(comp\) is invoked.
- \(proj2\) – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation after the actual predicate \(comp\) is invoked.

Returns The partial_sort_copy algorithm returns partial_sort_copy_result<range_iterator_t<Rng1>, range_iterator_t<Rng2>>. The algorithm returns \{last, result_first + N\}. 

706 Chapter 2. What’s so special about HPX?
Sorts some of the elements in the range [first, last) in ascending order, storing the result in the range [r_first, r_last). At most r_last - r_first of the elements are placed sorted to the range [r_first, r_first + n) where n is the number of elements to sort (n = min(last - first, r_last - r_first)).

The application of function objects in parallel algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: $O(N \log(\min(D,N)))$, where $N = \text{std::distance(first, last)}$ and $D = \text{std::distance(r_first, r_last)}$ comparisons.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **Rng2** – The type of the destination range used (deduced). The iterators extracted from this range type must meet the requirements of a random iterator.
- **Comp** – The type of the function/function object to use (deduced). Comp defaults to `detail::less`.
- **Proj1** – The type of an optional projection function for the input range. This defaults to `hpx::identity`.
- **Proj2** – The type of an optional projection function for the output range. This defaults to `hpx::identity`.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the source range.
• **rng2** – Refers to the destination range.
• **comp** – comp is a callable object. The return value of the INVOKE operation applied to an object of type Comp, when contextually converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. It is assumed that comp will not apply any non-constant function through the dereferenced iterator. This defaults to detail::less.
• **proj1** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation before the actual predicate **comp** is invoked.
• **proj2** – Specifies the function (or function object) which will be invoked for each pair of elements as a projection operation after the actual predicate **comp** is invoked.

**Returns** The `partial_sort_copy` algorithm returns a `hpx::future<partial_sort_copy_result<range_iterator_t<Rng1>, range_iterator_t<Rng2>>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `partial_sort_copy_result<range_iterator_t<Rng1>, range_iterator_t<Rng2>>` otherwise. The algorithm returns `{last, result_first + N}`.

**hpx/parallel/container_algorithms/partition.hpp**

See Public API for a list of names and headers that are part of the public HPX API.

namespace hpx

namespace ranges

**Functions**

```cpp
template<typename Rng, typename Pred, typename Proj = hpx::identity>
subrange_t<hpx::traits::range_iterator_t<Rng>> partition(Rng &&rng, Pred &&pred, Proj &&proj = Proj())
```

Reorders the elements in the range `rng` in such a way that all elements for which the predicate `pred` returns true precede the elements for which the predicate `pred` returns false. Relative order of the elements is not preserved.

The assignments in the parallel `partition` algorithm invoked without an execution policy object execute in sequential order in the calling thread.

**Note:** Complexity: Performs at most 2 * N swaps, exactly N applications of the predicate and projection, where N = std::distance(begin(rng), end(rng)).

**Template Parameters**

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `partition` requires `Pred` to meet the requirements of `CopyConstructible`.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

**Parameters**

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
• **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by the range `rng`. This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `partition` algorithm returns `subrange_t<hpx::traits::range_iterator_t<Rng>>`

The `partition` algorithm returns a subrange starting with an iterator to the first element of the second group and finishing with an iterator equal to last.

```
template<typename ExPolicy, typename Rng, typename Pred, typename Proj = hpx::identity>
parallel::util::detail::algorithm_result<ExPolicy, subrange_t<hpx::traits::range_iterator_t<Rng>>> partition(ExPolicy &&policy, Rng &&rng, Pred &&pred, Proj &&proj = Proj())
```

Reorders the elements in the range `rng` in such a way that all elements for which the predicate `pred` returns true precede the elements for which the predicate `pred` returns false. Relative order of the elements is not preserved.

The assignments in the parallel `partition` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `partition` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs at most $2 \times N$ swaps, exactly $N$ applications of the predicate and projection, where $N = \text{std::distance}($begin($rng$), $\text{end}($rng$))$.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `partition` requires `Pred` to meet the requirements of `CopyConstructible`.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`
• **rng** – Refers to the sequence of elements the algorithm will be applied to.
• **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by the range `rng`. This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `partition` algorithm returns a `hpx::future<subrange_t<hpx::traits::range_iterator_t<Rng>>>` if the execution policy is of type `parallel_task_policy` and returns `subrange_t<hpx::traits::range_iterator_t<Rng>>`. The `partition` algorithm returns a subrange starting with an iterator to the first element of the second group and finishing with an iterator equal to last.

```cpp
template<typename FwdIter, typename Sent, typename Pred, typename Proj = hpx::identity>
subrange_t<FwdIter> partition(FwdIter first, Sent last, Pred &&pred, Proj &&proj = Proj())
```

Reorders the elements in the range `[first, last)` in such a way that all elements for which the predicate `pred` returns true precede the elements for which the predicate `pred` returns false. Relative order of the elements is not preserved.

The assignments in the parallel `partition` algorithm invoked without an execution policy object execute in sequential order in the calling thread.

**Note:** Complexity: At most 2 * (last - first) swaps. Exactly `last - first` applications of the predicate and projection.

**Template Parameters**
• **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
• **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for `FwdIter`.
• **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `partition` requires `Pred` to meet the requirements of `CopyConstructible`.
• **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**
• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
• **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `InIter` can be dereferenced and then implicitly converted to `Type`.
• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `partition` algorithm returns a subrange starting with an iterator to the first element of the second group and finishing with an iterator equal to last.

```cpp
template<typename ExPolicy, typename FwdIter, typename Sent, typename Pred, typename Proj = hpx::identity>
parallel::util::detail::algorithm_result<ExPolicy, subrange_t<FwdIter>>::type
partition(ExPolicy &&policy, FwdIter first, Sent last, Pred &&pred, Proj &&proj
= Proj())
```

Reorders the elements in the range [first, last) in such a way that all elements for which the predicate `pred` returns true precede the elements for which the predicate `pred` returns false. Relative order of the elements is not preserved.

The assignments in the parallel `partition` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `partition` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most 2 * (last - first) swaps. Exactly `last - first` applications of the predicate and projection.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `partition` requires `Pred` to meet the requirements of `CopyConstructible`.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:
bool pred(const Type &a);

The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type InitIter can be dereferenced and then implicitly converted to Type.

• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *f* is invoked.

**Returns** The *partition* algorithm returns a *hpx::future*<subrange_t<Iter>> if the execution policy is of type *parallel_task_policy* and returns subrange_t<Iter> otherwise. The *partition* algorithm returns a subrange starting with an iterator to the first element of the second group and finishing with an iterator equal to last.

```cpp
template<typename Rng, typename Pred, typename Proj = hpx::identity>
subrange_t<hpx::traits::range_iterator_t<Rng>> stable_partition(Rng &&rng, Pred &&pred, Proj &&proj = Proj())
```

Permutates the elements in the range [first, last) such that there exists an iterator *i* such that for every iterator *j* in the range [first, *i*) \( \text{INVOKE}(f, \text{INVOKE}(proj, *j)) \neq \text{false} \), and for every iterator *k* in the range [i, last), \( \text{INVOKE}(f, \text{INVOKE}(proj, *k)) \neq \text{false} \).

The invocations of *f* in the parallel *stable_partition* algorithm invoked without an execution policy object executes in sequential order in the calling thread.

**Note:** Complexity: At most (last - first) \* log(last - first) swaps, but only linear number of swaps if there is enough extra memory. Exactly last - first applications of the predicate and projection.

**Template Parameters**

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a bidirectional iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of *partition* requires *Pred* to meet the requirements of *CopyConstructible*.
- **Proj** – The type of an optional projection function. This defaults to *hpx::identity*.

**Parameters**

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Unary predicate which returns true if the element should be ordered before other elements. Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```cpp
bool fun(const Type &a);
```

The signature does not need to have const&. The type *Type* must be such that an object of type *BidirIter* can be dereferenced and then implicitly converted to *Type*.

• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate *f* is invoked.

**Returns** The *stable_partition* algorithm returns an iterator \( i \) such that for every iterator \( j \) in the range [first, *i*) \( \text{INVOKE}(f, \text{INVOKE}(proj, *j)) \neq \text{false} \), and for every iterator \( k \) in the range [i, last), \( \text{INVOKE}(f, \text{INVOKE}(proj, *k)) \neq \text{false} \). The relative order of the elements in both groups is preserved.

```cpp
template<typename ExPolicy, typename Rng, typename Pred, typename Proj = hpx::identity>
```
Permutes the elements in the range \([\text{first}, \text{last})\) such that there exists an iterator \(i\) such that for every iterator \(j\) in the range \([\text{first}, i)\), \(f(\text{proj}, *j)\) \(!=\) false, and for every iterator \(k\) in the range \([i, \text{last})\), \(f(\text{proj}, *k)\) \(!=\) false.

The invocations of \(f\) in the parallel stable_partition algorithm invoked with an execution policy object of type sequenced_policy executes in sequential order in the calling thread.

The invocations of \(f\) in the parallel stable_partition algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most \((\text{last} - \text{first}) \times \log(\text{last} - \text{first})\) swaps, but only linear number of swaps if there is enough extra memory. Exactly \(\text{last} - \text{first}\) applications of the predicate and projection.

### Template Parameters
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of \(f\).
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a bidirectional iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of partition requires Pred to meet the requirements of CopyConstructible.
- **Proj** – The type of an optional projection function. This defaults to hpx::identity.

### Parameters
- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Unary predicate which returns true if the element should be ordered before other elements. Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\). The signature of this predicate should be equivalent to:

```
bool fun(const Type &a);
```

The signature does not need to have const&. The type Type must be such that an object of type BidirIter can be dereferenced and then implicitly converted to Type.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate \(f\) is invoked.

### Returns
The stable_partition algorithm returns an iterator \(i\) such that for every iterator \(j\) in the range \([\text{first}, i)\), \(f(\text{proj}, *j)\) \(!=\) false, and for every iterator \(k\) in the range \([i, \text{last})\), \(f(\text{proj}, *k)\) \(!=\) false. The
relative order of the elements in both groups is preserved. If the execution policy is of type `parallel_task_policy` the algorithm returns a future<> referring to this iterator.

```cpp
template<typename BidirIter, typename Sent, typename Pred, typename Proj = hpx::identity>
subrange_t<BidirIter> stable_partition(BidirIter first, Sent last, Pred &pred, Proj &&proj = Proj())
```

Permutes the elements in the range [first, last) such that there exists an iterator i such that for every iterator j in the range [first, i) \( \text{INVOKE}(f, \text{INVOKE}(\text{proj}, *j)) \neq \text{false} \), and for every iterator k in the range [i, last), \( \text{INVOKE}(f, \text{INVOKE}(\text{proj}, *k)) == \text{false} \).

The invocations of \( f \) in the parallel `stable_partition` algorithm invoked without an execution policy object executes in sequential order in the calling thread.

**Note:** Complexity: At most \( (\text{last} - \text{first}) \times \log(\text{last} - \text{first}) \) swaps, but only linear number of swaps if there is enough extra memory Exactly \( \text{last} - \text{first} \) applications of the predicate and projection.

**Template Parameters**

- **BidirIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for BidirIter.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `partition` requires `Pred` to meet the requirements of `CopyConstructible`.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **pred** – Unary predicate which returns true if the element should be ordered before other elements. Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). The signature of this predicate should be equivalent to:

```cpp
bool fun(const Type &a);
```

The signature does not need to have \( \text{const} \& \). The type `Type` must be such that an object of type `BidirIter` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate \( f \) is invoked.

**Returns** The `stable_partition` algorithm returns an iterator i such that for every iterator j in the range [first, i), \( f(*j) \neq \text{false} \) \( \text{INVOKE}(f, \text{INVOKE}(\text{proj}, *j)) \neq \text{false} \), and for every iterator k in the range [i, last), \( f(*k) == \text{false} \) \( \text{INVOKE}(f, \text{INVOKE}(\text{proj}, *k)) == \text{false} \). The relative order of the elements in both groups is preserved.

```cpp
template<typename ExPolicy, typename BidirIter, typename Sent, typename Pred, typename Proj = hpx::identity>
```
Permutations the elements in the range \([\text{first}, \text{last})\) such that there exists an iterator \(i\) such that for every iterator \(j\) in the range \([\text{first}, i)\) \(\text{INVOKE}(f, \text{INVOKE}(\text{proj}, *j)) \neq \text{false}\), and for every iterator \(k\) in the range \([i, \text{last})\), \(\text{INVOKE}(f, \text{INVOKE}(\text{proj}, *k)) = \text{false}\)

The invocations of \(f\) in the parallel \texttt{stable_partition} algorithm invoked with an execution policy object of type \texttt{sequenced_policy} executes in sequential order in the calling thread.

The invocations of \(f\) in the parallel \texttt{stable_partition} algorithm invoked with an execution policy object of type \texttt{parallel_policy} or \texttt{parallel_task_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most \((\text{last} - \text{first}) \times \log(\text{last} - \text{first})\) swaps, but only linear number of swaps if there is enough extra memory Exactly \(\text{last} - \text{first}\) applications of the predicate and projection.

### Template Parameters
- **\texttt{ExPolicy}** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the invocations of \(f\).
- **\texttt{BidirIter}** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an input iterator.
- **\texttt{Sent}** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for \texttt{BidirIter}.
- **\texttt{Pred}** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \texttt{partition} requires \texttt{Pred} to meet the requirements of \texttt{CopyConstructible}.
- **\texttt{Proj}** – The type of an optional projection function. This defaults to \texttt{hpx::identity}

### Parameters
- **\texttt{policy}** – The execution policy to use for the scheduling of the iterations.
- **\texttt{first}** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **\texttt{last}** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **\texttt{pred}** – Unary predicate which returns true if the element should be ordered before other elements. Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [\text{first}, \text{last}). The signature of this predicate should be equivalent to:

```cpp
bool fun(const Type &a);
```
The signature does not need to have const&. The type Type must be such that an object of type BidirIter can be dereferenced and then implicitly converted to Type.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate f is invoked.

**Returns**
The stable_partition algorithm returns an iterator i such that for every iterator j in the range [first, i), f(*j) != false INVOKE(f, INVOKE(proj, *j)) != false, and for every iterator k in the range [i, last), f(*k) == false INVOKE(f, INVOKE (proj, *k)) == false. The relative order of the elements in both groups is preserved. If the execution policy is of type parallel_task_policy the algorithm returns a future<> referring to this iterator.

```cpp
template<typename Rng, typename OutIter2, typename OutIter3, typename Pred, typename Proj = hpx::identity>
partition_copy_result<hpx::traits::range_iterator_t<Rng>, OutIter2, OutIter3> partition_copy(Rng &&rng,
OutIter2 dest_true,
OutIter3 dest_false,
Pred &&pred,
Proj &&proj
= Proj())
```

Copies the elements in the range rng, to two different ranges depending on the value returned by the predicate pred. The elements, that satisfy the predicate pred are copied to the range beginning at dest_true. The rest of the elements are copied to the range beginning at dest_false. The order of the elements is preserved.

The assignments in the parallel partition_copy algorithm invoked without an execution policy object execute in sequential order in the calling thread.

**Note:** Complexity: Performs not more than N assignments, exactly N applications of the predicate pred, where N = std::distance(begin(rng), end(rng)).

**Template Parameters**
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **OutIter2** – The type of the iterator representing the destination range for the elements that satisfy the predicate pred (deduced). This iterator type must meet the requirements of an forward iterator.
- **OutIter3** – The type of the iterator representing the destination range for the elements that don't satisfy the predicate pred (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of partition_copy requires Pred to meet the requirements of CopyConstructible.
- **Proj** – The type of an optional projection function. This defaults to hpx::identity

**Parameters**
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
• **dest_true** – Refers to the beginning of the destination range for the elements that satisfy the predicate `pred`.

• **dest_false** – Refers to the beginning of the destination range for the elements that don’t satisfy the predicate `pred`.

• **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`.

• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `partition_copy` algorithm returns a `partition_copy_result<traits::range_iterator_t<Rng>, FwdIter2, FwdIter3>>`. The `partition_copy` algorithm returns the tuple of the source iterator `last`, the destination iterator to the end of the `dest_true` range, and the destination iterator to the end of the `dest_false` range.

```
template<typename ExPolicy, typename Rng, typename FwdIter2, typename FwdIter3, typename Pred, typename Proj = hpx::identity>
parallel::util::detail::algorithm_result<ExPolicy, partition_copy_result<traits::range_iterator_t<Rng>, FwdIter2, FwdIter3>>
```

Copies the elements in the range `rng`, to two different ranges depending on the value returned by the predicate `pred`. The elements, that satisfy the predicate `pred` are copied to the range beginning at `dest_true`. The rest of the elements are copied to the range beginning at `dest_false`. The order of the elements is preserved.

The assignments in the parallel `partition_copy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `partition_copy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs not more than N assignments, exactly N applications of the predicate `pred`, where N = std::distance(begin(rng), end(rng)).
Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the iterator representing the destination range for the elements that satisfy the predicate \( \text{pred} \) (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter3** – The type of the iterator representing the destination range for the elements that don’t satisfy the predicate \( \text{pred} \) (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \texttt{partition_copy} requires \( \text{Pred} \) to meet the requirements of \texttt{CopyConstructible}.
- **Proj** – The type of an optional projection function. This defaults to \texttt{hpx::identity}

Parameters

- **policy** – The type of the execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest_true** – Refers to the beginning of the destination range for the elements that satisfy the predicate \( \text{pred} \)
- **dest_false** – Refers to the beginning of the destination range for the elements that don’t satisfy the predicate \( \text{pred} \).
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

  ```cpp
  bool \text{pred}(\text{const Type } &a);
  ```

  The signature does not need to have \text{const\&}, but the function must not modify the objects passed to it. The type \text{Type} must be such that an object of type \texttt{FwdIter1} can be dereferenced and then implicitly converted to Type.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate \( \text{is invoked} \).

Returns

The \texttt{partition_copy} algorithm returns a \texttt{hpx::future<partition_copy_result<\texttt{range_iterator_t<Rng>}, \texttt{FwdIter2}, \texttt{FwdIter3}>}} if the execution policy is of type \texttt{parallel_task_policy} and returns partition_copy_result<\texttt{range_iterator_t<Rng>}, \texttt{FwdIter2}, \texttt{FwdIter3}> otherwise. The \texttt{partition_copy} algorithm returns the tuple of the source iterator \texttt{last}, the destination iterator to the end of the \texttt{dest_true} range, and the destination iterator to the end of the \texttt{dest_false} range.

```cpp
template<typename \texttt{InIter}, typename \texttt{Sent}, typename \texttt{OutIter2}, typename \texttt{OutIter3}, typename \texttt{Pred}, typename \texttt{Proj} = \texttt{hpx::identity}>
partition_copy_result<\texttt{InIter}, \texttt{OutIter2}, \texttt{OutIter3}> \texttt{partition_copy}(\texttt{InIter} \texttt{first}, \texttt{Sent} \texttt{last}, \texttt{OutIter2} \texttt{dest_true}, \texttt{OutIter3} \texttt{dest_false}, \texttt{Pred} &&\texttt{pred}, \texttt{Proj} &&\texttt{proj} = \texttt{Proj}())
```

Copies the elements in the range, defined by \([\text{first}, \text{last})\), to two different ranges depending on the value returned by the predicate \( \text{pred} \). The elements, that satisfy the predicate \( \text{pred} \) are copied to the range beginning at \texttt{dest_true} \( \texttt{last} \). The rest of the elements are copied to the range beginning at \texttt{dest_false}. The order of the elements is preserved.

The assignments in the parallel \texttt{partition_copy} algorithm invoked without an execution policy object
execute in sequential order in the calling thread.

**Note:** Complexity: Performs not more than last - first assignments, exactly last - first applications of the predicate \( f \).

### Template Parameters

- **InIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter.
- **OutIter2** – The type of the iterator representing the destination range for the elements that satisfy the predicate \( pred \) (deduced). This iterator type must meet the requirements of an forward iterator.
- **OutIter3** – The type of the iterator representing the destination range for the elements that don’t satisfy the predicate \( pred \) (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `partition_copy` requires \( Pred \) to meet the requirements of `CopyConstructible`.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

### Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **dest_true** – Refers to the beginning of the destination range for the elements that satisfy the predicate \( pred \).
- **dest_false** – Refers to the beginning of the destination range for the elements that don’t satisfy the predicate \( pred \).
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \( [first, last) \). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

  ```cpp
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type \( Type \) must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

### Returns

The `partition_copy` algorithm returns a `partition_copy_result<FwdIter, OutIter2, OutIter3>`. The `partition_copy` algorithm returns the tuple of the source iterator `last`, the destination iterator to the end of the `dest_true` range, and the destination iterator to the end of the `dest_false` range.

```cpp
template<typename ExPolicy, typename FwdIter, typename Sent, typename OutIter2, typename OutIter3, typename Pred, typename Proj = hpx::identity>
```
Copies the elements in the range, defined by \([\text{first}, \text{last})\), to two different ranges depending on the value returned by the predicate \(\text{pred}\). The elements, that satisfy the predicate \(\text{pred}\) are copied to the range beginning at \(\text{dest\_true}\). The rest of the elements are copied to the range beginning at \(\text{dest\_false}\). The order of the elements is preserved.

The assignments in the parallel \(\text{partition\_copy}\) algorithm invoked with an execution policy object of type \(\text{sequenced\_policy}\) execute in sequential order in the calling thread.

The assignments in the parallel \(\text{partition\_copy}\) algorithm invoked with an execution policy object of type \(\text{parallel\_policy}\) or \(\text{parallel\_task\_policy}\) are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs not more than \(\text{last} - \text{first}\) assignments, exactly \(\text{last} - \text{first}\) applications of the predicate \(f\).

**Template Parameters**
- **\(\text{ExPolicy}\)** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **\(\text{FwdIter}\)** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **\(\text{Sent}\)** – The type of the source sentinel (deduced). This sentinel type must be a sentinel for FwdIter.
- **\(\text{OutIter2}\)** – The type of the iterator representing the destination range for the elements that satisfy the predicate \(\text{pred}\) (deduced). This iterator type must meet the requirements of an forward iterator.
- **\(\text{OutIter3}\)** – The type of the iterator representing the destination range for the elements that don’t satisfy the predicate \(\text{pred}\) (deduced). This iterator type must meet the requirements of an forward iterator.
- **\(\text{Pred}\)** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \(\text{partition\_copy}\) requires \(\text{Pred}\) to meet the requirements of \(\text{CopyConstructible}\).
- **\(\text{Proj}\)** – The type of an optional projection function. This defaults to \(\text{hpx::identity}\).
Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to sentinel value denoting the end of the sequence of elements the algorithm will be applied.
- **dest_true** – Refers to the beginning of the destination range for the elements that satisfy the predicate `pred`.
- **dest_false** – Refers to the beginning of the destination range for the elements that don’t satisfy the predicate `pred`.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate for partitioning the source iterators. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter1` can be dereferenced and then implicitly converted to `Type`.

- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Returns

The `partition_copy` algorithm returns a `hpx::future<partition_copy_result<FwdIter, OutIter2, OutIter3>>` if the execution policy is of type `parallel_task_policy` and returns `partition_copy_result<FwdIter, OutIter2, OutIter3>` otherwise. The `partition_copy` algorithm returns the tuple of the source iterator `last`, the destination iterator to the end of the `dest_true` range, and the destination iterator to the end of the `dest_false` range.

Functions

```cpp
template<
    typename ExPolicy,
    typename FwdIter,
    typename Sent,
    typename F,
    typename T =
    typename std::iterator_traits<FwdIter>::value_type>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, T> reduce(ExPolicy &&policy, FwdIter first,
    Sent last, T init, F &&f)
```

Returns `GENERALIZED_SUM(f, init, *first, ... , *(first + (last - first) - 1))`.

The reduce operations in the parallel `reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The reduce operations in the parallel `copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
The difference between reduce and accumulate is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

**Note:** Complexity: $O(last - first)$ applications of the predicate $f$.

**Note:** GENERALIZED_SUM(op, a1, ..., aN) is defined as follows:
- $a1$ when $N$ is 1
- op(GENERALIZED_SUM(op, b1, ..., bK), GENERALIZED_SUM(op, bM, ..., bN)), where:
  - $b1, ..., bN$ may be any permutation of $a1, ..., aN$ and
  - $1 < K+1 = M <= N$.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel used (deduced). This iterator type must meet the requirements of an forward iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of copy_if requires $F$ to meet the requirements of CopyConstructible.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is a binary predicate. The signature of this predicate should be equivalent to:
  ```
  Ret fun(const Type1 &a, const Type1 &b);
  ```
  The signature does not need to have const&. The types Type1 Ret must be such that an object of type FwdIterB can be dereferenced and then implicitly converted to any of those types.
- **init** – The initial value for the generalized sum.

**Returns** The reduce algorithm returns a hpx::future<T> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns $T$ otherwise. The reduce algorithm returns the result of the generalized sum over the elements given by the input range [first, last).

```cpp
template<typename ExPolicy, typename Rng, typename F, typename T = typename std::iterator_traits<hpx::traits::range_iterator_t<Rng>>::value_type>
    hpx::parallel::util::detail::algorithm_result_t<ExPolicy, T> reduce(ExPolicy &&policy, Rng &&rng, T init, F &&f)
```

Returns GENERALIZED_SUM(f, init, *first, ..., *(first + (last - first) - 1)).

The reduce operations in the parallel reduce algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.
The reduce operations in the parallel `copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `reduce` and `accumulate` is that the behavior of `reduce` may be non-deterministic for non-associative or non-commutative binary predicate.

**Note:** Complexity: \(O(last - first)\) applications of the predicate \(f\).

**Note:** GENERALIZED_SUM(op, a1, ..., aN) is defined as follows:
- \(a_1\) when \(N\) is 1
- \(op(GENERALIZED_SUM(op, b_1, ..., b_K), GENERALIZED_SUM(op, b_M, ..., b_N))\), where:
  - \(b_1, ..., b_N\) may be any permutation of \(a_1, ..., a_N\) and
  - \(1 < K + 1 = M \leq N\).

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `copy_if` requires \(F\) to meet the requirements of `CopyConstructible`.
- **T** – The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([first, last)\). This is a binary predicate. The signature of this predicate should be equivalent to:

```cpp
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`. The types `Type1 Ret` must be such that an object of type `FwdIterB` can be dereferenced and then implicitly converted to any of those types.
- **init** – The initial value for the generalized sum.

**Returns** The `reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `T` otherwise. The `reduce` algorithm returns the result of the generalized sum over the elements given by the input range \([first, last)\).

```cpp
template<typename ExPolicy, typename FwdIter, typename Sent, typename T = typename std::iterator_traits<FwdIter>::value_type>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, T> reduce(ExPolicy &&policy, FwdIter first, Sent last, T init)
```

Returns GENERALIZED_SUM(+, init, *first, ..., *(first + (last - first) - 1)).
The reduce operations in the parallel `reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The reduce operations in the parallel `copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `reduce` and `accumulate` is that the behavior of `reduce` may be non-deterministic for non-associative or non-commutative binary predicate.

**Note:** Complexity: \(O(\text{last} - \text{first})\) applications of the operator+().

**Note:** `GENERALIZED_SUM(\(+, a_1, \ldots, a_N\)` is defined as follows:
- \(a_1\) when \(N = 1\)
- \(\text{op}(\text{GENERALIZED_SUM}(\(+, b_1, \ldots, b_K\)), \text{GENERALIZED_SUM}(\(+, b_M, \ldots, b_N\)))\), where:
  - \(b_1, \ldots, b_N\) may be any permutation of \(a_1, \ldots, a_N\) and
  - \(1 < K+1 = M \leq N\).

**Template Parameters**
- `ExPolicy` – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter` – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- `Sent` – The type of the source sentinel used (deduced). This iterator type must meet the requirements of an forward iterator.
- `T` – The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**
- `policy` – The execution policy to use for the scheduling of the iterations.
- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements the algorithm will be applied to.
- `init` – The initial value for the generalized sum.

**Returns** The `reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `T` otherwise. The `reduce` algorithm returns the result of the generalized sum (applying operator+) over the elements given by the input range \([\text{first}, \text{last})\).

```
template<typename ExPolicy, typename Rng, typename T = typename std::iterator_traits<hpx::traits::range_iterator_t<Rng>>::value_type> hpx::parallel::util::detail::algorithm_result_t<ExPolicy, T> reduce(ExPolicy &&policy, Rng &&rng, T init)
```

Returns `GENERALIZED_SUM(+, init, *first, \ldots, *(first + (last - first) - 1))`.

The reduce operations in the parallel `reduce` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The reduce operations in the parallel `copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
The difference between `reduce` and `accumulate` is that the behavior of `reduce` may be non-deterministic for non-associative or non-commutative binary predicate.

**Note:** Complexity: $O(\text{last} - \text{first})$ applications of the operator +().

**Note:** GENERALIZED\_SUM(+, a1, ..., aN) is defined as follows:
- $a_1$ when $N$ is 1
- op(GENERALIZED\_SUM(+, b1, ..., bK), GENERALIZED\_SUM(+, bM, ..., bN)), where:
  - $b_1, ..., b_N$ may be any permutation of $a_1, ..., a_N$ and
  - $1 < K+1 = M <= N$.

**Template Parameters**
- `ExPolicy` – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `Rng` – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- `T` – The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**
- `policy` – The execution policy to use for the scheduling of the iterations.
- `rng` – Refers to the sequence of elements the algorithm will be applied to.
- `init` – The initial value for the generalized sum.

**Returns** The `reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced\_task\_policy` or `parallel\_task\_policy` and returns $T$ otherwise. The `reduce` algorithm returns the result of the generalized sum (applying operator +()) over the elements given by the input range [first, last).

```cpp
template<typename ExPolicy, typename FwdIter, typename Sent>
hpx::parallel::util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<FwdIter>::value_type>::type reduce(ExPolicy&& policy, FwdIter first, Sent last)
```

Returns GENERALIZED\_SUM(+, T(), *first, ..., *(first + (last - first) - 1)).

The reduce operations in the parallel `reduce` algorithm invoked with an execution policy object of type `sequenced\_policy` execute in sequential order in the calling thread.

The reduce operations in the parallel `copy\_if` algorithm invoked with an execution policy object of type `parallel\_policy` or `parallel\_task\_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between `reduce` and `accumulate` is that the behavior of `reduce` may be non-deterministic for non-associative or non-commutative binary predicate.
Note: Complexity: O(last - first) applications of the operator+().

Note: The type of the initial value (and the result type) T is determined from the value_type of the used FwdIterB.

Note: GENERALIZED_SUM(+, a1, ..., aN) is defined as follows:
  • a1 when N is 1
  • op(GENERALIZED_SUM(+, b1, ..., bK), GENERALIZED_SUM(+, bM, ..., bN)), where:
    – b1, ..., bN may be any permutation of a1, ..., aN and
    – 1 < K+1 = M <= N.

Template Parameters
  • ExPolicy – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
  • FwdIter – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
  • Sent – The type of the source sentinel used (deduced). This iterator type must meet the requirements of an forward iterator.

Parameters
  • policy – The execution policy to use for the scheduling of the iterations.
  • first – Refers to the beginning of the sequence of elements the algorithm will be applied to.
  • last – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns The reduce algorithm returns a hpx::future<T> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns T otherwise (where T is the value_type of FwdIterB). The reduce algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

template<typename ExPolicy, typename Rng>
  hpx::parallel::util::detail::algorithm_result<ExPolicy, typename std::iterator_traits<typename hpx::traits::range_traits<Rng>::iterator_type>::value_type>::type
  reduce(ExPolicy&& policy, Rng&& rng)

Returns GENERALIZED_SUM(+, T(), *first, ..., *(first + (last - first) - 1)).

The reduce operations in the parallel reduce algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The reduce operations in the parallel copy_if algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

The difference between reduce and accumulate is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.
Note: Complexity: $O(last - first)$ applications of the operator+().

Note: The type of the initial value (and the result type) $T$ is determined from the value_type of the used `FwdIterB`.

Note: GENERALIZED_SUM(+, a1, ..., aN) is defined as follows:
- $a1$ when $N$ is 1
- $\text{op}(\text{GENERALIZED}_{\text{SUM}}(+, b1, ..., bK), \text{GENERALIZED}_{\text{SUM}}(+, bM, ..., bN))$, where:
  - $b1, ..., bN$ may be any permutation of $a1, ..., aN$ and
  - $1 < K+1 = M <= N$.

Template Parameters
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

Parameters
- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.

Returns The `reduce` algorithm returns a `hpx::future<T>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns $T$ otherwise (where $T$ is the value_type of `FwdIterB`). The `reduce` algorithm returns the result of the generalized sum (applying operator+() over the elements given by the input range `[first, last)`).

```
template<typename FwdIter, typename Sent, typename F, typename T = typename std::iterator_traits<FwdIter>::value_type>
T reduce(FwdIter first, Sent last, T init, F &&f)
    Returns GENERALIZED_SUM(f, init, *first, ..., *(first + (last - first) - 1)).
```

The difference between `reduce` and `accumulate` is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note: Complexity: $O(last - first)$ applications of the predicate $f$.

Note: GENERALIZED_SUM(op, a1, ..., aN) is defined as follows:
- $a1$ when $N$ is 1
- $\text{op}(\text{GENERALIZED}_{\text{SUM}}(op, b1, ..., bK), \text{GENERALIZED}_{\text{SUM}}(op, bM, ..., bN))$, where:
  - $b1, ..., bN$ may be any permutation of $a1, ..., aN$ and
  - $1 < K+1 = M <= N$.

Template Parameters
- **FwdIter** – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel used (deduced). This iterator type must meet the requirements of an forward iterator.
• **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `copy_if` requires `F` to meet the requirements of `CopyConstructible`.

• **T** – The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**

• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.

• **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

• **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is a binary predicate. The signature of this predicate should be equivalent to:

```cpp
Ret fun(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const&`. The types `Type1 Ret` must be such that an object of type `FwdIterB` can be dereferenced and then implicitly converted to any of those types.

• **init** – The initial value for the generalized sum.

**Returns**

The `reduce` algorithm returns `T`. The `reduce` algorithm returns the result of the generalized sum over the elements given by the input range `[first, last)`.

```cpp
template<typename Rng, typename F, typename T = typename std::iterator_traits<hpx::traits::range_iterator_t<Rng>>::value_type>
T reduce(Rng &&rng, T init, F &&f)
```

Returns `GENERALIZED_SUM(f, init, *first, ..., *(first + (last - first) - 1))`.

The difference between `reduce` and `accumulate` is that the behavior of `reduce` may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity: O(last - first) applications of the predicate `f`.

---

**Note:** `GENERALIZED_SUM(op, a1, ..., aN)` is defined as follows:

• `a1` when `N` is 1

• \( \text{op}(\text{GENERALIZED_SUM}(\text{op}, b1, ..., bK), \text{GENERALIZED_SUM}(\text{op}, bM, ..., bN)) \), where:
  - `b1, ..., bN` may be any permutation of `a1, ..., aN` and
  - `1 < K+1 = M <= N`.

---

**Template Parameters**

• **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

• **F** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `copy_if` requires `F` to meet the requirements of `CopyConstructible`.

• **T** – The type of the value to be used as initial (and intermediate) values (deduced).

**Parameters**

• **rng** – Refers to the sequence of elements the algorithm will be applied to.

• **f** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is a binary predicate. The signature of this predicate should be equivalent to:
fun(const Type1 &a, const Type1 &b);

The signature does not need to have const&. The types Type1 Ret must be such that an object of type FwdIterB can be dereferenced and then implicitly converted to any of those types.

- init – The initial value for the generalized sum.

Returns The reduce algorithm returns T. The reduce algorithm returns the result of the generalized sum over the elements given by the input range [first, last).

```
template<typename FwdIter, typename Sent, typename T = typename std::iterator_traits<FwdIter>::value_type>
T reduce(FwdIter first, Sent last, T init)
```

Returns GENERALIZED_SUM(+, init, *first, ..., *(first + (last - first) - 1)).

The difference between reduce and accumulate is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note: Complexity: O(last - first) applications of the operator+().

Note: GENERALIZED_SUM(+, a1, ..., aN) is defined as follows:
- a1 when N is 1
- op(GENERALIZED_SUM(+, b1, ..., bK), GENERALIZED_SUM(+, bM, ..., bN)), where:
  - b1, ..., bN may be any permutation of a1, ..., aN and
  - 1 < K+1 = M <= N.

Template Parameters
- FwdIter – The type of the source begin iterator used (deduced). This iterator type must meet the requirements of an forward iterator.
- Sent – The type of the source sentinel used (deduced). This iterator type must meet the requirements of an forward iterator.
- T – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters
- first – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- last – Refers to the end of the sequence of elements the algorithm will be applied to.
- init – The initial value for the generalized sum.

Returns The reduce algorithm returns T. The reduce algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

```
template<typename Rng, typename T = typename std::iterator_traits<hpx::traits::range_iterator_t<Rng>>::value_type>
T reduce(Rng &&rng, T init)
```

Returns GENERALIZED_SUM(+, init, *first, ..., *(first + (last - first) - 1)).

The difference between reduce and accumulate is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

Note: Complexity: O(last - first) applications of the operator+().
Note: GENERALIZED_SUM(+, a1, ..., aN) is defined as follows:
• a1 when N is 1
• op(GENERALIZED_SUM(+, b1, ..., bK), GENERALIZED_SUM(+, bM, ..., bN)), where:
  – b1, ..., bN may be any permutation of a1, ..., aN and
  – 1 < K+1 = M <= N.

Template Parameters
• Rng – The type of the source range used (deduced). The iterators extracted from this
  range type must meet the requirements of an input iterator.
• T – The type of the value to be used as initial (and intermediate) values (deduced).

Parameters
• rng – Refers to the sequence of elements the algorithm will be applied to.
• init – The initial value for the generalized sum.

Returns The reduce algorithm returns T. The reduce algorithm returns the result of the gen-
  eralized sum (applying operator+()) over the elements given by the input range [first, last).

template<typename FwdIter, typename Sent>
std::iterator_traits<FwdIter>::value_type reduce(FwdIter first, Sent last)
Returns GENERALIZED_SUM(+, T(), *first, ..., *(first + (last - first) - 1)).

The difference between reduce and accumulate is that the behavior of reduce may be non-deterministic
for non-associative or non-commutative binary predicate.

Note: Complexity: O(last - first) applications of the operator+().

Note: The type of the initial value (and the result type) T is determined from the value_type of the
used FwdIterB.

Note: GENERALIZED_SUM(+, a1, ..., aN) is defined as follows:
• a1 when N is 1
• op(GENERALIZED_SUM(+, b1, ..., bK), GENERALIZED_SUM(+, bM, ..., bN)), where:
  – b1, ..., bN may be any permutation of a1, ..., aN and
  – 1 < K+1 = M <= N.

Template Parameters
• FwdIter – The type of the source begin iterator used (deduced). This iterator type must
  meet the requirements of an forward iterator.
• Sent – The type of the source sentinel used (deduced). This iterator type must meet the
  requirements of an forward iterator.

Parameters
• first – Refers to the beginning of the sequence of elements the algorithm will be applied
  to.
• last – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns The reduce algorithm returns T (where T is the value_type of FwdIterB). The reduce
algorithm returns the result of the generalized sum (applying operator+()) over the elements
given by the input range [first, last).

template<typename Rng>
```
std::iterator_traits<typename hpx::traits::range_traits<Rng>::iterator_type>::value_type reduce(Rng &&rng)

Returns GENERALIZED_SUM(+, T(), *first, ..., *(first + (last - first) - 1)).

The difference between reduce and accumulate is that the behavior of reduce may be non-deterministic for non-associative or non-commutative binary predicate.

---

**Note:** Complexity: O(last - first) applications of the operator+().

---

**Note:** The type of the initial value (and the result type) T is determined from the value_type of the used FwdIterB.

---

**Note:** GENERALIZED_SUM(+, a1, ..., aN) is defined as follows:
• a1 when N is 1
• op(GENERALIZED_SUM(+, b1, ..., bK), GENERALIZED_SUM(+, bM, ..., bN)), where:
  – b1, ..., bN may be any permutation of a1, ..., aN and
  – 1 < K+1 = M <= N.

---

**Template Parameters** Rng – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

**Parameters** rng – Refers to the sequence of elements the algorithm will be applied to.

**Returns** The reduce algorithm returns T (where T is the value_type of FwdIterB). The reduce algorithm returns the result of the generalized sum (applying operator+()) over the elements given by the input range [first, last).

**hpx/parallel/container_algorithms/remove.hpp**

See Public API for a list of names and headers that are part of the public HPX API.

namespace hpx

namespace ranges

---

**Functions**

template<typename Iter, typename Sent, typename Pred, typename Proj = hpx::identity>
subrange_t<Iter, Sent> remove_if(Iter first, Sent sent, Pred &&pred, Proj &&proj = Proj())

Removes all elements for which predicate pred returns true from the range [first, last) and returns a subrange [ret, last), where ret is a past-the-end iterator for the new end of the range.

The assignments in the parallel remove_if algorithm execute in sequential order in the calling thread.
Note: Complexity: Performs not more than last - first assignments, exactly last - first applications of the predicate pred and the projection proj.

Template Parameters
- **Iter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for FwdIter.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of remove_if requires Pred to meet the requirements of CopyConstructible.
- **Proj** – The type of an optional projection function. This defaults to hpx::identity

Parameters
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns true for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type FwdIter can be dereferenced and then implicitly converted to Type.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Returns The remove_if algorithm returns an subrange_t<FwdIter, Sent>. The remove_if algorithm returns an object {ret, last}, where ret is a past-the-end iterator for a new subrange of the values all in valid but unspecified state.

```cpp
template<typename Rng, typename Pred, typename Proj = hpx::identity>
subrange_t<hpx::traits::range_iterator_t<Rng>> remove_if(Rng &&rng, Pred &&pred, Proj &&proj = Proj())
```

Removes all elements that are equal to value from the range rng and and returns a subrange [ret, util::end(rng)), where ret is a past-the-end iterator for the new end of the range.

The assignments in the parallel remove_if algorithm execute in sequential order in the calling thread.

Note: Complexity: Performs not more than util::end(rng)
- **util::begin(rng) assignments, exactly util::end(rng) - util::begin(rng) applications of the operator==() and the projection proj.

Template Parameters
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of remove_if requires Pred to meet the requirements of CopyConstructible.
- **Proj** – The type of an optional projection function. This defaults to hpx::identity

Parameters

---

Chapter 2. What’s so special about HPX?
• **rng** – Refers to the sequence of elements the algorithm will be applied to.

• **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `remove_if` algorithm returns a `subrange_t<hpx::traits::range_iterator_t<Rng>>`. The `remove_if` algorithm returns an object `{ret, last}`, where `ret` is a past-the-end iterator for a new subrange of the values all in valid but unspecified state.

```cpp
template<typename ExPolicy, typename FwdIter, typename Sent, typename Pred, typename Proj = hpx::identity>
parallel::util::detail::algorithm_result<ExPolicy, subrange_t<FwdIter, Sent>>::type remove_if(ExPolicy &&policy,
FwdIter first,
Sent sent,
Pred &&pred,
Proj &&proj
= Proj())
```

Removes all elements for which predicate `pred` returns true from the range `[first, last)` and returns a subrange `[ret, last)`, where `ret` is a past-the-end iterator for the new end of the range.

The assignments in the parallel `remove_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `remove_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs not more than `last - first` assignments, exactly `last - first` applications of the predicate `pred` and the projection `proj`.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for `FwdIter`. 
• **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `remove_if` requires `Pred` to meet the requirements of `CopyConstructible`.

• **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

### Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

### Returns

The `remove_if` algorithm returns a `hpx::future<subrange_t<FwdIter, Sent>>`. The `remove_if` algorithm returns an object `{ret, last}`, where `ret` is a past-the-end iterator for a new subrange of the values all in valid but unspecified state.

```cpp
template<typename ExPolicy, typename Rng, typename Pred, typename Proj = hpx::identity>
parallel::util::detail::algorithm_result<ExPolicy, subrange_t<hpx::traits::range_iterator_t<Rng>>> remove_if(ExPolicy &&policy, Rng &&rng, Pred &&pred, Proj &&proj = Proj())
```

Removes all elements that are equal to `value` from the range `rng` and and returns a subrange `[ret, util::end(rng))`, where `ret` is a past-the-end iterator for the new end of the range.

The assignments in the parallel `remove_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `remove_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

---

**Note:** Complexity: Performs not more than `util::end(rng)`

- `util::begin(rng)` assignments, exactly `util::end(rng) - util::begin(rng)` applications of the operator `==()` and the projection `proj`.

---

### Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it
executes the assignments.

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `remove_if` requires `Pred` to meet the requirements of `CopyConstructible`.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the required elements. The signature of this predicate should be equivalent to:

  ```cpp
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns**

The `remove_if` algorithm returns a `hpx::future<subrange_t<hpx::traits::range_iterator_t<Rng>>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `remove_if` algorithm returns an object `{ret, last}`, where `ret` is a past-the-end iterator for a new subrange of the values all in valid but unspecified state.

```cpp
template<typename Iter, typename Sent, typename Proj = hpx::identity, typename T = typename hpx::parallel::traits::projected<Iter, Proj>::value_type>
subrange_t<Iter, Sent> remove(Iter first, Sent last, T const &value, Proj &&proj = Proj())
```

Removes all elements that are equal to `value` from the range `[first, last)` and and returns a subrange `[ret, last)`, where `ret` is a past-the-end iterator for the new end of the range.

The assignments in the parallel `remove` algorithm execute in sequential order in the calling thread.

**Note:** Complexity: Performs not more than `last - first` assignments, exactly `last - first` applications of the operator==() and the projection `proj`.

**Template Parameters**

- **Iter** – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for `FwdIter`.
- **T** – The type of the value to remove (deduced). This value type must meet the requirements of `CopyConstructible`.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **value** – Specifies the value of elements to remove.
• proj – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The remove algorithm returns a subrange_t<FwdIter, Sent>. The remove algorithm returns an object {ret, last}, where ret is a past-the-end iterator for a new subrange of the values all in valid but unspecified state.

```cpp
template<typename Rng, typename Proj = hpx::identity, typename T = typename hpx::parallel::traits::projected<hpx::traits::range_iterator_t<Rng>, Proj>::value_type>
subrange_t<hpx::traits::range_iterator_t<Rng>> remove(Rng &&rng, T const &value, Proj &&proj = Proj())
```

Removes all elements that are equal to value from the range rng and and returns a subrange [ret, util::end(rng)), where ret is a past-the-end iterator for the new end of the range.

The assignments in the parallel remove algorithm execute in sequential order in the calling thread.

**Note:** Complexity: Performs not more than util::end(rng) • util::begin(rng) assignments, exactly util::end(rng) - util::begin(rng) applications of the operator==() and the projection proj.

**Template Parameters**
- Rng – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- T – The type of the value to remove (deduced). This value type must meet the requirements of CopyConstructible.
- Proj – The type of an optional projection function. This defaults to hpx::identity

**Parameters**
- rng – Refers to the sequence of elements the algorithm will be applied to.
- value – Specifies the value of elements to remove.
- proj – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The remove algorithm returns a subrange_t<hpx::traits::range_iterator_t<Rng>>.

The remove algorithm returns an object {ret, last}, where ret is a past-the-end iterator for a new subrange of the values all in valid but unspecified state.

```cpp
template<typename ExPolicy, typename FwdIter, typename Sent, typename Proj = hpx::identity, typename T = typename hpx::parallel::traits::projected<FwdIter, Proj>::value_type>
parallel::util::detail::algorithm_result<ExPolicy, subrange_t<FwdIter, Sent>>::type remove(ExPolicy &&policy, FwdIter first, Sent last, T const &value, Proj &&proj = Proj())
```

Removes all elements that are equal to value from the range [first, last) and and returns a subrange [ret, last), where ret is a past-the-end iterator for the new end of the range.

The assignments in the parallel remove algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.
The assignments in the parallel `remove` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs not more than `last - first` assignments, exactly `last - first` applications of the operator==() and the projection `proj`.

**Template Parameters**
- `ExPolicy` – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter` – The type of the source iterators used for the This iterator type must meet the requirements of a forward iterator.
- `Sent` – The type of the end iterators used (deduced). This sentinel type must be a sentinel for `FwdIter`.
- `T` – The type of the value to remove (deduced). This value type must meet the requirements of `CopyConstructible`.
- `Proj` – The type of an optional projection function. This defaults to `hpx::identity`.

**Parameters**
- `policy` – The execution policy to use for the scheduling of the iterations.
- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- `last` – Refers to the end of the sequence of elements the algorithm will be applied to.
- `value` – Specifies the value of elements to remove.
- `proj` – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `remove` algorithm returns a `hpx::future<subrange_t<FwdIter, Sent>>`. The `remove` algorithm returns an object `{ret, last}`, where ret is a past-the-end iterator for a new subrange of the values all in valid but unspecified state.

```cpp
template<typename ExPolicy, typename Rng, typename Proj = hpx::identity, typename T = typename hpx::parallel::traits::projected<hpx::traits::range_iterator_t<Rng>, Proj>::value_type>
parallel::util::detail::algorithm_result<ExPolicy, subrange_t<hpx::traits::range_iterator_t<Rng>>> remove(ExPolicy &&policy, Rng &&rng, T const &value, Proj &&proj = Proj())
```

Removes all elements that are equal to `value` from the range `rng` and and returns a subrange `[ret, util::end(rng))`, where ret is a past-the-end iterator for the new end of the range.

The assignments in the parallel `remove` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `remove` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
Note: Complexity: Performs not more than `util::end(rng)` assignments, exactly `util::end(rng) - util::begin(rng)` applications of the operator `==()` and the projection `proj`.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an forward iterator.
- **T** – The type of the value to remove (deduced). This value type must meet the requirements of CopyConstructible.
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **value** – Specifies the value of elements to remove.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `remove` algorithm returns a `hpx::future< subrange_t<hpx::traits::range_iterator_t<Rng>>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `FwdIter` otherwise. The `remove` algorithm returns the iterator to the new end of the range.

template<
    typename Iter,
    typename Sent,
    typename Pred,
    typename Proj = hpx::identity,
    typename T = hpx::parallel::traits::projected<
        Iter,
        Proj>::value_type
>
Iter replace_if(
    Iter first, 
    Sent sent, 
    Pred &&pred, 
    T const &new_value, 
    Proj &&proj = Proj())

Replaces all elements satisfying specific criteria (for which predicate \( f \) returns true) with \( \text{new_value} \) in the range \([\text{first}, \text{sent})\).

Effects: Substitutes elements referred by the iterator \( \text{it} \) in the range \([\text{first}, \text{sent})\) with \( \text{new_value} \), when the following corresponding conditions hold: \( \text{INVOKE(f, INVOKE(proj, *it))} \neq \text{false} \).

The assignments in the parallel \( \text{replace\_if} \) algorithm execute in sequential order in the calling thread.

Note: Complexity: Performs exactly \( \text{sent} - \text{first} \) applications of the predicate.

Template Parameters
- **Iter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for \( \text{Iter} \).
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \( \text{equal} \) requires \( \text{F} \) to meet the requirements of \( \text{CopyConstructible} \). (deduced).
- **T** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to \( \text{hpx::identity} \).

Parameters
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \([\text{first}, \text{last})\). This is an unary predicate which returns \( \text{true} \) for the elements which need to replaced. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have \( \text{const} \& \), but the function must not modify the objects passed to it. The type \( \text{Type} \) must be such that an object of type \( \text{Iter} \) can be dereferenced and then implicitly converted to \( \text{Type} \).
- **new_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate \( f \) is invoked.

Returns The \( \text{replace\_if} \) algorithm returns \( \text{Iter} \). It returns \( \text{last} \).

template<
    typename Rng,
    typename Pred,
    typename Proj = hpx::identity,
    typename T = hpx::parallel::traits::projected<hpx::traits::range_iterator_t<Rng>, Proj>::value_type
>

hpx::traits::range_iterator_t<Rng> replace_if(
    Rng &&rng, 
    Pred &&pred, 
    T const &new_value, 
    Proj &&proj = Proj())

Replaces all elements satisfying specific criteria (for which predicate \( \text{pred} \) returns true) with \( \text{new_value} \) in the range \( \text{rng} \).
**Effects:** Substitutes elements referred by the iterator it in the range rng with new_value, when the following corresponding conditions hold: INVOKE(f, INVOKE(proj, *it)) != false

**Note:** Complexity: Performs exactly \( \text{util::end(rng)} - \text{util::begin(rng)} \) applications of the predicate.

**Template Parameters**
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires \( F \) to meet the requirements of `CopyConstructible`. (deduced).
- **T** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by rng. This is an unary predicate which returns `true` for the elements which need to replaced. The signature of this predicate should be equivalent to:

  ```cpp
  bool pred(const Type &a);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- **new_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `replace_if` algorithm returns an `hpx::traits::range_iterator<Rng>::type`. It returns `last`.

```cpp
template<typename ExPolicy, typename Iter, typename Sent, typename Pred, typename Proj = hpx::identity, typename T = typename hpx::parallel::traits::projected<Iter, Proj>::value_type>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, Iter> replace_if(ExPolicy &&policy, Iter first, Sent sent, Pred &&pred, T const &new_value, Proj &&proj = Proj())
```

Replaces all elements satisfying specific criteria (for which predicate `pred` returns `true`) with `new_value` in the range `rng`.

**Effects:** Substitutes elements referred by the iterator it in the range rng with new_value, when the following corresponding conditions hold: INVOKE(f, INVOKE(proj, *it)) != false

The assignments in the parallel `replace_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `replace_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.
Complexity: Performs exactly `util::end(rng) - util::begin(rng)` applications of the predicate.

### Template Parameters
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for Iter.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible` (deduced).
- **T** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

### Parameters
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the elements which need to replaced. The signature of this predicate should be equivalent to:

  ```cpp
  bool pred(const Type &a);
  ```

  The signature does not need to have `const&`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- **new_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

### Returns
The `replace_if` algorithm returns a `hpx::future<Iter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy`. It returns `last`.

```cpp
template<typename ExPolicy, typename Rng, typename Pred, typename Proj = hpx::identity, typename T = typename hpx::parallel::traits::projected<hpx::traits::range_iterator_t<Rng>, Pred>::value_type>
parallel::util::detail::algorithm_result<ExPolicy, hpx::traits::range_iterator_t<Rng>> replace_if(ExPolicy &&policy, Rng &&rng, Pred &&pred, T const &new_value, Proj &&proj = Proj())
```

Replaces all elements satisfying specific criteria (for which predicate `pred` returns true) with `new_value`.
in the range rng.

Effects: Substitutes elements referred by the iterator it in the range rng with new_value, when the following corresponding conditions hold: INVOKE(f, INVOKE(proj, *it)) != false

The assignments in the parallel replace algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The assignments in the parallel replace algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: Performs exactly util::end(rng) - util::begin(rng) applications of the predicate.

Template Parameters
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of equal requires F to meet the requirements of CopyConstructible. (deduced).
- **T** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to hpx::identity

Parameters
- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by rng. This is an unary predicate which returns true for the elements which need to replaced. The signature of this predicate should be equivalent to:

  ```cpp
  bool pred(const Type &a);
  ```

  The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type FwdIter can be dereferenced and then implicitly converted to Type.
- **new_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Returns The replace_if algorithm returns a hpx::future<hpx::traits::range_iterator_t<Rng>> if the execution policy is of type sequenced_task_policy or parallel_task_policy. It returns last.

```cpp
template<typename Iter, typename Sent, typename Proj = hpx::identity, typename T1 = typename hpx::parallel::traits::projected<Iter, Proj>::value_type, typename T2 = T1>
Iter replace(Iter first, Sent sent, T1 const &old_value, T2 const &new_value, Proj &&proj = Proj())
```

Replaces all elements satisfying specific criteria with new_value in the range [first, last).
Effects: Substitutes elements referred by the iterator it in the range [first,last) with new_value, when the following corresponding conditions hold: INVOKE(proj, *i) == old_value

The assignments in the parallel replace algorithm execute in sequential order in the calling thread.

**Note:** Complexity: Performs exactly last - first assignments.

**Template Parameters**
- **Iter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for Iter.
- **T1** – The type of the old value to replace (deduced).
- **T2** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to hpx::identity

**Parameters**
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **old_value** – Refers to the old value of the elements to replace.
- **new_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The replace algorithm returns an Iter.

```cpp
template<typename Rng, typename Proj = hpx::identity, typename T1 = typename hpx::parallel::traits::projected<hpx::traits::range_iterator_t<Rng>, Proj>::value_type, typename T2 = T1>
    hpx::traits::range_iterator_t<Rng> replace(Rng &&rng, T1 const &old_value, T2 const &new_value, 
        Proj &&proj = Proj())
```

Replaces all elements satisfying specific criteria with new_value in the range rng.

Effects: Substitutes elements referred by the iterator it in the range rng with new_value, when the following corresponding conditions hold: INVOKE(proj, *i) == old_value

The assignments in the parallel replace algorithm execute in sequential order in the calling thread.

**Note:** Complexity: Performs exactly util::end(rng) - util::begin(rng) assignments.

**Template Parameters**
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **T1** – The type of the old value to replace (deduced).
- **T2** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to hpx::identity

**Parameters**
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **old_value** – Refers to the old value of the elements to replace.
- **new_value** – Refers to the new value to use as the replacement.
• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `replace` algorithm returns an `hpx::traits::range_iterator<Rng>::type`.

```cpp
template<typename ExPolicy, typename Iter, typename Sent, typename Proj = hpx::identity, typename T1 = typename hpx::parallel::traits::projected<Iter, Proj>::value_type, typename T2 = T1> hpx::parallel::util::detail::algorithm_result_t<ExPolicy, Iter> replace(ExPolicy &&policy, Iter first, Sent sent, T1 const &old_value, T2 const &new_value, Proj &&proj = Proj())
```

Replaces all elements satisfying specific criteria with `new_value` in the range `[first, last)`.

**Effects:** Substitutes elements referred by the iterator `it` in the range `[first, last)` with `new_value`, when the following corresponding conditions hold: `INVOKE(proj, *i) == old_value`

The assignments in the parallel `replace` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `replace` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs exactly `last - first` assignments.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of a forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for `Iter`.
- **T1** – The type of the old value to replace (deduced).
- **T2** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **old_value** – Refers to the old value of the elements to replace.
- **new_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `replace` algorithm returns a `hpx::future<Iter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `Iter` otherwise.

```cpp
template<typename ExPolicy, typename Rng, typename Proj = hpx::identity, typename T1 = typename hpx::parallel::traits::projected<hpx::traits::range_iterator_t<Rng>, Proj>::value_type, typename T2 = T1>
```
Replaces all elements satisfying specific criteria with \textit{new\_value} in the range \textit{rng}.

**Effects:** Substitutes elements referred by the iterator \textit{it} in the range \textit{rng} with \textit{new\_value}, when the following corresponding conditions hold: \texttt{INVOKE(proj, \*i) == old\_value}

The assignments in the parallel \texttt{replace} algorithm invoked with an execution policy object of type \texttt{parallel\_policy} or \texttt{parallel\_task\_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs exactly \texttt{util::end(rng) - util::begin(rng)} assignments.

**Template Parameters**

- \texttt{ExPolicy} – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- \texttt{Rng} – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- \texttt{T1} – The type of the old value to replace (deduced).
- \texttt{T2} – The type of the new values to replace (deduced).
- \texttt{Proj} – The type of an optional projection function. This defaults to \texttt{hpx::identity}

**Parameters**

- \texttt{policy} – The execution policy to use for the scheduling of the iterations.
- \texttt{rng} – Refers to the sequence of elements the algorithm will be applied to.
- \texttt{old\_value} – Refers to the old value of the elements to replace.
- \texttt{new\_value} – Refers to the new value to use as the replacement.
- \texttt{proj} – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate \texttt{is} invoked. The assignments in the parallel \texttt{replace} algorithm invoked with an execution policy object of type \texttt{sequenced\_policy} execute in sequential order in the calling thread.

**Returns** The \texttt{replace} algorithm returns an \texttt{hpx::future<hpx::traits::range\_iterator<Rng>::type>} if the execution policy is of type \texttt{sequenced\_task\_policy} or \texttt{parallel\_task\_policy} and returns \texttt{hpx::traits::range\_iterator<Rng>::type} otherwise.

```cpp
template<typename InIter, typename Sent, typename OutIter, typename Pred, typename T = typename std::iterator_traits<OutIter>::value_type, typename Proj = hpx::identity>
replace_copy_if_result<InIter, OutIter> replace_copy_if(InIter first, Sent sent, OutIter dest, Pred &&pred, T const &new_value, Proj &&proj = Proj())
```

Copies all the elements from the range \texttt{[first, sent)} to another range beginning at \texttt{dest} replacing all elements satisfying a specific criteria with \texttt{new\_value}.
Effects: Assigns to every iterator it in the range \([\text{result}, \text{result} + (\text{sent} - \text{first}))\) either new_value or *(\text{first} + (\text{it} - \text{result})) depending on whether the following corresponding condition holds: INVOKE(f, INVOKE(proj, *(\text{first} + (\text{i} - \text{result})))) != false

The assignments in the parallel \textit{replace_copy_if} algorithm execute in sequential order in the calling thread.

\textbf{Note:} Complexity: Performs exactly \textit{sent} - \textit{first} applications of the predicate.

**Template Parameters**
- \textit{InIter} – The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- \textit{Sent} – The type of the end iterators used (deduced). This sentinel type must be a sentinel for \textit{InIter}.
- \textit{OutIter} – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- \textit{Pred} – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of \textit{equal} requires \textit{Pred} to meet the requirements of \textit{CopyConstructible}. (deduced).
- \textit{T} – The type of the new values to replace (deduced).
- \textit{Proj} – The type of an optional projection function. This defaults to \textit{hpx::identity}

**Parameters**
- \textit{first} – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- \textit{sent} – Refers to the end of the sequence of elements the algorithm will be applied to.
- \textit{dest} – Refers to the beginning of the destination range.
- \textit{pred} – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by \textit{[first, last)}. This is an unary predicate which returns \textit{true} for the elements which need to replaced. The signature of this predicate should be equivalent to:

\begin{verbatim}
bool pred(const Type &a);
\end{verbatim}

The signature does not need to have \textit{const}, but the function must not modify the objects passed to it. The type \textit{Type} must be such that an object of type \textit{FwdIter} can be dereferenced and then implicitly converted to \textit{Type}.
- \textit{new_value} – Refers to the new value to use as the replacement.
- \textit{proj} – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The \textit{replace_copy_if} algorithm returns a \textit{in_out_result<InIter, OutIter>}. The \textit{replace_copy_if} algorithm returns the input iterator \textit{last} and the output iterator to the element in the destination range, one past the last element copied.

\begin{verbatim}
template<typename Rng, typename OutIter, typename Pred, typename T = typename std::iterator_traits<OutIter>::value_type, typename Proj = hpx::identity>
replace_copy_if_result<hpx::traits::range_iterator_t<Rng>, OutIter> replace_copy_if(Rng &&rng, OutIter dest, Pred &&pred, T const &new_value, Proj &&proj = Proj())
\end{verbatim}

Chapter 2. What’s so special about \textit{HPX}?
Copies all the elements from the range rng to another range beginning at dest replacing all elements satisfying a specific criteria with new_value.

Effects: Assigns to every iterator it in the range [result, result + (util::end(rng) - util::begin(rng))) either new_value or *(first + (it - result)) depending on whether the following corresponding condition holds: INVOKE(f, INVOKE(proj, *(first + (i - result)))) != false

The assignments in the parallel replace_copy_if algorithm execute in sequential order in the calling thread.

Note: Complexity: Performs exactly util::end(rng) - util::begin(rng) applications of the predicate.

Template Parameters
  - Rng – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
  - OutIter – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
  - Pred – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of equal requires Pred to meet the requirements of CopyConstructible. (deduced).
  - T – The type of the new values to replace (deduced).
  - Proj – The type of an optional projection function. This defaults to hpx::identity

Parameters
  - rng – Refers to the sequence of elements the algorithm will be applied to.
  - dest – Refers to the beginning of the destination range.
  - pred – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last). This is an unary predicate which returns true for the elements which need to replaced. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type Type must be such that an object of type FwdIter can be dereferenced and then implicitly converted to Type.

  - new_value – Refers to the new value to use as the replacement.
  - proj – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Returns The replace_copy_if algorithm returns an in_out_result<hpx::traits::range_iterator_t<Rng>, OutIter>. The replace_copy_if algorithm returns the input iterator last and the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename Sent, typename FwdIter2, typename Pred, typename T = typename std::iterator_traits<FwdIter2>::value_type, typename Proj = hpx::identity>
```
Copies the all elements from the range \([first, sent)\) to another range beginning at \(dest\) replacing all elements satisfying a specific criteria with \(new\_value\).

**Effects:** Assigns to every iterator \(it\) in the range \([result, result + (sent - first))\) either \(new\_value\) or \(*(first + (it - result))\) depending on whether the following corresponding condition holds: \(\text{INVOLVE}(f, \text{INVOLVE}(proj, *(first + (i - result)))) \neq \text{false}\)

The assignments in the parallel `replace_copy_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `replace_copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs exactly \(sent - first\) applications of the predicate.

**Template Parameters**
- `ExPolicy` – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- `FwdIter1` – The type of the source iterator used (deduced). The iterator type must meet the requirements of a forward iterator.
- `Sent` – The type of the end iterators used (deduced). This sentinel type must be a sentinel for InIter.
- `FwdIter2` – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- `Pred` – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible`. (deduced).
- `T` – The type of the new values to replace (deduced).
- `Proj` – The type of an optional projection function. This defaults to `hpx::identity`

**Parameters**
- `policy` – The execution policy to use for the scheduling of the iterations.
- `first` – Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
• **dest** – Refers to the beginning of the destination range.
• **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by [first, last]. This is an unary predicate which returns `true` for the elements which need to replaced. The signature of this predicate should be equivalent to:

```cpp
bool pred(const Type &a);
```

The signature does not need to have const&, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.

• **new_value** – Refers to the new value to use as the replacement.
• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `replace_copy_if` algorithm returns an `hpx::future<FwdIter1, FwdIter2>`. The `replace_copy_if` algorithm returns the input iterator `last` and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename Rng, typename FwdIter, typename Pred, typename T = typename std::iterator_traits<FwdIter>::value_type, typename Proj = hpx::identity>
parallel::util::detail::algorithm_result<ExPolicy, replace_copy_if_result<hpx::traits::range_iterator_t<Rng>, FwdIter>>::type
replace_copy_if(ExPolicy &&policy, Rng &&rng, FwdIter dest, Pred &&pred, T const &new_value, Proj &&proj = Proj())
```

Copies the all elements from the range `rng` to another range beginning at `dest` replacing all elements satisfying a specific criteria with `new_value`.

**Effects:** Assigns to every iterator it in the range [result, result + (util::end(rng) - util::begin(rng))) either `new_value` or *(first + (it - result)) depending on whether the following corresponding condition holds: `INVOKE(f, INVOKE(proj, *(first + (i - result)))) != false`

The assignments in the parallel `replace_copy_if` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `replace_copy_if` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs exactly `util::end(rng) - util::begin(rng)` applications of the predicate.
Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Pred** – The type of the function/function object to use (deduced). Unlike its sequential form, the parallel overload of `equal` requires `Pred` to meet the requirements of `CopyConstructible`. (deduced).
- **T** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **pred** – Specifies the function (or function object) which will be invoked for each of the elements in the sequence specified by `[first, last)`. This is an unary predicate which returns `true` for the elements which need to replaced. The signature of this predicate should be equivalent to:

  ```
  bool pred(const Type &a);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type` must be such that an object of type `FwdIter` can be dereferenced and then implicitly converted to `Type`.
- **new_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Returns

The `replace_copy_if` algorithm returns an `hpx::future<in_out_result<hpx::traits::range_iterator_t<Rng>, OutIter>>`. The `replace_copy_if` algorithm returns the input iterator `last` and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename InIter, typename Sent, typename OutIter, typename Proj = hpx::identity, typename T1 = typename hpx::parallel::traits::projected<InIter, Proj>::value_type, typename T2 = T1>
replace_copy_result<InIter, OutIter> replace_copy(InIter first, Sent sent, OutIter dest, T1 const &old_value, T2 const &new_value, Proj &&proj = Proj())
```

Copies the all elements from the range `[first, sent)` to another range beginning at `dest` replacing all elements satisfying a specific criteria with `new_value`.

Effects: Assigns to every iterator it in the range `[result, result + (sent - first))` either `new_value` or `*(first + (it - result))` depending on whether the following corresponding condition holds: `INVOLVE(proj, *(first + (i - result))) == old_value`

The assignments in the parallel `replace_copy` algorithm execute in sequential order in the calling thread.

Note: Complexity: Performs exactly `sent - first` applications of the predicate.

Template Parameters
• **InIter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
• **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for Iter.
• **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
• **T1** – The type of the old value to replace (deduced).
• **T2** – The type of the new values to replace (deduced).
• **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

**Parameters**
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **old_value** – Refers to the old value of the elements to replace.
- **new_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns**
The `replace_copy` algorithm returns an `in_out_result<InIter, OutIter>`. The `copy` algorithm returns the pair of the input iterator `last` and the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename Rng, typename OutIter, typename Proj = hpx::identity, typename T1 = typename hpx::parallel::traits::projected<hpx::traits::range_iterator_t<Rng>, Proj>::value_type, typename T2 = T1>
replace_copy_result<hpx::traits::range_iterator_t<Rng>, OutIter> replace_copy(Rng &&rng, OutIter dest, T1 const &old_value, T2 const &new_value, Proj &&proj = Proj())
```

Copies the all elements from the range `rng` to another range beginning at `dest` replacing all elements satisfying a specific criteria with `new_value`.

Effects: Assigns to every iterator it in the range `[result, result + (util::end(rng) - util::begin(rng))) either `new_value` or `*(first + (it - result))` depending on whether the following corresponding condition holds: `INVOKE(proj, *(first + (i - result))) == old_value`

The assignments in the parallel `replace_copy` algorithm execute in sequential order in the calling thread.

**Note:** Complexity: Performs exactly `util::end(rng) - util::begin(rng)` applications of the predicate.
• **old_value** – Refers to the old value of the elements to replace.
• **new_value** – Refers to the new value to use as the replacement.
• **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns** The `replace_copy` algorithm returns an `in_out_result<hpx::traits::range_iterator_t<Rng>, OutIter>`. The `copy` algorithm returns the pair of the input iterator `last` and the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename FwdIter1, typename Sent, typename FwdIter2, typename Proj = hpx::identity, typename T1 = typename hpx::parallel::traits::projected<FwdIter1, Proj>::value_type, typename T2 = T1>
parallel::util::detail::algorithm_result<ExPolicy, replace_copy_result<FwdIter1, FwdIter2>>::type replace_copy(ExPolicy&& policy, FwdIter1 first, Sent sent, FwdIter2 dest, T1 const& old_value, T2 const& new_value, Proj&& proj = Proj())
```

Copies the all elements from the range `[first, sent)` to another range beginning at `dest` replacing all elements satisfying a specific criteria with `new_value`.

Effects: Assigns to every iterator `it` in the range `[result, result + (sent - first))` either `new_value` or `*(first + (it - result))` depending on whether the following corresponding condition holds: `INVoke(proj, *(first + (i - result))) == old_value`

The assignments in the parallel `replace_copy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `replace_copy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs exactly `sent - first` applications of the predicate.

**Template Parameters**
• **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• **FwdIter1** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an forward iterator.
• **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for `Iter`.
• **FwdIter2** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
• **T1** – The type of the old value to replace (deduced).
• **T2** – The type of the new values to replace (deduced).
• **Proj** – The type of an optional projection function. This defaults to `hpx::identity`.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **old_value** – Refers to the old value of the elements to replace.
- **new_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

**Returns**
The `replace_copy` algorithm returns a `hpx::future<in_out_result<FwdIter1, FwdIter2>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `in_out_result<FwdIter1, FwdIter2>` otherwise. The `copy` algorithm returns the pair of the forward iterator `last` and the output iterator to the element in the destination range, one past the last element copied.

```
template<typename ExPolicy, typename Rng, typename FwdIter, typename Proj = hpx::identity, typename T1 = typename hpx::parallel::traits::projected<hpx::traits::range_iterator_t<Rng>, Proj>::value_type, typename T2 = T1>
parallel::util::detail::algorithm_result<ExPolicy, replace_copy_result<hpx::traits::range_iterator_t<Rng>, FwdIter>>::type
```

Copies the all elements from the range `rbg` to another range beginning at `dest` replacing all elements satisfying a specific criteria with `new_value`.

**Effects:**
Assigns to every iterator it in the range `[result, result + (util::end(rng) - util::begin(rng)))` either `new_value` or `*(first + (it - result))` depending on whether the following corresponding condition holds:

`INVOKE(proj, *(first + (i - result))) == old_value`

The assignments in the parallel `replace_copy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `replace_copy` algorithm invoked with an execution policy object of type
parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: Performs exactly `util::end(rng) - util::begin(rng)` applications of the predicate.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.
- **T1** – The type of the old value to replace (deduced).
- **T2** – The type of the new values to replace (deduced).
- **Proj** – The type of an optional projection function. This defaults to `hpx::identity`

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **old_value** – Refers to the old value of the elements to replace.
- **new_value** – Refers to the new value to use as the replacement.
- **proj** – Specifies the function (or function object) which will be invoked for each of the elements as a projection operation before the actual predicate is invoked.

Returns The replace_copy algorithm returns a `hpx::future<in_out_result< hpx::traits::range_iterator_t<Rng>, FwdIter>>` if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns `in_out_result< hpx::traits::range_iterator_t<Rng>, FwdIter>>` The copy algorithm returns the pair of the input iterator last and the forward iterator to the element in the destination range, one past the last element copied.

See Public API for a list of names and headers that are part of the public HPX API.

namespace hpx

namespace ranges

Functions

template<typename Iter, typename Sent>
Iter reverse(Iter first, Sent sent)

Reverses the order of the elements in the range [first, last). Behaves as if applying std::iter_swap to every pair of iterators first+i, (last-i) - 1 for each non-negative i < (last-first)/2.

The assignments in the parallel reverse algorithm execute in sequential order in the calling thread.
Note: Complexity: Linear in the distance between `first` and `last`.

**Template Parameters**
- **Iter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for `Iter`.

**Parameters**
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The `reverse` algorithm returns a `Iter`. It returns `last`.

```cpp
template<typename Rng>
hpx::traits::range_iterator_t<Rng> reverse(Rng &&rng)
```

Uses `rng` as the source range, as if using `util::begin(rng)` as `first` and `ranges::end(rng)` as `last`. Reverses the order of the elements in the range `[first, last)`. Behaves as if applying `std::iter_swap` to every pair of iterators `first+i, (last-i) - 1` for each non-negative `i < (last-first)/2`.

The assignments in the parallel `reverse` algorithm execute in sequential order in the calling thread.

Note: Complexity: Linear in the distance between `first` and `last`.

**Template Parameters** `Rng` – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a bidirectional iterator.

**Parameters** `rng` – Refers to the sequence of elements the algorithm will be applied to.

**Returns** The `reverse` algorithm returns a `hpx::traits::range_iterator<Rng>::type`. It returns `last`.

```cpp
template<typename ExPolicy, typename Iter, typename Sent>
hpx::parallel::util::detail::algorithm_result_t<ExPolicy, Iter> reverse(ExPolicy &&policy, Iter first, Sent sent)
```

Reverses the order of the elements in the range `[first, last)`. Behaves as if applying `std::iter_swap` to every pair of iterators `first+i, (last-i) - 1` for each non-negative `i < (last-first)/2`.

The assignments in the parallel `reverse` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `reverse` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: Linear in the distance between `first` and `last`.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• **Iter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
• **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for Iter.

**Parameters**

• **policy** – The execution policy to use for the scheduling of the iterations.
• **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
• **sent** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns**

The `reverse` algorithm returns a `hpx::future<Iter>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `Iter` otherwise. It returns `last`.

```cpp
template<typename ExPolicy, typename Rng>
parallel::util::detail::algorithm_result<ExPolicy, hpx::traits::range_iterator_t<Rng>> reverse(ExPolicy &&policy, Rng &&rng)
```

Uses `rng` as the source range, as if using `util::begin(rng)` as `first` and `ranges::end(rng)` as `last`. Reverses the order of the elements in the range `[first, last)`. Behaves as if applying `std::iter_swap` to every pair of iterators `first+i, (last-i) - 1` for each non-negative `i < (last-first)/2`.

The assignments in the parallel `reverse` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `reverse` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Linear in the distance between `first` and `last`.

**Template Parameters**

• **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
• **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a bidirectional iterator.

**Parameters**

• **policy** – The execution policy to use for the scheduling of the iterations.
• **rng** – Refers to the sequence of elements the algorithm will be applied to.

**Returns**

The `reverse` algorithm returns a `hpx::future<hpx::traits::range_iterator_t<Rng>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `hpx::future<hpx::traits::range_iterator_t<Rng>>` otherwise. It returns `last`.

```cpp
template<typename Iter, typename Sent, typename OutIter>
reverse_copy_result<Iter, Sent, OutIter> reverse_copy(Iter first, Sent last, OutIter result)
```

Copies the elements from the range `[first, last)` to another range beginning at result in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment `*(result + (last - first) - 1 - i) = *(first + i)` once for each non-negative `i < (last - first)` If the source and destination ranges (that is, `[first, last)` and `[result, result+(last-first))` respectively) overlap, the behavior is undefined.

The assignments in the parallel `reverse_copy` algorithm execute in sequential order in the calling thread.
**Note:** Complexity: Performs exactly last - first assignments.

**Template Parameters**
- **Iter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for Iter.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

**Parameters**
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **result** – Refers to the begin of the destination range.

**Returns**
The reverse_copy algorithm returns a reverse_copy_result<Iter, OutIter>. The reverse_copy algorithm returns the pair of the input iterator forwarded to the first element after the last in the input sequence and the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename Rng, typename OutIter>
reverse_copy_result<hpx::traits::range_iterator_t<Rng>, OutIter> reverse_copy(Rng&& rng, OutIter result)
```

Uses rng as the source range, as if using util::begin(rng) as first and ranges::end(rng) as last. Copies the elements from the range [first, last) to another range beginning at result in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment *(result + (last - first) - 1 - i) = *(first + i) once for each non-negative i < (last - first) If the source and destination ranges (that is, [first, last) and [result, result+(last-first)) respectively) overlap, the behavior is undefined.

The assignments in the parallel reverse_copy algorithm execute in sequential order in the calling thread.

**Note:** Complexity: Performs exactly last - first assignments.

**Template Parameters**
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a bidirectional iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

**Parameters**
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **result** – Refers to the begin of the destination range.

**Returns**
The reverse_copy algorithm returns a ranges::reverse_copy_result<
hpx::traits::range_iterator_t<Rng>, OutIter>. The reverse_copy algorithm returns an object equal to {last, result + N} where N = last - first

```cpp
template<typename ExPolicy, typename Iter, typename Sent, typename FwdIter>
```

2.8. API reference 757
Copies the elements from the range [first, last) to another range beginning at result in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment *(result + (last - first) - 1 - i) = *(first + i) once for each non-negative i < (last - first) If the source and destination ranges (that is, [first, last) and [result, result+(last-first)) respectively) overlap, the behavior is undefined.

The assignments in the parallel reverse_copy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The assignments in the parallel reverse_copy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs exactly last - first assignments.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Iter** – The type of the source iterator used (deduced). The iterator type must meet the requirements of an input iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for Iter.
- **FwdIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **result** – Refers to the begin of the destination range.

**Returns** The reverse_copy algorithm returns a hpx::future<reverse_copy_result<Iter, FwdIter>> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns reverse_copy_result<Iter, FwdIter> otherwise. The reverse_copy algorithm returns the pair of the input iterator forwarded to the first element after the last in the input sequence and the output iterator to the element in the destination range, one past the last element copied.

template<typename ExPolicy, typename Rng, typename OutIter>
**parallel::util::detail::algorithm_result<ExPolicy, reverse_copy_result<hpx::traits::range_iterator_t<Rng>, OutIter>>::type** reverse_copy

Uses `rng` as the source range, as if using `util::begin(rng)` as `first` and `ranges:end(rng)` as `last`. Copies the elements from the range `[first, last)` to another range beginning at result in such a way that the elements in the new range are in reverse order. Behaves as if by executing the assignment `*(result + (last - first) - 1 - i) = *(first + i)` once for each non-negative `i < (last - first)` If the source and destination ranges (that is, `[first, last)` and `[result, result+(last-first))` respectively) overlap, the behavior is undefined.

The assignments in the parallel `reverse_copy` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `reverse_copy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs exactly `last - first` assignments.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a bidirectional iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **result** – Refers to the begin of the destination range.

**Returns** The `reverse_copy` algorithm returns a `hpx::future<ranges::reverse_copy_result<hpx::traits::range_iterator_t<Rng>, OutIter>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::reverse_copy_result<hpx::traits::range_iterator_t<Rng>, OutIter>` otherwise. The `reverse_copy` algorithm returns an object equal to `{last, result + N}` where `N = last - first`.
namespace hpx

namespace ranges

Functions

template<typename FwdIter, typename Sent>
subrange_t<FwdIter, Sent> rotate(FwdIter first, FwdIter middle, Sent last)

Performs a left rotation on a range of elements. Specifically, rotate swaps the elements in the range [first, last) in such a way that the element middle becomes the first element of the new range and middle - 1 becomes the last element.

The assignments in the parallel rotate algorithm execute in sequential order in the calling thread.

**Note:** Complexity: Linear in the distance between first and last.

**Note:** The type of dereferenced FwdIter must meet the requirements of MoveAssignable and Move-Constructible.

Template Parameters

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for FwdIter.

Parameters

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the element that should appear at the beginning of the rotated range.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

Returns The rotate algorithm returns a subrange_t<FwdIter, Sent>. The rotate algorithm returns the iterator equal to pair(first + (last - middle), last).

template<typename ExPolicy, typename FwdIter, typename Sent>
parallel::util::detail::algorithm_result<ExPolicy, subrange_t<FwdIter, Sent>>::type rotate(ExPolicy &&policy, FwdIter first, FwdIter middle, Sent last)

Performs a left rotation on a range of elements. Specifically, rotate swaps the elements in the range [first, last) in such a way that the element middle becomes the first element of the new range and middle - 1 becomes the last element.
The assignments in the parallel rotate algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The assignments in the parallel rotate algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Linear in the distance between first and last.

**Note:** The type of dereferenced FwdIter must meet the requirements of MoveAssignable and MoveConstructible.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for FwdIter.

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the element that should appear at the beginning of the rotated range.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.

**Returns** The rotate algorithm returns a std::future<std::tuple<T, U>> if the execution policy is of type parallel_policy and returns a std::tuple<T, U> otherwise. The rotate algorithm returns the iterator equal to pair(first + (last - middle), last).

```cpp
template<typename Rng>
subrange_t<hpx::traits::range_iterator_t<Rng>, hpx::traits::range_iterator_t<Rng>> rotate(Rng &&rng, hpx::traits::range_iterator_t<Rng> middle)
```

Uses rng as the source range, as if using util::begin(rng) as first and ranges::end(rng) as last. Performs a left rotation on a range of elements. Specifically, rotate swaps the elements in the range [first, last) in such a way that the element middle becomes the first element of the new range and middle - 1 becomes the last element.

The assignments in the parallel rotate algorithm execute in sequential order in the calling thread.

**Note:** Complexity: Linear in the distance between first and last.

**Note:** The type of dereferenced FwdIter must meet the requirements of MoveAssignable and MoveConstructible.
Template Parameters

- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.

Parameters

- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the element that should appear at the beginning of the rotated range.

Returns The `rotate` algorithm returns a `subrange_t<hpx::traits::range_iterator_t<Rng>, hpx::traits::range_iterator_t<Rng>>`. The `rotate` algorithm returns the iterator equal to `pair(first + (last - middle), last).

```cpp
template<typename ExPolicy, typename Rng>
parallel::util::detail::algorithm_result<ExPolicy, subrange_t<hpx::traits::range_iterator_t<Rng>, hpx::traits::range_iterator_t<Rng>>> rotate(ExPolicy&& policy, Rng&& rng, hpx::traits::range_iterator_t<Rng> middle)
```

Uses `rng` as the source range, as if using `util::begin(rng)` as `first` and `ranges::end(rng)` as `last`. Performs a left rotation on a range of elements. Specifically, `rotate` swaps the elements in the range `[first, last)` in such a way that the element `middle` becomes the first element of the new range and `middle - 1` becomes the last element.

The assignments in the parallel `rotate` algorithm invoked with an execution policy object of type `sequenced_policy` execute in sequential order in the calling thread.

The assignments in the parallel `rotate` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Linear in the distance between `first` and `last`.

**Note:** The type of dereferenced `FwdIter` must meet the requirements of `MoveAssignable` and `MoveConstructible`.

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the element that should appear at the beginning of the rotated range.

Returns The `rotate` algorithm returns a `hpx::future` `<subrange_t<hpx::traits::range_iterator_t<Rng>, hpx::traits::range_iterator_t<Rng>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `subrange_t<hpx::traits::range_iterator_t<Rng>, hpx::traits::range_iterator_t<Rng>>`, otherwise. The `rotate` algorithm returns the iterator equal to `pair(first + (last - middle), last).`
template<typename FwdIter, typename Sent, typename OutIter>
rotate_copy_result<FwdIter, OutIter> rotate_copy(FwdIter first, FwdIter middle, Sent last, OutIter dest_first)

Copies the elements from the range [first, last), to another range beginning at dest_first in such a way, that the element middle becomes the first element of the new range and middle - 1 becomes the last element.

The assignments in the parallel rotate_copy algorithm execute in sequential order in the calling thread.

**Note:** Complexity: Performs exactly last - first assignments.

**Template Parameters**

- **FwdIter** – The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the end iterators used (deduced). This sentinel type must be a sentinel for FwdIter.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the element that should appear at the beginning of the rotated range.
- **last** – Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest_first** – Output iterator to the initial position of the range where the reversed range is stored. The pointed type shall support being assigned the value of an element in the range [first,last).

**Returns** The rotate_copy algorithm returns a rotate_copy_result<FwdIter, OutIter>. The rotate_copy algorithm returns the output iterator to the element past the last element copied.

template<typename ExPolicy, typename FwdIter1, typename Sent, typename FwdIter2>
parallel::util::detail::algorithm_result<ExPolicy, rotate_copy_result<FwdIter1, FwdIter2>>::type rotate_copy(ExPolicy&& policy, FwdIter1 first, FwdIter1 middle, Sent last, FwdIter2 dest_first)

Copies the elements from the range [first, last), to another range beginning at dest_first in such a way, that the element middle becomes the first element of the new range and middle - 1 becomes the last element.

The assignments in the parallel rotate_copy algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The assignments in the parallel rotate_copy algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified
threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs exactly last-first assignments.

### Template Parameters

- **ExPolicy** — The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter1** — The type of the source iterators used (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** — The type of the end iterators used (deduced). This sentinel type must be a sentinel for FwdIter.
- **FwdIter2** — The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **policy** — The execution policy to use for the scheduling of the iterations.
- **first** — Refers to the beginning of the sequence of elements the algorithm will be applied to.
- **middle** — Refers to the element that should appear at the beginning of the rotated range.
- **last** — Refers to the end of the sequence of elements the algorithm will be applied to.
- **dest_first** — Output iterator to the initial position of the range where the reversed range is stored. The pointed type shall support being assigned the value of an element in the range [first,last).

### Returns

The `rotate_copy` algorithm returns areturns hpx::future< rotate_copy_result<FwdIter1, FwdIter2>> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns rotate_copy_result<FwdIter1, FwdIter2> otherwise. The `rotate_copy` algorithm returns the output iterator to the element past the last element copied.

```cpp
template<typename Rng, typename OutIter>
rotate_copy_result<hpx::traits::range_iterator_t<Rng>, OutIter> rotate_copy(Rng &&rng, hpx::traits::range_iterator_t<Rng> middle, OutIter dest_first)
```

Uses `rng` as the source range, as if using util::begin(rng) as first and ranges::end(rng) as last. Copies the elements from the range [first, last), to another range beginning at dest_first in such a way, that the element middle becomes the first element of the new range and middle - 1 becomes the last element.

The assignments in the parallel rotate_copy algorithm execute in sequential order in the calling thread.

**Note:** Complexity: Performs exactly last-first assignments.

### Template Parameters

- **Rng** — The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **OutIter** — The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an forward iterator.

### Parameters

- **rng** — Refers to the sequence of elements the algorithm will be applied to.
- **middle** — Refers to the element that should appear at the beginning of the rotated range.
• **dest_first** – Output iterator to the initial position of the range where the reversed range is stored. The pointed type shall support being assigned the value of an element in the range [first, last).

**Returns** The `rotate` algorithm returns a `rotate_copy_result<hpx::traits::range_iterator_t<Rng>, OutIter>`. The `rotate_copy` algorithm returns the output iterator to the element past the last element copied.

```cpp
template<typename ExPolicy, typename Rng, typename OutIter>
parallel::util::detail::algorithm_result<ExPolicy, rotate_copy_result<hpx::traits::range_iterator_t<Rng>, OutIter>> rotate_copy(ExPolicy&& policy, Rng&& rng, hpx::traits::range_iterator_t<Rng> middle, OutIter dest_first)
```

Uses `rng` as the source range, as if using `util::begin(rng)` as `first` and `ranges::end(rng)` as `last`. Copies the elements from the range `[first, last)`, to another range beginning at `dest_first` in such a way, that the element `new_first` becomes the first element of the new range and `new_first - 1` becomes the last element.

The assignments in the parallel `rotate_copy` algorithm invoked with an execution policy object of type `sequence_policy` execute in sequential order in the calling thread.

The assignments in the parallel `rotate_copy` algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: Performs exactly `last - first` assignments.

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of a forward iterator.
- **OutIter** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

**Parameters**
- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng** – Refers to the sequence of elements the algorithm will be applied to.
- **middle** – Refers to the element that should appear at the beginning of the rotated range.
- **dest_first** – Output iterator to the initial position of the range where the reversed range is stored. The pointed type shall support being assigned the value of an element in the range [first, last).

**Returns** The `rotate_copy` algorithm returns a `hpx::future<rotate_copy_result<hpx::traits::range_iterator_t<Rng>, OutIter>>` if the execution policy is of type `parallel_task_policy` and returns `rotate_copy_result<hpx::traits::range_iterator_t<Rng>, OutIter>` otherwise. The `rotate_copy` algorithm returns the output iterator to the element past the last element copied.
namespace hpx

namespace ranges

Functions

template<typename FwdIter, typename Sent, typename FwdIter2, typename Sent2, typename Pred = hpx::ranges::equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
FwdIter search(FwdIter first, Sent last, FwdIter2 s_first, Sent2 s_last, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())

Searches the range [first, last) for any elements in the range [s_first, s_last). Uses a provided predicate to compare elements.

The comparison operations in the parallel search algorithm execute in sequential order in the calling thread.

Note: Complexity: at most (S*N) comparisons where S = distance(s_first, s_last) and N = distance(first, last).

Template Parameters

- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel used for the first range (deduced). This iterator type must meet the requirements of an sentinel.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the source sentinel used for the second range (deduced). This iterator type must meet the requirements of an sentinel.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of adjacent_find requires Pred to meet the requirements of CopyConstructible. This defaults to std::equal_to>
- **Proj1** – The type of an optional projection function. This defaults to hpx::identity and is applied to the elements of type dereferenced FwdIter.
- **Proj2** – The type of an optional projection function. This defaults to hpx::identity and is applied to the elements of type dereferenced FwdIter2.

Parameters

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **s_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
- **s_last** – Refers to the end of the sequence of elements the algorithm will be searching for.
- **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. The signature of the function should be equivalent to
bool pred(const Type1 &a, const Type2 &b);

The signature does not need to have const &, but the function must not modify the objects passed to it. The types Type1 and Type2 must be such that objects of types FwdIter1 and FwdIter2 can be dereferenced and then implicitly converted to Type1 and Type2 respectively.

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced FwdIter1 as a projection operation before the actual predicate is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced FwdIter2 as a projection operation before the actual predicate is invoked.

**Returns** The search algorithm returns a hpx::future<FwdIter> if the execution policy is of type task_execution_policy and returns FwdIter otherwise. The search algorithm returns an iterator to the beginning of the first subsequence [s_first, s_last) in range [first, last). If the length of the subsequence [s_first, s_last) is greater than the length of the range [first, last), last is returned. Additionally if the size of the subsequence is empty first is returned. If no subsequence is found, last is returned.

```
template<typename ExPolicy, typename FwdIter, typename Sent, typename FwdIter2, typename Sent2, typename Pred = hpx::ranges::equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type search(ExPolicy &&policy, FwdIter first, Sent last, FwdIter2 s_first, Sent2 s_last, Pred &&op = Pred(), Proj1 &&&proj1 = Proj1(), Proj2 &&&proj2 = Proj2())
```

Searches the range [first, last) for any elements in the range [s_first, s_last). Uses a provided predicate to compare elements.

The comparison operations in the parallel search algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The comparison operations in the parallel search algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: at most (S*N) comparisons where S = distance(s_first, s_last) and N = distance(first, last).

**Template Parameters**
- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent** – The type of the source sentinel used for the first range (deduced). This iterator type must meet the requirements of an sentinel.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
• **Sent2** – The type of the source sentinel used for the second range (deduced). This iterator type must meet the requirements of an sentinel.

• **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to`.

• **Proj1** – The type of an optional projection function. This defaults to `hpx::identity` and is applied to the elements of type dereferenced `FwdIter`.

• **Proj2** – The type of an optional projection function. This defaults to `hpx::identity` and is applied to the elements of type dereferenced `FwdIter2`.

**Parameters**

• **policy** – The execution policy to use for the scheduling of the iterations.

• **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

• **last** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

• **s_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.

• **s_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.

• **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. The signature of the function should be equivalent to

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

• **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `FwdIter1` as a projection operation before the actual predicate is invoked.

• **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `FwdIter2` as a projection operation before the actual predicate is invoked.

**Returns**
The `search` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `search` algorithm returns an iterator to the beginning of the first subsequence `[s_first, s_last)` in range `[first, last)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, last), last` is returned. Additionally if the size of the subsequence is empty `first` is returned. If no subsequence is found, `last` is returned.

```cpp
template<typename Rng1, typename Rng2, typename Pred = hpx::ranges::equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
hpx::traits::range_iterator_t<Rng1> search(Rng1 &&rng1, Rng2 &&rng2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Searches the range `[first, last)` for any elements in the range `[s_first, s_last)`. Uses a provided predicate to compare elements.

The comparison operations in the parallel `search` algorithm execute in sequential order in the calling thread.

**Note:** Complexity: at most $(S*N)$ comparisons where $S = \text{distance}(s\_first, s\_last)$ and $N = \text{dis-}
Template Parameters
- **Rng1** – The type of the examine range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the search range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`.
- **Proj1** – The type of an optional projection function. This defaults to `hpx::identity` and is applied to the elements of `Rng1`.
- **Proj2** – The type of an optional projection function. This defaults to `hpx::identity` and is applied to the elements of `Rng2`.

Parameters
- **rng1** – Refers to the sequence of elements the algorithm will be examining.
- **rng2** – Refers to the sequence of elements the algorithm will be searching for.
- **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. The signature of the function should be equivalent to

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.
- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of `rng1` as a projection operation before the actual predicate is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of `rng2` as a projection operation before the actual predicate is invoked.

Returns The search algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The search algorithm returns an iterator to the beginning of the first subsequence `[s_first, s_last)` in range `[first, last)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, last)`, `last` is returned. Additionally if the size of the subsequence is empty `first` is returned. If no subsequence is found, `last` is returned.

```cpp
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred = hpx::ranges::equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
```
Searches the range [first, last) for any elements in the range [s_first, s_last). Uses a provided predicate to compare elements.

The comparison operations in the parallel search algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The comparison operations in the parallel search algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: at most (S*N) comparisons where \( S = \text{distance}(s\text{\_first}, s\text{\_last}) \) and \( N = \text{distance}(\text{first}, \text{last}) \).

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1** – The type of the examine range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the search range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of adjacent_find requires Pred to meet the requirements of CopyConstructible. This defaults to std::equal_to<>.
- **Proj1** – The type of an optional projection function. This defaults to hpx::identity and is applied to the elements of Rng1.
- **Proj2** – The type of an optional projection function. This defaults to hpx::identity and is applied to the elements of Rng2.

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the sequence of elements the algorithm will be examining.
- **rng2** – Refers to the sequence of elements the algorithm will be searching for.
- **op** – Refers to the binary predicate which returns true if the elements should be treated
as equal. the signature of the function should be equivalent to

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const &; but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of `rng1` as a projection operation before the actual predicate is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of `rng2` as a projection operation before the actual predicate is invoked.

**Returns** The `search` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `search` algorithm returns an iterator to the beginning of the first subsequence `[s_first, s_last)` in range `[first, last)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, last)`, `last` is returned. Additionally if the size of the subsequence is empty `first` is returned. If no subsequence is found, `last` is returned.

```cpp
template<typename FwdIter, typename FwdIter2, typename Sent2, typename Pred = hpx::ranges::equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
FwdIter search_n(FwdIter first, std::size_t count, FwdIter2 s_first, Sent s_last, Pred &&op = Pred(),
                 Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Searches the range `[first, last)` for any elements in the range `[s_first, s_last)`. Uses a provided predicate to compare elements.

The comparison operations in the parallel `search_n` algorithm execute in sequential order in the calling thread.

**Note:** Complexity: at most \((S*N)\) comparisons where \(S = \text{distance}(s\text{\_first, } s\text{\_last})\) and \(N = \text{count}\).

**Template Parameters**

- **FwdIter** – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.
- **FwdIter2** – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the source sentinel used for the second range (deduced). This iterator type must meet the requirements of an sentinel.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`
- **Proj1** – The type of an optional projection function. This defaults to `hpx::identity` and is applied to the elements of type dereferenced `FwdIter`.
- **Proj2** – The type of an optional projection function. This defaults to `hpx::identity` and is applied to the elements of type dereferenced `FwdIter2`.

**Parameters**

- **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **count** – Refers to the range of elements of the first range the algorithm will be applied to.
- **s_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.
• \texttt{s\_last} – Refers to the end of the sequence of elements of the algorithm will be searching for.

• \texttt{op} – Refers to the binary predicate which returns true if the elements should be treated as equal. the signature of the function should be equivalent to

\begin{verbatim}
bool pred(const Type1 &a, const Type2 &b);
\end{verbatim}

The signature does not need to have \texttt{const \&}, but the function must not modify the objects passed to it. The types \texttt{Type1} and \texttt{Type2} must be such that objects of types \texttt{FwdIter1} and \texttt{FwdIter2} can be dereferenced and then implicitly converted to \texttt{Type1} and \texttt{Type2} respectively.

• \texttt{proj1} – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced \texttt{FwdIter1} as a projection operation before the actual predicate \texttt{is} invoked.

• \texttt{proj2} – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced \texttt{FwdIter2} as a projection operation before the actual predicate \texttt{is} invoked.

Returns The \texttt{search\_n} algorithm returns \texttt{FwdIter}. The \texttt{search\_n} algorithm returns an iterator to the beginning of the last subsequence \([s\_first, s\_last)\) in range \([\text{first}, \text{first+count})\). If the length of the subsequence \([s\_first, s\_last)\) is greater than the length of the range \([\text{first}, \text{first+count})\), \texttt{first} is returned. Additionally, if the size of the subsequence is empty or no subsequence is found, \texttt{first} is also returned.

\begin{verbatim}
template<typename ExPolicy, typename FwdIter, typename FwdIter2, typename Sent2, typename Pred = hpx::ranges::equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
  hpx::parallel::util::detail::algorithm_result<ExPolicy, FwdIter>::type search_n(ExPolicy &&policy, FwdIter first, std::size_t count, FwdIter2 s_first, Sent2 s_last, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
\end{verbatim}

Searches the range \([\text{first}, \text{last})\) for any elements in the range \([s\_first, s\_last)\). Uses a provided predicate to compare elements.

The comparison operations in the parallel \texttt{search\_n} algorithm invoked with an execution policy object of type \texttt{sequenced\_policy} execute in sequential order in the calling thread.

The comparison operations in the parallel \texttt{search\_n} algorithm invoked with an execution policy object of type \texttt{parallel\_policy} or \texttt{parallel\_task\_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

\textbf{Note:} Complexity: at most \((S*N)\) comparisons where \(S = \text{distance}(s\_first, s\_last)\) and \(N = \text{count}\).

\textbf{Template Parameters}

• \texttt{ExPolicy} – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.

• \texttt{FwdIter} – The type of the source iterators used for the first range (deduced). This iterator type must meet the requirements of an forward iterator.

• \texttt{FwdIter2} – The type of the source iterators used for the second range (deduced). This iterator type must meet the requirements of an forward iterator.
• **Sent2** – The type of the source sentinel used for the second range (deduced). This iterator type must meet the requirements of an sentinel.

• **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>

• **Proj1** – The type of an optional projection function. This defaults to `hpx::identity` and is applied to the elements of type dereferenced `FwdIter`.

• **Proj2** – The type of an optional projection function. This defaults to `hpx::identity` and is applied to the elements of type dereferenced `FwdIter2`.

**Parameters**

• **policy** – The execution policy to use for the scheduling of the iterations.

• **first** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

• **count** – Refers to the range of elements of the first range the algorithm will be applied to.

• **s_first** – Refers to the beginning of the sequence of elements the algorithm will be searching for.

• **s_last** – Refers to the end of the sequence of elements of the algorithm will be searching for.

• **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. The signature of the function should be equivalent to

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have const & , but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

• **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `FwdIter1` as a projection operation before the actual predicate is invoked.

• **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of type dereferenced `FwdIter2` as a projection operation before the actual predicate is invoked.

**Returns** The `search_n` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `search_n` algorithm returns an iterator to the beginning of the last subsequence `[s_first, s_last)` in range `[first, first+count)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, first+count)`, `first` is returned. Additionally if the size of the subsequence is empty or no subsequence is found, `first` is also returned.

```cpp
template<typename Rng1, typename Rng2, typename Pred = hpx::ranges::equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
(hpx::traits::range_iterator_t<Rng1> search_n(Rng1 &&rng1, std::size_t count, Rng2 &&rng2, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Searches the range `[first, last)` for any elements in the range `[s_first, s_last)`. Uses a provided predicate to compare elements.

The comparison operations in the parallel `search` algorithm execute in sequential order in the calling thread.

**Note:** Complexity: at most (S*N) comparisons where S = distance(s_first, s_last) and N = dis-
Template Parameters

- **Rng1** – The type of the examine range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the search range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `adjacent_find` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::equal_to<>`.
- **Proj1** – The type of an optional projection function. This defaults to `hpx::identity` and is applied to the elements of `Rng1`.
- **Proj2** – The type of an optional projection function. This defaults to `hpx::identity` and is applied to the elements of `Rng2`.

Parameters

- **rng1** – Refers to the sequence of elements the algorithm will be examining.
- **count** – The number of elements to apply the algorithm on.
- **rng2** – Refers to the sequence of elements the algorithm will be searching for.
- **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. The signature of the function should be equivalent to

  ```cpp
  bool pred(const Type1 &a, const Type2 &b);
  ```

  The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.
- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of `rng1` as a projection operation before the actual predicate is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of `rng2` as a projection operation before the actual predicate is invoked.

Returns The `search` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `search` algorithm returns an iterator to the beginning of the first subsequence `[s_first, s_last)` in range `[first, last)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, last)`, `last` is returned. Additionally if the size of the subsequence is empty, `first` is returned. If no subsequence is found, `last` is returned.

```cpp
template<typename ExPolicy, typename Rng1, typename Rng2, typename Pred = hpx::ranges::equal_to, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
```
Searches the range [first, last) for any elements in the range [s_first, s_last). Uses a provided predicate to compare elements.

The comparison operations in the parallel search algorithm invoked with an execution policy object of type sequenced_policy execute in sequential order in the calling thread.

The comparison operations in the parallel search algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

Note: Complexity: at most (S*N) comparisons where S = distance(s_first, s_last) and N = distance(first, last).

Template Parameters

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it executes the assignments.
- **Rng1** – The type of the examine range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the search range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of adjacent_find requires Pred to meet the requirements of CopyConstructible. This defaults to std::equal_to<>
- **Proj1** – The type of an optional projection function. This defaults to hpx::identity and is applied to the elements of Rng1.
- **Proj2** – The type of an optional projection function. This defaults to hpx::identity and is applied to the elements of Rng2.

Parameters

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the sequence of elements the algorithm will be examining.
• **count** – The number of elements to apply the algorithm on.
• **rng2** – Refers to the sequence of elements the algorithm will be searching for.
• **op** – Refers to the binary predicate which returns true if the elements should be treated as equal. The signature of the function should be equivalent to

```cpp
bool pred(const Type1 &a, const Type2 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The types `Type1` and `Type2` must be such that objects of types `FwdIter1` and `FwdIter2` can be dereferenced and then implicitly converted to `Type1` and `Type2` respectively.

• **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of `rng1` as a projection operation before the actual predicate *is* invoked.
• **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of `rng2` as a projection operation before the actual predicate *is* invoked.

**Returns** The `search` algorithm returns a `hpx::future<FwdIter>` if the execution policy is of type `task_execution_policy` and returns `FwdIter` otherwise. The `search` algorithm returns an iterator to the beginning of the first subsequence `[s_first, s_last)` in range `[first, last)`. If the length of the subsequence `[s_first, s_last)` is greater than the length of the range `[first, last)`, `last` is returned. Additionally if the size of the subsequence is empty `first` is returned. If no subsequence is found, `last` is returned.

### hpx/parallel/container_algorithms/set_difference.hpp

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace hpx

namespace ranges

**Functions**

```cpp
template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3, typename Pred = hpx::parallel::detail::less, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
```
Constructs a sorted range beginning at dest consisting of all elements present in the range [first1, last1) and not present in the range [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate $f$.

Equivalent elements are treated individually, that is, if some element is found $m$ times in [first1, last1) and $n$ times in [first2, last2), it will be copied to dest exactly std::max($m-n$, 0) times. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (sequenced_policy) or in a single new thread spawned from the current thread (for sequenced_task_policy).

The application of function objects in parallel algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most $2*(N_1 + N_2 - 1)$ comparisons, where $N_1$ is the length of the first sequence and $N_2$ is the length of the second sequence.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Iter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
• **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
• **Iter2** – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
• **Sent2** – The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for Iter2.
• **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
• **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_difference` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`.
• **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `hpx::identity`
• **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `hpx::identity`.

**Parameters**

• **policy** – The execution policy to use for the scheduling of the iterations.
• **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
• **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
• **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
• **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
• **dest** – Refers to the beginning of the destination range.
• **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`.
• **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.
• **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

**Returns** The `set_difference` algorithm returns a `hpx::future<ranges::set_difference_result<Iter1, Iter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::set_difference_result<Iter1, Iter3>` otherwise. The `set_difference` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename Rng1, typename Rng2, typename Iter3, typename Pred = hpx::parallel::detali::less, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
```
Constructs a sorted range beginning at dest consisting of all elements present in the range [first1, last1) and not present in the range [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate $f$.

Equivalent elements are treated individually, that is, if some element is found $m$ times in [first1, last1) and $n$ times in [first2, last2), it will be copied to dest exactly std::max($m-n$, 0) times. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (sequenced_policy) or in a single new thread spawned from the current thread (for sequenced_task_policy).

The application of function objects in parallel algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most $2^*(N_1 + N_2 - 1)$ comparisons, where $N_1$ is the length of the first sequence and $N_2$ is the length of the second sequence.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
• **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_difference` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`

• **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `hpx::identity`

• **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `hpx::identity`

**Parameters**

• **policy** – The execution policy to use for the scheduling of the iterations.

• **rng1** – Refers to the first sequence of elements the algorithm will be applied to.

• **rng2** – Refers to the second sequence of elements the algorithm will be applied to.

• **dest** – Refers to the beginning of the destination range.

• **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`.

• **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.

• **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

**Returns** The `set_difference` algorithm returns a `hpx::future<ranges::set_difference_result<Iter1, Iter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::set_difference_result<Iter1, Iter3>` otherwise. Where `Iter1` is `range_iterator_t<Rng1>` and `Iter2` is `range_iterator_t<Rng2>` The `set_difference` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3,
         typename Pred = hpx::parallel::detail::less, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
set_difference_result<Iter1, Iter3> set_difference(Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2,
                                                   Iter3 dest, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Constructs a sorted range beginning at `dest` consisting of all elements present in the range `[first1, last1)` and not present in the range `[first2, last2)`. This algorithm expects both input ranges to be sorted with the given binary predicate `f`.

Equivalent elements are treated individually, that is, if some element is found `m` times in `[first1, last1)` and `n` times in `[first2, last2)`, it will be copied to `dest` exactly std::max(`m-n`, 0) times. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

**Note:** Complexity: At most `2*(N1 + N2 - 1)` comparisons, where `N1` is the length of the first sequence and `N2` is the length of the second sequence.

**Template Parameters**
• **Iter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.

• **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.

• **Iter2** – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of a forward iterator.

• **Sent2** – The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for Iter2.

• **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

• **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_difference` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`

• **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `hpx::identity`

• **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `hpx::identity`

**Parameters**

• **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.

• **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.

• **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.

• **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.

• **dest** – Refers to the beginning of the destination range.

• **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
def pred(const Type1 &a, const Type1 &b);```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`.

• **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.

• **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

**Returns** The `set_difference` algorithm returns `ranges::set_difference_result<Iter1, Iter3>`. The `set_difference` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<
typename Rng1, typename Rng2, typename Iter3, typename Pred = hpx::parallel::detail::less,
typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
set_difference_result<hpx::traits::range_iterator_t<Rng1>, Iter3> set_difference(Rng1 &&rng1,
Rng2 &&rng2, Iter3 dest, Pred &&op = Pred(),
Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2());```
Constructs a sorted range beginning at `dest` consisting of all elements present in the range `[first1, last1)` and not present in the range `[first2, last2)`. This algorithm expects both input ranges to be sorted with the given binary predicate `f`.

Equivalent elements are treated individually, that is, if some element is found `m` times in `[first1, last1)` and `n` times in `[first2, last2)`, it will be copied to `dest` exactly `std::max(m-n, 0)` times. The resulting range cannot overlap with either of the input ranges.

**Note:** Complexity: At most \(2^*(N1 + N2 - 1)\) comparisons, where \(N1\) is the length of the first sequence and \(N2\) is the length of the second sequence.

**Template Parameters**
- `Rng1` – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- `Rng2` – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- `Iter3` – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- `Pred` – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_difference` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`.
- `Proj1` – The type of an optional projection function applied to the first sequence. This defaults to `hpx::identity`.
- `Proj2` – The type of an optional projection function applied to the second sequence. This defaults to `hpx::identity`.

**Parameters**
- `rng1` – Refers to the first sequence of elements the algorithm will be applied to.
- `rng2` – Refers to the second sequence of elements the algorithm will be applied to.
- `dest` – Refers to the beginning of the destination range.
- `op` – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &; but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`.
- `proj1` – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.
- `proj2` – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

**Returns** The `set_difference` algorithm returns `ranges::set_difference_result<Iter1, Iter3>`, where `Iter1` is `range_iterator_t<Rng1>` and `Iter2` is `range_iterator_t<Rng2>`. The `set_difference` algorithm returns the output iterator to the element in the destination range, one past the last element copied.
See *Public API* for a list of names and headers that are part of the public *HPX* API.

```cpp
namespace hpx

namespace ranges

Functions

template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3, typename Pred = hpx::parallel::detail::less, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
    hpx::parallel::util::detail::algorithm_result<ExPolicy, set_intersection_result<Iter1, Iter2, Iter3>>::type set_intersection(
        ExPolicy &&policy,
        Iter1 first1, Sent1 last1,
        Iter2 first2, Sent2 last2,
        Iter3 dest,
        Pred &&op = Pred(),
        Proj1 &&proj1 = Proj1(),
        Proj2 &&proj2 = Proj2())
```

Constructs a sorted range beginning at dest consisting of all elements present in both sorted ranges [first1, last1) and [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate \( f \).

If some element is found \( m \) times in [first1, last1) and \( n \) times in [first2, last2), the first std::min(m, n) elements will be copied from the first range to the destination range. The order of equivalent elements is preserved. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (*sequenced_policy*) or in a single new thread.
spawned from the current thread (for `sequenced_task_policy`).

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most \( 2(N_1 + N_2 - 1) \) comparisons, where \( N_1 \) is the length of the first sequence and \( N_2 \) is the length of the second sequence.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Iter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2** – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for Iter2.
- **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_intersection` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `hpx::identity`
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `hpx::identity`

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have `const &`, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op`
is invoked.

**Returns** The `set_intersection` algorithm returns a `hpx::future<ranges::set_intersection_result<Iter1, Iter2, Iter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::set_intersection_result<Iter1, Iter2, Iter3>` otherwise.

The `set_intersection` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename Rng1, typename Rng2, typename Iter3, typename Pred = hpx::parallel::detail::less, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
hpx::parallel::util::detail::algorithm_result<ExPolicy, set_intersection_result<hpx::traits::range_iterator_t<Rng1>, hpx::traits::range_iterator_t<Rng2>, Iter3>>
set_intersection(ExPolicy&& policy, Rng1&& rng1, Rng2&& rng2, Iter3 dest, Pred&& op = Pred(), Proj1&& proj1 = Proj1(), Proj2&& proj2 = Proj2())
```

Constructs a sorted range beginning at `dest` consisting of all elements present in both sorted ranges `[first1, last1)` and `[first2, last2)`. This algorithm expects both input ranges to be sorted with the given binary predicate `f`.

If some element is found `m` times in `[first1, last1)` and `n` times in `[first2, last2)`, the first `std::min(m, n)` elements will be copied from the first range to the destination range. The order of equivalent elements is preserved. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (`sequenced_policy`) or in a single new thread spawned from the current thread (for `sequenced_task_policy`).

The application of function objects in parallel algorithm invoked with an execution policy object of type `parallel_policy` or `parallel_task_policy` are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most $2^*(N1 + N2 - 1)$ comparisons, where $N1$ is the length of the first sequence and $N2$ is the length of the second sequence.

**Template Parameters**
• **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.

• **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

• **Rng2** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.

• **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

• **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_intersection` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>`.

• **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `hpx::identity`

• **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `hpx::identity`

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`.

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.

- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

**Returns**

The `set_intersection` algorithm returns a `hpx::future<ranges::set_intersection_result<Iter1, Iter2, Iter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::set_intersection_result<Iter1, Iter2, Iter3>` otherwise. Where `Iter1` is `range_iterator_t<Rng1>` and `Iter2` is `range_iterator_t<Rng2>`. The `set_intersection` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3,
         typename Pred = hpx::parallel::detail::less, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
set_intersection_result<Iter1, Iter2, Iter3> set_intersection(Iter1 first1, Sent1 last1, Iter2 first2,
                                                             Sent2 last2, Iter3 dest, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Constructs a sorted range beginning at dest consisting of all elements present in both sorted ranges `[first1, last1)` and `[first2, last2)`. This algorithm expects both input ranges to be sorted with the given binary predicate `f`.
If some element is found \( m \) times in \([\text{first1}, \text{last1})\) and \( n \) times in \([\text{first2}, \text{last2})\), the first \( \min(m, n) \) elements will be copied from the first range to the destination range. The order of equivalent elements is preserved. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

**Note:** Complexity: At most \( 2*(N1 + N2 - 1) \) comparisons, where \( N1 \) is the length of the first sequence and \( N2 \) is the length of the second sequence.

**Template Parameters**
- \( \text{Iter1} \) – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
- \( \text{Sent1} \) – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for \( \text{Iter1} \).
- \( \text{Iter2} \) – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
- \( \text{Sent2} \) – The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for \( \text{Iter2} \).
- \( \text{Iter3} \) – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- \( \text{Pred} \) – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of \( \text{set_intersection} \) requires \( \text{Pred} \) to meet the requirements of \( \text{CopyConstructible} \). This defaults to \( \text{std::less<}> \).
- \( \text{Proj1} \) – The type of an optional projection function applied to the first sequence. This defaults to \( \text{hpx::identity} \).
- \( \text{Proj2} \) – The type of an optional projection function applied to the second sequence. This defaults to \( \text{hpx::identity} \).

**Parameters**
- \( \text{first1} \) – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- \( \text{last1} \) – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- \( \text{first2} \) – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- \( \text{last2} \) – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- \( \text{dest} \) – Refers to the beginning of the destination range.
- \( \text{op} \) – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const & but the function must not modify the objects passed to it. The type \( \text{Type1} \) must be such that objects of type \( \text{InIter} \) can be dereferenced and then implicitly converted to \( \text{Type1} \).
- \( \text{proj1} \) – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate \( \text{op} \) is invoked.
- \( \text{proj2} \) – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate \( \text{op} \) is invoked.

**Returns** The \( \text{set_intersection} \) algorithm returns \( \text{ranges::set_intersection_result<Iter1, Iter2, Iter3>} \). The \( \text{set_intersection} \) algorithm returns the output iterator to the element in the destination range, one past the last element copied.
template<typename Rng1, typename Rng2, typename Iter3, typename Pred = hpx::parallel::detail::less, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
set_intersection_result<hpx::traits::range_iterator_t<Rng1>, hpx::traits::range_iterator_t<Rng2>, Iter3> set_intersection(Rng1 &&rng1, Rng2 &&rng2, Iter3 dest, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())

Constructs a sorted range beginning at dest consisting of all elements present in both sorted ranges [first1, last1) and [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate \( f \).

If some element is found \( m \) times in [first1, last1) and \( n \) times in [first2, last2), the first \( \min(m, n) \) elements will be copied from the first range to the destination range. The order of equivalent elements is preserved. The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

**Note:** Complexity: At most \( 2^*(N1 + N2 - 1) \) comparisons, where \( N1 \) is the length of the first sequence and \( N2 \) is the length of the second sequence.

**Template Parameters**
- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_intersection` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to std::less<>.
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `hpx::identity`.
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `hpx::identity`.

**Parameters**
- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
- **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal.
The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`.

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

**Returns** The `set_intersection` algorithm returns `ranges::set_intersection_result<Iter1, Iter2, Iter3>`, where `Iter1` is `range_iterator_t<Rng1>` and `Iter2` is `range_iterator_t<Rng2>`.

The `set_intersection` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

**hpx/parallel/container_algorithms/set_symmetric_difference.hpp**

See [Public API](/) for a list of names and headers that are part of the public HPX API.

namespace hpx

namespace ranges

**Functions**

```cpp
template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3, typename Pred = hpx::parallel::detail::less, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
```
Constructs a sorted range beginning at dest consisting of all elements present in either of the sorted ranges \([\text{first}_1, \text{last}_1)\) and \([\text{first}_2, \text{last}_2)\), but not in both of them are copied to the range beginning at dest. The resulting range is also sorted. This algorithm expects both input ranges to be sorted with the given binary predicate \(f\).

If some element is found \(m\) times in \([\text{first}_1, \text{last}_1)\) and \(n\) times in \([\text{first}_2, \text{last}_2)\), it will be copied to dest exactly \(\text{std}:\text{abs}(m-n)\) times. If \(m>n\), then the last \(m-n\) of those elements are copied from \([\text{first}_1,\text{last}_1)\), otherwise the last \(n-m\) elements are copied from \([\text{first}_2,\text{last}_2)\). The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (\textit{sequenced\_policy}) or in a single new thread spawned from the current thread (for \textit{sequenced\_task\_policy}).

The application of function objects in parallel algorithm invoked with an execution policy object of type \textit{parallel\_policy} or \textit{parallel\_task\_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

\textbf{Note:} Complexity: At most \(2^*(N1 + N2 - 1)\) comparisons, where \(N1\) is the length of the first sequence and \(N2\) is the length of the second sequence.
• **Iter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
• **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
• **Iter2** – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
• **Sent2** – The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for Iter2.
• **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
• **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of set_symmetric_difference requires Pred to meet the requirements of CopyConstructible. This defaults to std::less<>
• **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to hpx::identity
• **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to hpx::identity

**Parameters**
• **policy** – The execution policy to use for the scheduling of the iterations.
• **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
• **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
• **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
• **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
• **dest** – Refers to the beginning of the destination range.
• **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not have to have const &, but the function must not modify the objects passed to it. The type Type1 must be such that objects of type InIter can be dereferenced and then implicitly converted to Type1.
• **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate op is invoked.
• **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate op is invoked.

**Returns**
The set_symmetric_difference algorithm returns a hpx::future<ranges::set_symmetric_difference_result<Iter1, Iter2, Iter3>> if the execution policy is of type sequenced_task_policy or parallel_task_policy and returns ranges::set_symmetric_difference_result<Iter1, Iter2, Iter3> otherwise. The set_symmetric_difference algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename ExPolicy, typename Rng1, typename Rng2, typename Iter3, typename Pred = hpx::parallel::detail::less, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
```
Constructs a sorted range beginning at dest consisting of all elements present in either of the sorted ranges [first1, last1) and [first2, last2), but not in both of them are copied to the range beginning at dest. The resulting range is also sorted. This algorithm expects both input ranges to be sorted with the given binary predicate f.

If some element is found m times in [first1, last1) and n times in [first2, last2), it will be copied to dest exactly std::abs(m-n) times. If m>n, then the last n-m of those elements are copied from [first1,last1), otherwise the last n-m elements are copied from [first2,last2). The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (sequenced_policy) or in a single new thread spawned from the current thread (for sequenced_task_policy).

The application of function objects in parallel algorithm invoked with an execution policy object of type parallel_policy or parallel_task_policy are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

**Note:** Complexity: At most 2*(N1 + N2 - 1) comparisons, where N1 is the length of the first sequence and N2 is the length of the second sequence.

**Template Parameters**

- **ExPolicy** – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
• **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.

• **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_symmetric_difference` requires `Pred` to meet the requirements of `CopyConstructible`. This defaults to `std::less<>

• **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `hpx::identity`

• **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `hpx::identity`

**Parameters**

• **policy** – The execution policy to use for the scheduling of the iterations.

• **rng1** – Refers to the first sequence of elements the algorithm will be applied to.

• **rng2** – Refers to the second sequence of elements the algorithm will be applied to.

• **dest** – Refers to the beginning of the destination range.

• **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const & but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`

• **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.

• **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

**Returns** The `set_symmetric_difference` algorithm returns a `hpx::future<ranges::set_symmetric_difference_result<Iter1, Iter2, Iter3>>` if the execution policy is of type `sequenced_task_policy` or `parallel_task_policy` and returns `ranges::set_symmetric_difference_result<Iter1, Iter2, Iter3>` otherwise. Where `Iter1` is `range_iterator_t<Rng1>` and `Iter2` is `range_iterator_t<Rng2>`. The `set_symmetric_difference` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

```cpp
template<typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3, typename Pred = hpx::parallel::detail::less, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
set_symmetric_difference_result<Iter1, Iter2, Iter3> set_symmetric_difference(Iter1 first1, Sent1 last1, Iter2 first2, Sent2 last2, Iter3 dest, Pred &&op = Pred(), Proj1 &&proj1 = Proj1(), Proj2 &&proj2 = Proj2())
```

Constructs a sorted range beginning at `dest` consisting of all elements present in either of the sorted ranges `[first1, last1) and [first2, last2)`, but not in both of them are copied to the range beginning at `dest`. The resulting range is also sorted. This algorithm expects both input ranges to be sorted with the given binary predicate `f`.

If some element is found `m` times in `[first1, last1) and `n` times in `[first2, last2)`, it will be copied to `dest`
exactly std::abs(m-n) times. If m>n, then the last m-n of those elements are copied from [first1, last1), otherwise the last n-m elements are copied from [first2, last2). The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

**Note:** Complexity: At most 2*(N1 + N2 - 1) comparisons, where N1 is the length of the first sequence and N2 is the length of the second sequence.

### Template Parameters
- **Iter1** – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of a forward iterator.
- **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
- **Iter2** – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
- **Sent2** – The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for Iter2.
- **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of set_symmetric_difference requires Pred to meet the requirements of CopyConstructible. This defaults to std::less<>
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to hpx::identity
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to hpx::identity

### Parameters
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type Type1 must be such that objects of type InIter can be dereferenced and then implicitly converted to Type1

- **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate op is invoked.
- **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate op is invoked.

### Returns
The set_symmetric_difference algorithm returns ranges::set_symmetric_difference_result<Iter1, Iter2, Iter3>. The set_symmetric_difference algorithm returns the output iterator to the element in the
destination range, one past the last element copied.

\begin{verbatim}
template<typename Rng1, typename Rng2, typename Iter3, typename Pred = hpx::parallel::detail::less, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
set_symmetric_difference_result<hpx::traits::range_iterator_t<Rng1>, hpx::traits::range_iterator_t<Rng2>, Iter3> set_sym
\end{verbatim}

Constructs a sorted range beginning at dest consisting of all elements present in either of the sorted ranges \([\text{first1}, \text{last1})\) and \([\text{first2}, \text{last2})\), but not in both of them are copied to the range beginning at dest. The resulting range is also sorted. This algorithm expects both input ranges to be sorted with the given binary predicate \(f\).

If some element is found \(m\) times in \([\text{first1}, \text{last1})\) and \(n\) times in \([\text{first2}, \text{last2})\), it will be copied to dest exactly \(\text{std::abs}(m-n)\) times. If \(m\geq n\), then the last \(m-n\) of those elements are copied from \([\text{first1},\text{last1})\), otherwise the last \(n-m\) elements are copied from \([\text{first2},\text{last2})\). The resulting range cannot overlap with either of the input ranges.

The resulting range cannot overlap with either of the input ranges.

**Note:** Complexity: At most \(2*(N1 + N2 - 1)\) comparisons, where \(N1\) is the length of the first sequence and \(N2\) is the length of the second sequence.

**Template Parameters**
- **Rng1** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Rng2** – The type of the source range used (deduced). The iterators extracted from this range type must meet the requirements of an input iterator.
- **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
- **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of \(set\_symmetric\_difference\) requires \(Pred\) to meet the requirements of \(Copy\_Constructible\). This defaults to std::less<>
- **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to \(hpx::identity\)
- **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to \(hpx::identity\)

**Parameters**
- **rng1** – Refers to the first sequence of elements the algorithm will be applied to.
• **rng2** – Refers to the second sequence of elements the algorithm will be applied to.
• **dest** – Refers to the beginning of the destination range.
• **op** – The binary predicate which returns true if the elements should be treated as equal.

The signature of the predicate function should be equivalent to the following:

```plaintext
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`.

• **proj1** – Specifies the function (or function object) which will be invoked for each of the elements of the first sequence as a projection operation before the actual predicate `op` is invoked.
• **proj2** – Specifies the function (or function object) which will be invoked for each of the elements of the second sequence as a projection operation before the actual predicate `op` is invoked.

**Returns** The `set_symmetric_difference` algorithm returns `ranges::set_symmetric_difference_result<Iter1, Iter2, Iter3>`. where `Iter1` is `range_iterator_t<Rng1>` and `Iter2` is `range_iterator_t<Rng2>`. The `set_symmetric_difference` algorithm returns the output iterator to the element in the destination range, one past the last element copied.

See *Public API* for a list of names and headers that are part of the public HPX API.

namespace **hpx**

namespace **ranges**

**Functions**

```plaintext
template<typename ExPolicy, typename Iter1, typename Sent1, typename Iter2, typename Sent2, typename Iter3, typename Pred = hpx::parallel::detail::less, typename Proj1 = hpx::identity, typename Proj2 = hpx::identity>
```
Constructs a sorted range beginning at dest consisting of all elements present in one or both sorted ranges [first1, last1) and [first2, last2). This algorithm expects both input ranges to be sorted with the given binary predicate \( f \).

If some element is found \( m \) times in [first1, last1) and \( n \) times in [first2, last2), then all \( m \) elements will be copied from [first1, last1) to dest, preserving order, and then exactly std::max(n-m, 0) elements will be copied from [first2, last2) to dest, also preserving order.

The resulting range cannot overlap with either of the input ranges.

The application of function objects in parallel algorithm invoked with a sequential execution policy object execute in sequential order in the calling thread (\textit{sequenced\_policy}) or in a single new thread spawned from the current thread (for \textit{sequenced\_task\_policy}).

The application of function objects in parallel algorithm invoked with an execution policy object of type \textit{parallel\_policy} or \textit{parallel\_task\_policy} are permitted to execute in an unordered fashion in unspecified threads, and indeterminately sequenced within each thread.

\textbf{Note:} Complexity: At most \( 2*(N1 + N2 - 1) \) comparisons, where \( N1 \) is the length of the first sequence and \( N2 \) is the length of the second sequence.

\textbf{Template Parameters}

- \textbf{ExPolicy} – The type of the execution policy to use (deduced). It describes the manner in which the execution of the algorithm may be parallelized and the manner in which it applies user-provided function objects.
- \textbf{Iter1} – The type of the source iterators used (deduced) representing the first sequence. This iterator type must meet the requirements of an forward iterator.
• **Sent1** – The type of the end source iterators used (deduced). This iterator type must meet the requirements of an sentinel for Iter1.
• **Iter2** – The type of the source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an forward iterator.
• **Sent2** – The type of the end source iterators used (deduced) representing the second sequence. This iterator type must meet the requirements of an sentinel for Iter2.
• **Iter3** – The type of the iterator representing the destination range (deduced). This iterator type must meet the requirements of an output iterator.
• **Pred** – The type of an optional function/function object to use. Unlike its sequential form, the parallel overload of `set_union` requires `Pred` to meet the requirements of Copy-Constructible. This defaults to `std::less<>`.
• **Proj1** – The type of an optional projection function applied to the first sequence. This defaults to `hpx::identity`
• **Proj2** – The type of an optional projection function applied to the second sequence. This defaults to `hpx::identity`

**Parameters**

- **policy** – The execution policy to use for the scheduling of the iterations.
- **first1** – Refers to the beginning of the sequence of elements of the first range the algorithm will be applied to.
- **last1** – Refers to the end of the sequence of elements of the first range the algorithm will be applied to.
- **first2** – Refers to the beginning of the sequence of elements of the second range the algorithm will be applied to.
- **last2** – Refers to the end of the sequence of elements of the second range the algorithm will be applied to.
- **dest** – Refers to the beginning of the destination range.
- **op** – The binary predicate which returns true if the elements should be treated as equal. The signature of the predicate function should be equivalent to the following:

```cpp
bool pred(const Type1 &a, const Type1 &b);
```

The signature does not need to have const &, but the function must not modify the objects passed to it. The type `Type1` must be such that objects of type `InIter` can be dereferenced and then implicitly converted to `Type1`.
